

Euroanaesthesia 2025 The European Anaesthesiology Congress

Abstract Programme

The abstracts published in this Supplement have been typeset from electronic submissions and camera-ready copies prepared by the authors. Every effort has been made to reproduce faithfully the abstracts as submitted. These abstracts have been prepared in accordance with the requirements of the European Society of Anaesthesiology and have not been subjected to review nor editing by the European Journal of Anaesthesiology. However, no responsibility is assumed by the organisers or publisher for any injury and/or damage to persons or property as a matter of products liability, negligence or otherwise, or from any use or operation of methods, products, instructions or ideas contained in the material herein. Because of the rapid advances in medical sciences, we recommend that independent verification of diagnoses and drug doses should be made.

Call for abstracts

The ESAIC solicits the submission of abstracts for the Euroanaesthesia 2026 Congress Rotterdam, The Netherlands 06-08 June 2026

All abstracts must be submitted online via the
Euroanaesthesia website
The submission module will be available to
submitters as of Fall 2025

Submission Conditions

The submission conditions will be made available on the Euroanaesthesia website at least one month before opening of the submission system.

Abstracts

EUROANAESTHESIA 2025

The European Anaesthesiology and Intensive Care Congress

European Journal of Anaesthesiology

Editor-in-Chief

Marc Van de Velde, Leuven, Belgium

Deputy Editors-in-Chief

Nicolas Bruder, Marseille, France
Patrice Forget, Aberdeen, UK
Tom G. Hansen, Oslo, Norway
Dan Longrois, Paris, France
Anne-Claire Lukaszewicz, Lyon, France
Ornella Piazza, Salerno, Italy
Esther Pogatzki-Zahn, Muenster, Germany
Charles Marc Samama, Paris, France

Language and Scientific Editors

Ian Jenkins, *Bristol, UK* Gordon Lyons, *Leeds, UK* Ian F. Russel, *Hull, UK* Andrew Wolf, *Bristol, UK*

Associate Editors

Fanny Bonhomme, Geneva, Switzerland Michele Carella, Liège, Belgium Michelle Chew, Linköping, Sweden Alistair McNarry, Edinburgh, UK Basak Ceyda Meco, Ankara, Turkey Annelies Moerman, Ghent, Belgium Mona Momeni, Bruxelles, Belgium Tino Münster, Regensburg, Germany

Deputy Associate Editors

Jurgen De Graaf, Rotterdam, The Netherlands Pierre-Grégoire Guinot, Dijon, France Ana Kowark, Bonn, Germany Giovanna Lurati-Buse, Düsseldorf, Germany Claire Roger, Nîmes, France Rui Shi, Guangzhou, China

Assistant Editors

Stefan Andrei, Paris, France Nicolas Boulet, Nîmes, France Christian De Tymowski, Paris, France Pierre-Yves Dewandre, Liège, Belgium Peter Frykholm, Uppsala, Sweden Francesca Gargano, Rome, Italy Marc Gimenez, Barcelona, Spain Yann Gricourt, Nîmes, France Nicola Groes Clausen, Odense, Denmark Wan-Jie Gu, Guangzhou, China Gregory Hans, Liege, Belgium Danny Hoogma, Leuven, Belgium Gözde inan, Ankara, Turkey Jacob Karlsson, Stockholm, Sweden Céline Khalifa, Leuven, Belgium Koen Lapage, Ghent, Belgium Anita Luthy, Zurich, Switzerland Tamar Macharadze, Tbilisi, Georgia Alexandre Mansour, Rennes, France Eckhard Mauermann, Zurich, Switzerland

Rene M'Pmbele, Duesseldorf, Germany Nadia Najafi, Brussels, Belgium Giuseppe Pascarella, Rome, Italy Martin Petzoldt, Hamburg, Germany Eva Roofthooft, Leuven, Belgium Sebastian Roth, Duesseldorf, Germany Stephanie Roullet, Paris, France Giuliana Scarpati, Salerno, Italy Alexander Schnabel, Münster, Germany Sneh Shah, London, UK Pierre Simeone, Marseille, France Rachele Simonte, Perugia, Italy Jennifer Summers, Aberdeen, UK Paul Tarpin, Amiens, France Victoria Van Regemorter, Louvain-la-Neuve, Belgium Patrick Wanner, Basel, Switzerland Patrick Ward, Livingston, UK Piet Wyffels, Ghent, Belgium Argyro Zoumprouli, London, UK

Methods, Statistics, Epidemiology

Malachy Columb, *Manchester, UK*Salomé Dell-Kuster, *Basel, Switzerland*

Book and Media Reviews

Paola Aceto, Rome, Italy

Managing Editor

Lizzy Seal, London, UK

European Journal of Anaesthesiology is the official publication of the European Society of Anaesthesiology and Intensive Care. The Journal publishes original scientific work. Preference is given to experimental work or clinical observations in man, and to laboratory work of clinical relevance.

Information for contributors

Papers should be submitted online at: www.editorialmanager.com/eja.

European Journal of Anaesthesiology (ISSN: 0265-0215) is published monthly by Wolters Kluwer Health, Inc. and distributed in the US by Mercury Airfreight International, Inc., 365 Blair Road, Avenel, NJ 07001. Periodicals postage paid at Rahway, NJ. POSTMASTER: send address changes to European Journal of Anaesthesiology, PO Box 1610, Hagerstown, MD 21740, USA.

All correspondence should be addressed to the Editorial Office: European Journal of Anaesthesiology, Lippincott Williams & Wilkins, 8th Floor, 30 Churchill Place, Canary Wharf, London, E14 5RE, UK **Publisher** Daniel Hyde

Production Editor Duncan Martin-Holloway

Disclaimer

Although every effort is made by the publisher and editorial board to see that no inaccurate or misleading data, opinion or statement appear in this journal, they wish to make it clear that the data and opinions appearing in the articles and advertisements herein are the responsibility of the contributor or advertiser concerned. Accordingly, the publisher, the editorial board and their respective employees accept no liability for the consequences of any such inaccurate or misleading data, opinion or statement.

Drugs and drug dosages

Readers are advised that new methods and techniques described involving drug usage should be followed only in conjunction with drug manufacturers' own published literature.

2025 Subscription rates

Individual \$768 (USA); \$768 (Rest of the World). Institutional \$3,049 (USA); \$3,526 (Rest of the World). On-line only subscriptions for Institutions are available through Ovid (www.ovid.com). Prices include handling and shipping, but not sales tax, e.g. VAT, GST, MVG, MWS, AST and regional sales tax. Where applicable, please add sales tax to the listed prices at the appropriate rate. (The Canadian GST of 7% will be added to the subscription price of all orders shipped to Canada. Wolters Kluwer Health, Inc. GST Identification Number is 895524239.) Copies will be replaced without charge if the publisher receives a request within 90 days of the mailing date, both in the USA and worldwide.

Subscription information

European Journal of Anaesthesiology, Subscription Department, Wolters Kluwer Health, Inc., 1800 Dual Highway, Suite 200, Hagerstown, MD 21740-6636, USA; phone +1 800 638 3030; fax +1 301 223 2400.

Euroanaesthesia 2025

The European Anaesthesiology Congress

LISBON, PORTUGAL, 25 - 27 MAY 2025

ABSTRACT PRESENTATION PROGRAMME

Please note that all abstracts are presented as poster presentations: abstract presenters do not make a formal presentation of their abstract in a separate room, using audiovisual aids (except for the Best Abstract Prize Competition). Instead, two chairpersons will conduct, in front of each poster, a short discussion of each abstract with the presenter and the audience, for every abstract in that session. Poster presenters have been asked to stand by their poster at least 15 minutes before the start of the session and 15 minutes after, to address further questions.

Epidemiological trends of acute respiratory distress syndrome in the 21st century: a nationwide, population-based retrospective study

M. Bardají Carrillo^{1,2}, L. Alonso-Villalobos¹,

E. Gómez Pesquera^{1,2}, R. López-Herrero^{1,2}, A. García-Concejo², E. Tamayo^{1,2} ¹Clinic Universitary Hospital of Valladolid, Anaesthesiology and Critical Care, Valladolid, Spain, ²BioCritic, Group for Biomedical Research in Critical Care Medicine, Valladolid,

Background and Goal of Study: Acute respiratory distress syndrome (ARDS) is a prevalent respiratory condition associated with significant mortality. Current literature on ARDS epidemiology reports a wide range of incidence (7.2-78.9/100,000 population/year), hospital mortality (32-51%) and associated costs (\$8,476-\$547,974). We analyzed the epidemiological trends of ARDS in Spain from 2000 to 2022 using the Minimum Basic Data Set (MBDS), focusing on ARDS incidence, associated mortality, and economic impact.

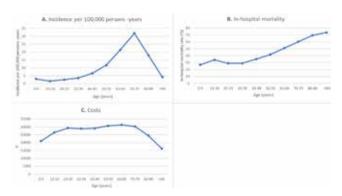

Materials and Methods: We conducted a nationwide, population-based retrospective study of all hospitalizations for ARDS in all Spanish hospitals from January 1, 2000, to December 31, 2022, using MBDS records, which have an estimated coverage of 99.5%. The study reports ARDS incidence per 100,000 population/year, hospital mortality rate, and mean cost per patient.

Results and Discussion: We analyzed 93,192 records of patients with a new diagnosis of ARDS during the study period. ARDS incidence ranged from 2.96 to 20.14/100,000 population-years, peaking in 2021 during COVID-19 pandemic, and being around 10/100,000 during most of the study like reported by other European studies in that period. The variability in ARDS incidence in our study is probably due to changes in the International Classification of Diseases coding and in ARDS diagnostic criteria.

Mortality ranged between 38.0% and 55.0%, showing a declining trend, which may be attributed to advancements in ARDS treatment and the implementation of lung-protective mechanical ventilation, and has lately stabilized around 40-45%.

Cost per patient increased throughout the study period, stabilizing in late years around 30,000€ to 40,000€ after reaching a peak of 42,812€ in 2011. These costs are comparable to the ones reported by other European studies.

Incidence, mortality and costs by age group are depicted in the figure.

Conclusions: This is the largest epidemiological study on ARDS in Europe. ARDS incidence has stabilized in recent years, with mortality declining to 40-45%. ARDS-related costs have increased nearly four-fold. Research using MBDS data could enhance ARDS understanding and guide future studies.

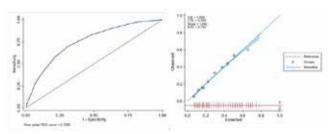

BAPC-02

Development and validation of a score to predict postoperative intensive care unit admission after non-cardiac surgery

R. M'Pembele¹, T. Tenge¹, S. Roth¹, A. Stroda-Hartmann¹, J. Larmann², G. Lurati Buse¹, MET-REPAIR Investigators ¹University Hospital Duesseldorf, Department of Anaesthesiology, Düsseldorf, Germany, ²University Hospital RWTH Aachen, Department of Anaesthesiology, Aachen, Germany

Background and Goal of Study: Intensive care unit (ICU) capacities after non-cardiac surgeries are limited. As both numbers of high-risk surgeries performed and comorbidity burden are rising, an efficient resource management strategy is crucial to avoid overtreatment without increasing rates of postoperative complications. To date, there are no convincing tools available to support decision making for postoperative need for ICU admission. This study reports the development and internal validation of the PREDICT-ICU score.

Materials and Methods: This is a secondary analysis of the MET-REPAIR international cohort study which recruited patients ≥45 years with increased cardiovascular risk undergoing non-cardiac surgery. The primary endpoint was postoperative elective or unplanned ICU admission. Preoperative variables were chosen based on clinical relevance. Lasso logistic regression with internal cross validation was performed for predictor selection. Variables with the greatest impact were chosen based on their coefficients. Predictor selection for the PREDICT-ICU score was confirmed in a second lasso logistic regression. Model and score performances were tested using ROC-AUC and calibration curves.

Results and Discussion: The total dataset contained 15,600 patients with complete data. 4,342 (27.8%) of these patients had a postoperative ICU admission (3,850 planned, 492 unplanned). The full model including 14 variables showed moderate to good discrimination and calibration (ROC-AUC 0.75 95% CI 0.74-0.76, Calibration slope 1.000).

The PREDICT-ICU score contains the following variables and score points: High surgical risk (10), duration of surgery \geq 150 min (10), ASA class \geq 3 (7), severe valve pathology (5), history of can-

cer (4), history of coronary artery disease (2). The PREDICT-ICU score showed similar performance as compared to the general model (ROC-AUC 0.75 95% CI 0.74-0.76, Calibration slope 1.000). **Conclusion(s)**: The PREDICT-ICU score including six preoperative variables is a tool that can predict postoperative ICU admissions in patients undergoing non-cardiac surgery. The score might help improving resource management and should be externally validated.

BAPC-03 Saving or not saving an 80-year-old isn't just a question of age

<u>I. Balenović</u>¹, R. Baronica¹, D. Ivanković¹, I. Tucić¹, T. Tomić Mahečić¹, I. Šitum¹

"UHC Zagreb, Department for Anesthesiology and Intensive care Medicine, Zagreb, Croatia

Background: An average patient is already older than a research subject.

Case Report: With the case of an 82-year-old retired lady who had always been active despite her age and suffered from head trauma, a clinical dilemma was raised. She was on apixaban for atrial fibrillation. A CT scan after the fall quickly confirmed an epidural brain hematoma threatening her life.

Indication for an emergency craniotomy and apixaban, taken the same morning, increases the risk of uncontrollable bleeding. Time was critical, and despite her advanced age, she gets andexanet alfa, a reversal agent for apixaban. Within minutes of the infusion, her clotting began to stabilize. The surgical team moved swiftly to drain the hematoma.

Hours later, she emerged from surgery, weak but stable. The bleeding had stopped. The goal was achieved over the next few days as she recovered in the ICU.

Discussion: This was a significant ethical and clinical dilemma, highlighting the challenge of treating older patients, mainly because medical researches are often based on data from younger populations (like 60-year-olds). Older patients (over 80) in clinical trials are frequently underrepresented, mainly because of more complex health conditions, multiple medications, and decreased physiological reserve. Yet, as the population ages, the medical community increasingly encounters older patients who could benefit from treatments but for whom we need more evidence of safety and efficacy. We risk denying them potentially life-saving interventions based on their age, which raises ethical questions about fairness and equal access to care.

Learning points: Doctors can assess each patient individually and consider factors such as overall health, frailty, cognitive function, and life expectancy beyond the immediate illness.

The solution is not to deny treatment to older patients but to take a more nuanced, patient-centered approach. Research on younger populations provides a foundation, but in real-world practice, clinicians must adapt this knowledge and tailor treatments. Saving or not saving an 80-year-old isn't just a question of age—it's a question of the person's overall health, values, and potential for meaningful recovery.

BAPC-04

Al-driven predictions: tackling postoperative delirium with the Swiss Safe Brain Initiative data

B. Morel¹, A. Berger¹, M. Gisselbaek^{2,3}, S. Saxena^{4,5}, A. Devos¹, J. Berger-Estilita^{6,7} ¹Swiss Federal Institute of Technology Zurich (ETH Zurich), ETH AI Center, Zürich, Switzerland, ²Geneva University Hospitals and Faculty of Medicine, Division of Anesthesiology, Department of Anesthesiology, Clinical Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland, 3University of Geneva, Unit of Development and Research in Medical Education (UDREM), Faculty of Medicine, Geneva, Switzerland, ⁴Helora, Department of Anesthesiology, Mons. Belgium. ⁵University of Mons, Department of Surgery, UMons, Research Institute for Health Sciences and Technology. Mons. Belgium. 6Salemspital, Hirslanden Medical Group. Department of Anaesthesiology and Intensive Care, Bern, Switzerland, ⁷University of Bern, Institute for Medical Education, Bern, Switzerland

Background and Goal of Study: Postoperative delirium (POD), a common complication of surgery and anaesthesia, increases morbidity, mortality, and healthcare costs. The Safe Brain Initiative (SBI) care bundle comprises 18 non-pharmacological measures to enhance perioperative brain health. This study aims to develop and validate a predictive model for POD using pre-induction features from the SBI dataset, comparing it to a known model (PIPRA).

Materials and Methods: The study used an anonymized dataset of 1,419 observations from a private hospital, reduced to 600 cases after excluding patients <60 years or undergoing intracranial/cardiac surgeries. Seventy pre-induction features were included, such as anaesthesia type, pain levels, and preventive measures. POD was defined as a Nu-DESC score ≥ 2. Logistic regression with SMOTE and XGBoost models were developed for binary classification. Feature importance and SHAP values were analyzed to enhance interpretability.

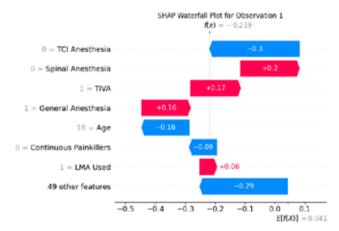

Figure 1: SHAP waterfall plot displaying the 7 most important features and their effects on model prediction for observation 1.

Results and Discussion: Key predictors included anesthesia type (spinal/general), intubation, surgical subspecialty, and pain perception. Environmental factors like noise reduction and temperature monitoring also improved predictions. The logistic regression model with SMOTE achieved the best performance (AUC: 0.792,

Sensitivity: 0.919), outperforming the model described in PIPRA (AUC: 0.789, Sensitivity: 0.856) trained on our data. XGBoost performed slightly lower (AUC: 0.772, Sensitivity: 0.902).

Conclusion(s): This study demonstrates the potential of Al-based predictive tools to identify POD risk preoperatively, enabling early non-pharmacological interventions. Integrating such models into clinical practice can improve perioperative brain health and patient outcomes.

BAPC-05

Plasma biomarkers of inflammation are associated with neurocognitive disorders two years after anaesthesia and surgery

B. Silbert^{1,2}, K. Atkins^{1,2}, D. Scott^{1,2}, L. Evered^{1,2,3}
¹St Vincent's Hospital, Anaesthesia and Acute Pain Medicine, Fitzroy, Australia, ²University of Melbourne, Department of Critical Care, Parkville, Australia, ³Weill Cornell Medicine, Anesthesiology, New York, United States

Background and Goal of Study: Circulating biomarkers of inflammation are associated with postoperative delirium, however the association with postoperative Neurocognitive Disorders (NCD) has received little attention.

The aim of this study was to assay inflammatory biomarkers (IL-6, IL-10, IL-18) and investigate associations with NCD.

Materials and Methods: After ethics approval and informed consent, we analysed plasma biomarkers of 62 participants who had also undergone cognitive assessments. Plasma was taken at baseline, and at 30 min, 6, 24, and 48h after incision. Proteomic assays were processed on a multiplex biomarker assay platform using electrochemiluminescence. Postoperative NCD was assessed using 8 cognitive tests in addition to functional and subjective assessments.

Major and mild NCD were defined according to current nomenclature and combined to yield a composite NCD outcome at 3 months and a longer term assessment at 28.7 (8.7) [mean (SD)] months.

To analyse the association between biomarker change and subsequent cognition we used linear mixed-effects models.

Results and Discussion: 63 participants were assessed at 3 months and 46 at long term follow-up. At 3 months 18/63 (28.6%) participants and at long term 17/46 (37%) were classified as NCD. Plasma IL-6 and IL-10 significantly increased and IL-18 significantly decreased over the sampling period (Fig 1).

Participants with long term NCD had a significant increase in IL-6 levels at 24 hours (p=0.04) (Fig 2).

Conclusion(s): Approximately one third of older subjects demonstrated NCD at 3 months and 2 years. IL-6 and IL-10 increase along different time courses in the immediate perioperative period. IL-6, which peaks at 24 hours is associated with long term NCD.

This opens up the possibility of assaying IL-6 to use as a screening test for long term NCD after anesthesia and surgery.

BAPC-06

Lung aeration following PEEP individualization during laparoscopic surgery in obese patients: A secondary analysis of the PEEP LAP study

E. Verdina^{1,2}, D. Rosalba^{1,2}, G. Furlan², L. Carrera², R. Vaschetto^{1,2}, G. Cammarota^{3,2}, PEEP LAP Study Group ¹AOU Maggiore Della Carita', ANESTESIA E RIANIMAZIONE, Novara, Italy, ²Università degli Studi del Piemonte Orientale "Amedeo Avogadro", MEDICINA TRASLAZIONALE, Vercelli, Italy, ³AOU SS Antonio e Biagio E Cesare Arrigo, ANESTESIA E RIANIMAZIONE, Alessandria, Italy

Background and Goal of Study: Intraoperative protective ventilation is a strategy to minimize lung injury during surgery. However, recommendations on PEEP settings remain inconsistent. In obese patients, high PEEP may prevent atelectasis; however, evidence of its effect on postoperative complications is limited, likely due to the need for individualized PEEP based on lung mechanics. This study explores the effect of PEEP, set with the Recruitment-to-Inflation Ratio (RIR) maneuver, on lung aeration in obese patients undergoing laparoscopic/robotic surgery.

Materials and Methods: We recruited adult obese patients (BMI ≥ 30 kg/m2) who underwent laparoscopic or robotic abdominal/pelvic surgery. Volume-controlled ventilation (6-7 ml/kg IBW) was used. PEEP was set according to RIR. Electrical impedance tomography (EIT) was performed at five timepoints: pre-intubation, post-intubation, post-pneumoperitoneum, post-Best PEEP, and post-extubation. Global inhomogeneity index (GI), Regional Ventilation Delay (RVD), and regional aeration were analyzed.

4 ESAIC Best Abstract Prize Competition (BAPC)

Results and Discussion: Among 32 patients screened (January-September 2024), 20 were analyzed. Of these, 35% were high recruiters (RIR > 0.5), Median PEEP was 7.5 cmH₂O (5-12.25): 5 cmH₂O (5-7) in low recruiters and 15 cmH₂O, (12-16.5) in high recruiters. Airway opening pressure was observed in 35% of patients (8 cmH₂O, 7.5-10). Lung inhomogeneity worsened intraoperatively (RVD: 10% to 11.76%; GI: 55.61% to 79%) but returned to baseline after extubation (RVD: 9.7%; GI: 55.67%). High recruiters exhibited greater inhomogeneity at baseline and post-extubation but showed the most significant improvement after PEEP (GI: 81% to 68.2%), with notable recovery in dorsal-mediodorsal aeration. In contrast low recruiters had smaller changes and regional aeration was less affected by mechanical ventilation. Patients with compliance improvement after Best PEEP (75%) showed better RVD (7.93% vs. 11.54%), GI (66.58% vs. 84.20%), and dependent zone aeration (38.33% vs. 17.6%), highlighting the protective role of individualized PEEP. Interestingly, we found a substantial normalization of GI, RVD and dorsal-mediodorsal aeration to the preoperative values in most patients in our cohort.

Conclusion(s): Individualized PEEP based on RIR improves lung aeration and reduces inhomogeneity, particularly in high recruiters, emphasizing the role of tailored ventilation strategies in preventing atelectasis during surgery.

Perioperative Care

10AP01-2

A late-onset case of congenital central hypoventilation syndrome (CCHS) with the PHOX2B gene mutation after exposure to general anesthesia

K. Ando¹, J. Oshida¹
¹Saitama Municipal hospital, Department of
Anesthesiology and Critical Care, Saitama, Japan

Background: Congenital central hypoventilation syndrome (CCHS) is a very rare disease characterized by apnea or hypoventilation during sleep. This disease is caused by the failure of brainstem autonomic control of ventilation due to PHOX2B gene mutation!

Although patients typically present with CCHS as newborns and rarely in later infancy, there have been several reports of patients presenting with CCHS in adulthood. This is called late-onset CCHS (LO-CCHS), which may be triggered by severe respiratory infection or exposure to sedatives or general anesthesia².

Case Report: We report a case of 59-years-old woman who was diagnosed LO-CCHS after general anesthesia. She was diagnosed with unexplained carbon dioxide narcosis after receiving treatment for pneumonia and heart failure and was wearing continuous positive airway pressure (CPAP) at night. She was subsequently diagnosed with bilateral breast cancer. She got bilateral mastectomy under general anesthesia.

After surgery, she returned to consciousness, but remained apnea, therefore she entered ICU without extubation. A day after the surgery, she was extubated, but she became hypoventilation and showed desaturation during sleep. Arterial carbon dioxide tension (PaCO₂) increases progressively with severe respiratory acidosis, somnolence, and coma. She was reintubated and then tracheostomy was performed. Later, genetic analysis revealed a mutation in the PHOX2B gene, and she was diagnosed with LO-CCHS.

Discussion: In cases of LO-CCHS, most patients report having had some symptoms since childhood, and they have parents with a history of CCHS. Symptoms of right-sided heart failure are generally observed at the time of diagnosis, and nocturnal noninvasive ventilation is frequently indicated.

These presentations involve cardiac rhythm disturbance, transient asystole, decreased heart rate variability. In this case, she frequently became bradycardia and lost consciousness, so she underwent pacemaker implantation.

Patients who may be suspected of LO-CCHS, which is triggered by sedatives or general anesthesia, should be avoid general anesthesia if possible.

References:

- 1. Weese-Mayer DE et al. Am J Respir Crit Care Med. 2010;181:626-44.
- 2. Basu SM et al. Anesth Analg. 2017;124:169-178.

Learning Points: Anesthesiologists need to include undiagnosed LO-CCHS in the differential diagnosis of patients with unexplained postoperative respiratory depression.

10AP01-4

GIP/GLP-1 Co-agonist is not associated with higher risk of aspiration pneumonia compared to GLP-1 agonists

C. Peng¹, X.Y. See², Y.-C. Chang¹, Y. Chang³, C.-H. Chiang⁴

¹Danbury Hospital, Internal Medicine, Danbury, United States, ²Unity Hospital, Internal Medicine, Rochester, United States, ³National Cheng Kung University Hospital, Neurosurgery, Tainan, Taiwan, ⁴Mount Auburn Hospital, Internal Medicine, Cambridge, United States

Background and Goal of Study: Glucagon-like peptide-1 agonists (GLP-1a) can delay gastric emptying, raising concerns about the risk of pulmonary aspiration during elective procedures and surgeries. Despite this, the American Society of Anesthesiologists (ASA) recently updated its guidance, allowing most patients to continue GLP-1a therapy before surgery. Tirzepatide, a glucose-dependent insulinotropic polypeptide (GIP)/GLP-1 co-agonist, has shown superior efficacy in weight loss and glycemic control compared to GLP-1a. However, it remains unclear whether tirzepatide poses a greater risk of aspiration pneumonia than GLP-1a.

This study evaluated the risk of aspiration pneumonia in patients using GIP/GLP-1 co-agonist versus GLP-1a during endoscopy and ambulatory surgery.

Materials and Methods: We performed a retrospective, propensity-score-matched cohort study using the TriNetX Database. We included adult (age≥18) patients with either type 2 diabetes (T2DM) or obesity who underwent endoscopy or ambulatory surgery. Patients in the GIP/GLP-1a and GLP-1a cohorts had at least two prescription refills within one year before the index procedure

The primary outcome was the incidence of aspiration pneumonia within 14 days post-procedure. The secondary outcome was the incidence of acute respiratory failure. Covariates included demographics, BMI, HbA1c, comorbidities, and use of T2DM and GI medications.

Propensity score matching was used with a standardized mean difference of <0.1 to indicate balanced covariates. Risk estimates were calculated using logistic regression on the TriNetX platform, and risk ratios were reported. Statistical significance was set at p < 0.05.

Results and Discussion: After matching, each cohort included 4,627 patients, and all covariates were balanced. The incidence of aspiration pneumonia did not differ significantly between the GIP/GLP-1a and GLP-1a cohorts (Risk ratio 0.69 [95% CI 0.43–1.11]). Similarly, no significant difference was observed in acute respiratory failure rates (Risk ratio 0.91 [95% CI 0.49–1.68]).

These findings suggest that GIP/GLP-1 co-agonist is not associated with a higher risk of aspiration pneumonia or acute respiratory failure compared to GLP-1a in patients undergoing elective procedures.

Conclusion(s): The risk of post-procedure aspiration pneumonia did not differ between patients using GIP/GLP-1 co-agonist and those using GLP-1a before endoscopy and ambulatory surgery.

10AP01-5

GLP-1 analogs do not associate with increased aspiration pneumonia compared to DPP-4 inhibitors in ambulatory surgery

C. Peng¹, X.Y. See², Y.-C. Chang¹, Y. Chang³, C.-H. Chiang⁴
¹Danbury Hospital, Internal Medicine, Danbury, United
States, ²Unity Hospital, Internal Medicine, Rochester,
United States, ³National Cheng Kung University Hospital,
Neurosurgery, Tainan, Taiwan, ⁴Mount Auburn Hospital,
Internal Medicine, Cambridge, United States

Background and Goal of Study: The use of glucagon-like peptide-1 agonists (GLP-1a) has raised concerns about a potential increase in aspiration pneumonia during surgery. Many hospitals follow the American Society of Anesthesiologists (ASA) 2023 guidance to hold GLP-1a before elective procedures. However, this guidance does not apply to dipeptidyl peptidase-4 inhibitors (DPP-4i), which also act on the GLP-1 pathway. Whether GLP-1a presents a higher risk of aspiration pneumonia compared to DPP-4i during ambulatory surgeries remains unclear.

This study aimed to investigate the incidence of aspiration pneumonia in patients using GLP-1a versus DPP-4i after ambulatory surgeries.

Materials and Methods: We conducted a retrospective cohort study using the TriNetX Database. Adult (age ≥18) patients with either type 2 diabetes (T2DM) or obesity who underwent 1-day ambulatory surgeries were included. The GLP-1a and DPP-4i cohorts consisted of patients with at least two prescription refills within one year and who continued medication use within 1 month prior to surgery. The primary outcome was the incidence of aspiration pneumonia within 14 days post-surgery. Secondary outcomes included aspiration pneumonitis and acute respiratory failure. Covariates included demographics, BMI, HbA1c, comorbidities, and T2DM and GI medications. Propensity score matching was performed, with a standardized mean difference of <0.1 indicating balanced covariates. Risks were estimated and compared using a logistic regression model on the TriNetX platform and reported risk ratio (RR). A p-value < 0.05 was considered statistically significant.

Results and Discussion: After matching, each cohort included 4,831 patients with balanced covariates. The risk of aspiration pneumonia in the GLP-1a cohort was similar to the DPP-4i cohort (RR: 0.93, 95% Cl: 0.61-1.43). No significant differences were observed in the rates of aspiration pneumonitis (RR: 0.71, 95% Cl: 0.32-1.61) or acute respiratory failure (RR: 0.71, 95% Cl: 0.42-1.19). Our findings suggest that GLP-1a use was not associated with an increased risk of aspiration pneumonia compared to DPP-4i following ambulatory surgeries.

Conclusion(s): The risk of post-surgery aspiration pneumonia did not differ between users of GLP-1a and DPP-4i undergoing ambulatory surgeries. Further research is warranted to guide an individualized approach to GLP-1a management during the perioperative period.

10AP01-6

Should we divide the preoperative ASA 2 group into smaller subgroups to better evaluate our patients?

T. Ildikó¹, G. Simon¹

¹Pécs University Medical School, Anesthesiology and Intensive Care, Pécs, Hungary

Background and Goal of Study: The preoperative ASA 2 group is very heterogeneous having patients from different ages. All the preoperative scores evaluate patients for the postoperative period; however, the intraoperative period is more important e.g. hindering hypotension. Patients' reactions to our anesthetic drugs represent their general conditions. Propofol is a drug that can cause hypotension, so it is automatically decreased by anesthetists in elderly patients. More studies have already focused on a new drug, ciprofol, that causes more stable hemodynamic parameters in elderly patients (1).

Materials and Methods: We analyzed retrospectively patients' preoperative data and their anesthesia induction parameters. We aimed to search for parameters that might differentiate between young and old ASA 2 patients' groups with different general conditions. A young (Group I, age < 40 years) and an elderly (GII, age > 70 years) ASA 2 group was created on the age scale of our examined patients. Patients' ASA scores and two other score points (Charlson Comorbidity Index /CCI/ and Possum-P /PP/ score) were compared with patients' induction parameters. Statistical analysis was performed with the SPSS program, significance level was p<0.05. Ethical Approval Nr: 9337-PTE 2022.

Results and Discussion: The two groups (80-80 patients) differentiated significantly in the administered propofol dosage/bodyweight (Gl: 2.9 ± 0.9 mg vs GlI: 2.39 ± 0.7 mg, p= 0.016) and in the post-induction blood pressure drop (Gl: 20 ± 12 mmHg, GlI: 34 ± 17 mmHg, p< 0.001). Based on their CCI and PP scores we realized significant differences in their total score and the predicted mortality/morbidity percentage, proven by the frequency of the postoperative complications. However, as we compared the subparameters of the score systems, a significant difference was visible only in the cardiac function and the kidney parameters (CN Gl: 4 ± 1 , GlI: 7 ± 3 mmol/I, p=0.02) besides age.

Conclusion(s): We differentiated two in their parameters significantly different groups within the ASA 2 patients based on their age. Parameters representing patients' age and frailty need to be identified and a new score system should be designed to predict intraoperative management difficulties.

1. Chen, W. et al. A meta-analysis and systematic review based on perioperative management of elderly patients: is ciprofol an alternative to propofol?. Eur J Clin Pharmacol (2024). https://doi.org/10.1007/s00228-024-03782-7

10AP01-7 Perioperative hyperlactatemia: can it just be shivering?

A.S. M. Fernandes¹, <u>P. Vieito</u>¹, D. Santos¹, M.F. Martins¹ 'Unidade Local de Saúde de Santo António, Department of Anaesthesiology, Porto, Portugal

Postoperative hyperlactatemia is a marker of physiological stress after surgical procedures. While lactic acidosis is associated with high mortality, isolated serum lactate increase is a condition with poorly understood underlying causes and prognosis. We present a clinical case of substantial increase in postoperative lactate, possibly due to shivering.

A 74-year-old male patient was admitted to PACU immediately after a radical cystoprostatectomy with ileal conduit urinary diversion in the context of bladder neoplasm. He had a personal history of hypertension, atrial fibrillation, dyslipidemia, diabetes, grade I obesity, and sleep apnea. Preoperative haemoglobin was 11.9 g/dL. An intravenous general anaesthesia was performed. He was initially scheduled for laparoscopic surgery, but surgical technical difficulties arose in prostate dissection, leading to a small rectal laceration and a conversion into infra-umbilical laparotomy. Although total estimated bleeding losses were 1500 mL, serial arterial blood lactates range was 0.7-1mmol/L. There was no need for vasopressors and normothermia was maintained. The patient arrived in PACU conscious, haemodynamically stable, normothermic, and painless. Approximately 60 minutes after admission, an episode of shivering occurs and was treated with meperidine. In a new arterial blood gasometry, there was a substantial and isolated increase in lactates (maximum 8mmol/L). The patient was promptly evaluated by his surgeon to exclude surgical complications. Venous blood sample confirmed haemoglobin of 9.9g/dl and normal CK, LDH, and ionic balance. Lactates returned to baseline after 5 hours (minimum 1.9mmol/L). During hospitalization, the patient maintained a subfebril temperature. although with a declining CRP and no need for antibiotherapy. He was discharged on the 8th postoperative day.

Postanaesthetic shivering is a common event and a major contributor to patient discomfort in the postoperative setting. It is associated with increased metabolic demand and oxygen consumption, which can be the basis to explain transient postoperative hyperlactatemia. Nevertheless, it is essential to exclude other underlying causes of postoperative hyperlactatemia.

- Postoperative hyperlactatemia should be promptly investigated to determine a differential diagnosis of benign and pathological causes
- Postanaesthetic shivering is associated with a catabolic state and therefore can explain transient postoperative hyperlactatemia.

Urmann³</u> ¹Universidade Regional Integrada do Alto Uruguai e das Missões (URI), Department of Health Sciences, Erechim, Brazil, ²Universidade Regional Integrada do Alto Uruguai e das Missões (URI), Department of Health Sciences, Department of Food Engineering, Erechim, Brazil, ³Universidade Regional Integrada do Alto Uruguai e das Missões, Department of Health Sciences, Erechim, Brazil

Background and Objective of the Study: The study addresses the importance of abbreviating the traditionally long preoperative fasting period, which brings adverse effects such as thirst, hunger, and anxiety for patients. Based on protocols like ERAS and ACERTO, the research aims to develop and characterize an instant coffee-flavored product enriched with carbohydrates and free of caffeine. This product is designed to be consumed up to two hours before elective surgeries to reduce the discomfort caused by prolonged fasting and improve patient well-being.

Materials and Methods: The study involved the development of a preoperative product composed of carbohydrates and decaffeinated coffee, meeting the criteria for clear liquids, alongside the presentation of its nutritional information. Analyses were conducted to determine the product's moisture, ash, protein, fat, dietary fiber, carbohydrate, and mineral (sodium) content to create its nutritional table. Microbiological quality was ensured through tests for the identification of *Salmonella* spp. and *Escherichia coli*.

Results and Discussion: The formulation, registered under number BR102022022016-6 with the National Institute of Industrial Property, has a hypercaloric composition of 296.12 kcal per 78.53 g serving, free of fat, gluten, and lactose. Microbiological tests confirmed sanitary compliance, with no detection of Sal-

monella spp. or Escherichia coli. The product is characterized as an instant coffee-flavored powder recommended for preparation by dissolving the contents in 200 ml of water at 60°C. This solution can be consumed up to two hours before the surgical procedure.

Conclusion: The development of the instant coffee-flavored product proved to be a viable solution for abbreviating preoperative fasting while meeting the nutritional needs of patients. Its hypercaloric composition reinforces its practical applicability in hospital settings. These results suggest that the product can contribute to improving patient well-being and perioperative experience, aligning with evidence-based protocols such as ERAS and ACERTO.

10AP01-9

Barcelona, Spain

Improving adherence to Multimodal Prehabilitation: what do patients say?

E. Moret-Ruiz¹, M. Nájera², J. Moreno³, P. Carrasco⁴, C. Bassa⁵, M. Macias⁶ ¹University Hospital Germans Trias i Pujol, Anaesthesiology, Postoperative ICU and Pain Treatment, Badalona/Barcelona, Spain, ²University Hospital Germans Trias i Pujol, Hospital Administration, Badalona/Barcelona, Spain, ³University Hospital Germans Trias i Pujol, Psychology, Badalona/Barcelona, Spain, ⁴University Hospital Germans Trias i Pujol, Physiotherapy, Badalona/Barcelona, Spain, ⁵University Hospital Germans Trias i Pujol, Nursey, Badalona/Barcelona, Spain, ⁵University Hospital Germans Trias i Pujol, Nutrition, Badalona/

Background and Goal of Study: Multimodal prehabilitation (MP) programs (exercise, nutrition, anxiety reduction) have been developed to enhance patients' physical and mental status before surgery, although adherence remains a challenge. Maintaining adherence during a short pre-operative period of 4 weeks is crucial to maximizing program effectiveness. Aim of the study was to better understand patients' perspective of MP and to identify factors related to program adherence.

Materials and Methods: A qualitative descriptive study was conducted over a 9-month period with patients scheduled for complex cancer surgery who were enrolled in a MP program at a tertiary university hospital. Data were collected with an anonymous, voluntary, structured questionnaire designed to evaluate the MP program. Patients were excluded if they were unable to complete the survey due to illiteracy, language, cognitive impairment, or visual/hearing deficits.

Results and Discussion: From a total of 163 consecutive prehabilitated adult patients awaiting major gastrointestinal, urological, gynaecological surgeries, 131 met inclusion criteria and were asked to fill in the form at the end of the program with a response rate of 55% (72 patients, 55.5 % male, mean age 71.5 ys). 94.4% of participants were unfamiliar with the concept of prehabilitation but 97.2% were interested in it after explanation. 93 % had never attended a gym nor had nutritional or psychological support before. Medical recommendation increased willingness to participate, while number of visits was a potential barrier to participation. All the patients were very satisfied with the program and will recommend it (mean Likert score 9 out of 10). Patients particularly enjoyed the supervised training and psycho-educative group

sessions. Primary motivating factor for participation was the desire to be "strong for surgery". Patients reported learning "healthy habits to help you live longer". 21% of patients expressed interest in continuing the program postoperatively. The biggest barrier to participation was related to transportation.

Conclusion(s): These findings highlight the importance of making Multimodal prehabilitation programs more patient-centred. Effective therapeutic strategies should be designed to align with patients' expectations, adding value to the surgical process and improving adherence to the program.

Acknowledgements: I would like to thank all the MP team members for the their enormous effort and dedication.

10AP01-10

Impact of frailty on postoperative complications during Multimodal Prehabilitation in patients scheduled for radical cystectomy due to bladder cancer

E. Marroquín¹, C. Acosta², R. Coll³, M. Dinu¹, E. Moret², L. Chakkour El Onsri².⁴

¹University Hospital Germans Trias i Pujol/Autonomous University Barcelona, Anaesthesiology, Postoperative ICU and Pain Treatment, Badalona/Barcelona, Spain, ²University Hospital Germans Trias i Pujol, Anaesthesiology, Postoperative ICU and Pain Treatment, Badalona/Barcelona, Spain, ³University Hospital Germans Trias i Pujol, Physical Medicine and Rehabilitation, Badalona/Barcelona, Spain, ⁴Autonomous University Barcelona, Medicine Faculty, Badalona, Spain

Background and Goal of Study: Multimodal prehabilitation (MP) is designed to enhance patients' physical and mental capacity before complex surgeries, aiming to minimize postoperative complications, improving outcomes. Frailty is highly prevalent in cancer patients and should be routinely assessed and addressed through MP. The aim of this study was to analyse the prevalence of frailty and its impact on postoperative outcomes in prehabilitated patients scheduled for radical cystectomy due to bladder cancer.

Materials and Methods: Over a 4-week period before surgery, patients received personalized physical training, nutritional and psychological support from a multidisciplinary team. The Short Physical Performance Battery (SPPB), 6-Minute Walk Test (6MWT), handgrip strength, International Physical Activity Questionnaire (IPAQ), and maximal inspiratory pressure (MIP) were assessed before and after MP. Patients with an SPPB score < 7 were considered frail. Non-frail patients performed home-based training, while frail patients underwent supervised in hospital training twice a week. Anaemia was treated if haemoglobin (Hb) < 13 g/dL. Postoperative complications within 90 days were recorded.

Results and Discussion: A total of 28 consecutive prehabilitated patients were enrolled over an 8-month period (75% male, mean age 71.6 years, all ASA III, 29.6% non-smokers). Of these, 25% were classified as frail (57.1% male). Baseline mean values for G1 (frail) and G2 (non-frail) were: 6MWT (m) was 79.2 vs 102.5 (p=0.002), handgrip (kg) 24 vs 33.6 (p=0.023), MIP (cmH $_2$ O) 39 vs 91.5 (0.004), 85.7% of G1 patients had a low IPAQ score, Hb (g/dL) 10.1 vs 13.4 (0.001). All frail patients were iron-deficient and were treated with IV iron and 28.6% of them required transfusion before surgery. Values after MP were not significantly different

among groups. In the frail group, one patient visited the ER postoperatively, one patient required a reoperation and one patient died. G1 patients did not experienced significantly more postoperative complications compared to G2 patients. LOS was similar among groups.

Conclusion(s): In this study, the prevalence of frailty among our patients was 25%. Frail patients showed improvement in their baseline values before surgery.

The findings highlight that frail patients with bladder cancer who underwent radical cystectomy did not experience significantly more postoperative complications compared to non-frail patients after multimodal prehabilitation.

10AP01-11

Development of Remote Photoplethysmography (rPPG) technology for blood pressure and hemoglobin level assessment in the preoperative assessment setting

S. Tan¹, H. Abdullah¹, J. Chai¹, U. Javaid², B. Tan¹, K.Y. Fong¹ Singapore General Hospital, Division of Anesthesiology and Perioperative Medicine, Singapore, Singapore, 2Nervotec, Nervotec, Singapore, Singapore

Background and Goal of Study: There are various studies about noninvasive, remote photoplethysmography (rPPG)-based measurement of blood pressure (BP) and hemoglobin (Hb) concentration. Most studies are on healthy subjects with similar skin tones. There is limited data on rPPG BP and Hb measurements in patients with medical comorbidities and diverse skin tones.

The aim was to develop a model for non-invasive rPPG systolic BP (SBP), diastolic BP (DBP) and Hb measurements in diverse patient populations, which could be used for telemedicine-based preoperative evaluation.

Materials and Methods: The study was conducted at Singapore General Hospital from 1 March 2023 to 28 June 2024. 200 patients with a mean age of 56.4 years participated. 47.5% had comorbid conditions such as hypertension. Each group had a range of skin tones according to the Monk Skin Tone scale. Reference readings were measured with the Welch Allyn Connex[®] Vital Signs Monitor 6000 Series[™].

Simultaneously, vital signs were captured using rPPG technology via a laptop and webcam-based facial scan. Hb concentration was derived from the rPPG scans.

The primary analysis compared rPPG SBP and DBP measurements with measurements using automated blood pressure measuring devices. The secondary analysis compared rPPG Hb measurements with laboratory measurements.

Results and Discussion: Mean absolute percentage error (MAPE) for rPPG systolic BP and diastolic BP measurements were 9.52 and 7.52%. The mean difference between rPPG and reference measurements for SBP and DBP was 2.68 and 0.15 mmHg, standard deviation (SD) 7.86 and 3.22 mmHg. The model showed greater accuracy in predicting DBP than SBP. The 95% confidence interval for the mean difference between measurements was: SBP [1.153, 3.825]; DBP [-0.426, 0.726]. Our model predicted Hb with a MAPE of 8.52% and SD 0.74 g/dL. The mean predicted Hb was 12.71 g/dL (SD 1.13 g/dL), compared to the reference Hb of 12.95 g/dL (SD 1.81 g/dL). The mean difference was 0.23 g/dL (SD 0.67 g/dL). Strongest performance was noted in the mid-quartile ranges for DBP and Hb.

Conclusion(s): Our study is the first to evaluate contactless rPPG BP and Hb measurements in a population with varying skin tones and medical comorbidities. rPPG offers a scalable, contactless solution for vital signs monitoring. Further research could expand its utility and transform preoperative and chronic care through telehealth innovations.

10AP01-12

Splenectomy in secondary refractory Haemophagocytic lymphohistiocytosis in patient with severe thrombocytopenia - a perioperative challenge

M. Donga¹, R. Felgueiras¹, C. Silva¹, J. Pinto¹, E. Figueiredo¹, A. Guedes¹ ¹Unidade Local de Saúde Viseu Dão-Lafões, Anesthesiology, Viseu, Portugal

Background: Haemophagocytic lymphohistiocytosis (HLH) is a syndrome of severe immune activation and dysregulation rarely present in adults, usually secondary to a rheumatologic, infectious, or malignant disease(1). Common clinical features include fever, splenomegaly, cytopenias, hemophagocytosis, and coagulopathy(2). Seldom presented to the anesthesiologist, treatment is primarily medical and when refractory, splenectomy may be performed. Perioperative management and optimization in a multidisciplinary approach is fundamental with anesthesiology playing a key role.

Case report: 74 y.o. man, ASA IV proposed for therapeutic and diagnostic open splenectomy for refractory HLH secondary to suspected splenic lymphoma. He presented with severe thrombocytopenia (7x10^9/L), anemia (9,8g/dL), coagulopathy and acute renal injury. We performed a multidisciplinary evaluation with surgical team, ICU physicians and hemotherapy opting for prior splenic embolization. A TIVA was performed, with invasive arterial monitorization and a central venous line. Due to blood losses of 1,7L, anemia and coagulopathy treatment were guided by rotational thromboelastometry. Despite our effords, the patient remained in the ICU intubated under controlled mechanical ventilation, continuous dialysis and with increasing vasopressors passing away 4 days after surgery.

Discussion: Evidence for splenectomy in refractory HLH secondary to malignancy is scarce, with few case-reports. Due to pancytopenia, coagulopathy and multiorgan damage, high anesthesia and surgical risk exists, with patient blood management (PBM) as one of the most challenging aspects. Therefore, a multidisciplinary evaluation and optimization, as well selection of optimal surgical timing is fundamental in order to improve patient outcomes.

References:

- 1. Daver N, et al. A consensus review on malignancy-associated hemophagocytic lymphohisticcytosis in adults. Cancer. 2017 Sep 1;123(17):3229-3240.
- 2. Henter JI, et al. Diagnostic guidelines for hemophagocytic lymphohistiocytosis. The FHL Study Group of the Histiocyte Society. Semin Oncol. 1991;18:29–33.

Learning points: Splenectomy in refractory HLH secondary to malignancy is rarely presented to the anesthesiologist. Perioperative management is difficult making multidisciplinary evaluation, PBM and optimal timing for surgery fundamental.

Predicthor: Al-powered predictive risk model for 30-day mortality and 30-day complications in patients undergoing thoracic surgery for lung cancer

X. Durand¹, <u>J. Hédou</u>¹, G. Bellan¹, A. Gillibert², J.-M. Baste²

¹SurgeCare, SAS, Illkirch-Graffenstaden, France, ²CHU Rouen, Inserm U1096, UNIVROUEN, Department of Cardio-Thoracic Surgery, Rouen, France

Background and Goal of Study: The significance of predicting postoperative complications in thoracic surgery lies in the impact on patient outcomes and the efficient allocation of healthcare resources. The longstanding use of the Thoracoscore for over 15 years in hospital settings emphasizes the opportune moment for an update, leveraging new artificial intelligence methodologies to enhance predictive precision and relevance. The objective is to assess the predictive performance of Predicthor, an artificial intelligence model, for 30-day mortality and complications following major pulmonary resections.

Materials and Methods: The EPITHOR French population-based database linked to the National Institute of Statistics and Economic Studies database has been queried from January 1, 2016, through December 31, 2022 on six selected hospital centers (Rouen, Dijon and Toulouse CHUs, Strasbourg CHRU, Centre Hospitalier Général de Bayonne and AP-HM) with curated data collection. 6,508 patients who have undergone primary lung cancer surgery via lobectomy or bilobectomy, aged over 18 years, and with an ASA score under 4, were selected. In a retrospective analysis using a three-dataset scheme (training cohort, internal and external validation), we assessed the predictive performance of Predicthor for 30-day complications and mortality following major pulmonary resections.

Results and Discussion: Postoperative complications occurred in 39% of patients, with 31.5% experiencing complications of Clavien-Dindo grade III or higher. Overall mortality was 1.3%. Predicthor excelled in predicting 30-day mortality with an AUC of 0.81(95% CI:0.68-0.93, P=2.06E-05), surpassing the Thoracoscore at 0.73(95% CI:0.62-0.84, P=1.5E-03). Predicthor identified nine key variables, including age, comorbidity scores, tumor characteristics, FEV1 and dyspnea. They were utilized for predicting Comprehensive Complication Index (Pearson-r:0.24, 95% CI:0.18-0.29, P=1E-18) and complications with Clavien-Dindo≥III (AUC:0.64, 95% CI:0.60-0.69, P=4E-09).

Conclusion(s): Predicthor's predictive performance for 30-day mortality and complications highlighted its potential as a valuable tool in clinical decision-making. The study's methodology and comprehensive dataset contribute to its relevance in using machine learning on large available databases for shaping thoracic surgery practices and patient management.

10AP02-2

Meta-analysis of mortality in patients with chronic coronary artery disease: Surgical or percutaneous interventions versus optimized medical therapy – Implications for perioperative management. From PEARL investigators: Perioperative Evidence-based Approach Research Laboratory

J.V. Alvachian¹, L. Pimenta¹, G. Pitanga¹, F. Costa¹, P. Romero¹, G. Sanine¹

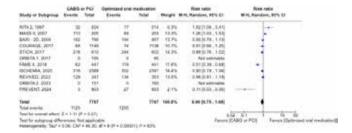

¹São Camilo Hospital, Anesthesia and Perioperative Medicine, Sao Paulo, Brazil

Background and Goal of Study:Chronic coronary artery disease (CAD) complicates perioperative decision-making, delaying critical surgeries like oncological procedures. This study evaluates mortality outcomes in CAD patients treated with coronary artery bypass grafting (CABG), percutaneous coronary intervention (PCI), or optimized medical therapy (OMT).

Materials and Methods: A meta-analysis of randomized controlled trials (RCTs) was conducted using studies retrieved from Cochrane, Embase, and Medline databases. Inclusion criteria: adult patients (≥18 years) with chronic CAD, comparing CABG/PCI versus OMT groups, with mortality as the primary outcome within study-defined follow-up periods. Studies published from 1990 to May 2024 were included. Data were analyzed using RevMan 5.0 software, applying a random-effects model and relative risk calculation to account for anticipated heterogeneity among the included studies.

Results and Discussion: A search found 7,278 articles (PubMed 1,673, Cochrane 659, Embase 4,946); after removing duplicates and non-eligible studies, 11 were included in the meta-analysis. No significant differences in mortality were observed between the intervention groups (CABG/PCI) and the control group (OMT). High heterogeneity (elevated I² values) was noted, indicating variability across studies and necessitating cautious interpretation.

The observed equivalence in mortality outcomes suggests that in CAD patients, invasive interventions may be reconsidered in perioperative contexts. This approach could reduce delays in surgical management and improve outcomes for patients with severe comorbid conditions, such as cancer. However, these findings are hypothesis-generating due to limited robust data on direct perioperative impacts.

Conclusion(s):The meta-analysis demonstrates no significant difference in mortality between CABG/PCI and OMT strategies in stable CAD patients. These results support the possibility of maintaining OMT during the perioperative period, avoiding invasive procedures that could delay urgent surgeries. Further studies are needed to validate these findings and assess their influence on perioperative outcomes.

The effect of combining music therapy and preoperative educational videos on preoperative anxiety in gynecological patients

D. Fan1

¹Sichuan Provincial People's Hospital, Anesthesiology, Chengdu, China

Background and Goal of Study: This study aims to evaluate the impact of combining preoperative music therapy and educational videos within the framework of Enhanced Recovery After Surgery (ERAS) strategies on preoperative anxiety in gynecological patients.

Additionally, the study assesses the intervention's effects on postoperative pain, fatigue, and overall recovery quality.

Materials and Methods: A single-center, prospective, randomized controlled trial was conducted on 80 patients who underwent gynecological laparoscopic surgery at Sichuan Provincial People's Hospital from July 2022 to September 2023. Patients were randomly assigned to the control group (receiving standard ERAS care) or the experimental group (receiving a combination of music therapy and preoperative educational videos).

Anxiety levels were measured using the State-Trait Anxiety Inventory (STAI) at four time points: upon admission (T0), before anesthesia induction (T1), 24 hours post-surgery (T2), and before discharge (T3).

Postoperative pain and fatigue were assessed using the Numeric Rating Scale (NRS), and postoperative nausea and vomiting (PONV) along with catheter-related bladder discomfort (CRBD) were monitored.

Results and Discussion:Baseline characteristics such as age, BMI, education level, and surgery duration showed no statistically significant differences between the two groups (P > 0.05). Compared to the control group, the experimental group exhibited significantly lower STAI scores at T1 and T2 (P < 0.05).

Furthermore, the experimental group reported reduced resting pain, movement pain, and fatigue scores at T2 (P < 0.05), although these differences were not significant at T3. The experimental group also demonstrated significantly higher recovery quality and hospital satisfaction (P < 0.05). No significant differences were observed between the two groups regarding PONV, CRBD, or the time to first ambulation or bowel movement.

Conclusion(s):The combination of preoperative music therapy and educational videos can significantly reduce anxiety, pain, and fatigue in patients undergoing gynecological laparoscopic surgery, thereby improving recovery quality and patient satisfaction.

10AP02-4

Use of perioperative hypnosis by anesthesiologists for surgical and medical procedures: A systematic review with meta-analyses

M.J. Lahoud¹, S.T. Gurary², N. Elia^{1,2}
¹Geneva University Hospital, Department of
Anaesthesiology, Pharmacology, Intensive Care and
Emergency Medicine,, Geneva, Switzerland, ²Geneva
University, Faculty of Medicine, Geneva, Switzerland

Background and Goal of Study: Hypnosis is used in different settings during the perioperative period. Its impact on hypnotic requirements, pain, anxiety, or adverse effects remains unclear. This systematic review with meta-analyses addresses this question.

Materials and Methods: We searched PubMed, Cochrane Library, and Embase for studies (any design) where hypnosis was used perioperatively, alone or with any type of anaesthesia, in children and adults. Two authors selected the studies and extracted the data independently. Risk of bias was assessed for randomized controlled trials (RCT). Random effects meta-analyses were performed using RevManAPP if more than five studies or 100 patients including a comparator group reported on a similar outcome.

Results are reported as weighted mean differences (WMD), standardized mean differences (SMD) when an outcome was reported using different scales, or relative risk (RR) with 95% confidence interval (CI).

The primary outcome was the intraoperative use of hypnotic and opioids. Secondary outcomes included all reported outcomes related to pain, anxiety or adverse events. (PROSPERO: CRD42024538362).

Results and Discussion: 117 articles (7882 patients) were included: 56 RCT, 24 non-randomized studies including a comparator group (NRCS), 17 cohort studies without comparator or case series, and 10 case reports. Studies originating from 18 countries were published from 1974 to 2024.

Hypnosis reduced propofol (number of studies (n) = 6; WMD **-43.5 mg**, 95% CI [-73.3, -13.7]), intraoperative opioids (n=9; SMD -0.86, 95% CI: [-1.68, -0.04]), the number of patients needing class I-II (n=7; RR 0.51, 95%CI [0.32, 0.82] and class III analgesics (n=6; RR 0.66, 95%CI [0.54, 0.79]). Postoperative anxiety (n=13; SMD: -0.68, 95%CI [-0.96, -0.40]) remained unchanged.

Hypnosis had no impact on pain scores, procedure time, duration of ICU or hospital stays, but shortened PACU stay (n=7; WMD -28 minutes 95% CI [-48, -7.9]) and decreased the risk of postoperative nausea and vomiting (n=8; RR 0.48, 95%CI [0.31, 0.74]). The level of evidence for all outcomes ranged from very low to moderate.

Ten uncontrolled studies suggested that most procedures were successfully completed with hypnosis (median 92%), and 8 that patients would repeat the experience (median 95.5%).

Conclusion: Hypnosis may reduce analgosedation and improve postoperative outcomes, but the level of evidence is low.

Postoperative abnormal vital signs in patients recovering from elective non-cardiac surgery on the general ward: a prospective observational study

<u>A. Bergholz</u>¹, M. Flick¹, H. Sadtler¹, J. Auinger¹, L. Krause², B. Saugel^{1,3}

¹University Medical Center Hamburg-Eppendorf, Department of Anesthesiology, Hamburg, Germany, ²University Medical Center Hamburg-Eppendorf, Institute of Medical Biometry and Epidemiology, Hamburg, Germany, ³UTHealth, Outcomes Research Consortium, Houston, TX, United States

Background and Goal of Study: Mortality in the first month after non-cardiac surgery remains high, with the majority of patients dying on general wards during their hospital stay. Abnormal vital signs often precede severe complications, but vital sign alterations often remain undetected by current intermittent manual vital sign monitoring. Due to the lack of continuous vital sign monitoring in patients recovering from surgery on general wards, the incidence and severity of postoperative vital sign abnormalities in this patient population remain largely unknown.

We thus aimed to investigate the incidence, severity, and duration of postoperative abnormal vital signs in patients recovering from elective non-cardiac surgery on the general ward within the first five postoperative days.

Materials and Methods: We conducted a single-centre prospective observational study in 190 patients after elective non-cardiac surgery. Continuous vital sign monitoring (peripheral oxygen saturation (SpO₂), systolic arterial pressure, heart rate, respiratory rate, and body temperature) was performed using a wearable wrist sensor (Biobeat wrist sensor; Biobeat Technologies, Petah Tikva, Israel) for up to five postoperative days. The primary outcome was the normalized cumulative duration (% of monitoring time) with any abnormal vital sign.

Secondary outcomes included the incidence, severity, and duration of abnormal vital signs. We defined abnormal vital signs as: $SpO_2 \le 91\%$, systolic arterial pressure ≤ 90 mmHg or ≥ 220 mmHg, heart rate ≤ 40 beats per min or ≥ 131 beats per min, respiratory rate ≤ 8 breaths per min or ≥ 25 breaths per min, and body temperature ≤ 35 °C or ≥ 39.1 °C.

Results and Discussion: The median normalized cumulative duration with any abnormal vital sign was 6% (3%, 12%). Abnormal vital signs were common, occurring in 76% of patients for at least 5 consecutive minutes.

Hypoxemia and bradypnea were the most common vital sign abnormalities, affecting 60% and 44% of patients for at least 5 consecutive minutes, respectively. Severe abnormal vital signs lasting ≥30 consecutive minutes were less common (18% of patients).

Conclusions: Abnormal vital signs were common in patients recovering from non-cardiac surgery on general wards – with bradypnea and hypoxemia being the most common. One of five patients experienced prolonged episodes with abnormal vital signs. It needs to be determined whether continuous vital sign monitoring on general wards improves patient outcomes.

10AP02-6

Perioperative acute myocardial injury in women: is there any difference with men?

<u>A. Mases</u> ¹, L. Bosch¹, S. Sabaté², M. Núñez¹, E. Alonso¹, S. Beltrán de Heredia¹

¹Hospital del Mar, Department of Anesthesiology, Barcelona, Spain, ²Hospital de la Santa Creu i Sant Pau, Department of Anesthesiology, Barcelona, Spain

Background and Goal of Study: Male sex has been demonstrated to be an independent predictor for acute perioperative myocardial injury (PMI). We aimed to investigate differences between men and women who present PMI.

Materials and Methods: Post-hoc analysis of the MINSMAR data base. Prospective, single-centre cohort study enrolling patients (≥45 years) at risk for major adverse cardiovascular and cerebrovascular events (MACCE) scheduled for intermediate-to-high risk noncardiac surgery. Baseline high-sensitivity troponin T (hsTnT) and N-terminal fragment of pro-B-type natriuretic peptide (NT-proBNP), as well as hsTnT on the first 3 postoperative days were obtained.

Main outcome was the occurrence of acute PMI on the day of surgery or within the first three postoperative days. PMI was defined by at least one hsTnT value ≥30ng/L provided there was a rise and/or fall of at least 20% of the baseline hsTnT concentration. We also registered all-cause mortality and MACCE at 30 days and one year follow-up.

Results and Discussion: Of 732 patients analysed, 243 (33%) were women and 489 (67%) were men. PMI occurred in 161 patients (22%), of whom 43 (27%) were women. We found differences in the incidence of PMI between both sexes (18% in women vs 24% in men, *P*=0,048). Women who suffered PMI were older than those who did not [(78 yr.; 95% CI (74-83) vs 72 yr. (63-78)] and had more comorbidities: more prevalence of anaemia, hypertension, diabetes, heart failure, atrial fibrillation, worse kidney function and poorer functional capacity.

Compared to men, women with PMI were more obese, more anaemic and had higher cholesterol levels, but men had higher prevalence of known coronary and peripheral arterial disease and tobacco consumption.

In patients with PMI, we did not find sex differences in the prevalence of elevated preoperative hsTnT (\geq 14ng/L), 88% in women vs. 82% in men (P=0,460); however, elevated preoperative NT-proBNP (\geq 300pg/mL) was more prevalent in women (81% vs. 54%, P=0,002). In patients with PMI, we did not find differences between women and men in 30 days MACCE (18,6% vs. 25,4%; P=0,410) and mortality (4,7% vs. 3,4%; P=0,658) and 1 year mortality (18,6% vs. 25,4%; P=0,410), but MACCE at 1 year was higher in men (25,6% vs 50,8%; P=0,002).

Conclusion(s): The most notable differences between men and women with PMI are a higher prevalence of preoperative elevated NT-proBNP (≥300pg/mL) in women and a higher MACCE incidence at one year in men.

Perioperative Care

10AP02-7

Assessment of post-operative sore throat at the post-anesthetic care unit

I. Ferreira¹, I. Braga², A. Sá¹, F. Martins¹, H. Machado¹¹Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Serviço de Anestesiologia, Porto, Portugal, ²Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Serviço de Anestesiologia, Coimbra, Portugal

Background and Goal of Study: Postoperative Sore Throat (POST) is a frequent complaint following surgeries under general anesthesia with airway management. Its incidence varies between 33–61%, impacting patients' satisfaction. Factors suggested as potentiators of POST include ventilation device, number of intubation attempts, use of naso/orogastric tubes, and airway adjuncts like bougies or stylets. Pharmacological interventions have also been proposed as protective.

This study aims to evaluate the incidence of POST in the Post-Anesthetic Care Unit (PACU) of the Santo António Local Health Unit (ULSSA) and verify whether it aligns with reported rates. It also assesses POST intensity using the Visual Analog Scale (VAS, 0–10) and seeks to identify variables associated with higher or lower POST incidence.

Materials and Methods: Following institutional approval of an internal audit, we retrospectively analyzed the medical records of patients undergoing surgeries performed under general anesthesia with airway management between August and September 2024 in ULSSA. Those younger than 18 years, undergoing head, neck, or throat surgeries, or with a respiratory infection in the past month were excluded.

Demographic data, airway management techniques, pharmacological measures (dexamethasone, ketamine, lidocaine, NSAIDs), and POST VAS scores were analyzed using SPSS Statistics®.

Results and Discussion: Of 106 patients, 66% were male, with a mean age of 62. Most were ASA III (41.5%) and underwent general surgery procedures (35.8%). POST was identified in 21.7% of cases, with moderate pain reported in 5%, predominantly linked to endotracheal tube use. Airway approach with direct laryngoscopy or videolaryngoscopy did not lead to significant differences in POST, nor did the use of an orotracheal tube vs supraglottic devices. Pharmacological measures showed no protective effect against POST, nor was an association found between POST and the use of bougies or stylets. However, difficult laryngoscopies and multiple intubation attempts were associated with increased POST risk. The limited number of cases with moderate pain (n=5) may have restricted conclusions.

Conclusion(s): It is up to anesthesiologists to act according to the best evidence to prevent POST and treat it appropriately. Difficult laryngoscopies and multiple airway management attempts were related to a higher risk of POST, underscoring the importance of optimizing conditions during the first airway attempt.

10AP02-8

Every second counts: The dangers of delayed dantrolene administration in malignant hyperthermia

M. Blesa¹, J. Fernández-Ruiz¹, A. Marqués-Marí², O. Díaz-Cambronero^{3,4}, N. Moreno-Puigdollers⁵, M.P. Argente-Navarro⁶

¹Hospital Universitario y Politécnico La Fe, Anesthesiology, Valencia, Spain, ²Hospital Universitario y Politécnico La Fe, Malignant Hyperthermia Unit EMHG, Valencia, Spain, ³Hospital Universitario y Politécnico La Fe, Head Perioperative Medicine-Department Anesthesiology, Valencia, Spain, ⁴Lab-EMHG-Valencia, Chairman Malignant Hyperthermia, Valencia, Spain, ⁵Hospital Universitario y Politécnico La Fe, Head of Section, Coordinator of Anaesthesiology Department, Valencia, Spain, ⁵Hospital Universitario y Politécnico La Fe, Head of Anaesthesiology and Resuscitation Department. Director of Anaesthesia, Resuscitation and Surgical Block., Valencia, Spain

Background: Malignant hyperthermia (MH) represents a critical perioperative emergency with potentially fatal consequences. Due to limited reported cases in our region, professional awareness and early diagnostic precision remain challenging.

This case presentation explores MH diagnostic complexities and strategic management, adhering to the European Malignant Hyperthermia Group's 2024 guidelines (1).

Case Report: We present a case of a 21-year-old male without significant medical history who underwent surgical excision of anal condylomas in a private medical center. Administered medications during general anesthesia included midazolam, ketamine, propofol, fentanyl, rocuronium, and sevoflurane.

Postoperatively, the patient exhibited altered consciousness with pronounced sympathetic and muscular hyperactivity. Additional clinical findings included renal dysfunction with rhabdomyolysis, fever, hyperckemia, and increased lactate levels.

Given the critical nature of his condition, the patient was transferred to a tertiary-level medical center with a specialized MH Unit after 24 hours. Dantrolene was promptly administered, resulting in an adequate clinical response.

Following consciousness improvement, the patient presented with neurological sequelae, including immediate memory deficit and proximal lower extremity muscle weakness.

Genetic investigation through sequencing identified the patient as a heterozygous carrier of a variant of unknown significance (VOUS) in the CACNA1S gene, likely pathogenic of malignant hyperthermia.

Ongoing genetic screening is being performed in family members and in vitro contracture test (IVCT) is scheduled.

Discussion: By examining the diagnostic process, we aim to enhance clinical awareness among medical professionals confronting this rare but life-threatening condition. Timely Dantrolene administration is critical, as it not only reduces mortality but also mitigates potential long-term morbidity associated with delayed treatment.

Additionally, current guidelines suggest that DNA screening serves as a viable alternative to traditional diagnostic methods for primary evaluation (2).

References:

- 1. British journal of anaesthesia, 105(4), 417-420.
- 2. British journal of anaesthesia, 115(4), 531-539.

Learning points:

Malignant hyperthermia requires rapid recognition and immediate intervention with dantrolene.

Genetic screening provides crucial insights into familial risk and diagnostic evaluation.

10AP02-9

Adherence to recommendations and real situation of preoperative fasting in elective surgery patients of a Lithuanian tertiary center

M. Grasevic¹, D. Paulėkaitė¹, J. Gudaitytė¹
¹Lithuanian University of Health Sciences, Department of Anaesthesiology, Kaunas, Lithuania

Background and Goal of Study: Current fasting guidelines state that no clear liquids should be consumed <2h, solid food <6h before surgery [1,2]. However, following guidelines is a problem.

The aim of the study was to evaluate the situation in Lithuanian University of Health Sciences Hospital Kaunas Clinics (KC) in terms of awareness, real-time intake and possible adverse symptoms of dehydration.

Materials and Methods: The anonymous survey study received ethical approval (No 2023-BEC2-263) and was performed at KC in 11.2023 – 10.2024. Adult consecutive Lithuanian speaking, mentally healthy and admitted for elective surgery in 24h patients were asked to fill an original questionnaire.

Anaesthesiologists were asked to report intraoperative complications possibly related to fasting. Statistical analysis was performed with SPSS 29.0.0.0. Data is presented as mean±SD, number or % of cases.

Results and Discussion: The study included 87 patients, 36 males and 51 females. Mean time of last intake before surgery was 10.82±5.72 h for fluid and 16.16±4.39 h for solid food. According to patients, fluids must not be taken preoperatively: <2h in 16(18.4%), <6h in 51(58.6%), <24h in 16(18.4%) and indefinitely in 4(4.6%) cases, respectively.

Patients stated they knew the definition of clear fluids in 65(74.7%) cases but only 42(48.3%) of them marked the correct list of clear fluids. 79(90.8%) patients were informed about preoperative fluid intake: 52 by the surgeon, 35 - a resident doctor or another specialist, 29 - family doctor or nurse, 23 - an anaesthesiologist, 12 - relied on previous knowledge or social media.

Complaints related to prolonged fasting were xerostomia (n=45), thirst (n=43), heart palpitations (n=19), headache (n=11), fatigue (n=7), dizziness (n=5), muscle cramps (n=4), nausea (n=2).

Anaesthesiologists reported the following intraoperative adverse effects related to prolonged fasting: 7 cases of arterial hypotension, 3 cases requiring iv fluids and vasopressors and 1 case of bradycardia requiring atropine.

Conclusions: Patient awareness of preoperative fasting is low: 18.4% of respondents define recommended intervals correctly. Mean duration of last oral intake exceeds the recommended interval by 5 times for clear fluids and 2.5 times - solid food. This leads to subjective and objective haemodynamic adverse effects of hypovolaemia.

Anesthesia for a patient with Steinert myotonic dystrophy and Neurofibromatosis type 1: a case report

F. Sugawara¹, D.S. Schaedlich¹, M.H.R. Gama¹

¹Hospital das Clínicas da Faculdade de Medicina da Universidade de São Paulo, Departamento de Anestesiologia, São Paulo, Brazil

Background: Neurofibromatosis type 1 (NF1) is an autosomal dominant disease with complete penetrance which affects 1 in every 3,500 individuals¹. Myotonic dystrophy type 1 (Steinert's disease) is an autosomal dominant disease with variable expression, affecting 1 in every 20,000 individuals².

This study describes the anesthetic management of a patient with both conditions.

Case report: A 28-year-old male (VJJS), diagnosed with NF 1 and Steinert's disease, was admitted for excision of a neurofibroma in the brachial plexus. Electroneuromyography showed sensory and motor impairment of the left ulnar nerve, as well as motor impairment in all nerves studied. He presented with cutaneous neurofibromas in the trunk, macroglossia, macrocephaly and elongated face. He denied cardiac, endocrine, or gastrointestinal issues. Induction was made with fentanyl, lidocaine, propofol and rocuronium and orotracheal intubation was performed with videolaryngoscopy. Maintenance was attained with propofol, remifentanil and dexmedetomidine, followed by methadone 10mg IV. The surgical team infiltrated the surgical wound with 10 mL of 0.5% levobupiyacaine.

At the end of surgery, extubation was performed without reversal agents as TOF ration of 92. He was transferred to the post-anesthesia care unit and was discharged after 1 hour without complaints.

Discussion: The patient's airway management is potentially difficult due to intraluminal neurofibromas, difficult face mask ventilation and the increased sensitivity to neuromuscular blocking agents¹. Patients with Steinert's disease are more sensitive to all neurmuscular blockers³.

Analgesia is also challenging, especially in NF1, as neurofibromas often cause chronic neuropathic pain¹. Additionally, uncontrolled pain can induce mytonia in patients with Steinert's disease³.

Learning points: There is limited evidence regarding the anesthetic management of patients with NF1 or Steinert's myotonic dystrophy.

Measuring quality of recovery-9 in adult patients following lower limb orthopaedic surgery

M.D. Hoang¹, D. Cui¹, A. Wong², S. Satari², <u>A. Wu¹</u>
¹Eastern Health, Department of Anaesthesia and Pain Medicine, Melbourne, Australia, ²Monash University, Eastern Health Clinical School, Melbourne, Australia

Background and Goal of Study: The nine-item quality of recovery (QoR-9) score is a validated patient-centred outcome measure of postoperative recovery. The maximum score is 18, with a score ≥ 17 indicating a good recovery and a score of ≤15 indicating poor recovery[1]. This study aimed to evaluate the quality of recovery in adult patients at weeks one, two and six post lower limb orthopaedic surgery

Materials and Methods: A longitudinal study was conducted from October 2020 to March 2021, including adult patients aged ≤70 years who underwent orthopaedic surgery at or below the knee level. Patients readmitted within six weeks of surgery were excluded. Eligible patients completed telephone interviews at weeks one, two and six postoperatively, during which the QoR-9 questionnaire was administered. Participants were grouped by surgical complexity (minor vs non-minor) and descriptive statistics was used for comparison between groups. Data from 220 patients were analysed; 123 patients were lost to follow-up during the study.

Results and Discussion: Results are shown below:

	Week 1		Week 2		Week 6	
	Mean	95%CI	Mean	95%CI	Mean	95%CI
Overall (n=220)	14.6	[14.2,15.0]	15.8	[15.4,16.2]	16	[15.5,16.5]
Minor Surgery (n=74)	14.9	[14.3,15.6]	15.9	[15.1,16.6]	15.8	[14.8,16.6]
Non- Minor Surgery (n=146)	14.4	[14.0,14.9]	15.8	[15.3,16.2]	16.1	[15.6,16.7]

In the first week, 120 patients (55%) experienced poor quality of recovery, with a mean score [95%CI] of 12.7 [12.3,13.1]. Their recovery improved in weeks two and six, with a mean score of 14.8 [14.2,15.1] and 15.4 [14.6,16.1], respectively.

Whilst a *clinically important* improvement (a score increase ≥ validated threshold of 0.9) was observed in all patients, including in those with poor recovery in the second week, further improvements in the following weeks were not clinically important [2]. Pain was the leading cause of poor recovery, with 54-74% of these patients reporting persistent or severe pain throughout the study.

Conclusion(s): Patients experienced poor recovery in the first week, with significant improvement observed by the second week. Subsequent improvements were not clinically important, suggesting an extended follow-up period is needed to better capture recovery trajectories. Pain is the main contributor to poor recovery, highlighting the importance of prolonged postoperative analgesia in patients undergoing lower limb orthopaedic surgery.

Preoperative serum concentrations of Alzheimer's disease(AD)-related biomarkers, amyloid beta $(A\beta)$ and total tau (t-tau), and postoperative delirium (POD) incidence after cardiac surgery

W. Ferron¹, B. Hanseeuw^{2,3}, M. Momeni^{1,3,4}, C. Khalifa^{1,3,4}
¹Cliniques Universitaires Saint-Luc, Anaesthesiology,
Brussels, Belgium, ²Cliniques Universitaires Saint-Luc,
Neurology, Brussels, Belgium, ³UCLouvain, Institute of
Neuroscience, Brussels, Belgium, ⁴UCLouvain, Institute of
Experimental and Clinical Research, Brussels, Belgium

Background-Goal of Study: AD and related dementias pathology is a significant predisposing risk factor for POD.¹ A β peptides and tau proteins are known to play a central role in AD-related dementia pathogenesis. We aimed to assess associations between A \Box , t-tau and delirium after cardiac surgery. We also tested correlations between these biomarkers and preoperative cognitive status.

Materials-Methods: Serum quantification of A β 40, A β 42 and t-tau, and determination of A β 42/40 ratio were performed preoperatively in 220 adult patients undergoing elective cardiac surgery (B403201837550).

Preoperative cognitive status was evaluated using five neurocognitive tests, from which a cohort-specific *Z*-score was calculated. CAM-ICU, CAM and a chart review were used for POD screening until hospital discharge. Biomarkers concentrations were log-transformed to obtain normally distributed data.

Comparisons between groups were performed using either Mann-Whitney U test or Student t-test, and Chi-square test. Pearson coefficients assessed correlations between biomarkers and preoperative cognitive *Z*-score.

	POD (-) (n=155)	POD(+) (n=65)	P-value
Age, years	67 (59, 74)	74 (64, 79)	<0.001
Preoperative cognitive Z-score	0.21 ± 0.84	-0.52 ± 1.14	<0.001
Surgical time, min	226 ± 57	238 ± 60	0.170
Aβ40, pg/ml	147.5 (94.8, 199.4) (n=154)	160.4 (102.3, 212.4) (n=63)	0.182
Aβ42, pg/ml	8.9 (6.5, 11.3) (n=154)	8.2 (5.8, 11.7)	0.384
Αβ42/40	0.06 ± 0.02	0.06 ± 0.02	0.197
t-tau, pg/ml	0.6 (0.4, 1.0) (n=143)	0.9 (0.5, 1.1) (n=60)	0.033

Table 1.

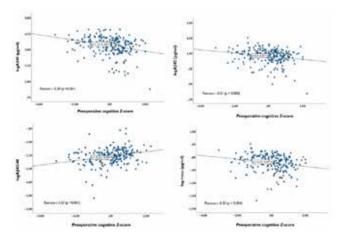

Figure 1.

Results-Discussion: Preoperative data are detailed in Table 1. Among AD-related biomarkers, only t-tau concentrations were significantly higher in patients who developed POD (P=0.033). Statistically significant correlations were found between these biomarkers and preoperative cognitive testing (Fig.1), although these correlations were poor (all Pearson coefficient r <0.29).

Conclusions: Preoperative serum concentrations of AD-related biomarkers were poorly associated with POD and preoperative cognitive scores. These observations suggest that the relationship between AD and POD is complex despite apparent epidemiological similarities.

Virtual reality versus pharmacological sedation during regional anesthesia: a prospective, randomized controlled study on patient satisfaction

L. Trinh¹, J. Ostertag¹, M. Michels¹, I. Grüner¹, G. Schneider¹, K. Wagner¹
¹Technical University of Munich, Department of Anesthesiology and Intensive Care, Munich, Germany

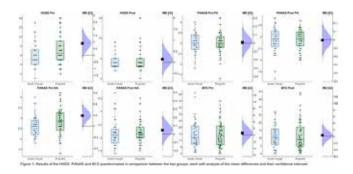

Background: Virtual reality (VR) is becoming a valuable tool in medicine. It can be used for training purposes, diagnostics, or intraoperative support. In the anesthesia setting, it can, e.g., help educate patients and manage their anxiety. Our study evaluated the non-inferiority of audiovisual sedation (AVS) during regional anesthesia compared to pharmacological sedation.

Methods: After obtaining ethical approval, we conducted a controlled, randomized, monocentric study involving 146 patients. Patients who had to undergo regional anesthesia with sedation were randomized into two groups. One group received propofol, the other was exposed to calming audiovisual content using HappyMed video glasses.

We evaluated anxiety, stress, and overall state of mind before and after surgery through questionnaires, i.e., the Hospital Anxiety and Depression Scale (HADS), Positive and Negative Affect Schedule (PANAS NA/PA), and the "Befindlichkeitsskala" (BFS, state of mind scale). Student-t and Fisher exact tests were used to compare demographic and surgical variables and the mean difference with 95% confidence intervals was used as effect size to assess non-inferiority.

Results and Discussion: 125 patients were included in the analysis, 53 in the AVS and 72 in the propofol group. Baseline characteristics (e.g., age, gender, BMI) were not significantly different, but procedures with VR averaged 24.5 minutes shorter than pharmacological sedation. This was because 11 patients either requested sedation or discontinued AVS after a certain time. Regarding patient well-being, AVS was non-inferior to propofol sedation. Patients in the propofol group had (non-significantly) higher HADS (propofol: 7 [5;9]; AVS: 5 [4;7]) and PANAS-NA (propofol: 2.9 [2.4;3.3]; AVS: 2.6 [2.2;2.9]) before the intervention. All other scores were in the same range as presented in the Figure.

Conclusion: The first results of our study indicate that AVS may be a viable and economical alternative to pharmacological sedation for non-emergency regional anesthesia with a shorter duration, enabling optimized, patient-tailored care. Future investigations will also consider heart rate variability as a parameter.

10AP03-4 Low opioid anaesthesia in bariatric patients: a retrospective cohort study

N.L. Debelian-Solheim¹, C.M. Eie¹, D. Romero¹, E.T. Finsberg², N.G. Bronebakk¹ ¹Bærum Sykehus, Vestre Viken, Anestesi, Intensiv, Operasjon (AIO), Bærum, Norway, ²Bærum Sykehus, Vestre Viken, Kirurgisk avd, Ortopedisk avd, Bærum, Norway

Background and Goal of Study: The risk of opioid-induced respiratory depression is heightened by obesity-related physiological changes¹. To reduce perioperative opioid requirement our institution introduced low opioid anaesthesia (LOA) in bariatric patients in 2023. The goal of this study was to examine post-operative morphine and oxygen requirements as well as the length of stay (LOS) on the post-anaesthesia care unit (PACU) before and after the introduction of LOA.

Materials and Methods: Retrospective data from 2023 (n=130), after the introduction of LOA, was analysed and compared with data from 2021 (n=123) when opioid balanced anaesthesia (OBA) was practiced. We defined LOA as "an effort to reach a TCI dose of 2 ng/ml remifentanil intraoperatively without other opioids". Standardised doses of non-opioid analgesia were administered to the LOA group; 600mg magnesium, 100mg lidocaine, 150μg clonidine and 10mg S-ketamine. Propofol was used as standard hypnotic in the LOA group, while desflurane was standard in the OBA group. Paracetamol, ketorolac and dexamethasone were the same in both groups. Remifentanil doses were reduced according to patient response. All drugs were administered intravenously perioperatively. Groupwise comparisons were carried out with Kruskal-Wallis test due to right-skewedness of the endpoint distributions.

Results and Discussion: The LOA group had significantly reduced opioid requirement postoperatively compared with the OBA group, the medians and interquartile intervals for the morphine equivalent dose were 2.0 (0.0, 4.0) mg vs 7.5 (0.0, 15.0) mg (p<0,001). In the LOA group, 10,8% required oxygen postoperatively vs 49,5% in the OBA group. PACU LOS was 125.5 (102.0, 156.0) min in the LOA group vs 147.0 (128.0, 172.0) min in the OBA group (p<0,001). These results indicate benefits of multimodal and LOA compared to OBA.

Conclusion: Implementation of standardised LOA significantly reduced postoperative morphine requirements, the need for supplemental oxygen administration, as well as reducing the PACU LOS in bariatric patients. This method effectively introduced LOA without requiring additional resources, yielding clear benefits for patients.

1. Efficacy of nonopioid analgesics and adjuvants in multimodal analgesia for reducing postoperative opioid consumption and complications in obesity: a systematic review and network meta-analysis. Carron, Michele et al. British Journal of Anaesthesia, Volume 133, Issue 6, 1234 - 1249

10AP03-5

Comparison of the effects of isoflurane and desflurane on the optic nerve sheath diameter in elderly patients undergoing robot-assisted laparoscopic urological surgeries in steep trendelenburg position: a randomized controlled trial

S. Mundekkat¹, F. Suhana¹, N. A Rajmohan¹, S. P Srinivasan¹, S. Omkarappa¹, S. G Nair¹ ¹Aster Medcity, Anaesthesiology & Critical Care, Ernakulam, India

Background and Goal of Study: Optic nerve sheath diameter (ONSD) serves as a reliable surrogate marker for intracranial pressure (ICP) during robot-assisted laparoscopic radical prostatectomies (RARP). The steep Trendelenburg position and carbon dioxide pneumoperitoneum used in RARP elevate ICP, with patients over 60 years experiencing worsened cerebral autoregulation and compliance. Among factors influencing ONSD, the choice of anesthetic agents holds particular significance.

While total intravenous anesthesia with propofol has demonstrated better control of ONSD compared to inhalational agents, the latter's dose-dependent vasodilatory effects on cerebral vessels remain understudied.

This trial aimed to compare the effects of isoflurane and desflurane on ONSD in elderly patients undergoing RARP.

Secondary goals included the incidence and duration of neurological complications, postoperative cognitive impairment, delayed recovery, and hospital stay period.

Materials and Methods: A prospective randomized controlled study was conducted on 54 elderly patients aged 60 years and above, undergoing RARP.

These patients were randomized to receive isoflurane or desflurane for maintenance of anesthesia. ONSD measurements were obtained at baseline, during pneumoperitoneum, and postoperatively using ultrasound. Hemodynamic parameters and recovery profiles were also recorded.

Data analyses utilized Pierson Chi-square test, independent sample T-test and Mann Whitney Test.

Results: A total of 54 patients were analyzed. While mean ONSD values at T2, T3, and T4 raised from baseline in both groups, the values remained within normal limits without significant intergroup differences.

At T5, ONSD values returned to baseline in all patients. Neither group exhibited postoperative complications, cognitive impairment, or delayed recovery.

These findings indicate that both agents are viable anesthetic options for elderly patients undergoing RALP, as their effects on ICP are minimal and transient.

Conclusion: Isoflurane and desflurane exhibit comparable and safe profiles in terms of ICP elevation during RARP. Both agents are effective for maintenance anesthesia in elderly patients requiring steep Trendelenburg positioning for procedures.

Reference: Verdonck P, Kalmar AF, Suy K, Geeraerts T, Vercauteren M, Mottrie A, De Wolf AM, Hendrickx JF. Optic nerve sheath diameter remains constant during robot assisted laparoscopic radical prostatectomy. PLoS One. 2014 Nov 4;9(11):e111916.

10AP03-6

Feasibility and efficacy of multimodal prehabilitation in patients awaiting pancreaticoduodenectomy: results from a prospective cohort study

M. Ubré¹, R. Sebio-García², R. Risco¹, J. Farguell³, F. Ausania³, G. Martínez-Pallí¹

¹Hospital Clínic, Anaesthesiology, Barcelona, Spain, ²Hospital Clínic, Physical Medicine and Rehabilitation, Barcelona, Spain, ³Hospital Clínic, Hepatobiliary Surgery, Barcelona, Spain

Background and Goal of Study: Pancreaticoduodenectomy (PD) is a highly aggressive surgical procedure frequently associated with a high incidence of postoperative complications (30-50%). Reduced cardiorespiratory fitness has been associated with an increased risk of complications in various surgical procedures, including PD.

The aim of this study was to evaluate the feasibility and efficacy of multimodal prehabilitation in improving cardiorespiratory fitness in patients awaiting PD for pancreatic cancer.

Materials and Methods: Prospective cohort study. Patients awaiting PD for pancreatic cancer were assessed for surgical risk using a cardiopulmonary exercise test (CPET). Patients with an anaerobic threshold (VO₂AT) <11 ml/kg/min were classified as high risk and referred to the Prehabilitation Unit. Multimodal prehabilitation, including nutritional optimization and supplementation, stress reduction, behavioural change, and supervised exercise training three times per week, was provided to optimize functional capacity. Patients were evaluated by a multidisciplinary team at baseline and prior to surgery.

The main outcomes were:

 i. Difference between pre- and post-prehab in maximal (VO₂peak) and submaximal (VO₂AT) exercise capacity;

ii. Feasibility and adherence to the intervention.

Results and Discussion: Between January 2021 and July 2023, 77 patients were screened for eligibility, and 67 underwent a baseline CPET (87%). Thirty-nine patients (58%) were classified as high risk based on a VO₂AT < 11ml/kg/min. Multimodal prehabilitation was feasible (defined as a duration of ≥3 weeks) in 25 patients (64%). Patients completed a median of 10 sessions (Q1–Q3: 7.5–12.5), with adherence reaching 83% (Q1–Q3: 67–93). Only 22 patients (56%) underwent a CPET before surgery, primarily due to logistical reasons (n=9), disease progression (n=3), or changes in surgical scheduling (n=5).

A significant increase was observed in VO_2 peak (ml/min/kg) (Z = -3.180, p < .001), VO_2 AT (ml/min/kg) (Z = -3.516, p < .001), as well as in maximum and submaximal load (Z = -4.11, p < .001 and Z = -3.623, p = .003, respectively). After undergoing multimodal prehabilitation, half of the patients (54.5%) achieved a VO_2 AT of \ge 11 ml/kg/min.

Conclusion(s): Multimodal prehabilitation appears feasible in patients awaiting PD and may lead to an increase in preoperative cardiorespiratory reserve, potentially reducing surgical risk.

10AP03-7

Adaption and validation of the Greek version of Addenbrooke's Cognitive Examination III scale as a screening tool for perioperative cognitive impairment detection

G. Tsaousi¹, E. Chatsiou¹, A. Nikopoulou¹, E. Palaska¹, V. Birba¹, M. Zouka²

¹Aristotle University of Thessaloniki, Anesthesiology and ICU, Thessaloniki, Greece, ²Aristotle University of Thessaloniki, Emergency Medicine, Thessaloniki, Greece

Background and Goal of Study: Postoperative cognitive dysfunction (POCD) denotes a subtle to extensive decline in cognitive performance persisting after the acute phase (4–6 weeks), surpassing the time needed for recovery from the acute impact of surgery.

We aim to assess the validity and reliability of a culturally adapted Greek version of the Addenbrooke's Cognitive Examination III (ACE-III) scale as a screening tool for perioperative neurocognitive status determination in elderly surgical patients.

Materials and Methods: A cross-cultural adaptation and validation of instruments throughout the cross-sectional study was conducted. The study sample consisted of 128 individuals over 55 years old scheduled for surgical intervention.

All participants were screened twice; at the preadmission clinic and the day before surgery using the already established MoCA scale and the culturally adapted Greek version of the ACE-III scale. Subjects with a MoCA score of < 26 constituted the cognitively impaired group.

Results and Discussion: In terms of validity, ACE-III's performance in detecting cognitive impairment was excellent (AUC =0.942; 95%CI 0.899-0.971; cutoff ≤ 86). The discriminant validity of the ACE-III components highlighted memory (AUC =0.899) and language (AUC =0.881) as the most powerful subdomains for screening cognitive dysfunction in surgical patients, followed by visuospatial function (AUC =0.755), verbal fluency (AUC =0.724) and attention (AUC =0.685). Convergent validity between ACE-III and MoCA scales was excellent (r= 0.876; 95%CI 0.839-0.905). Known group validity was confirmed since advanced age and lower educational attainment adversely impacted ACE-III's total score (p<0.001).

Additionally, face validity was suggested by specialists (mean 8.7 out of 10, SD 1.1). In terms of reliability, ACE-III demonstrated good internal consistency (Cronbach's alpha 0.786) and high interrater (ICC=0.936 [95%CI 0.921-0.941]) and test-retest reliability (ICC=0.972 (95%CI 0.958-0.981). Age (p<0.05) and education level (p<0.001) but not gender and dominant hand were identified as major contributors to MoCA and ACE-III scores.

Conclusion(s): It occurs that the Greek version of ACE-III is a valid, and reliable screening tool that could be routinely employed perioperatively as a valid alternative to the MoCA test to distinguish the mild cognitively impaired from healthy elderly candidates for surgical interventions.

10AP03-8

Orthopaedics trauma list pre-operative fasting time at Mater Dei Hospital in Malta

S. Farrugia¹, E. Hunter¹, S. Mifsud¹

¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care and Pain, Msida, Malta

Background and Goal of Study: Preoperative fasting helps prevent pulmonary aspiration but prolonged fasting leads to dehydration, hypoglycaemia, acute kidney injury and insulin resistance. Local and international guidelines recommend fasting times of 6 hours for solid food, milk, tea, coffee, juices and fizzy drinks and 2 hours for clear fluids.

This audit assesses preoperative fasting practices in trauma-list patients within Mater Dei Hospital.

Materials and Methods: Data protection and organisational approval was obtained.

Two hundred patients undergoing orthopaedic trauma surgery between April and July 2024 were included with selection being done via convenience sampling.

Data was collected from medical records and included patients' demographics, surgery underwent, fasting duration, intravenous (IV) fluid administration, and rescheduled cases' details.

Results and Discussion: 196 (98%) patients were aged between 60 and 89 years and were graded as American Society of Anaesthesiologists (ASA) grade 2. Dynamic Hip Screw (DHS) was the most common surgery performed.

Fasting times ranged from 6 to 22.5 hours with a median fasting time of 13 hours 22 minutes and a mean of 12hours 57minutes. 136 (68 %) patients began fasting at midnight, despite 69 (50.7 %) of these having afternoon procedures.

85 (42.5%) patients received no preoperative IV fluids, with 38 amongst these having afternoon surgeries.

73 (36.5 %) surgeries were postponed by 1 to 4 days, primarily due to insufficient theatre time. Decision of rescheduling was most commonly taken in the afternoon.

Conclusion(s): Since observed fasting practices exceed guideline recommendations, multidisiplinary interventions are needed to optimise practice. Information sessions should be held for nurses, junior doctors, surgeons and anesthetists.

Detailed, real-time trauma list planning may help decrease number of postponed surgeries and the associated futile fasting whilst allowing patients on afternoon trauma lists to have an early breakfast

This should be followed up by future re-auditing to ensure ongoing optimization of fasting practices.

10AP03-9 Breaking Barriers in thyroid surgery: the role of ERAS protocols in modern surgical practice

<u>S. Mastrangeli</u>¹, F. Cantaluppi¹, B. Milan¹, G. Lazzari², G. Di Filippo², K. Donadello^{1,3}

¹University Hospital Integrated Trust of Verona, Anaesthesia and Intensive Care Unit B, Verona, Italy, ²University Hospital Integrated Trust of Verona, Endocrine Surgery, Verona, Italy, ³University of Verona, Department of Surgery, Dentistry, Gynecology and Paediatrics, Verona, Italy

Background and Goal of Study: Enhanced Recovery After Surgery (ERAS) protocols aim to optimize perioperative management, reducing both complications and hospital stay. Although widely used in colorectal surgery, its application in thyroid surgery is limited. Our ERAS thyroid protocol, jointly developed by the Endocrine Surgery and Anaesthesia units at University Hospital Integrated Trust of Verona, was introduced for thyroid surgeries in May 2024.

This study evaluates protocol's effectiveness, particularly for perioperative pain management.

Materials and Methods: Consecutive patients undergoing thyroid surgery for benign or malignant conditions before and after ERAS implementation. Propensity score matching (PSM) minimized bias, matching patients per group by age, gender, BMI, procedure type, and preoperative vitamin D use. Within the ERAS group, the effect of bilateral superficial cervical plexus block (BSCPB) was also examined.

Results and Discussion: 128 patients were analyzed (64 per group). Following PSM, matched patient pairs showed a significant reduction in hospital stay (p < 0.001), postoperative nausea/vomiting (3.1% vs. 12.5%, p = 0.04), and pain scores (NRS > 5) within 12 hours post-surgery (9.4% vs. 26.6%, p = 0.01) among ERAS patients. ERAS patients also had higher calcium levels 6 and 24 hours post-op, reducing calcium gluconate therapy needs (0% vs. 12.5%, p = 0.003).

Among ERAS patients, BSCPB recipients had higher pain scores on the morning of postoperative day 2 (p = 0.009) and required more rescue analgesics (p = 0.025), with a greater incidence of headaches (p = 0.027).

Conclusion(s): ERAS significantly improved pain control, reduced rescue analgesia, and shortened recovery time, with fewer hospital days. It also lowered nausea and vomiting rates, optimized calcium management, and decreased calcium infusion needs. These benefits, driven by preemptive analgesia, early mobilization, and refeeding, underscore ERAS as an advance in thyroid surgery management, enhancing clinical outcomes and quality of life.

Contrary to existing data, BSCPB offered no added benefit over wound infiltration alone, with greater headache incidence linked to BSCPB, possibly from neurological and muscular factors. Ultrasound guidance and meticulous technique may help reduce these complications. Further studies could clarify ERAS pain management strategies for headache-prone patients.

10AP03-10

Assessment of a novel smartphone-based digital health tool for post-operative care in Zambia

K. Chawla¹, C. Chanda², K. Mumbaa, O Ramoseki, K Lombe, N Twiyala², A. Crawford³¹Mayo Clinic, Anesthesiology and Perioperative Medicine, Rochester, United States, ²University Teaching Hospital, Anesthesiology, Lusaka, Zambia, ³Stanford Medicine, Anesthesiology, Perioperative and Pain Medicine, Stanford, United States

Background and Goal of Study: More than 4 million people annually die within 30 days after surgery, with a disproportionate burden in low- and middle-income countries (LMICs). Reducing the rate of failure to rescue (FTR), defined as the death of a patient after potentially treatable complications, could reduce in-hospital postoperative mortality, in these settings.

Many frontline healthcare personnel lack optimal support to be able to provide this timely, essential post-operative care to potentially prevent failure to rescue events. To facilitate such support, we developed a smartphone-based tool to guide consistent, high quality post-operative care.

This research project evaluated Zambian healthcare professionals' initial feedback on this novel tool's usability.

Materials and Methods: In 2023, a post-operative care task force was established including representatives from the Zambian Ministry of Health. the Zambian Institute of Digital Health, and Zambian healthcare providers to reach consensus regarding gaps in post-operative care. Based on their input, a smartphone-based, high-fidelity prototype application was developed using glideapps.com.

Volunteer physician and non-physician providers conducted hands-on interaction sessions with the digital tool at 3 medical center sites across the Lusaka province in November 2024. A validated System Usability Scale queried user perception of utility analyzed using descriptive statistics.

Results and Discussion: Twenty nurses, 2 physicians, 7 non-physician anesthesia providers, and 1 medical officer participated, with 22 of the 30 aged 20-40 years. Most (26/30) reported that "they would like to use this system frequently" and 28/30 reported they "felt very confident using the system."

A majority (29/30) strongly disagreed that the system was "unnecessarily complex" and 24/30 reported that the "various functions were well integrated."

Yet, almost half of the participants (14/30) picked responses of strongly agree to neutral for "needed to learn a lot of things before I could get going with this system."

Conclusion(s): Initial feedback on ease of use, navigation, and perceived relevance was favorable of this novel post-operative care digital health tool. Based on these encouraging results we will pursue further iterative refinements in digital tool design and conduct efficacy testing.

Management of emergence delirium in 17-year-old patient: case report

M. Brízido¹, <u>M. Cardiga¹</u>, L. Cortes Pacheco¹, J. Costa Mendes¹, V. Schuler¹ ¹Hospital da Luz de Lisboa, Anesthesiology, Lisboa, Portugal

Background: Emergence delirium is an acute state characterized by agitation, disinhibition, restlessness and mental confusion. It may manifest as agitation (hyperactive subtype) or as somnolence with altered mental status (hypoactive subtype), occurring in the postoperative period after initial emergence of anaesthesia.¹

There are multiple causes for this entity. Risk factors include preoperative anxiety, age < 6 years, use of volatile anaesthetics, use of perioperative corticosteroids, postoperative pain, among others. Nevertheless, this entity can occur in all age groups and all types of anaesthesia.

Case Report: We report the case of a 17-year-old man scheduled for colonoscopy under sedation with propofol. After the procedure, he was transferred to the post-anaesthetic care unit, where he became disoriented and started exhibiting aggressive and combative behaviour.

He was re-sedated with propofol and midazolam. Upon reawakening, aggressive behaviour persisted and disorganized speech and hallucinations followed. Haloperidol 5 mg IV was administrated, resulting in a gradual decrease in agitation and aggressiveness. When waking up again, the patient exhibited total amnesia regarding the event but was fully oriented.²

After a full recovery, he was discharged home with a follow-up appointment for paediatric psychiatry to undergo further evaluation and and to rule out organic causes. This evaluation confirmed the absence of an organic aetiology.

Discussion: Emergence delirium is an acute confusional state characterized by an alteration of consciousness. This is more commonly seen in pre-school children who are anaesthetized using inhalation anaesthetics, rarely needing pharmacological intervention.

However, it also occurs in older children and young adults given intravenous anaesthetics. Clinicians should be familiarized with the clinical features of emergence delirium and therapeutic options available.

References:

 Hall RJ, Meagher DJ, MacLullich AMJ. Best Pract Res Clin Anaesthesiol. 2012 Sep;26(3):367-83. doi: 10.1016/j. bpa.2012.07.002.

Learning Points: Emergence delirium can occur in all patients, including those without risk factors. Swift identification of emergence delirium and appropriate management are paramount to reduce its duration and severity and significantly improve outcomes.

Bridging the gap in perioperative pain caresetting up the first transitional pain clinic in Switzerland. Tips, tricks, hurdles

C. Heim¹, C. Grüninger¹, J. Wegrzyn², M.R. Suter¹¹Lausanne University Hospital CHUV, Anesthesiology, Lausanne, Switzerland, ²Lausanne University Hospital CHUV, Department of Orthopedics and Traumatology, Lausanne, Switzerland

Background: Prolonged postoperative pain (PPP) is frequent after surgery. It has major socioeconomic implications, putting patients at risk of opioid dependence and transition to chronic pain. Orthopedic operations have the highest rate of PPP. Access to specialized care allows to reduce opioid use and limit chronic pain. We describe the setup of the 1. transitional pain clinic (TPC) in Switzerland.

Materials, Methods: A retrospective chart query of orthopedic patients analysed opioid prescription at discharge. Patients on opioids at the 6 week control were identified for TPC. We presumed 3 consultations/patient and 30% of interventional approaches. Integrating TPC into our existing pain center avoids additional material/administrative investments (Fig 1).

Fia 1.

Results: In June 21, 228 patients were included. 90% were discharged on opioids, 84% without a time limit. At 6 weeks, 26% were on opioids. An 80% position covers 3600 visits/year in a 30-min pace. Projecting a positive cash flow obtained the budget for a pain physician.

During Nov'24, 88% were discharged on opioids, 48% with a time-limit (+38%). 13% (-48%) were on opioids at 6 weeks. Of 68% sent by surgeons, 23% met TPC-criteria. Examining each patient chart, we identified additional 32% on opioids. 37% had interventional pain treatments.

Discussion: This project was highly welcomed by surgeons and governance. A business plan with positive cash flow obtained the required funding. First results are seen at its start: -40% of unlimited opioid prescription, -50% prolonged opioid use. A high rate of interventional treatments is attractive for the anesthesia curriculum. Surgical TPC-address was lower than expected despite clear criteria. Negative replies were "He only takes opioids to sleep" or "Continued pain is not unusual".

Conclusion: Lack of pain specialist for patients with PPP is a gap in perioperative care. The opioid crisis is an important driver for hospital governments to support TPC.

Clear admission criteria must be defined and information on interventional pain treatments might help to bring change to the paradigm of "normal postoperative pain" trajectory.

Anesthesia management with SmartPilot® View for the first time in ENT surgeries in Turkey: a case series

D. Yediçocuklu Sergin¹, N. Sertoz¹, O.A. Ozturk¹, M. Soyhan¹, A. Derbent¹ ¹Ege University, Anesthesiology and Reanimation, Izmir, Turkey

Background: The SmartPilot® View (SPV) system is an advanced anesthesia management system that provides a comprehensive visualization concept for analyzing complex drug effects and visualizing current and predicted anesthesia dept. In our country, this method was applied for the first time in anesthesia management during Ear, Nose, and Throat surgeries in our university hospital across three different cases. We aim to share our experiences with this innovative approach.

Case Report: Case 1: A 42-year-old female, 163cm, 57kg, ASAII, hard palate carcinoma.

Case 2: A 34-year-old male, 182cm, 78kg, ASAI, cervical lipoma. Case 3: A 63-year-old female, 150cm, 56 kg, ASAII, tongue cancer.

For anesthesia induction, propofol and remifentanil prepared in Braun Perfusor Space syringes which enable data transfer to the anesthesia station. Induction for all patients was achieved with Target Controlled Infusion of propofol.

Following the manual injection of 0.5mg atropine, 1mg/kg lidocaine, propofol infusion at $4\mu g/mL$ was started to achieve enough plasma concentration, followed by intubation using 0.6mg/kg rocuronium bromide.

The surgeries were conducted without any change in the hemodynamics of the patients. Based on data from the SPV for patients whose anesthesia levels deepened, the plasma concentrations of propofol-remifentanil were reduced to maintain them within the safe range.

The amount of dose was managed individually for each patient. At the end of the surgeries, the anesthetic agents infusion stopped, all patients were transferred to the PACU awake, cooperative, hemodynamically stable.

Discussion: SPV enables the analysis of patients' vital signs and plasma concentrations of administered drugs,maintaining anesthesia depth at an optimal level, preserving hemodynamic stability, and optimizing drug dosages throughout the anesthesia process. It supports fast recovery and smooth transition to the postoperative period. SPV enhances patient safety and reduces the workload of anesthesiologists. SPV facilitates timely and painless patient emergence addressing key challenges in the anesthesia process.

References:

- 1. BrJAnaesth.2022Jun;128(6):959-970.
- 2. BMCAnesthesiol2022Feb28;22(1):5.
- 3. BrJAnaesth.2017Nov1;119(5):1022-1029

Learning points: With SPV the anesthesiologist can predict the current anesthesia level and the expected course of anesthesia even while administering the drugs. This capability facilitates the optimization of anesthesia application, an algesia management.

10AP04-3

Acute right heart failure in a patient with undiagnosed pulmonary hypertension following spinal surgery: a case report

A. Agulló¹, A.C. Carpintero¹, E.X. López¹, E. Vila¹¹Hospital del Mar, Anesthesiology and Resuscitation, Barcelona, Spain

Background: Pulmonary hypertension (PH), defined as a mean pulmonary artery pressure (mPAP) ≥ 25 mmHg, causes right ventricular overload, increasing the risk of right heart failure, and cardiogenic shock. This significantly raises morbidity, mortality and challenging perioperative management in major surgeries.

Case Report: A 72-year-old woman with hypertension, chronic bronchitis, chronic kidney disease, and previous spinal surgeries was scheduled for spinal arthrodesis (T3-Sacro) due to failed prior instrumentation.

Anesthesia was initiated with intrathecal morphine, followed by general anesthesia. Perioperative monitoring included BIS, NOL, and the Vigileo® hemodynamic monitor. During surgery, the patient experienced hypotension, 900 mL blood loss, and ventricular tachycardia, which were managed with fluid resuscitation, blood transfusion, vasopressors, and amiodarone.

Postoperatively, she was transferred to the ICU. She developed hemodynamic instability and right ventricular hypokinesis, identified via bedside echocardiography. AngioCT excluded pulmonary embolism. Shock secondary to right heart failure was attributed to hypovolemia and previously undiagnosed PH. Treatment with vasopressors and milrinone stabilized her within 72 hours.

Despite respiratory failure caused by fluid overload and chronic bronchitis, she was extubated after one week. The patient recovered after a prolonged hospitalization of 106 days and is now under close follow-up with the pulmonary hypertension unit.

Discussion: This case highlights the challenges of managing PH during major surgeries, where it often remains undiagnosed until exacerbated by surgical stress. PH places additional strain on the right ventricle, increasing the risk of failure under stressors like hypovolemia and mechanical ventilation.

Early detection, fluid resuscitation, vasopressors, and vigilant monitoring are vital for effective management. Multidisciplinary monitoring, including Vigileo for real-time hemodynamic data and Swan-Ganz catheterization to confirm elevated pulmonary pressures, was crucial in guiding treatment.

Echocardiography and AngioCT were key in excluding pulmonary embolism and identifying right ventricular dysfunction.

Learning Points: PH enhances the risk of perioperative complications, particularly right heart failure. Early detection, hemodynamic stability, and a multidisciplinary approach are essential for improving surgical outcomes in patients with PH.

Associations of intraoperative and postoperative hypotension with delirium after noncardiac surgery: a retrospective cohort analysis

J. Rössler¹, O. Kopac², K. Ruetzler³, L. Wang⁴, A. Turan² ¹University Hospital Zurich, Institute of Anaesthesiology, Zürich, Switzerland, ²The University of Texas Health Science Center at Houston, Department of Anesthesiology, Houston, United States, ³Cleveland Clinic, Departement of Anesthesiology, Cleveland, United States, ⁴Cleveland Clinic, Department of Quantitative Health Sciences, Cleveland, United States

Background and Goal of Study: Postoperative delirium is a common and serious complication following noncardiac surgery. A possible precipitating factor may be intraoperative and postoperative hypotension, with subsequent brain hypoperfusion.

This study aims to investigate whether intraoperative and postoperative hypotension are associated with postoperative delirium.

Materials and Methods: We conducted a retrospective cohort study analyzing adult noncardiac surgery patients from a single academic center between 2018 and 2022. The exposure was intraoperative and postoperative hypotension, defined by lowest mean arterial pressure (MAP) or MAP reduction from baseline for cumulative 3 and 10 minutes.

The outcome was the incidence of postoperative delirium, assessed twice daily using the bCAM and CAM-ICU. Association between intraoperative hypotension with postoperative delirium was assessed through multivariable generalized mixed effects logistic regression model accounting for within-patient correlation among repeated surgeries from the same patient.

Association between postoperative hypotension and postoperative delirium was assessed through a Cox proportional model treating all the postoperative MAP as a time-varying covariate to avoid the bias that delirium-positive patients having less MAP measurements

Results and Discussion: We included 38,940 noncardiac surgeries. The incidence of postoperative delirium was 6.56%. Analysis revealed a linear association between the lowest MAP for cumulative 3 or 10 minutes and postoperative delirium, with higher MAP linked to decreased delirium risk.

The odds ratio was 0.987 (95%CI 0.974-1.001, p=0.014) when the lowest MAP for cumulative 3-minutes increased 5 mmHg, or 0.984 (95%CI 0.968-0.999, p=0.006) for cumulative 10-minutes. Relative MAP reductions showed similar associations. Postoperative MAP as a time-varying covariate had a nonlinear relationship with postoperative delirium (nonlinear p<0.001).

When postoperative MAP was less than 80 mmHg, the hazard ratio of postoperative delirium was 0.989 (95%CI 0.981-0.997, p=0.002). For postoperative MAP greater or equal to 80 mmHg, the hazard ratio per 1 mmHg increment was 1.034 (95%CI 1.023-1.045, p<0.001).

Conclusion(s): Intraoperative and postoperative hypotension, as well as postoperative hypertension, was a significant risk factor for the development of postoperative delirium, although the association was small and – on its own – probably not clinically relevant.

10AP04-7

Associations of intraoperative and postoperative blood pressure variability with delirium after noncardiac surgery: a retrospective cohort analysis

J. Rössler¹, O. Kopac², L. Wang³, K. Ruetzler⁴, A. Turan² ¹University Hospital Zurich, Institute of Anaesthesiology, Zürich, Switzerland, ²The University of Texas Health Science Center at Houston, Department of Anesthesiology, Houston, United States, ³Cleveland Clinic, Department of Quantitative Health Sciences, Cleveland, United States, ⁴Cleveland Clinic, Department of Anesthesiology, Cleveland, United States

Background and Goal of Study: Postoperative delirium is a common and serious complication following noncardiac surgery. A possible precipitating factor may be perioperative hemodynamic changes - especially rapid variability or liability blood pressure - with subsequent changes in brain perfusion.

This study aims to investigate whether blood pressure variability is associated with postoperative delirium.

Materials and Methods: We conducted a retrospective cohort study analyzing adult noncardiac surgery patients from a single academic center between 2018 and 2022. The exposure was intraoperative and postoperative mean arterial pressure (MAP) variability, defined through average real variability of MAP. The outcome was the incidence of postoperative delirium, assessed twice daily using the bCAM and CAM-ICU.

We used a multivariable generalized mixed effects logistic regression model, adjusting for with-patient correlation among repeated surgeries from the same patient. Nonlinear relationship was tested and change point analysis was performed.

Results and Discussion: In 38,940 noncardiac surgeries, the incidence of postoperative delirium was 6.56%. The association of intraoperative average real variability of MAP with postoperative delirium was non-linear, with an estimated change point at 2.6 (95% CI: 2.2, 3.1).

When intraoperative average real variability of MAP was below the change point, the estimated odds ratio of postoperative delirium per 1 unit increment was 1.024 (95% CI: 0.988-1.061, p=0.19). When intraoperative average real variability of MAP was above the change point, the estimated odds ratio was 0.961 (95% CI: 0.941-0.980, p<0.001).

The association of postoperative average real variability of MAP with postoperative delirium was non-linear, with two change point at 4.6 (95% CI: 4.4, 4.9) and 7.9 (95% CI: 7.4, 8.4).

When postoperative average real variability of MAP was <4.6, the estimated odds ratio of postoperative delirium per 1 unit increment was 0.911 (95% CI: 0.898-0.925, p<0.001); when postoperative average real variability of MAP was between 4.6 and 7.9, the estimated odds ratio was 0.925 (95% CI: 0.907-0.943, p<0.001); when postoperative average real variability of MAP was above 7.9, the estimated odds ratio was 1.129 (95% CI: 1.1.0-1.156, p<0.001).

Conclusion(s): We identified blood pressure lability to be associated with postoperative delirium, especially during the postoperative period.

Evaluation of patient feedback for Colorectal Cancer Prehabilitation Service at a tertiary teaching hospital in Central London

J. Harrington¹, S. Yoon¹, H. Ainsworth¹, R. Bradshaw¹, A. Raga¹, H. Bidd¹
¹Guy's and St Thomas' NHS Foundation Trust, Anaesthesia, London, United Kingdom

Background and Goal of Study: The prehabilitation service for colorectal cancer has been established since 2021 and includes a personalised nutrition and physiotherapy led supervised exercise programme. It is often challenging to provide sufficient time in a prehabilitation programme to make a meaningful difference, without overwhelming patients through information overload and appointment burden. Successful prehabilitation relies on achieving this balance to enhance patient engagement and satisfaction. We aimed to evaluate our prehabilitation service through patient feedback.

Materials and Methods: Feedback was collected from patients who were enrolled in the prehab programme for at least 14 days between May and October 2024, and discharged following colorectal cancer surgery. Feedback was collected through telephone calls made by two anaesthetists using a questionnaire, collecting both qualitative (open ended questions) and quantitative (Likert scales) responses.

Results and Discussion: A total of 30 patients provided feedback. When asked to rank the prehab programme overall, the median value on a likert scale (0 - not beneficial, 10 - highly beneficial) was 9 (IQR = 8.25 - 10). The breakdown of components of the programmes are represented in Table 1 below.

Component of prehal	programme	N=/30	%	Median ranked score on Likert scale /10 (IQR)
	Home exercise programme only	9	30.0%	9 (IQR 8-10)
F	Face to face exercise classes	3	10.0%	10 (IQR 8-10)
Exercise programme	Online live exercise classes	14	46.7%	10 (IQR 8-10)
	None or external programme attended	4	13.4%	N/A
Dietician consultation		28	93%	9 (IQR 8-10)

Table 1.

The qualitative feedback of the exercise programmes revealed five common themes; motivating (8/30), able to tailor to the patient's needs (7/30), patients felt stronger for surgery (4/30), benefits of the inspiratory muscle trainer (4/30) and the programme being thorough/comprehensive (4/30).

Drawbacks to the programme included timing of sessions (4/30) and intensity (2/30). 8/30 patients stated they would have liked psychology input as part of the prehab programme, which is not currently offered.

Conclusion(s): The current prehab programme at our centre has consistently high rates of patient uptake and satisfaction across the multidisciplinary team. This data allows us to improve our service delivery; areas identified as needing improvement include decreasing appointment burden during a short stressful period of time before major surgery, and incorporating psychology services for some patients.

10AP04-9

Postoperative elements have the lowest compliance after implementing an Enhanced Recovery after Surgery (ERAS) protocol for liver surgery: a single center analysis

I. Hernandez Zubelzu¹, A. Abad Motos¹, S. Gonzalez Santos¹, A. Arregi Rodriguez¹, D. Padilla Varona¹, J. Ariño Larrañaga¹ ¹Hospital Universitario Donostia, Anestesiología y Reanimación, San Sebastian, Spain

Background and Goal of Study: ERAS has shown to improve postoperative complications and decrease length of stay after several types of surgery. The first ERAS guidelines for liver surgery were released in 2016 and updated in 2023.

The goal of this study was to assess the adherence to ERAS items and outcomes of patients undergoing liver resection after implementation of an ERAS protocol in January 2024 in a tertiary hospital.

Materials and Methods: descriptive analysis of prospective cohort. All consecutive adult patients undergoing liver resection from February to

September 2024 were included and followed up for 30 days. Collected data included patient characteristics, adherence to 23 ERAS items, complications, readmissions and Length of Stay. The discrete and continuous variables were described as number and percentage and mean (SD) or median [IQR].

Results and Discussion: 30 patients were included, 35.5% women, mean age 71 (SD 17), 40% ASA II and 57% ASA III physical status. 30% patients underwent laparoscopic surgery. The overall adherence rate to the ERAS protocol components was 85.4%. Compliance was 87% for the preoperative elements, 88% for the intraoperative and 75% for the postoperative items.

Preoperative education, nutritional optimization and preoperative fasting had 100% of adherence; PONV prophylaxys and multimodal analgesia 93% and early feeding (60%) and early mobilization (61.2%) were the items with the lowest compliance.

Patients who had open surgery had a lower overall adherence to the postoperative elements (84% vs 70%). 8 patients (26.6%) suffered postoperative complications, and median LOS was 4 days [3–7].

The overall adherence to the ERAS items was high in our cohort, with the lowest rate for the postoperative elements. Many of the components of ERAS could be considered as standard care.

Nevertheless, there are still barriers for its full implementation. Recent studies in colorectal and hepatic surgery have shown low adherence to ERAS protocols in the early postoperative phase, which was independently associated with an impaired recovery.

Conclusion(s): although compliance with the ERAS pathway was high, our results additionally support that postoperative compliance is the most difficult to achieve, and requires a multidisciplinary and motivated team. In addition, more effort should be put in patients receiving open surgery.

Influencting factors in patients' adherence to a prehabilitation program: an exploratory study

R. Risco Martínez¹, R. Sebio-García², G. Martínez-Pallí¹, R. González-Colom³, M. Ubré¹, F. Dana⁴¹Hospital Clinic of Barcelona, Anesthesiology, Barcelona, Spain, ²Hospital Clinic of Barcelona, Rehabilitation, Barcelona, Spain, ³Hospital Clinic of Barcelona, IDIBAPS, Barcelona, Spain, ⁴Hospital Clinic of Barcelona, Nursing, Barcelona, Spain

Background and Goal of Study: The real impact of prehabilitation in the healthcare setting is controversial due to the efficacy-effectiveness gap. The effectiveness of prehabilitation in a real-world scenario has been associated with program attrition and adherence.

The aim of this study was to identify potential factors linked to patient adherence to a prehabilitation program.

Materials and Methods: This is a subanalysis of a prospective trial conceived to explore the implementation of prehabilitation in a real life setting at a tertiary hospital. Participants were patients enrolled in our multimodal prehabilitation program, candidates for major surgery, at high risk for postoperative complications and a preoperative schedule allowing \geq 4 weeks of prehabilitation.

The study variables were sociodemographic and clinical variables. The main outcome was adherence to the prehabilitation program, defined as attendance at \geq 80% of the prescribed sessions. Initial analyses were conducted to examine 1-to-1 associations between adherence and the study variables.

For categorical variables contingency tables and Fisher's exact test were used and for numerical variables, parametric (t-tests) or non-parametric (Mann-Whitney U tests) analyses were applied. A binary logistic regression model was applied to identify predictors of adherence

Results and Discussion: 782 patients were referred to our prehabilitation program. Data on adherence and compliance were available only for 559 (71.5%). According to our classification criteria, 356 (63.7%) were labelled as adherent (39.7%).

The analysis revealed significant associations between adherence and working status, type of exercise program prescribed (p<.001), smoking status (p=.023), age (t = -3.00, p = .003), comorbidities (t = -2.19, p = .029), and self-reported physical activity (t = -2.45, p = .015).

The logistic regression identified as independent factors the type of exercise prescription, smoking status, residential area, working status and neoadjuvant therapy. The model demonstrated good discriminative abilitywith an AUC of 0.777 (95% CI: 0.729 – 0.824). Specificity was high at 86.1%, sensitivity was lower at 50.6% and the predictive value (NPV) was 74.7%, indicating that the model could accurately predict that a patient would not achieve good adherence.

Conclusion: Multiple factors are associated with adherence during prehabilitation. Our model identified exhibited good accuracy and specificity, but poor sensitivity.

10AP04-11 Malta's quenching insights

S. Farrugia¹, L.F. Valletta¹, A. Attard Montalto¹, M.A. Zerafa Simler², A.M. Camilleri Podesta¹ ¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care and Pain, Msida, Malta, ²Leicester NHS Trust, Intensive Care, Theatres, Anaesthesia, Pain and Sleep, Leicester, United Kingdom

Background and Goal of Study: The complications of prolonged liquid fasting, such as dehydration, insulin resistance, increased stress response, delirium, and various postoperative complications have historically been overlooked.

Recent studies revealed that preoperative liquid fasting times remain unnecessarily long. A large-scale observational study including over 900 oncological surgery patients found an average liquid fasting duration of over nine hours, a duration beyond the recommended two hours.

Evidence suggests that shorter liquid fasting periods enhance patient well-being, reduce postoperative complications, enhance recovery, decrease hospital stays and lower healthcare costs.

The objective of this observational study is to observe current preoperative liquid fasting times in hospitals in Malta, raise awareness of the associated complications, and implement a campaign to observe shorter fasting times.

Materials and Methods: Date protection and ethical approval was obtained.

Data was collected over a period of 2 weeks between November and December 2024 from the main hospitals in the Maltese Islands where elective surgeries are carried out on a daily basis. Patients (> 18 years) scheduled for an elective procedure requiring general or regional anaesthesia or sedation were recruited. Informed consent was obtained from participants who were then interviewed whilst awaiting their surgery.

Data was collected via a standardised collection tool, anonymized and then entered into a national database for processing. Type of surgery underwent and fasting time for clear liquids (as a few sips taken most commonly with morning medications and as more than a few sips taken to relieve thirst) were noted.

Results and Discussion: 300 patients were recruited in this national observational study. Most paticipants (33.97%) underwent an endoscopy procedure under sedation.

Fasting times amongst the 82 patients who had a few sips preoperatively ranged from 30 minutes to 9 hours 20 minutes with a mean of 3 hours 45 minutes.

Fasting times for more than a few sips (for all 300 patients) ranged from 1 hour 45 minutes to 27 hours 50 minutes with a mean of 12 hours 51 minutes.

Conclusion(s): Excessive preoperative fasting is still common practice in Malta. A patient-centered approach with further education and training is recommended to prevent complications associated with this practice.

Low serratus intercostal interfascial plane block is associated with early extubation patients undergoing open hepatobiliary surgery: a single centre observational retrospective study

A. Abad-Motos¹, L. Gómez de la Lastra¹, M. Amelburu Egoscozabal¹, C. Garicano Goldaraz¹, L.J. Esnaola Ormazábal¹, N. Gonzalez Jorrin¹ ¹Donostia University Hospital, Anaesthesia and Critical Care, San Sebastian, Spain

Background and Goal of Study: Multimodal analgesia reduces opioid related side effects enhancing postoperative recovery. Serratus intercostal interfascial plane block (SIIPB) at the 8th rib provides analgesia at the lateral and anterior cutaneous branches of the lower intercostal nerves (T7-11).

Our objective was to analyse whether the SIIPB was an opioid sparing technique in patients undergoing open hepatobiliary surgery

Materials and Methods: Single centre retrospective study. All adult patients undergoing open hepatobiliary surgery under general anaesthesia and intrathecal morphine from October 23 to August 24 were included. Outcomes were analysed depending on whether the patient received a SIIPB or not.

Primary outcome was total i.v. morphine consumption in the first 24 postoperative hours. Secondary outcomes included Visual numeric scale (VNS) after extubation and on the1st postoperative day.

The discrete and continuous variables were described as number(%) and mean(SD) or median[IQR] and their differences analysed via Fisher's exact test or Pearson and Wilcoxon rank sum tests. P<0.05 was considered statistically significant.

Results and Discussion: 49 patients were included (24 received SIIPB and 25 no block). Patients in the no-block group received more intratecal morphine (170 vs 152mcg), less intraoperative fentanyl (248(SD160) vs 385(SD148)mcg) and more i.v. morphine before extubation (6[0–8] vs 2[0–5]mg).

More patients in the no-block group underwent cephalic duodenopancreatectomy (76 vs 37.5%). We found no differences in morphine consumption and pain scores, although SIIPB was associated with early extubation:

	SIIPB (N=24)	No block (N=25)	P value
Extubation in the operating room	24 (100%)	19 (76%)	0.022
VNS after extubation	3 [0-6.5]	3 [0-5.5]	0.462
Minimum VNS day +1, median [IQR]	0 [0–1]	0 [0-0]	0.222
Maximum VNS day +1, median [IQR]	4.5 [3-6]	5 [1.8-5.3]	0.620
Patients requiring rescue morphine (24h), n(%)	13 (54%)	12 (48%)	0.666
Morphine consumption 0-24h(mg), median [IQR]	3 [0-7]	0 [0-5]	0.475
Seating out of the bed, day, median [IQR]	1 [1–1]	1 [1–2]	0.040

Epidural use is declining due to its side effects, and combination of intrathecal morphine and truncal blocks can be a good alternative, providing adequate analgesia for extubation in the OR and early mobilization. Nevertheless our results are limited by the heterogeneous study groups.

Conclusion(s): SIIPB should be considered as part of a multimodal analgesic regime enhancing recovery in open abdominal surgery with subcostal incision.

10AP05-1

Does abdominal perfusion pressure-guided haemodynamic optimisation during elective laparoscopic colorectal surgery ensure adequate splanchnic perfusion pressure and reduce perioperative complications?

P. Morillon¹, S. Ashok¹

¹Croydon Univeristy Hospital, Anaesthetics and Intensive Care Department, London, United Kingdom

Background and Goal of Study: In laparoscopic colorectal surgery, raised intra-abdominal pressures (IAP) from pneumoperitoneum results in decreased splanchnic perfusion pressures (SPP) due to compromise of auto-regulatory mechanisms secondary to anaesthesia. This is well documented to increase perioperative morbidity due to reduced intraoperative perfusion of major visceral organs¹.

The utility of targeting adequate SPP in averting these adverse effects has not been explored fully in a perioperative setting.

Materials and Methods: We are undertaking a retrospective study reviewing the relationship between SPP and post-operative outcomes. SPP will be measured by subtracting values of IAP from MAP. We will calculate their average intraoperative mean arterial pressure and use a constant value of IAP of 15 mmHg to calculate the SPP.

All non-pregnant adult patients ASA 1 to 3 undergoing elective colorectal laparoscopic surgery >90 minutes will be included. We will compare perioperative outcomes of patients whose SPP was maintained >/= 60 mmHg to those whose SPP was not.

Results and Discussion: The outcome of interest will be Clavien-Dindo complications and hospital length of stay. Appropriate statistical analysis will be applied taking into consideration the current 30-day morbidity and mortality rate in laparoscopic colorectal surgery of 12.4% and 1.7% respectively².

Conclusion: This study will provide feasibility data for our planned multi-centre randomised controlled trial, with a control group compared to an intervention group targeting SPP >/= 60mmHg using goal directed fluid therapy and vasopressors. We hope this will provide stronger evidence for clinicians involved in the care of these patients.

Evaluating the efficacy of home-based preoperative questionnaires in assessing patient medical readiness compared to anesthesiologist examinations

R. Agur¹, I. Kleiman¹, S. Sperber¹, R. Eshel¹, B. Cohen¹, Y. Brzezinski Sinai¹

¹Tel Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel

Background and Goal of Study: Preoperative assessments are vital for identifying medical conditions and necessary workup before surgery but can be time-consuming when conducted by anesthesiologists during clinic visits.

This study evaluates whether a home-completed preoperative questionnaire can effectively replicate anesthesiologist evaluations in determining patient readiness or the need for further medical workup.

Materials and Methods: Patients scheduled for elective surgeries completed a home-based questionnaire covering perioperative history, functional capacity, current medications, and health habits like smoking before their preoperative clinic appointment. An anesthesiologist – blinded to the questionnaire results – then evaluated the patients at the clinic.

We compared the questionnaire assessments with the anesthesiologist's evaluations, considering the latter as the gold standard, to assess the questionnaire's efficacy in patient evaluation and preparation.

Results and Discussion: Out of the 415 patients who completed the questionnaires, 135 cases who complete the questionnaire and had anesthesiologist assessments were included in the final analysis. Among these patients: 51.9% (n=70) were female, 44.4% (n=60) were aged 65 or older. Agreement was found in 58.5% (n=79) of cases. A discrepancy was defined as a different outcome between the questionnaire and anesthesiologist assessments

Among the 56 discrepant cases (41.5%): 7 cases (12.5%) were not approved by the anesthesiologist, representing the most critical outcome where patient safety could be at risk. 49 cases (87.5%) involved discrepancies related to management decisions, such as providing additional instructions not covered by the questionnaire. 6 cases (10.7%) involved the questionnaire instructing patients about preoperative fasting requirements that the anesthesiologist did not mention.

Conclusion(s): The suggested home-based questionnaire shows significant potential as a safe additional screening method for preoperative anesthesiology evaluations. Its sensitivity enables anesthesiologists to focus more on high-risk cases, thereby saving time, optimizing resources, improving healthcare accessibility, and enhancing overall efficiency – all while maintaining patient safety.

Nevertheless, further development and validation of this tool are necessary to refine its effectiveness and ensure its efficacy and guarantee its integration into clinical practice.

10AP05-3

A rare cause of ischemic stroke post sedation for Drug Induced Sleep Endoscopy (DISE)

A. Cruz¹, <u>R. Marques Pinto de Sá</u>¹, C. Gomes¹ ¹ULS de Braga, Anesthesiology, Braga, Portugal

Background: Drug induced sleep endoscopy (DISE) is a diagnostic method for patients with Obstructive Sleep Apnea (OSA) that allows the visualization of the upper airways with a flexible endoscope, while the patient is sedated. It is a quick and simple procedure, carried out on an outpatient basis.

This case describes an unusual adverse reaction following a DISE using dexmedetomidine (DEX) sedation.

Case Report: A 47-year-old male, smoker, with OSA was submitted to a DISE with positive airway pressure. Sleep was induced using a DEX perfusion, with sedation depth monitored and it occurred uneventfully.

In the post anesthesia care unit (PACU), 1 hour after, he presented an episode of bradycardia, promptly reversed with iv atropine, that motivated a longer stay. 3 hours later, he developed weakness in the right hand and dysarthria. As angio-CT confirmed a thrombus in the middle cerebral artery, he underwent emergency thrombectomy, with reversal of neurological deficits. In the months following, he experienced other 2 transient ischemic attacks and was diagnosed with peripheral venous thrombosis.

Further investigation revealed Lyme disease, for which the patient was treated with a cycle of doxycycline. In the following year he presented no further symptoms of thrombotic disease.

Discussion: DEX was believed to more accurately replicate physiologic sleep than propofol as it induces arousable sedation, with minimal respiratory depression. However, it takes longer to induce sleep and the more common side effects, bradycardia and hypotension, can persist for 3 hours after the end of perfusion.

It is impossible to determine if the initial bradycardia had any causal relationship with the subsequent neurological symptoms or if they appeared as an epiphenomenon.

As the patient exhibited solely bradycardia without any episodes of hypotension, and there is no evidence in the literature including bradycardia or DEX administration as risk factors for stroke, we lean toward the latter interpretation.

It appears fortuitous that the patient, being monitored in the PACU, received prompt diagnosis and treatment for his condition, ultimately leading to the identification of a rare preexisting clinical condition.

Learning points: This case report describes a rare and unexpected epiphenomenon following DISE, emphasizing the importance of close monitoring during and after outpatient procedures and a thorough evaluation of patients with neurological symptoms following sedation.

10AP05-5

Preventing postoperative pulmonary complications after general anaesthesia in adult surgical patients – an interim analysis

<u>B. Trautwein</u>¹, R. Huf¹, B. Ulm¹, B. Jungwirth¹, M. Götz², S. Kagerbauer¹

¹University Hospital Ulm, Anaesthesiology and Intensive Care Medicine, Ulm, Germany, ²University Hospital Ulm, Experimental Radiology, Ulm, Germany

Background: The incidence of postoperative pulmonary complications (POPC) after general anaesthesia varies between 9-40%, depending on the surgical procedure and the definition used. In 2018, the StEP collaboration introduced a standardised definition¹. Risk prediction is critical to reduce the resulting mortality². The currently best-evaluated preoperative risk score (ARISCAT³) has not yet been tested concerning the StEP endpoint.

Methods: The study represents an interim analysis of an ongoing prospective study on machine-learning-assisted risk prediction (ethics approval 369/22). Adult patients undergoing surgery under general anaesthesia were included and stratified by ARISCAT (high (HR), intermediate (IR), low risk (LR)).

We combined clinical routine data, structured patient examinations on postoperative days 1,3 and 7, and a chart review to detect POPC, defined by StEP criteria.

Results: 259 patients were included so far, of which 41% were female, 24% were smokers, ASA III was the dominant classification (65%), and the median age was 66 years. 45% patients experienced at least one POPC. POPC prevalence was highest in the HR group (Table 1). Severe complications were rare (Table 1). The most common type of POPC was respiratory failure, followed by pleural effusion and pneumothorax (Figure 1).

		ARISCAT High Risk (n = 61)	ARISCAT Intermediate Risk (n = 122)	ARISCAT Low Risk (n = 76)	p-value*
POPC Occurence		84.4%	46.1%	27.4%	<0.001
Severity	mid	97.4%	04.3%	100.0%	0.7
	sovere	2.6%	5.7%	0.0%	
Timepoint da	y of surgery	18.0%	15.6%	21.1%	40.001
	P00 1	32.8%	21.3%	1.3%	
	POD 3	6.6%	1.3%	2.6%	
	3:P007	4.9%	3.3%	1.3%	

Table 1. Descriptive statistics of endpoint POPC

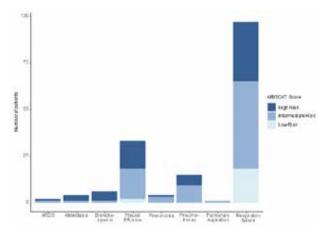

Figure 1. Distribution of different types of POPC.

Conclusion: POPC are common, and showed a higher prevalence than previously published, most likely due to the improved accuracy resulting from the prospective study design. The ARISCAT

showed good prediction of POPC. Most complications occurred during the first 48 hours, where preventive measures should have already commenced.

Laparostomy: an anesthetic challenge - a case of a laparostomized awake patient on spontaneous ventilation

J. Nogueira¹, <u>B. Lemos Silva</u>¹, B. Vieira², A. Reigota¹, N. Lareiro¹

¹Unidade Local de Saúde da Região de Aveiro, Anesthesiololy, Aveiro, Portugal, ²Unidade Local de Saúde da Região de Aveiro, Intensive Care Medicine, Aveiro, Portugal

Background: Laparostomy allows peritonitis, ischemia and trauma treatment, facilitating re-exploration and preventing compartment syndrome. Most patients are mechanically ventilated.

Case Report: Male, 64 years old, ASA III, underwent exploratory laparotomy due to bowel obstruction. 12 days post-op, presented increased inflammatory markers and drainage of fecaloid content from the surgical wound leading to laparotomy, under general anesthesia and endotracheal intubation. Laparostomy with vacuum dressing was chosen. The patient was hemodynamically stable. without circulatory or respiratory dysfunction and, after multidisciplinary discussion, extubation and spontaneous ventilation were decided. A thoracic epidural catheter was placed. Before extubation, intravenous fentanyl and epidural ropivacaine were administered. When awake, the situation was explained to the patient. Postoperative analgesia was carried out with patient-controlled epidural analgesia protocol. The patient was assessed daily by the acute pain team. During his stay in ICU, he was conscious, cooperative and in good spirits, with controlled pain and good ventilatory dynamic. He returned to the operating room 3 days later where the abdomen was closed.

Discussion: Laparostomy allows treatment of critical conditions, being peritonitis the most common indication. Decision to keep patient intubated or to extubate depends on multiple factors. Maintaining patients supine and intubated under mechanical ventilation is more convenient, reducing risk of dehiscence and evisceration associated with agitation in awake patient. However, it creates a necessity for deeper sedation, risk of delirium and lower patient communication and satisfaction; as well as respiratory complications such as pneumonia and atelectasis. Keeping the laparostomized patient conscious and on spontaneous ventilation remains a challenge, with few case descriptions and no clear guidelines. We consider that key aspects are patient selection and collaboration; inform about risks; effective analgesia; adequate vigilance; expected time of closure.

Learning points: Risks, benefits and indications for spontaneous ventilation in laparotomized patients; Challenges regarding analgesia and ventilation.

10AP05-7

Anesthetic management for elective bilateral vasectomy in a patient with sickle cell anemia: a case report

C. Monteiro Ferreira¹, <u>F. Gama</u>¹, S. Alves¹, J. Borges¹ 'Unidade Local de Saúde de Braga, Anesthesiology, Braga, Portugal

Background: Sickle cell anemia (SCA) is a hereditary hemoglobinopathy associated with complications such as chronic hemolytic anemia, vaso-occlusive crises, acute chest syndrome, and an increased risk of infection (1).

Perioperative management of patients with SCA is complex and requires strategies to optimize oxygenation, hydration, temperature, hemodynamic stability, and pain management (1).

We present the anesthetic management of a patient with SCA scheduled for elective bilateral vasectomy.

Case Report: A 35-year-old male, ASA II, with a history of SCA, was scheduled for an elective bilateral vasectomy. His current medications included hydroxyurea and folic acid. He had previously undergone a cholecystectomy without anesthetic complications.

His preoperative hemoglobin value was 9.0 g/dL, and the patient was evaluated by the hematology department, which recommended the transfusion of one unit of red blood cells on the day before the surgery. His vital signs on admission were within normal limits. Standard ASA monitoring was applied along with BIS®. Normothermia was maintained using a forced-air warming blanket and a fluid warmer. Goal-directed fluid therapy was performed with crystalloid solutions. General anesthesia was maintained with sevoflurane.

Airway management was achieved with a laryngeal mask, allowing a secure airway with minimal stimulation. Prophylaxis for post-operative nausea and vomiting and multimodal analgesia were administered.

The surgery lasted 15 minutes, and the patient maintained hemodynamic stability throughout the procedure. Following the surgery, the patient was transferred to the post-anesthesia care unit and subsequently to the inpatient ward. He remained clinically stable and was discharged the following day without complications.

Discussion: The successful anesthetic management of patients with SCA provides valuable insights. In this case, the patient's elective vasectomy was performed to provide personal and lifestyle benefits.

Although this procedure is considered low-risk, meticulous anesthetic planning was essential to prevent complications associated with SCA.

References:

1. Walker I, Trompeter S, Howard J, et al. Guideline on the perioperative management of patients with sickle cell disease. Anaesthesia. 2021;76:805-817.

Learning points: With a meticulous anesthetic approach and close collaboration with the hematology team, patients with SCA can safely undergo elective procedures.

10AP05-8

Is the Montreal Cognitive Assessment test suitable for defining a postoperative delirium risk cohort? - evaluation of a mixed non-cardiac surgical patient cohort

S. Letz¹, M. Kreuzer¹, G. Schneider¹, S. Pilge¹
¹TUM University Hospital, Department of Anesthesiology and Intensive Care, Munich, Germany

Background and Goal of Study: Postoperative delirium (POD) is a critical medical condition associated with increased morbidity and mortality. Preventive strategies for POD involve preoperative risk stratification, -reduction, early detection and treatment. A key risk factor for the development of POD is pre-existing cognitive impairment. The Montreal Cognitive Assessment (MoCA) has been described in the literature as a potential tool for preoperative cognitive evaluation, with a score of <26 already indicating mild cognitive impairment.

The aim of the present study is to investigate whether this threshold, or an alternative, is associated with an increased risk of POD in a university-based cohort of mixed surgical patients, and whether it can be reliably applied as a screening parameter in routine clinical practice.

Materials and Methods: At the TUM University Hospital, 2007 patients aged ≥ 65 years were preoperatively assessed with the MoCA test prior to elective surgical procedures (including visceral, thoracic, vascular, trauma, orthopedic, and urological surgeries) as part of the preoperative anesthesiology visit.

Postoperatively, patients were examined twice daily until the third postoperative day using the 3D-CAM test to assess for POD.

Results and Discussion: Considering a MoCA threshold of 26 the sensitivity for POD would be 86.1% and the specificity would be 56.5% this means that the risk of having a false positive, i.e., low MoCA and no POD would be high. Looking at the distribution of scores, the median MoCA of the patients without POD was 26 [23,28] and it was 19 [15,23] for the POD patients.

The AUC with 10k-fold bootstrapped 95% confidence intervals was 0.87 [0.77,0.87]. Accuracy would be highest for a MoCA=12 with an accuracy of 0.96. For a MoCA=26, the accuracy was 0.58

Conclusion(s): The threshold of < 26 points for defining a risk collective for POD demonstrates high sensitivity; however, in clinical practice, it could be associated with a considerable resource burden due to its comparatively low specificity.

This emphasizes the need for a composite risk score to evaluate and include the main risk domains for POD in order to focus clinical human and financial resources.

Furthermore, the question arises whether a binary classification for the risk of POD is adequate or whether a more differentiated, graded categorization of the probability of POD, considering delirium in its clinical severity levels, would be more appropriate.

10AP05-9 When serotonin runs wild - unintentionally

C. Tan¹, L.L. Lean¹¹Ng Teng Fong General Hospital, Anaesthesia, Singapore, Singapore

Background: Nausea and vomiting is managed via different biochemical pathways. One mechanism frequently utilised is with a selective serotonin receptor antagonist - the most commonly used and studied is ondansetron, widely thought to be the "gold standard" for management of PONV. However, palonosetron - a longer-acting selective serotonin antagonist effective chemotherapy patients - is increasingly used in the peri-operative period in the past decade. The use of different drugs within the same class in different locations/settings within the hospital poses a risk of unintentional overdose which may result in serious adverse medication events.

We present a case of inadvertent repeated dosing of ondansetron given within the half-life palonosetron and suspicion of serotonin syndrome in a post-operative patient after she had returned to the general ward.

Case Report: 66 year old ASA 2 female presented for elective left breast implant reconstruction, nipple sparing mastectomy reconstruction, left nipple sparing mastectomy and level 2 axillary clearance. The patient was administered with IV palonosetron intra-operatively after discussion and request by the breast surgeon.

Anaesthesia post-operative instructions were written and IV palonosetron administration was documented and handed over to the primary surgical team.

However, post-procedurally the patient complained of non-vertiginous giddiness in the general ward and was subsequently administered with IV ondansetron within the half-life duration of palonosetron by the ward team.

Discussion: Increasingly widespread use of psychiatric medications due to increased awareness of mental health globally, prescription of analgesia which can potentially interact with the serotonin pathway.

Government funded, training hospitals comprises healthcare professionals of varying seniority and familiarity with less commonly used medication may result in inadvertent errors.

References:

Gan, T.J. (2020) Fourth Consensus Guidelines for the management of... Available at: https://www.ashp.org/-/media/assets/policy-guidelines/docs/endorsed-documents/endorsed-documents-fourth-consensus-guidelines-postop-nausea-vomiting.pdf (Accessed: 05 December 2024).

Learning points:

- Emphasises the importance of appropriate documentation and care handover between teams.
- Systems and workflow optimisation between operating theatre, post-anaesthesia care unit and the ward to prevent unintended repeated dosing of medications.

10AP05-10

Incidence of respiratory complications during deep sedation catheter ablations in patients with atrial fibrillation: a single centre retrospective study

M. Homberg¹, K. Betz^{2,3}, D. Linz^{2,4,5,6,7}, K. Vernooy^{2,4}, W. Buhre⁸, E. Bouman¹

¹MUMC+, Anesthesiology and Pain Management, Maastricht, Netherlands, ²Maastricht University, Cardiology, Cardiovascular Research Institute Maastricht (CARIM), Maastricht, Netherlands, ³Eifelklinik St. Brigida GmbH & CO KG, Internal Medicine, Simmerath, Germany, ⁴Radboud University Medical Center and Radboud Institute for Health Sciences, Cardiology, Nijmegen, Netherlands, ⁵Centre for Heart Rhythm Disorders, University of Adelaide and Royal Adelaide Hospital, Adelaide, Australia, °Flinders University, Caring Futures Institute, College of Nursing and Health Sciences, Adelaide, Australia, ¹Maastricht UMC+, Maastricht Heart+ Vascular Center, Maastricht, Netherlands, ³University Medical Center Utrecht, Anesthesiology, Utrecht, Netherlands

Background and Goal of Study: Catheter ablations (CA) in patients with atrial fibrillation (AF) are performed either under procedural sedation and analgesia (PSA) or under general anaesthesia (GA). The knowledge on the incidence and severity of respiratory complications during moderate or deep sedation for this population is limited.

The aim was to determine the incidence and severity of per-procedural respiratory complications during CA in patients with AF under PSA. This is aimed to optimize patient selection for PSA during CA.

Materials and methods: This single center retrospective cohort study was conducted in a tertiary teaching hospital in The Netherlands from October 2020 and July 2023. It involved adult, consecutive patients for a CA under PSA for AF. The ISOLATION cohort study and ISOLATION 'light' registry were approved by the ethical review boards MUMC⁺ (METC numbers 19-052, 2019 1022).

This study was conducted in compliance with the Declaration of Helsinki and the Good Clinical Practice guidelines. Per-procedural respiratory complications were defined as the use oral/nasal airway, or an indication for a non-rebreathing mask or high flow oxygen (Optiflow), or a hypoxemic event (a saturation <90% ≥120 seconds) or a conversion to GA with laryngeal mask airway (LMA) or tracheal intubation. For each hypoxemic event an AUC (by multiplying duration in minutes and the drop in saturation under 90%) were determined.

Results and Discussion: This study included 232 participants. The incidence of respiratory complications was 42.2%. An oral or nasal airway was used in 27.6% of the patients. In 13.8%, a hypoxic event occurred. In 0.9% of the cases a non-rebreathing mask was used. An Optiflow was applied in 6.9% of the cases. In 1.3% there was a cross over to GA, a LMA was placed in 0.9%. An endotracheal intubation was performed in 1 case (0.4%) due to intra-oral blood during the procedure.

There is no significant difference in lowest measured saturation and the duration of the lowest saturation between the two groups. The AUC varied from 4.0-360.0 with a mean $41.9(SD\pm68.1)$. The clinical effects of a relatively short duration of hypoxemia are yet unknown.

Conclusion: Respiratory complications during deep sedation catheter ablations in patients with atrial fibrillation occur in 42.2%. A follow-up study based on a prospective design is needed to investigate the clinical consequences of this cumulative hypoxemia.

10AP05-11 Perioperative fasting: a survey in an oncological center

J. Moniz¹, <u>D. Paixão¹</u>, P. Pinto¹, I. Rebelo¹ ¹Instituto Português de Oncologia de Lisboa, Anesthesiology, Lisboa, Portugal

Background and Goal of Study: Preoperative fasting remains a key concern for anaesthesiologists. While necessary to reduce the risk of pulmonary aspiration, prolonged fasting contributes to patient discomfort and may disrupt homeostasis. Current guidelines advocate for more liberal protocols, yet prolonged fasting remains common in practice.

This study aims to evaluate whether fasting practices in our center align with current guidelines.

Materials and Methods: All adult patients undergoing elective surgery during a standard working week (n = 83) in our Oncological Center answered a questionnaire regarding their last dietary intake. Collected data included fasting durations for solids and clear liquids, patient-reported discomfort (scored 0–10, with 10 being the most uncomfortable), adherence to regular medication intake, understanding of fasting requirements, and the source of fasting instructions.

Results and Discussion: The mean fasting durations were 12 hours for solids and 11 hours for clear liquids, with only 25% of patients consuming water 2–8 hours before surgery. No patients were identified as having an insufficient NPO period. Additionally, 56% of patients skipped their regular medications despite no specific instructions to do so. Fasting was associated with notable patient discomfort, with 66% of patients reporting moderate or severe discomfort (scores >3).

Moreover, over half of patients (56%) lacked a clear understanding of the rationale for fasting, often citing inadequate explanations. This may be linked to the fact that the majority of fasting instructions were given by the nursing staff (≥50%).

Addressing these challenges remains essential in high quality perioperative care making it is essential for anaesthesiologists to prioritize educating both patients and healthcare staff on fasting protocols to ensure adherence to evidence-based practices.

Conclusions: Our findings highlight that, despite efforts to implement updated guidelines, patients often experienced prolonged fasting durations, particularly for clear liquids.

Following this survey, we revised our internal fasting protocols and initiated educational sessions for ward nursing staff to promote adherence to current best practices. We plan to assess the effectiveness of these interventions through a future audit

10AP05-12

Analgesia for total minimally invasive oesophagectomy: a 6-year audit in a cancer centre

F. Sousa¹, <u>J.M.H.F. Moniz¹</u>, S. Maurício¹, C. Madeira¹, M. Bernardino¹, R. Ferreira¹ ¹Instituto Português de Oncologia de Lisboa, Anesthesiology, Lisboa, Portugal

Background and Goal of Study: Oesophagectomy transitioned to a totally minimally invasive technique (TMIO) by 2019 in our center. While the surgical approach has been standardized, optimal analgesic strategy for TMIO remains a debate, given its reduced invasiveness compared to traditional procedures. This study aims to provide a descriptive analysis of our Acute Pain Unit's management of TMIO patients over a six-year period.

Materials and Methods: we included all patients who underwent TMIO at our center from January 2019 - November 2024 (n = 161). Patients were categorized into five study groups based on the analgesic protocol used:

Paravertebral Continuous Infusion + Patient Boluses (PVB)	0.1% ropivacaine, 4–8 mL/h basal rate, 4 mL bolus, 30-min lockout.
CEI + Patient-Controlled Epidural Analgesia (PCEA)	0.1% ropivacaine \pm 20 mcg/mL morphine, 4–8 mL/h basal rate, 4 mL bolus, 30-min lockout
Continuous Epidural Infusion (CEI)	0.1% ropivacaine \pm 50 mcg/mL morphine, 4–8 mL/h
Spinal Morphine + Morphine PCA (Spinal)	No background infusion, 1 mg bolus, 8-min lockout
Morphine PCA (PCA)	infusion 0.3-0.5 mg/h, 1 mg bolus, 8-min lockout

We performed a descriptive analysis of patient demographics, pain scores, opioid requirements (IV morphine milligram equivalents - MME), and incidence of complications, namely hypotension (defined by mean arterial pressure or need for fluid boluses and/or vasopressors) and pulmonary morbidity (need for oxygen or ventilatory support). Then we compared the main groups for these outcomes.

Results and Discussion: The mean age of the patients was 65 years, with a majority being male (82%). 38% of patients were classified as ASA II, while the remaining 62% were ASA III. The table below briefly describes the main results for each group:

Modality	PCA	Spinal	CEI	PCEA	PVB
N (%)	33 (20,5%)	22 (13,7%)	47 (27,3%)	54 (33,5%)	8 (5,0%)
Intraop MME, mean (SD)	57,2 (16,7)	83,9 (28,9)	40,0 (12,1)	41,1 (13,5)	63,3 (18,4)
IV MME D5 cumulative, mean	88,7 (33,6)	61,0 (34,4)	117,7 (63,5)	71,7 (40,0)	42,2 (29,3)
NRS at rest D1-D3-D5, median	0.0 - 0.0 - 0.0	0.0 - 0.0 - 0.0	0.0 - 0.0 - 0.0	0.0 - 0.0 - 0.0	0.0 - 0.0 - 0.0
NRS on movement D1- D3-D5, median	4.0 4.0 - 2.0	3.0 - 2.0 - 3.0	2.0 - 3.0 - 2.0	3.0 - 3.0 - 3.0	3.5 - 4.5 - 3.0
Hypotension D1, n(%)	16 (48,5%)	11 (50%)	33 (75%)	34 (63%)	2 (25%)
O2/ventilatory support D1, n(%)	24 (72,7%)	17 (77,3%)	23 (52,3%)	44 (81,5%)	6 (75%)

Adequate analgesic control was achieved across all study groups, as demonstrated by consistently low NRS scores. When the main analgesia groups were compared (PCA vs CEI + PCEA), differences became apparent: upon movement, pain is better controlled with epidural techniques (p 0.002), which comes with an increased incidence of hypotension (p 0.040).

Conclusions: While all modalities demonstrated adequate pain relief and similar clinical outcomes, further research is required to determine how to tailor analgesia strategies to individual patients.

10AP06-1

Systematic review of the optimum haemodynamic monitoring strategy for patients following oesophagectomy

M. Hardwick¹, S. Prescott^{2,1}, A. Balu^{1,2}, J. Colfar¹, B. Johnston^{1,2}, I. Welters^{1,2}

¹Liverpool University Hospitals Group, Royal Liverpool University Hospital, Critical Care, Liverpool, United Kingdom, ²University of Liverpool, Institute of Life Course and Medical Sciences, Faculty of Health and Life Sciences, Liverpool, United Kingdom

Background and Goal of Study: Oesophageal cancer has the 7th highest mortality globally, and the main stay of treatment is oesophagectomy¹.

Oesophagectomies are complex, involving both abdominal and thoracic phases, lymph node clearance and ligation of vascular supplies to the organs involved. Consequently, oesophagectomies have a complication rate of up to 63%, with anastomotic leaks being common².

Haemodynamic optimisation has been identified as a key factor in maintaining anastomotic perfusion to reduce the risk of anastomotic leak³.

This systematic review aims to identify the most appropriate haemodynamic monitoring strategy for patients following oesophagectomy.

Methods: A comprehensive search strategy was performed on MEDLINE via Pubmed, MEDLINE via OVID, Embase via OVID and Emcare via OVID. Search terms included 'oesophagectomy or esophagectomy or oesophogastrectomy' and 'hypotension or haemodynamic(s)'.

Papers were screened using predetermined inclusion and exclusion criteria. Papers were screened by three independent reviewers (MH, SP, AB) using Rayyan (an application for systematic reviews) and conflicts were resolved by discussion. Following data extraction, risk of bias assessment was performed using the Cochrane risk of bias tool for RCTs, and Newcastle-Ottawa tool for non-RCTs.

Results and Discussion: The initial search retrieved 859 citations. Following title and abstract screening 35 citations were retrieved for full text screening. Following full text screening 13 citations were progressed to data extraction. Studies included 3 RCTs, 6 prospective observational studies, 3 retrospective observational studies, 1 systematic review and included 891 patients.

Many trials assessed the incidence of anastomotic leaks as a secondary outcome. Data extraction revealed heterogeneity in outcomes reported, haemodynamic targets and measurement methods.

Conclusion: Generalisability of the results is limited due to the heterogeneity and quality of the studies retrieved, and the lack of RCTs assessing anastomotic leaks as the primary outcome.

Further research into haemodynamic monitoring is justified and a core outcome set is required to produce generalisable evidence.

Validation of the parsimonious NELA model in emergency abdominal surgery

A.K. Hansen¹, S. Thorup¹, M.H. Møller²³, J. Burcharth³⁴, A.M. Møller¹³, M. Vester-Andersen¹³
¹Herlev Anaesthesia Critical and Emergency Care
Science Unit (ACES), Department of Anaesthesiology,
Copenhagen University Hospital Herlev-Gentofte,
Herlev, Denmark, ²Copenhagen University Hospital
- Rigshospitalet, Department of Intensive Care 4131,
Copenhagen, Denmark, ³University of Copenhagen,
Department of Clinical Medicine, Copenhagen, Denmark,
⁴Copenhagen University Hospital Herlev-Gentofte,
Department of Surgery, Herlev, Denmark

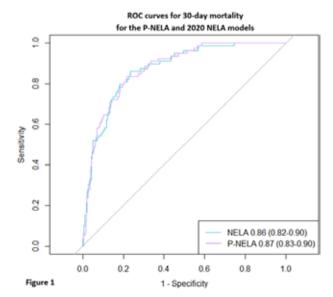

Background and Goal of Study: Emergency abdominal surgery has high postoperative mortality. While the National Emergency Laparotomy Audit (2020 NELA) model predicts mortality well, its complexity limits clinical use. The Parsimonious NELA (P-NELA) model simplifies predictions with only 13 variables.

This study externally validates the P-NELA model in a Danish cohort and compares it to the 2020 NELA model. We hypothesized that P-NELA performs well and comparably to NELA.

Materials and Methods: This retrospective study included adult patients undergoing emergency laparoscopy or laparotomy at Copenhagen University Hospital – Herlev between March 2017 and January 2020. We excluded appendectomy, cholecystectomy, and negative diagnostic procedures. Data was extracted from electronic patient records. The outcome was 30-day mortality. Model performance was assessed using discrimination (Area Under the Curve [AUC]) and calibration (Integrated Calibration Index, slope, and intercept). Missing data were imputed using multiple imputations. We performed a sensitivity analysis of complete cases.

Calibration	P-NELA model	2020 NELA model
Integrated calibration index	0.042	0.045
Calibration intercept	0.05 (0.04-0.08)	0.05 (0.03-0.07)
Calibration slope	1.08 (1.06-1.10)	1.09 (1.07-1.12)

Table 1. For a perfectly calibrated model, the Integrated Calibration Index would be 0, calibration intercept 0 and calibration slope 1.

Results and Discussion: Out of the 679 included patients, 90 (13.3%) died within 30-days. P-NELA demonstrated an AUC of 0.87 (95% CI: 0.83–0.90), comparable to the NELA model (AUC: 0.86, 95% CI: 0.82–0.90). Calibration was similar for the two models, and both tended to underestimate 30-day mortality. Sensitivity analyses supported the robustness of the findings.

Conclusion(s): The P-NELA model performed well in this external validation, with predictive accuracy comparable to the 2020 NELA model, suggesting that a high number of variables in risk prediction models is not always necessary.

10AP06-3

Predicting postoperative infectious complications – a systematic review of current prediction models and their validation and implementation status

N. de Mul¹, K.M. Scheffer-Wesdorp², G.E. Mondelli³, W.-J.M. Schellekens⁴¹, O.L. Cremer², L.M. Vernooij¹³³¹University Medical Center Utrecht, Anesthesiology & Intensive Care, Utrecht, Netherlands, ²University Medical Center Utrecht, Intensive Care, Utrecht, Netherlands, ³St. Antonius Ziekenhuis, Anesthesiology & Intensive Care, Nieuwegein, Netherlands, ⁴Cantonal Hospital Aarau, Anesthesiology, Aarau, Switzerland

Background and Goal of Study: Preoperative assessment of postoperative infection risk can help identify patients for personalized decision making and management. This systematic review evaluates existing prediction models for infection, focusing on their validation and implementation status.

Materials and Methods: Pubmed, Embase and the Cochrane Library were searched studies on the development, validation- and implementation of multivariable models utilizing preoperative predictors to estimate the risk of postoperative infections occurring within 30-days of elective, non-cardiac and non-intracranial surgical procedures.

Results and Discussion: We included 152 studies in total. Eightyseven studies described model development (267 models) and 86 studies assessed model validity (311 model validations of 41 unique models). No studies reported on model implementations. Most studies predicted surgical site infections (SSI, n=88 models), pneumonia (45 models) and infection in general (n=57). Most frequently incorporated predictors included age (66%), sex (53%) and ASA score (48%). Predictors were incompletely reported for 80 models. The American College of Surgeons National Surgical Quality Improvement Program surgical risk calculator (ACS NSQIP SRC) and SUrgical Risk Preoperative Assessment System (SURPAS) demonstrated most robust validation status, with 222 and 35 external validations, respectively. Reported c-statistics of the ACS NSQIP SRC were median 0.61 (0.43 - 0.85), 0.66 (range 0.44 - 0.95), and 0.64 (0.31-0.97) for prediction of SSI, pneumonia, and urinary tract infection (UTI), respectively. Median c-statistics of the SURPAS were 0.62 (range 0.52-0.78) and 0.59 (0.52-0.82) for UTI and general infection, respectively. Overall, most studies scored high risk of bias.

Conclusion(s): An abundance of prediction models for postoperative infection have been developed, with ACS NSQIP SRC and SURPAS being the most thoroughly validated. However, the clinical utility of even these models seems limited by poor predictive performance, and no implementations were identified.

10AP06-4

Probiotics in the perioperative period: optimising postoperative pain

<u>J.Á. Rodenas Rubio</u>¹, P. Cuesta Montero¹, J.J. Tortajada Soler²

¹Complejo Hospitalario Universitario de Albacete, Anesthesiology, Reanimation and Pain Therapy, Albacete, Spain, ²Hospital Virgen de los Lirios, Anesthesiology, Reanimation and Pain Therapy, Alcoy, Spain

Background and Goal of Study: The close relationship between the gut microbiome and pain perception is now well established. Procedures such as surgery, general anaesthesia or antibiotics can alter the homeostasis of the microbiota. The composition of the microbiome is known to influence the development, expression and progression of several diseases.

PROBIOTIC ADMINISTRATION PROTOCOL FOR ENHANCED POST-OPERATIVE PAIN CONTROL

General and objetives

Surgical procedures, the use of general anaesthesia and other perioperative factors significantly alter the diversity and composition of the gut microbiota, which can exacerbate local and systemic inflammation and delay postoperative recovery. Restoring the balance of the gut microbiome aims to:

- Reduce inflammation.
- Reduce post-operative somatic and visceral pain.
- Reduce the need for post-operative analogsics.
- · Promote faster gut recovery.

Indications

- Patients undergoing gastrointestinal surgery, major surgery elsewhere and/or general anaesthesia.
- Procedures involving preoperative mechanical bowel cleansing.
- Patients with chronic diseases with altered microbiota (irritable bowel syndrome, inflammatory bowel disease, diabetes, cirrhosis, non-alcoholic fatty liver disease, oncology patients, etc.).
- · Patients with chronic pain.
- Patients on antibiotic treatment.

Contraindications

- · Allergies or intolerances
- Severely immunosuppressed patients
- Presence of active systemic infection
- Risk/benefit assessment in pregnant women

Intervention

Probiotic Selection and Mechanism of Action

- Lactiplantibacillus plantarum exerts anti-inflammatory effects through the production of IL-10 and IL-4 and by directly limiting the production of pro-inflammatory cytokines such as TNF.
- Combinations of Lactobacillus spp. and Bifidobacterium spp. strains have antinociceptive effects by
 modulating pain signalling through the production of neurotransmitters such as GABA.
- L. acidophillus NCFM and L. salivarus Ls-33 induce increased expression of µ-opioid receptor mRNA (OPRM1). L. acidophillus NCFM also induces significant expression of cannabinoid receptor (CNR2) mRNA.
- Saccharomyces boulardii CNCM I-745: Prevention of diarrhoea associated with antibiotic treatment and Clostridium difficile.

Timing of Administration

- Start: 5 to 7 days before surgery
- Continuation: Up to 14 days postoperatively, depending on clinical evolution and patient tolerance.
 Dosage
- Lactiplantibacillus plantarum: ≥10^10 CFU/day.
- Lactobacillus spp.: ≥10^9 CFU/day.
- Bifidobacterium spp.: ≥10^9 CFU/day.
- . L. acidophillus NCFM: 2.5-5 x 10^9 CFU/day.
- L. salivarus Ls-33: ≥10^9 CFU/day.
- Saccharomyces boulardii**: 1-2 x 10^9 CFU/day or 250-500mg/day.

*Administer at commercially available standardised doses.

**Consider administration if antibiotic treatment is prolonged

- Route of Administration

 Oral, preferably in capsules or soluble sachets.
- For patients with oral restrictions, compatible formulations for gavage administration should be considered.

Evaluation and monitoring

Pre-operative

- Consider a stool culture study beforehand to assess the composition of the microbiota and personalise the intervention, especially in patients with chronic diseases.
- · Evaluate digestive tolerance to the probiotic (diarrhoea, constipation, flatulence etc.).

Post-operative period

Monitor digestive symptoms, use acute pain scales, assess control with analytical inflammatory parameters and a new stool culture.

Therefore, it seems reasonable to consider the use of probiotics in the perioperative period as a therapeutic option, given their involvement in the modulation of pain and inflammatory response. The present study aims to establish a probiotic administration protocol to improve postoperative pain control.

Materials and Methods: A systematic review of the literature was conducted using search engines (PubMed, ScienceDirect, TripDatabase and Google Scholar), as well as books and clinical practice guidelines on the subject.

A protocol for the administration of probiotics in the perioperative period was developed based on the most recent evidence-based recommendations.

Results and Discussion: Probiotics have gained popularity in the field of gut microbiome and perioperative medicine. Although there are doubts about their efficacy in preventing postoperative intestinal complications, good data on their use in modifying the intestinal environment and reducing inflammation have led to their use in reducing postoperative pain. In this context, we present a protocol (*Table*) on its use developed in our centre.

Conclusion(s): The inclusion of probiotics in perioperative management is an emerging and promising strategy in patient prehabilitation due to its potential effects on postoperative pain.

However, further clinical research is needed to standardise protocols given the heterogeneity of different probiotic formulations, doses and duration of treatment.

10AP06-5

Cancer patients can achieve moderate to high intensities during supervised online exercise classes: a pilot study at a tertiary teaching hospital in central London

H. Ainsworth¹, A. Ayoub¹, I. Veal¹, N. Peat¹, S. Yoon¹, H. Bidd¹

¹Guys and St Thomas' NHS Foundation Trust, Anaesthesia, London, United Kingdom

Background and Goal of Study: Exercise programs for cancer patients before and after surgery can improve surgical outcomes and recovery. Online delivery helps overcome logistical barriers to healthcare access, reducing travel time, costs and work-related disruptions. Achieving recommended moderate to high intensity levels improves their effectiveness.

This study aims to describe the exercise intensity achieved during a 60 minute online supervised exercise class.

Materials and Methods: Twelve adults (M:F 1:1, mean age 62.5 \pm 9 years) with colorectal or thoracic cancer enrolled in an online supervised exercise program from September to November 2024. All patients were scheduled for, or had recently undergone surgery.

Aerobic intensity was assessed using the patient's own fitness wearables or pulse oximeters provided by the hospital. Patients' heart rates (HR) were recorded at 5 and 10 minutes into the aerobic exercise.

Corresponding % Heart Rate Reserve (%HRR) zones were calculated at analysis, using the Karvonen formula (moderate intensity: 40–59%; high intensity 60–80%). Rate of Perceived Exertion (RPE) scores were recorded at 5 and 10 minutes into the strength exercises (moderate-to-high intensity: RPE 4-6/10 or higher). Baseline activity levels were assessed using the GODIN Leisure Time Activity Questionnaire (GLTAQ).

Results and Discussion: In total, 24 HR readings (2 per patient) were collected during aerobic exercise, with 71% corresponding with a moderate-to-high intensity %HRR (moderate:25%; high: 46%). Strength training elicited moderate-to-high RPE scores in 88% of datasets.

Overall, 100% of patients reached moderate-to-high intensity in at least one exercise component. Baseline GLTAQ scores categorised patients as 'sedentary' (n=7), 'moderately active' (n=2), and 'active' (n=3). 'Active' patients achieved consistent moderate-to-high intensity levels compared to 'moderately active' and 'sedentary' patients (100%, 75% and 50%, respectively).

Conclusion(s): The majority of patients reached moderate-to-high intensity during aerobic and strength components of the online supervised exercise program. These findings demonstrate the feasibility of delivering effective online exercise interventions. Our findings suggest that patients who are deemed 'sedentary' at baseline, may require supplementary strategies to optimise target intensities. Future research should explore strategies to optimise outcomes across varying baseline fitness levels.

10AP06-6

The association between perioperative acetaminophen administration and postoperative delirium

L. Kaiser¹, L.J. Wachtendorf¹, B.-S. Paschold¹, E. Ahrens¹, H. Ma¹, M.S. Schaefer¹

¹Beth Israel Deaconess Medical Center, Anesthesia & Critical Care, Boston, United States

Background and Goal of Study: Postoperative delirium (POD) is a frequent complication in older surgical patients and is linked to higher morbidity and mortality. Acetaminophen is widely used for perioperative analgesia, but its effect on POD remains unclear. We hypothesized that the perioperative use of acetaminophen decreases the risk of POD.

Methods: 29,830 hospitalized patients aged ≥60 years undergoing non-cardiac, non-neurosurgical procedures under general anesthesia were included. The primary exposure was acetaminophen administration at any time between holding area admission until discharge from post-anesthesia care unit.

The primary outcome was POD within 7 days, identified based on International Classification of Diseases (ICD) codes, Confusion Assessment Method for the Intensive Care Unit (CAM-ICU) scores, and manual chart review. Inverse probability-weighting-regression-adjustment was applied for the primary analysis.

Results: 23,914 (80.2%) patients received acetaminophen and overall 1,141 (3.8%) patients experienced POD within 7 days. The risk of POD was lower in patients receiving acetaminophen, with an average treatment effect (ATE) of -1.3% (95% confidence interval [CI] -2.0 to -0.6; number needed to treat [NNT]=77; p<0.001). This association varied by timing of acetaminophen administration.

Preoperative use showed the largest reduction in POD risk, with an ATE of -1.9% (95% CI -2.8 to -1.1; NNT=53; p<0.001), followed by postoperative use (ATE -1.4%; 95% CI -2.4 to -0.4; NNT=71; p=0.007), and combined pre- and postoperative use (ATE -0.9%; 95% CI -1.7 to -0.2; NNT=111; p=0.017).

Conclusion: Perioperative acetaminophen use was associated with a lower risk of POD, particularly when administered before surgery.

Patient characteristics	No acetaminophen N=5,916	Acetaminophen N=23,914	Absolute standardized difference

10AP06-7

Age- and sex-specific cut-offs for functional capacity and their predictive value for postoperative outcome in non-cardiac surgery – a secondary analysis of the international MET-REPAIR study

A. Kirkopoulos¹, D.M. Donaldson¹, G. Lurati Buse¹ **University Hospital Duesseldorf, Anesthesiology, Duesseldorf, Germany

Background and Goal of Study: Poor functional capacity is a widely used risk factor for adverse postoperative cardiac complications after non-cardiac surgery. Age is a potential confounder in the association between poor functional capacity and adverse outcome. Also, the impact of sex as additional modifier is increasingly investigated.

The aim of this study was to explore if risk prediction for postoperative adverse cardiac events was improved using sex- and age-specific cut-offs for functional capacity in patients submitted to non-cardiac surgery.

Materials and Methods: This is a secondary analysis of the international MET-REPAIR study, a prospective cohort study including non-cardiac surgery patients ≥ 45 years with increased cardiovascular risk. Functional capacity was estimated in metabolic equivalents (MET) using a validated questionnaire.

Primary endpoint was the incidence of major adverse cardiovascular events (MACE) at 30 days. Clustering methods were employed for detection of age- and sex-specific cut-offs.

Multivariable logistic regression models were calculated using general and age- and sex-specific cut-offs for functional capacity.

Results: Of 15,158 patients, 5,944 (39.2 %) were female. Based on clustering, cut-off for functional capacity in each sex primarily depended on presence of cardiac risk factors according to the Revised Cardiac Risk Index (RCRI) and whether patients were submitted to high-risk surgery. Age also played a role in categorization in risk groups, even though a secondary one.

Overall, after employing age- and sex-adapted cut-offs for functional capacity 5,238/9,214 (56.8%) men and 3,963/5,944 (66.7%) women presented with limited functional capacity.

The strength of the association between limited functional capacity and 30-day MACE was similar when using a general cut-off of 4 METs (OR_{4METs} = 1.22, 95% CI 0.97-1.55) and when using an age- and sex-adapted one ($OR_{adaptedMETs}$ = 1.17, 95% CI 0.92-1.48). The ROC AUC of a model including RCRI and age was 0.654 (95% CI 0.622-0.686) after the addition of limited functional capacity based on the general cut-off and 0.653 (95% CI 0.622-0.685) after the addition of age- and sex-adapted cut-offs.

Conclusion: Age- and sex-specific cut-offs for functional capacity did not improve risk prediction for MACE after non-cardiac surgery.

10AP06-8 A case of Horner's syndrome following central venous catheterization

M. Lazic¹, N. Petrovic²¹, J. Jovicic²¹, I. Markovic¹, V. Jovanovic²¹, N. Ladjevic²¹ ¹University Clinical Centre of Serbia, Center for Anesthesiology and Reanimatology, Belgrade, Serbia, ²University of Belgrade, School of Medicine, Belgrade, Serbia

Background: Horner syndrome (HS) is a neurological syndrome characterized by ipsilateral miosis,ptosis and anhidrosis due to sympathetic nerve trunk(SNT) block or injury. The syndrome has been described as a rare complication of central venous catheter (CVC) insertion, with an incidence of less than 5% after internal jugular vein (IJV) catheterization.

Case Report: A 31-year-old man with testicular cancer was scheduled to receive a CVC for chemotherapy. The procedure was performed by senior trainee without ultrasound guidance. After anesthetising the skin with local anesthetic lidocaine and initial unsuccessful puncture of the right IJV,CVC was placed from the left IJV, and position was confirmed with fluoroscopy.

Immediately after catheterization,patient reported "difficulty seeing" with right eye and blurred vision. Neurological examination revealed ptosis and miosis of the right upper eyelid. The symptoms were considered as transient HS caused by sympathetic nerve block caused by local anesthesia.

As the symptoms did not improve the next day, the patient was examined by neurologist who confirmed HS on the right side, most likely caused by SNT injury with the needle, while the other findings were normal.

Discussion: Previous studies have shown that, injury to the cervical SNT causing HS were reported as being uncommon, with an incidence up to 2%, and the incidence increases when the procedure is performed by trainees. The right IJV is the preferred site for CVC insertion due to its predictable anatomy,high success rate and low risk of complications. CVC insertion can cause HS in several ways, due to direct damage to the sympathetic chain, direct damage to the peri-subclavian nerve loops, and hematoma of the associated vessels (especially if the hematoma is trapped in the carotid sheath).

Recommendations to reduce the incidence of HS after a CVC include:direct ultrasound guidance;avoiding too steep needle angle; tilting head no more than 40 degrees lateral, and avoiding a posterior approach.

Conclusion: HS is a rare complication of a common procedure, the insertion of a CVC, that can easily prevented by using ultrasound guided technique and with higher education and experience.

Perioperative shock with complete recover after targeted treatment – a case report

S. Lourenço¹, <u>R. Macedo Campos</u>¹, P. Branquinho¹ *'Unidade Local de Saúde de Santa Maria, E.P.E., Anestesiologia, Lisboa, Portugal*

Background: Postoperative hemodynamic instability and depressed level of consciousness are common conditions with a broad differential diagnosis. Diabetic ketoacidosis (DKA) is a lifethreatening complication of type 1 or type 2 diabetes mellitus. It is characterized by metabolic acidosis with an increased anion gap, elevated capillary or urinary ketones, and hyperglycemia or euglycemia¹.

Given its nonspecific presentation, maintaining a high index of suspicion for DKA in the perioperative period is critical.

Case Report: We report the case of a 79-year-old male (ASA III) with a medical history of non-insulin-dependent type 2 diabetes mellitus treated with sodium-glucose co-transporter-2 inhibitors (SGLT2i) and peripheral vascular disease. The patient underwent an elective femoral endarterectomy under balanced general anesthesia, with an uneventful intraoperative course.

About two hours postoperatively in the Post-Anesthesia Care Unit, the patient developed sudden hemodynamic instability and a depressed level of consciousness, requiring vasopressor support to maintain a mean arterial pressure above 65 mmHg. No clear etiology was initially evident.

Arterial blood gas analysis revealed metabolic acidosis with an increased anion gap and elevated capillary ketones. Immediate treatment included fluid resuscitation with 5% dextrose in polyelectrolyte solution and an insulin infusion at 6 U/h. Over the following 12 hours, the patient showed gradual clinical improvement with resolution of the acidosis and normalization of bicarbonate levels.

Discussion: Euglycemic DKA is a life-threatening condition characterized by the triad of serum glucose levels typically <11.0 mmol/L, metabolic acidosis with an increased anion gap and ketonemia. Risk factors include infection, missed insulin doses, SGLT2i use and comorbidities commonly seen in surgical patients^{1,2}.

The global increase in SGLT2i prescriptions has made euglycemic DKA a more frequent diagnosis. A thorough preoperative clinical history is essential for risk stratification. Early recognition and intervention are key to reversing this condition and preventing complications².

References:

1. BJA Education. 2016. Volume 16, Issue 1, 8-14;

2. J Anesth. 2023 Jun;37(3):465-473.

Learning Points: DKA should be considered a differential diagnosis for shock in the perioperative period. Awareness of predisposing factors and mastery of the presentation and management of DKA can improve perioperative outcomes.

10AP06-10

The effectiveness of low-dose ketamine in reducing postoperative pain after abdominal surgery: a randomized, double-blind, placebo-controlled study

<u>V. Gherghina</u>¹, I. Cindea¹, A. Balcan², M. Prazaru¹, D. Iosif¹, R. Popescu¹

¹Constanta County Clinical Hospital, ICU, Constanta, Romania, ²Ovidius Faculty of Medicine Constanta, ATI, Constanta, Romania

Background and Goal of Study: Postoperative pain management is a critical component of recovery following abdominal surgery. Despite advances in postoperative pain management, the reliance on opioids remains high, contributing to significant side effects and prolonged recovery. Ketamine, particularly in low doses, has shown promising potential as an adjunct for pain relief but its optimal dose and clinical utility in reducing opioid consumption and postoperative pain in abdominal surgery remain underexplored, particularly in diverse patient populations.

This study aimed to evaluate the efficacy of low-dose intravenous ketamine in reducing postoperative pain and opioid consumption, with the potential to significantly improve patient outcomes.

Materials and Methods: A total of 60 patients, aged 18-75, scheduled for elective abdominal surgeries such as appendectomies, cholecystectomies, or hernia repairs under general anesthesia were randomly assigned to receive either 0.5 mg/kg of intravenous ketamine (Group A), 0.1 mg/kg (Group B), or a placebo (Group C) just before incision.

The primary outcome was the total opioid consumption in the first 24 hours postoperatively. Secondary outcomes included pain scores at rest and on movement, nausea, vomiting, and adverse events such as hallucinations or sedation.

Data were analyzed using SPSS (version 25). ANOVA was used for comparisons of continuous variables, and chi-square tests for categorical variables. A P-value < 0.05 was considered statistically significant.

Results and Discussion: Group A demonstrated a significant reduction in total opioid consumption compared to both Group B and Group C (P = 0.02). Pain scores at rest and on movement were significantly lower in Group A at 4, 8, and 24 hours post-operatively (P < 0.05). No significant differences were observed in the incidence of nausea, vomiting, or hallucinations between groups.

Conclusion(s): Low-dose intravenous ketamine (0.5 mg/kg) has been shown to effectively reduce postoperative pain and opioid consumption in patients undergoing abdominal surgery. Importantly, this reduction in pain and opioid use is achieved without an increase in adverse events, providing a safe and effective option for postoperative pain management.

10AP06-11

Air embolism after removal of a central venous catheter in the postoperative period of a liver transplant

M.J. Marono¹, E. Ganuza Martinez¹, A. Guereca Gala¹, A. Zabal Maeztu¹, G. Ojinaga García¹, M.L. Hernandez Sanz¹ ¹Hospital Universitario de Cruces, Anestesiología y Reanimación, Barakaldo, Spain

Background: Air embolism consists of the entry of air into the venous or arterial circulation. It is a rare complication, mainly iatrogenic, associated with invasive medical procedures with high morbidity and mortality. Severe forms are characterized by the sudden appearance of neurological symptoms together with cardiovascular manifestations after an invasive procedure. Performing imaging tests that reveal air bubbles in the vascular structures confirms the diagnosis.

Case Report: We present the case of a 63-year-old woman who presented a venous air embolism after the removal of a central venous catheter in the postoperative period of a liver transplant due to chronic liver cirrhosis due to hepatitis C virus.

This woman presents with a sudden decrease in the level of consciousness with deviation of gaze to the left, accompanied by hypoxemia and atrial fibrillation with a rapid ventricular response, after removal of a central venous catheter. Given the suspicion of air embolism, the bed was placed in Tredelemburg, non-invasive high-flow ventilatory support and hemodynamic support.

An urgent echocardiography was performed, which showed the presence of abundant air bubbles in the left cavities, and a cranial CT scan showed an air bubble was seen in the right cavernous sinus and intramedullary in the sphenoid body.

After clinical stabilization, the patient presented bradypsychia, left facial paralysis and complete left hemiplegia, which progressively improved throughout her stay in the unit. A brain MRI was performed in which ischemic lesions were seen in the right prefrontal cortex suggestive of ischemic origin.

Discussion: Air embolism is a rare and very serious complication of different medical-surgical procedures, potentially avoidable. The incidence is unknown due to the wide variety of clinical manifestations that can range from mild to cardiovascular collapse and death. In our unit, when faced with an adverse incident, we investigated how to avoid it. A protocol for the insertion, management and removal of central lines was created and distributed among the unit staff.

References:

Requenas et al. Embolismo aéreo venoso: una causa poco común de ictus isquémico agudo. 10.1016/j.regg.2014.09.00**Learning points:**

- Air embolism is a potentially fatal iatrogenic complication.
- Staff training is essential to reduce the incidence of adverse events.

Myxedema coma following urgent subdural hematoma drainage surgery: a case report

C. Pereira Pinto¹, M. Almeida Santos¹, P. Victor¹, J. Duarte¹, L. Ormonde¹ ¹ULS Santa Maria, Anesthesiology Department, Lisboa, Portugal

Background: Postoperative altered mental status demands a careful and systematic evaluation. While drug related effects or neurological complications are common considerations, others diagnoses must be excluded. Myxedema coma is a rare and severe cause specially in older adults with thyroid dysfunction.^{1,2} This report highlights a case of myxedema coma in the postoperative of an urgent subdural hematoma (SDH) drainage.

Case Report: A 92-years-old women with medical history of hypertension and hyperthiroidism, medicated with lanzoprazol 15 mg id, furosemide 40 mg id, perindopril 5 mg id, levetiracetam 500mg 3id, atorvastatina 10 mg id and methimazol 5 mg id, presented to the hospital with altered mental status scoring 9 to 14 in the Glasgow Coma Scale (GCS).

After drainage of SDH, under general anesthesia, the patient was transfered to the post-anesthesia care unit (PACU) but did not show the expected improvement, with a persistent GCS of 9. Other diagnosis were discussed, namely drug related effects and thyroid disfunction. The laboratory tests revealed a severe hypothyroidism (free thyroxine 0,11 ng/dl and thyroid-stimulating hormone 109 uU/ml).

After urgent endocrinological consultation the patient begun 200 mcg of intravenous levothyroxine followed by 25mcg orally with a rapid and significant improvement. The patient was discharged from PACU with a GCS 15.

Discussion: This case reinforces the importance of considering endocrine dysfunction in postoperative when neurological deterioration occurs, particularly in patients with thyroid disease. Myxedema coma is rare and presents insidiously, mimicking drug

overdose or worsening neurological states. Its diagnosis requires a higher degree of suspicion. Timely intervention and endocrinological collaboration are essential to reduce morbidity and mortality.

References:

- 1. Tran M et al. Critical Consideration of Myxedema Coma in the Postoperative Setting: A Case Report. A A Pract. 2019 Feb 15;12(4):119-121.
- 2. Yafit D et al. Postoperative myxedema coma in patients undergoing major surgery: Case series. Auris Nasus Larynx. 2019 Aug;46(4):605-608.

Learning points: Myxedema coma should be considered in the differential diagnosis of postoperative altered mental status, particularly in patients with pre-existing thyroid dysfunction. Drug related effects and neurological causes may hide and delay the diagnosis. Early endocrinological intervention with thyroid hormone replacement is critical for a favorable outcome.

10AP07-1 Continuous monitoring after PACU discharge – Does it have a role? A case report

B. Marques¹, R. De Oliveira¹, C. Bentes¹
¹Unidade Local de Saude Gaia Espinho, Anesthesiology, Vila Nova de Gaia, Portugal

Background: Currently, monitoring of patients in general wards is predominantly carried out intermittently, which can lead to late identification of signs of clinical deterioration. In this context, the Early Warning Score (EWS) was developed as a tool to assist in the early detection of complications, but its effectiveness is limited by the frequency of assessments, allowing the possibility of significant clinical changes going unnoticed between monitoring intervals. Continuous monitoring (CM) in the ward appears as a promising solution.

We report the case of a 68-year-old patient who underwent femoral endarterectomy (FE), whose clinical evolution was marked by early identification and effective management of an episode of acute pulmonary edema (APE).

Case Report: A 68-year-old patient who underwent FE was transferred to the surgical ward on the second postoperative day. Her stay in the PACU was uneventful. Upon arrival, she was continuously monitored with the Isansys LifeTouch device as part of a pilot project of CM in this ward (Figure 1).

An EWS of 13 prompted an assessment by the nursing staff. Signs of clinical deterioration were identified, including desaturation, tachycardia and hypertension, leading to the activation of the medical team, who identified APE. Management included stabilization measures and PACU readmission, given that non-invasive ventilation was not possible in the ward. Progressive clinical improvement was attained. She was discharged without further complications.

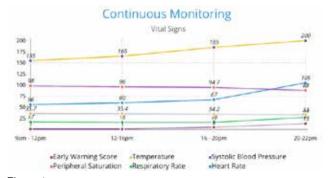

Figure 1.

Discussion: Postoperative mortality surpasses intraoperative mortality, emphasizing the need for robust monitoring tools. In this case, CM proved invaluable, enabling early detection and treatment of APE, which may have been delayed with an intermittent method. It also allowed real-time assessment of treatment efficacy while the patient awaited PACU vacancy, enhancing overall quality of care.

References:

BJA.2019;122(3):304e306. BJA.2024;132(3):519e527. Acta Anaesthesiol Scand. 2023 Jan;67(1):19-28.

Learning points: CM is advantageous in surgical inpatients as it can timely detect clinical deterioration, enhancing clinical outcomes and ensuring safety.

10AP07-2

Factors affecting postoperative nausea and vomiting in interventional radiology anesthesia: a prospective observational study

M. Tumer¹, <u>C. Bayrak²</u>, F.G. Eldem³, E. Ünal³, B. Peynircioğlu³, A.H. Karagoz² ¹VKV American Hospital, Anesthesiology, Istanbul, Turkey, ²Hacettepe University, Anesthesiology, Ankara, Turkey, ³Hacettepe University, Department of Radiology, Ankara, Turkey

Background and Goal of Study: Interventional radiology procedures, often performed under sedation, offer advantages such as reduced risk, pain, and recovery time compared to traditional surgery. Postoperative nausea and vomiting (PONV) are common and distressing side effects of anesthesia, affecting up to 30% of patients.^{1,2}

This study aims to investigate the risk factors associated with PONV in procedures under sedation during interventional radiology anesthesia.

Materials and Methods: After obtaining ethical approval, this study was conducted at Hacettepe University Hospital between January and August 2023. A total of 213 patients undergoing interventional radiology procedures under sedation were included to evaluate PONV incidence and associated factors. Demographic characteristics, medical history, anesthetic agents used, and peroperative monitoring data were collected. Nausea and vomiting were assessed using the Abramowitz emetic scoring scale at postoperative period.

Results and Discussion: Nausea occurred in 12.2% of patients, while vomiting occurred in 1.9%. All anesthetic agents increased the risk of PONV, but no significant relationship was found between the type of anesthetic, interventional procedure, and nausea/vomiting occurrence.

However, the combination of anesthetic drugs appeared to influence nausea incidence, with higher rates in patients receiving multiple agents.

Conclusion(s): A history of PONV was a significant risk factor for developing nausea during sedation anesthesia. Patients with a history of PONV were 12.4 times more likely to experience nausea ³

These findings highlight the importance of assessing patients' previous nausea and vomiting history to identify high-risk individuals and mitigate these risks. Further research is needed to optimize anesthesia management in interventional radiology settings.

References:

PMID: 22562482
 PMID: 24491648
 PMID: 36550611

Acknowledgements: Clinical Significance: The findings of this study underscore the importance of considering patients' history of postoperative nausea and vomiting (PONV) when administering sedation anesthesia for interventional radiology procedures. Identifying patients at higher risk for PONV can help healthcare providers implement appropriate preventive measures, potentially improving patient outcomes and satisfaction. Further research is warranted to refine anesthesia management strategies and minimize PONV in this setting.

10AP07-3

Seizures following cardiac surgery: A retrospective case series and literature review

C. Calvo de León¹, <u>E. Avilés García¹</u>, C. Pérez Torralba¹, A. Francés Ribera¹, C. García García¹ ¹Alicante General Hospital, Anesthesiology, Alicante, Spain

Background: Postoperative seizures are a recognized but uncommon complication of cardiac surgery, with potential implications for patient recovery and long-term outcomes. Understanding their etiology and risk factors is crucial for optimising perioperative care

Our objective is to analyze the incidence, characteristics, and potential contributing factors of postoperative seizures in patients undergoing cardiac surgery at our institution, complemented by a comprehensive literature review.

Case Report: We conducted a retrospective review of 25 cases of postoperative seizures in cardiac surgery patients treated at Alicante General Hospital between June 2018 and November 2024. Data collected included patient demographics, comorbidities, type of surgery, perioperative medications, and seizure characteristics. A literature review was performed to contextualize our findings within the broader evidence base.

Discussion: The incidence of postoperative seizures in cardiac surgery patients ranged from 0.8% to 1.6% at our institution. The most commonly associated procedures were valve replacements and coronary artery bypass grafting.

The majority of seizures were linked to perioperative complications, particularly left ventricular failure and atrial fibrillation. Most cases were successfully resolved with antiepileptic treatment, primarily using midazolam and levetiracetam.

Teller J, et al. "Stroke, Seizures, Hallucinations and Postoperative Delirium as Neurological Complications after Cardiac Surgery and Percutaneous Valve Replacement." Journal of Cardiovascular Development and Disease 2022

Learning points: The analysis of our case series, combined with existing literature, provides valuable insights into the potential predictors and management strategies for postoperative seizures in cardiac surgery patients. This work highlights the need for heightened perioperative vigilance and further research into preventive measures.

10AP07-4

Preoperative patient education significantly improves anxiety management and recovery after colon surgery

V. Kuzminskaite¹, E. Kontrimaviciute¹, A. Laurinavicius², T. Poskus¹, G. Martisiute², <u>I. Dereskeviciute¹</u>
¹Vilnius University, Faculty of Medicine, Vilnius, Lithuania, ²Vilnius University, Faculty of Philosophy, Vilnius, Lithuania

Background and Goal of Study: Patient education is one of the methods to control preoperative anxiety, postoperative pain, and improve recovery after the surgery. Our study investigates the effects preoperative patient education has on preoperative anxiety level and postoperative recovery, well-being, and satisfaction with provided healthcare

Materials and Methods: patients undergoing elective colon surgery were included in the study and randomly assigned to either intervention (education) or control group. Intervention group attended preoperative education course 10-14 days before the surgery.

Preoperative anxiety was assessed using APAIS score, QoR-40 and HCAPS scores were used to evaluate postoperative recovery and satisfaction. Mean values were compared between the groups using independent sample t-test. Clinical trial registration No. NCT05208580 (ClinicalTrials.gov).

Results and Discussion: 62 patients were included (38 in intervention group and 24 controls). Groups did not differ based on age, sex, education, preoperative risk or duration of surgery. Intervention group had lower APAIS anxiety scores (17.9 vs. 22.2, p=0.007). Reduced perioperative stress response positively affects postoperative recovery and could explain our findings that patients who underwent preoperative classes had better well-being score on the first postoperative day (7.2 vs. 6.4, p=0.001), were able to get up from the bed on the first postoperative day more often (36.8 vs. 12.5%, p=0.044), and had shorter duration of hospitalization (9.6 vs. 14.1 days, p=0.037). This translates into better recovery and satisfaction with provided healthcare: intervention group had better HCAPS (71.7 vs. 67.0, p=0.005) and QoR-40 scores (172.6 vs. 157.6, p<0.001).

No difference was found in postoperative pain on the first 3 days after the surgery, drowsiness or nausea and vomiting. This could be explained by the use of standard perioperative pain and postoperative nausea and vomiting prophylaxis for colon surgery in our hospital.

Conclusion(s): Preoperative patient education reduces preoperative anxiety. Informing patients before the surgery not only statistically, but also clinically improves postoperative recovery, satisfaction, and well-being of the patients after colon surgery.

10AP07-5

Epidemiology of lung ultrasound scores and venous excess ultrasound grades in the first 5 days after major gastrointestinal surgery

P. Klompmaker^{1,2}, J. van Zwol^{1,2}, A. Vlaar^{3,2}, D. Veelo^{1,2}, P. Tuinman^{3,2}

¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Amsterdam Cardiovascular sciences Research Institute, Amsterdam, Netherlands, ³Amsterdam UMC, Intensive Care, Amsterdam, Netherlands

Background and Goal of Study: Complications occur frequently after major gastrointestinal surgery and are associated with significant morbidity. Point of care ultrasound, e.g. lung ultrasound score (LUS) and the venous excess ultrasound score (VExUS) are readily available at the bedside and have been associated with adverse outcomes in patients after orthopaedic and cardiac surgery. However, little is known about the feasibility and range of these scores before and after major gastrointestinal surgery. Materials and Methods: This is a preliminary analysis of an ongoing observational study investigating post-operative complications.

Inclusion criteria: ≥18 years, and major gastrointestinal surgery. Exclusion criteria: major cardiac shunts, dialysis, expected unfeasible POCUS e.g. BMI>40.

Patients underwent LUS and VExUS before and 5 days after surgery for a total of 6 measurements. The study was approved by the local IRB and informed consent was obtained.

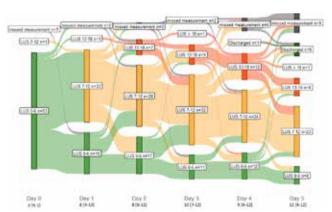

Figure 1.

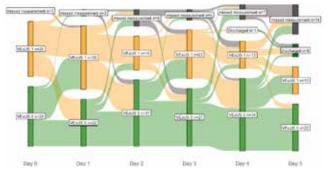

Figure 2.

Results and Discussion: Of the 55 patients included 11(20%) patients underwent liver resection, 26(47%) underwent pancreas resection, and 18(33%) underwent esophagectomy. Median age

was 71[61-76], median BMI was 24.5[21.6-27.1]. Median length of stay was 7[6-13] days and no patients died in the 30 days after surgery. Out of 330 assessments, 23(7%) LUS and 38(12%) VEx-US were missing. The most common reason for this was patient refusal (99%).

Figure 1 represents LUS scores over the first 5 days; showing an upward trend during the first 3 days.

Figure 2 represents VExUS grades, with little change throughout the first 5 days.

Conclusion: LUS and VExUS are feasible after major gastrointestinal surgery. LUS tends to increase after surgery while VExUS remains stable. This suggests that daily VExUS might not be very informative in this population. However, associations with relevant outcomes need to be further investigated.

10AP07-6

Evaluation of proenkephalin A 119-159 with biomarker panel (SEMA3A, RBP-4, KIM-1) following complex endovascular aneurysm repair: a prospective, observational study

P. Walczak-Wieteska¹, <u>K. Zuzda^{2,3}</u>, J. Małyszko³, P. Andruszkiewicz¹

¹Medical University of Warsaw, 2nd Department of Anaesthesiology and Intensive Care, Warsaw, Poland, ²Medical University of Warsaw, Doctoral School, Warsaw, Poland, ³Medical University of Warsaw, Department of Nephrology, Dialysis and Internal Medicine, Warsaw, Poland

Background and Goal of Study: Serum creatinine (SCr) has served as the gold standard for monitoring kidney function, including acute kidney injury (AKI) for 90 years, yet its limitations in perioperative settings necessitate the exploration of more sensitive biomarkers.

This study aimed to evaluate the utility of Proenkephalin A 119-159 (penKid) as an early biomarker for AKI after complex endovascular aneurysm repair (EVAR), comparing it with six other biomarkers: Semaphorin-3A (SEMA3A), Retinol Binding Protein-4 (RBP-4), Kidney Injury Molecule-1 (KIM-1), Netrin-1, Tissue Inhibitor of Metalloproteinase-2 (TIMP-2), and Insulin-like Growth Factor-Binding Protein-7 (IGFBP-7).

Materials and Methods: This single-centre, prospective, observational study was conducted between April 2022 and June 2024 at the Central Teaching Hospital, Medical University of Warsaw, Poland. 66 patients were included in the analysis. The samples were collected before EVAR and up to 24h, 48h, and 72h after. Using the ELISA method, the biomarker concentrations were measured perioperatively from the blood (RBP-4, SEMA3A) and urine (SEMA3A, RBP-4, KIM-1, netrin-1, TIMP-2, IGFBP-7) in 30 pts. penKid was measured using a bedside blood test with IB10 sphingotest® penKid® assay in 66 pts. AKI was diagnosed according to the KDIGO[1] SCr criteria.

Results and Discussion: Preexisting chronic kidney disease, particularly stages 3b and 4, was identified as a significant risk factor for postoperative AKI. The penKid demonstrated high accuracy (0.73), sensitivity (0.78), and specificity (0.71) with an AUC of 0.76 at a cut-point of ≥2.29 ng/mL. SEMA3A in serum showed exceptional performance with an AUC of 0.88 and high specificity (0.92) at ≥89.10 pg/mL. A biomarker panel combining penKid, SEMA3A, and KIM-1 achieved the highest discriminative perfor-

mance (AUC 0.89, 95% CI: 0.77-1.00). An alternative panel replacing SEMA3A with RBP-4 showed comparable performance (AUC 0.81, 95% CI: 0.65-0.99).

Conclusion(s): This study demonstrates that penKid is a reliable early biomarker for AKI detection after EVAR procedures. Combining penKid with either SEMA3A or RBP-4, plus KIM-1, provides robust diagnostic performance for early AKI detection.

Acknowledgements: The study was partially funded by the National Science Centre, Poland [2020/39/O/NZ5/02171]. Sphingo-Tec GmbH provided IB10 free of charge.

10AP07-7

Optic nerve sheath diameter in head-down pneumoperitoneum surgery and delirium

K. Wenjun¹, J. Zhu¹, D. Anggreni², S.J. Toh¹, L. Ne-Hooi Will¹, A. Balakrishnan¹

¹National University Hospital, Department of Anaesthesia, Singapore, Singapore, ²National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore

Background and Goal of Study: Surgeries in head-down, trendelenburg positions with pneumoperitoneum are common, and have been associated with increases in intracranial pressure (ICP). This rise in intracranial pressure has been assessed noninvasively via ultrasonographic assessment of optic nerve sheath diameter (ONSD). However, the effects of elevated ONSD on postoperative outcomes, specifically postoperative delirium, has not been assessed.

Materials and Methods: We included adult patients >18 years old undergoing non-neurological surgery requiring head down positioning with pneumoperitoneum. IRB approval was given (Ref: 2022/00064) and written informed consent was sought. Exclusion criteria were patients with pre-existing delirium, pre-existing ophthalmic diseases precluding ONSD assessment, or inadequate head down <15 degrees.

Primary outcome was presence of postoperative delirium in the postanaesthetic care unit (PACU) and on postoperative day 1 (POD1), as determined by NuDESC and 3D-CAM. Secondary outcomes were time to extubation, PACU stay, postoperative nausea/vomiting and postoperative headache.

Results and Discussion: A total 16 patients were recruited between Oct-23 to Jun-24. 2 patients were excluded due to inadequate head down positioning. 2 patients (14.28%) had post-operative delirium in PACU. ONSD increased significantly from baseline to end of procedure (4.62 vs 5.40. Mean difference 0.78, p<0.001). ONSD was significantly larger in patients with delirium (6.35 vs 5.24mm, mean difference -1.11, p=0.02). Patients with elevated ICP by ONSD more often had postoperative delirium in PACU (40% vs 0%), however this was not significant (p=0.110). No patient had delirium on POD1. Time to extubation and PACU stay were similar between groups. No patients had headache or nausea in the PACU.

Conclusion(s): Surgeries in head-down, trendelenburg positions with pneumoperitoneum are associated with a rise in ICP. This may be associated with postoperative delirium in the PACU. It remains to be determined if raised intracranial pressures noted from ONSD assessment should be treated.

10AP07-8

The predictive value of the Surgical Apgar Score compared to established tools for postoperative complications in vascular surgery: A retrospective ROC and multivariate regression analysis

R. Chesov¹, N. Banin¹, S. Sandru¹, I. Chesov¹
¹Nicolae Testemitanu State University of Medicine and
Pharmacy, Valeriu Ghereg Chair of Anesthesiology and
Reanimatology, Chisinau, Moldova, Republic of

Background and Goal of Study: Postoperative risk stratification in vascular surgery is vital for improving patient outcomes. The Surgical Apgar Score (SAS), developed to assess intraoperative risks, was evaluated against established risk tools (RCRI, SORT, CCI) for predicting mortality and major complications.

The study aimed to determine the predictive accuracy of SAS and its integration into perioperative protocols.

Materials and Methods: We conducted a retrospective analysis of 119 patients (aged 18-75) who underwent vascular surgeries (femoral-bypass with synthetic grafts) between 2010 and 2023. The study protocol was approved by research ethics committee of the Nicolae Testemitanu State University of Medicine and Pharmacy, Republic of Moldova. We analyzed SAS components alongside demographic and clinical data using regression models to predict postoperative outcomes.

Complications such as mortality, renal insufficiency, graft failure, unplanned intubation, pneumonia/embolism, and bleeding/transfusion were assessed. ROC analysis quantified predictive accuracy (AUC), while multivariate regression identified significant predictors, including SAS, age, and clinical interventions.

Results and Discussion: ROC analysis showed SAS as a strong predictor for mortality (AUC = 0.9186, p < 0.0001) and septic shock/acute myocardial infarction (AUC = 0.9497, p = 0.008), with significant odds reduction per SAS point for mortality (OR = 0.278, p = 0.0217) and unplanned intubation (OR = 0.426, p = 0.0152).

Multivariate regression highlighted vasopressor use (OR = 81.9, p = 0.0102) and angina (OR = 18.62, p = 0.0508) as additional predictors for mortality, while SAS reduced odds for bleeding/transfusion (OR = 0.419, p = 0.0342) and pneumonia/embolism (OR = 0.571, p = 0.0233). SAS was less predictive for graft failure (p = 0.0578) and renal insufficiency (p = 0.2929).

Conclusion(s): The Surgical Apgar Score demonstrated comparable or superior predictive accuracy for certain complications compared to traditional tools, particularly for mortality and unplanned intubation. Integrating SAS into vascular surgery protocols could enhance real-time risk stratification and postoperative management.

Further studies should evaluate its broader applicability and combination with other tools.

10AP07-10

Lactic acidosis in major abdominal surgery: role of the alteration of monocarboxylate transporters

G. Fresta¹, C. Cambise¹, C. Sassorossi², S.F. Favitta³, J. Evangelista⁴, <u>P. Aceto</u>¹

¹Fondazione Policlinico Universitario A. Gemelli IRCCS, Largo A. Gemelli, Dipartimento di Scienze dell'emergenza, anestesiologiche e della rianimazione, Rome, Italy, ²Fondazione Policlinico Universitario A. Gemelli IRCCS, Thoracic surgery unit, Rome, Italy, ³Fondazione Policlinico Universitario A. Gemelli IRCCS, Dipartimento di Scienze dell'emergenza, anestesiologiche e della rianimazione, Rome, Italy, ⁴Fondazione Policlinico Universitario A. Gemelli IRCCS, Largo A. Gemelli, Thoracic surgery unit, Rome, Italy

Background and Goal of Study: Lactate transport across membranes occurs through monocarboxylate transporters (MCTs), encoded by the SLC16gene family. It has been shown that MCT1 polymorphism (rs1049434) T1470Ais associated with defect in lactate transmembrane transport: T-allele is correlated with about 50% reduction in lactate transport rate compared to the A-allele¹. The aim of this study is to clarify the relation between lactate transporter polymorphism and lactate clearance in patients undergoing major elective abdominal surgery.

Materials and Methods:patients undergoing major elective abdominal surgery were enrolled. Intraoperative monitoring and anaesthesia protocol were the ones routinely used in our Unit. Together with first blood sample taken for blood gas analysis, an additional 3mL of blood was drawn for the genetic analysis of the MCT1-polymorphism. After genetic sequencing, population was divided into two groups: group with the T-allele in homozygous and heterozygous forms, and group with the A-allele in homozygous form.

Results and Discussion: Between 2/2024 and 5/2024, 109 patients were enrolled. After genetic categorization, population was divided into 2 groups: 66 patients carrying the T-allele in homozygous and heterozygous forms, and 43 patients with the A-allele only in homozygous form.

A significantly higher number of patients exhibited hyperlactatemia (blood lactate ≥2.2mmol/L) at T3 in the TT/TA group (p=0.02). Two-way ANOVA showed that time had an impact on lactate during the perioperative period in both groups (p<0.001). TT/TA group showed a higher number of total complications (39.4% vs 11.6%, p=0.002) and severe (24.2% vs 4.6%, p=0.007) compared to the AA group (Table 1).

	TT group (n=66)	AA group (n=43)	t o chisquare	р
Lactate ≥ 2.2 (mmol/L) a T3 n,(%)	53 (80.3)	26 (60.5)	5.14	0.02
Total complication, n (%)	26 (39.4)	5 (11.6)	9.86	0.002
Severe complication (C-D≥3a), n (%)	16 (24.2)	2 (4.6)	7.25	0.007

Table 1. Intra- and post-operative variables.

Conclusion(s): This study demonstrates that A140T-polymorphism of MCT1-lactate transporter is associated not only with a higher incidence of hyperlactatemia 3 hours after major elective abdominal surgery but also, with a higher incidence of complications and severe complications. Further studies are necessary to clarify its impact on postoperative outcomes.

10AP07-12

Tailored perioperative care in a young patient with functional paraganglioma after a severe hypertensive crisis

<u>J. Dias</u>¹, I. Rebelo¹, A. Saraiva¹¹Instituto Português de Oncologia de Lisboa Francisco Gentil, Anestesiologia, Lisboa, Portugal

Background: paragangliomas (PG) are rare neuroendocrine tumors arising from extra-adrenal paraganglia¹. Functional sympathetic PGs secrete catecholamines² and pose significant challenges due to a severe hemodynamic instability risk, throughout the entire perioperative period.

Case Report: a 27-year-old male with double functional sympathetic abdominal PG was deemed surgery-ready after protocolled preoperative optimization. During anesthesia induction he experienced a severe hypertensive crisis (systolic BP 300 mmHg), resulting in surgical postponement.

After stabilization, as he maintained refractory hypertension, a multidisciplinary team was assembled to optimize perioperative care. Optimal hemodynamic control was achieved with maximum daily doses of phenoxybenzamine, carvedilol and amlodipine, with alprazolam.

The patient was identified as being at exceptionally high risk for hemodynamic instability, especially for post-resection hypotension due to the dense pharmacological blockade. A tailored plan incorporated short-acting agents such as urapidil and vasopressin, unavailable at the institution, that were sourced for the rescheduled surgery.

The patient underwent open resection under total intravenous anesthesia. Hypertension during tumor manipulation was managed with esmolol, magnesium sulfate, and phentolamine. Post-resection hypotension required norepinephrine, adrenaline, vaso-pressin, and guided transfusion.

On postoperative day one, he was successfully weaned off vasopressors and later discharged without complications.

Discussion: This case highlights the challenges of managing functional and unpredictable PGs, where refractory hypertension limits standard pharmacological strategies.

Success was achieved through multidisciplinary collaboration, procurement of cardiovascular drugs, and a patient-specific perioperative plan, demonstrating the critical role of anesthesiologists in high-risk cases and resulting in improved patient outcomes.

References:

1. doi.org/10.1007/s12022-022-09704-6.

2. doi.org/10.6004/jnccn.2021.0032

Learning points: Functional PGs are unpredictable despite preoperative optimization. Effective management requires meticulous planning, adaptability, and multidisciplinary teamwork. Successful PG management requires adherence to protocols while adapting strategies to individual needs.

Anesthesiologists play a pivotal role in multidisciplinary teams, ensuring patient safety through resourceful and system-independent solutions.

10AP08-1

Prevalence and management of preoperative anemia and its outcomes in gastrointestinal cancer patients: preliminary results

R. Cayuela¹, G. Ballout¹, M. Salazar¹, M. Ubré¹, G. Martínez-Palli¹, E. Rivas¹

¹Hospital Clinic de Barcelona, Anesthesiology, Barcelona, Spain

Background and Goal of Study: Preoperative anemia affects approximately 30% of patients undergoing major surgery and is associated with increased morbidity and transfusion rates. Patient Blood Management (PBM) protocols aim to optimize hemoglobin (Hb) levels preoperatively. However, the efficacy of intravenous (IV) iron supplementation in reducing allogeneic blood transfusion (ABT) and postoperative complications remains uncertain.

This study evaluates whether IV iron supplementation in anemic patients prior to gastrointestinal oncologic surgery improves Hb levels, reduces ABT rates, and mitigates postoperative complications.

Materials and Methods: This prospective observational study included adult patients undergoing gastrointestinal oncologic surgery. Anemic patients (Hb <13 g/dL) received IV iron supplementation during their pre-anesthesia (PACE) visit.

The primary outcome was the change in Hb from the PACE visit to the day before surgery.

Secondary outcomes included ABT rates, postoperative complications (Clavien-Dindo classification), and length of stay (LOS). Outcomes were compared between anemic and non-anemic patients using unpaired non-parametric tests.

Results and Discussion: The analysis included 20 patients (mean age 68 \pm 14 years; 11 females, 9 males). Anemic patients (n=9) showed a significant Hb increase (1.0 \pm 1.1 g/dL) compared to a decrease in non-anemic patients (n=8) (-0.4 \pm 1.4 g/dL, p<0.05). The mean interval between IV iron administration and surgery was shorter than anticipated (10 \pm 5 days). There were no differences in ABT rates (0% vs 0%), postoperative complications (0% vs 18%), or LOS.

	Anemic patients (n=9)	Non anemic patients (n=11)	p-value
Age, y.o.	71±15	64 ± 13	0.147
Sex, male / female, n (%)	3 (33) / 6 (67)	6 (54)/5 (45)	0.406
ASA III-IV, n (%)	4 (45)	2 (22)	0.336
Colorectal / Gastroesophageal, n (%)	8 (73) / 3 (27)	11 (100) / 0 (0)	0.214
Preanesthesia Hb, g/dl	10.3 ± 1.8	14.1 ± 1.0	
Before surgery Hb, g/dl	11.5 ± 1.62	13.6 ± 1.8	
Length of stay, days	4.7 ± 3.6	3.64 ± 2.1	0.889

Table 1: Demographic and clinical characteristics.

Conclusion(s): IV iron supplementation before oncologic gastrointestinal surgery was associated with improved Hb levels in anemic patients. However, preliminary data were insufficient to draw conclusions regarding ABT rates or postoperative complications. The findings highlight the challenges of optimizing Hb levels in patients with active inflammation and active bleeding.

10AP08-2

Changes in arterial-venous pressure of CO₂ (ΔPCO₂) and arterial-venous pressure of O₂ (Ca-vO₂) as predictive factors of postsurgical complications

N.-I. Tighineanu¹, I. Ciobanu¹, V. Coșpormac¹, I. Feghiu¹, O. Cernei¹, C. Gutium¹

¹USMF Nicolae Testemitanu, Anesthesia and ICU, Chisinau, Moldova, Republic of

Background and Goal of Study: O_2 consumption (VO_2) depends on the cardiac output (CO) and the arterial-venous difference in the concentration of O_2 (Ca- vO_2) in the blood. CO correlates with the level of tissue perfusion and, according to the Fick formula, it is indirectly proportional to the veno-arterial difference in PCO_2 (ΔPCO_2). ΔPCO_2 >6 mmHg is considered as an index of inadequate tissue perfusion, and $Ca-vO_2$ - a marker of tissue hypoxia.

The goal of study was to evaluate the changes in ΔPCO_2 and $Ca-vO_2$ as predictive factors in the risk of developing postoperative complications.

Materials and Methods: In this prospective study ΔPCO_2 and $CavO_2$ were assessed in 42 patients undergoing non-cardiac surgery. Evaluation was performed in the early postoperative period, and the variations of laboratory tests was assessed pre- and 24 hours postoperatively.

The statistical analysis was performed with the statistical program Graph Prism 8.0, using the Fisher exact test. Relative risk (RR), test specificity (Sp), test sensitivity (Sn) were calculated. The results are presented as mean with a confidence interval of 95% (Cl95%).

Results and Discussion: A statistically significant correlation was observed between ΔPCO2, Ca-vO₂ and the risk of developing postoperative complications. Fisher exact test for liver dysfunction correlated with ΔPCO_a; RR - 1.33 (95% CI 0.8 - 2.1), with Sn - 0.57 (95% CI 0.42 - 0.70), Sp - 0.57 (95% CI 0.42 - 0.70); correlated with Ca-vO₂: RR - 1.6 (95%CI 1.0 - 2.5), Sn - 0.64 (95%CI 0.49 - 077) and Sp - 0.57 (95%Cl 0.42 - 0.70). Fisher's exact test for pancreatic dysfunction correlated with ΔPCO_a: RR - 2.1 (95%CI 1.35 - 3.2), Sn - 0.57 (95%CI 0.42 - 0.70) and Sp - 0.78 (95%CI 0.64 - 0.88); correlated with Ca-vO₂: RR - 2.4 (95%CI 1.55 -3.9), Sn - 0.64 (0.49 - 0.77), Sp - 0.78 (0.64 - 0.88). Fisher exact test for postoperative systemic inflammatory response syndrome (SIRS) correlated with ΔPCO₂: RR - 1.7 (95%CI – 1.60 – 2.77), Sn -0.57 (95%Cl 0.42 - 0.70), Sp - 0.71 (0.56 - 0.83); correlated with Ca-vO₂: RR - 2.07 (95%CI 1.33 - 3.36), Sn- 0.64 (5%CI 0.77 - 0.99) and Sp - 0.71 (5%CI 0.56 - 0.82).

Conclusion(s): ΔPCO_2 and $Ca-vO_2$ values statistically significantly correlates with the risk of developing postoperative complications (liver dysfunction, pancreatic dysfunction and SIRS). ΔPCO_2 , $Ca-vO_2$ may be the key goals of hemodynamic resuscitation in the patient undergoing surgery to prevent complications.

10AP08-3

Complex hernia repair with the Fasciotens® system under combined anesthesia

R. Felgueiras¹, M. Matos¹, D. Pereira², J. Magalhães¹, J. Pinto¹, A. Guedes¹ ¹ULS Viseu Dão-Lafões, Department of Anaesthesiology, Viseu, Portugal, ²ULS de Braga, Department of Anaesthesiology, Braga, Portugal

Background: The Fasciotens® Hernia system is a novel instrument for complex hernia surgical treatment. The anaesthetic management of these patients must account for alterations in ventilatory mechanics due to the procedure. This report details the perioperative management of a patient submitted to hernia correction with the Fasciotens® Hernia system.

Case Report: A 73-year-old male, ASA III, was scheduled for correction of a midline incisional hernia, with 16cm opening diameter and volume of 2725mL. Workup revealed a Low Anterior Resection and two hernioplasties. The patient was admitted 14 days prior for respiratory prehabilitation, abdominal wall injection of botulinum toxin and to create an 8.8 L pneumoperitoneum for tissue expansion.

Supplemental O2 (Nasal Cannula, 1L/min) was required on day 13, without other events. A Combined Anaesthesia was chosen. A cephalically-oriented epidural catheter was inserted at the T11-T12 level, followed by rapid sequence intubation with Propofol 2mg/kg, Fentanyl 2µg/kg and Rocuronium 1.2mg/kg.

The maintenance agent was Sevoflurane. Fractioned boluses of Ropivacaine 2mg/mL (total 24mg) were administered throughout. Analgesia included Ketamine 20mg, Paracetamol 1g, Tramadol 100mg and 1mg Epidural Morphine. A weight of 14kg was distributed over the abdominal wall. Ventilatory pressures were measured, with a final peak pressure of 17cmH₂O.

The surgery ended in four hours without adverse events. The PACU stay was uneventful and the patient was transferred to an intermediate-care unit. Postoperative analgesia included Paracetamol 1g 3x/d, Tramadol 100mg 3x/d, Epidural Ropivacaine 2mg/mL (20mg) 4x/d and Epidural Morphine 1.5mg 2x/d if required.

A switch from Ropivacaine to fixed Epidural Morphine 2.5mg 2x/d was conducted on day 2 due to hypotension.

Resting and movement pain were zero on the NPRS. Rehabilitation progressed adequately. The catheter was removed on day 3 and the patient was discharged on day 6.

Discussion: Repair of large hernias can alter a patient's ventilatory mechanics, making vigilance of airway and abdominal pressures during surgery mandatory. Postoperative pain can compromise the patient's respiratory function and rehabilitation, making locoregional techniques beneficial.

Learning points: The Fasciotens® system can aid surgeons in correcting large hernias. The anaesthesiologist must be familiar with these tools in order to better adapt the perioperative anaesthetic plan for each patient.

10AP08-4

Reporting of patients' satisfaction following general anaesthesia in a tertiary hospital of Greece

<u>D. Tsitoura</u>¹, V.F. Davidi¹, K. Manika¹, M. Mantouvalou¹, M. Tsoumani¹, P. Kouki¹

¹General Hospital of Nikaia-Pireus "St. Panteleimon", Anaesthesiology, Athens, Greece

Background and Goal of Study: Patient satisfaction is considered to be an important quality index in health care services. Goal of this study was to assess surgical patient satisfaction following general anaesthesia and clarify contributing factors of anaesthetic services.

Materials and Methods: After ethical committee approval and written consent, 60 adult patients received a standardised questionnaire after recovering from general anaesthesia for elective surgery. It was distributed a few hours postoperatively. Patients filled out the questionnaire on their own, while in the ward, and documents were collected the day after.

Eighteen questions were included, regarding three dimensions:

- 1. Preoperative communication with anaesthesiologist and level of involvement in decision making,
- 2. Possibility of awareness, sense of cold-shivering, pain levels, nausea-vomiting,
- 3. Anxiety, sense of safety (post-extubation and in PACU).

Two questions involved possible self-reporting adverse effects and dissatisfaction points.

Results and Discussion: As to dimension (1), 88,14% of responders mentioned that had time to address questions to anaesthesiologist and 84,75% were involved in decision making regarding type of anaesthesia preferred.

Regarding dimension (2), no patient reported awareness, 87% did not experience shivering, 81,36% felt least or no cold, 79,66% felt least or no pain after emergence, 86,44% did not feel nausea, and 98,31% did not vomit.

As for dimension (3), all responders agreed that anaesthesiologists did their best to take care of them, 96,61% reported feeling safe and 89,83% had no anxiety during their stay in PACU.

Overall, 98,31% of responders defined their experience with anaesthesia as being good to excellent. Reported dissatisfaction points were extreme noise and intense lighting in the operating room. One patient expressed dissatisfaction about delayed commencement of operation.

Conclusion: High satisfaction levels were reported among surgical patients in relation to anaesthesia services in a tertiary hospital of Greece. The main determinants of patient satisfaction are: interaction between patients and anaesthesiologists, patient involvement in decision making, effective pain management, avoidance of undesired effects and feeling of safety.

Anaesthesiologist's best effort correlated with high satisfaction levels reported in the present study. A greater number of patients should be included in order to reinforce aforementioned results.

10AP08-5

The impact of different doses of intravenous magnesium sulfate on postoperative shivering occurrence in elderly patients undergoing elective lower abdominal surgery under spinal anaesthesia

I. Cîndea¹, A. Balcan², V. Gherghina¹, B. Samoila³, A. Tabacaru¹, D.-O. Costea⁴ ¹Emergency Clinical Hospital of Constanta, Anesthesia-Intensive Care, Constanta, Romania, ²OVIDIUS University of Constanta, Anesthesia-Intensive Care, Constanta, Romania, ³John Radcliffe Hospital, Cardiothoracic Anaesthesia, Oxford, United Kingdom, ⁴Emergency Clinical Hospital of Constanta, General Surgery, Constanta, Romania

Background and Goal of Study: Shivering, a common complication following spinal anaesthesia, triggers potentially dangerous hemodynamic events, particularly in elderly. Our prospective randomized double-blind placebo-controlled clinical trial was designed to compare in terms of efficacy and safety the influence of two different doses of magnesium sulfate, a promising anti-shivering agent, on incidence of postoperative shivering in elderly undergoing elective lower abdominal surgery under spinal anaesthesia.

Materials and Methods: 60 patients (aged ≥65 years) scheduled for lower abdominal surgery under spinal anaesthesia were randomly assigned to one of the following groups: group A (n=20 patients) and group B (n=21 patients) that were given 80mg/kg and respectively 50mg/kg of magnesium sulfate, intravenously administered over 30 minutes after spinal anaesthesia and group C (n=19 patients) that received placebo according to the same protocol. Both the incidence and degree of shivering (Crossley Mahajan scale) were assessed during the first 2h postoperatively as primary outcomes.

Secondary outcomes targeted were the incidence of hypotension, bradycardia, oxygen desaturation and hypothermia recorded during the same interval. Data were analysed using Mann Whitney and Fisher's exact test, statistical significance being considered for p<0.05.

Results and Discussion:Concerning the incidence of shivering, we found similar values in groups A and B (p>0.05), which were statistically lower by comparison to group C (p<0,01). Significantly more patients experienced high-grade shivering in placebo versus magnesium sulfate groups (p<0.02), the latter being comparable in this respect, as well (p>0.05).

Hypotension, even mild and transient, was recorded with a significantly higher incidence in group A in contrast to groups B and C (p<0,05) that showed no difference. No episodes of desaturation, bradycardia or hypothermia were documented among groups during study period.

Conclusion(s): According to our findings, magnesium sulfate provided a substantial protection against shivering during first 2h after lower abdominal procedures under spinal anaesthesia in elderly. Between the two studied regimens, the dose of 50mg/kg seems to be optimal since it emphasizes similar efficacy in terms of occurrence and degree of shivering, while ensuring a statistical superior hemodynamic stability compared to 80mg/kg.

10AP08-7

Acute kidney injury in complex endovascular aneurysm repair: Exploring non-coding RNA and sirtuin pathways, in silico and validation analysis

K. Zuzda^{1,2}, C. Eyileten^{3,4}, Z. Wicik^{3,5}, P. Walczak-Wieteska⁶, J. Małyszko²

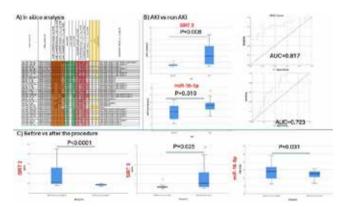

¹Medical University of Warsaw, Doctoral School, Warsaw, Poland, ²Medical University of Warsaw, Department of Nephrology, Dialysis and Internal Medicine, Warsaw, Poland, ³Medical University of Warsaw, Department of Experimental and Clinical Pharmacology, Center for Preclinical Research and Technology CEPT, Warsaw, Poland, ⁴University of Warsaw, Genomics Core Facility, Centre of New Technologies, Warsaw, Poland, ⁵Institute of Psychiatry and Neurology, Department of Neurochemistry, Warsaw, Poland, ⁵Medical University of Warsaw, 2nd Department of Anaesthesiology and Intensive Care, Warsaw, Poland

Background and Goal of Study: Acute kidney injury (AKI) remains a significant complication in perioperative settings, with incidence rates up to 50%. Despite current preventive measures, AKI continues to pose a significant healthcare challenge. This study investigated the role of microRNAs (miRNAs) and

This study investigated the role of microRNAs (miRNAs) and sirtuins (SIRTs) in AKI following endovascular aneurysm repair (EVAR).

Materials and Methods: We conducted a cross-sectional observational study from April 2022 to October 2024, enrolling 29 adult patients undergoing elective EVAR. Blood samples were collected pre-procedure and up to 24 hours post-procedure. AKI was diagnosed using SCr KDIGO (2012) criteria.

We performed bioinformatic analyses, including miRNA prediction, using a multimiR package. Gene lists were compiled from Malacards and DisgeNet databases, with additional SIRTs genes.

Results and Discussion: Through in silico analysis using bioinformatic tools, we identified the top 20 miRNAs associated with AKI in both AKI and the regulation of SIRTs.

We analyzed the expression levels of SIRT1–6 genes alongside miRNAs, including let-7b-5p, miR-124-3p, miR-155-5p, miR-16-5p, miR-182-5p, miR-34a-5p, miR-34b-5p, and miR-590-3p. Notably, SIRT2 and miR-16-5p expressions were significantly decreased, while SIRT3 expression was significantly increased post-procedure (p< 0.0001, p=0.025, p=0.031, respectively).

Baseline expression levels of SIRT2 and miR-16-5p were also significantly higher in patients with AKI than those without AKI (p=0.008, p=0.010, respectively). Receiver operating character-

istic (ROC) curve analysis highlighted the diagnostic potential of SIRT2 and miR-16-5p, with area under the curve (AUC) values of 0.817 and 0.723, respectively.

Conclusions(s): This study evaluates the RNA regulatory networks implicated in post-EVAR AKI. The identified molecular markers, particularly baseline SIRT2 and miR-16-5p, demonstrate diagnostic biomarker potential.

10AP08-8

Implementation of the ERAS protocol in hip arthroplasty: Reducing length of stay and improving recovery

L. Canga¹, L. Vandoni Pimenta¹, G. Badessa¹, C. Silveira¹, A. Alfano¹. B. Miron¹

¹GAAP-Centro Universitário São Camilo, Anesthesiology, Sao Paulo. Brazil

Background and goal of study: The Enhanced Recovery After Surgery (ERAS) protocol is revolutionizing the approach to hip surgeries, promoting faster and more efficient recovery. With integrated practices from preoperative preparation to postoperative care, ERAS aims to reduce surgical stress and minimize complications. Strategies such as optimizing nutrition, effective pain management, early mobilization, and reducing opioid use are key components. These practices not only improve the patient experience and accelerate recovery but also reduce hospital stay duration, allowing for a quicker return to daily activities.

Methods: This prospective interventional study evaluated the implementation of the ERAS protocol in total hip arthroplasties at a private hospital in São Paulo. The approach was multidisciplinary and covered all perioperative stages. A total of 211 patients were included in the program, which started in October 2021, with data analysis extending until early 2024. The study is still ongoing.

Results: The ERAS protocol was applied to 211 patients, of whom 55% received spinal anesthesia with sedation and 45% underwent general anesthesia with regional block. Both techniques followed the "opioid-less" concept, aiming to minimize complications associated with opioid use. The protocol included reducing preoperative fasting, with maltodextrin supplementation two hours before surgery to attenuate the inflammatory response. Early ambulation was encouraged in the postoperative period.

As a result of these interventions, 80% of patients were transferred to the post-anesthesia care unit (PACU), while 20% were transferred to the intensive care unit (ICU). Prior to the implementation of ERAS, these numbers were 52.6% and 47.4%, respectively. The most significant change was the reduction in the average length of stay, which decreased from 11.4 days to 1.7 days.

Conclusion: The implementation of the ERAS protocol for total hip arthroplasties at the private hospital in São Paulo resulted in significant improvements in postoperative recovery. The study demonstrated a substantial reduction in hospital stay length and a greater proportion of patients being directed to the PACU. These improvements are attributed to strategies such as the use of "opioid-spare" anesthesia, reduced preoperative fasting, and promotion of early mobilization. The continuation of the study is essential to refine clinical practices and provide even more effective recovery for patients.

10AP08-9

More data for guideline: GLP-1 agonists and perioperative respiratory complications

<u>B.-S. Paschold</u>¹, K. Liebich¹, J. Pensier^{1,2}, T. Tenge^{1,3}, V. Goodspeed¹, M.S. Schaefer^{1,3}

Background: Glucagon-like-peptide (GLP)-1-agonists are antidiabetic drugs that have become frequently used for their strong effects on weight loss and cardio protection. An important side effect in the peri-procedural setting is delayed gastric emptying, raising concerns about regurgitation and pulmonary aspiration [1,2]. Recent ASA guidelines recommend preoperative cessation of these drugs with limited supporting data [2]. We investigated the association between GLP-1-agonist-use and perioperative respiratory complications (PRC).

Patient characteristics	No GLP-1 agonist use N=327,064	GLP-1 agonist use N=6,176	Absolute std. diff.

Figure 1A Patient and procedural chai median (interquartile range) for continuo ASA: American Society of Anesthesiolo	us measures, and n (%) for cate	gorical measures.	resented as

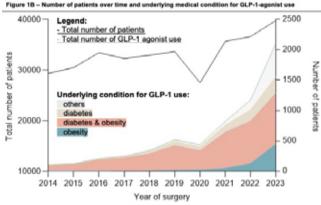

Figure 18 | Number of patients over time with the total amount of patients on the left y-axis and the total amount of patients with according underlying conditions for GLP-1 (Glucagon-like-peptide) agonists use on the right y-axis.

Methods: This single center retrospective cohort study included 339,168 patients undergoing anesthesia between 2014 and 2024. The primary exposure was GLP-1-agonist use and the primary outcome was PRC (pneumonia, reintubation, or emergency non-invasive ventilation within 7 days of surgery).

We performed Inverse Probability Weighted Regression Adjustment analysis with *a-priori* defined covariates (*Figure 1A*). Interrupted Time Series Analysis (ITSA) was conducted among GLP-

1-agonist users with the guideline publication date (06.29.2023 and subsequent institution-wide implementation) as intervention

Results: Among all patients, 6,176 (1.9%) used GLP-1-agonists preoperatively with an increase to 5.5% in 2024 and increasing frequency of obesity as underlying disease (*Figure 1B*).

The utilization of GLP-1 agonists was neither associated with PRC (average treatment effect (ATE) 2.9%, 95% CI -0.3 to 6.1%; p = 0.07) nor intraoperative hypoxemia (ATE 0.4%, 95% CI -3.0 to 3.9%; p = 0.83).

Among GLP-1-agonist users, there was no change in perioperative respiratory complications after implementation of the ASA guideline in adjusted ITSA for PRC (p-for-intercept=0.47 and p-for-slope change 0.49).

Conclusion: The study found no association between preoperative GLP-1-agonist use and perioperative respiratory complications. Neither were these affected by publication of a guideline to hold these medications prior to anesthesia

Post-transfusional hypertensive pulmonary edema – Is it always a transfusion reaction?

J.F. Costa¹, <u>F. Gama¹</u>, R. Loureiro¹
¹Unidade Local de Saúde de Braga, Anesthesiology,
Braga, Portugal

Background: Blood transfusions inherently carry risks, including immunological and non-immunological complications. (1) Prematurely assuming a specific transfusion reaction, without thorough evaluation, can result in inappropriate management and lead to adverse outcomes.

Case Report: A 19-year-old woman, 26 weeks pregnant (ASA IV-E), with no significant medical history or known allergies, presented with obstructive urosepsis, that required emergent ure-teral catheterization.

Preoperative fluids were administered to address hypotension. In the Post-Anesthesia Care Unit, a hemoglobin level of 6.9 g/dL prompted transfusion of two units of red blood cells (RBC). One hour after the transfusion, the patient developed dyspnea, respiratory failure with hypoxemia, hypertension, along periorbital and labial edema. Lung auscultation revealed scattered bilateral crackles.

Clinical improvement occurred after administration of a bolus of furosemide, morphine, and hydrocortisone, along with an infusion of isosorbide dinitrate. Although the temporal association with the RBC units suggested a transfusion reaction, alternative causes such as fluid overload or cardiovascular dysfunction were also considered.

The patient was evaluated collaboratively with Immunohematology and Obstetrics and transferred to a level 2 ICU, where her clinical progress was favorable. Hemolysis markers were negative. Post-discharge follow-up continued in outpatient consultation, but a definitive diagnosis could not be established, as the clinical presentation featured elements of both allergic reactions and fluid overload. Recommendations were provided to ensure safety in future transfusions.

Discussion: This case highlights the importance of considering a broad differential diagnosis for acute hypertensive pulmonary edema after transfusion. Timely recognition and multidisciplinary management ensured a positive outcome for both mother and fetus.

Reference: Khan, A. I., & Gupta, G. (2022). Non-infectious Complications Of Blood Transfusion. PubMed; StatPearls Publishing. https://www.ncbi.nlm.nih.gov/books/NBK574536/

Learning points: Thorough evaluation is essential to distinguish between transfusion reactions and alternative causes. Multidisciplinary collaboration is essential to managing post-transfusion complications effectively. Proper planning ensures safety during future transfusions.

10AP08-11

Cerebral oximetry as an index of microcirculation dysfunction in cardiac surgery

A. Gkiouliava¹, S. Mimikos², D. Sarridou¹, P. Antonitsis², G. Mitos¹, H. Argiriadou¹

¹Aristotle University of Thessaloniki, Anaesthesiology and Intensive Care, Thessaloniki, Greece, ²Aristotle University of Thessaloniki, Cardiothoracic Surgery, Thessaloniki, Greece

Background and Goal of Study: Hemodynamic incoherence prompts for alternative monitoring parameters to detect dysfunctional microcirculation and improve patient care.

The goal of this study is to investigate arterial blood pressure (ABP) and cerebral oximetry (rSO_2) as indices of microcirculation dysfunction through time-weighted average (TWA) analysis.

Materials and Methods: Patients who underwent cardiac surgery were included. The 3-minute mean values of ABP and rSO₂ measurements during 3 phases were computed: before Cardio-pulmonary Bypass (CPB), during CPB and after CPB. Events of decompensation were set as mean ABP <65 mmHg or rSO₂ decline >20% of baseline.

The TWA = (depth x decompensation time)/total duration of the procedure was determined for each case. Hemoglobin, lactates, creatinine, duration of vasoactive medication and mechanical ventilation (hours) and morbidity were recorded.

Results and Discussion: Twenty patients were analysed. Mean age was 65±10 years and CPB duration was 93±29 min. Seven (35%) patients underwent CABG. The median (IQR) of perioperative TWA_{ABP} and TWA_{rSO2} was 19.7(62.5) and 0 (21.9) respectively. Correlation was insignificant between these parameters (p>0.05). TWA_{ABP} was related to the duration of mechanical ventilation (ρ =0.49, p=0.037). An association of TWA_{ABP} after CPB and creatinine was found (ρ =0.51, p=0.03). TWA_{rSO2} correlated with maximum postoperative lactates (ρ =0.58, p=0.015) and duration of noradrenaline infusion (ρ =0.48, p=0.048).

Patients with higher TWA $_{\rm ISO2}$ presented with higher creatinine values postoperatively (p=0.49, p=0.052). TWA $_{\rm ISO2}$ relation with lactates was stronger during CPB (r=0.62, p=0.007).

Patients with higher decline of haemoglobin developed higher creatinine values during their hospitalisation (ρ =0.49, p=0.037). No clinically significant cutoff point could be determined with

ROC curve analysis to predict morbidity.

Conclusion(s): The cerebral tissue may be valuable as an index organ for microcirculation as cerebral oximetry can be used to monitor microcirculation dysfunction that cannot be identified with macrocirculatory indices, as ABP.

Perioperative Care

10AP08-12

From dyspnea to diagnosis: a case of intraoperative pulmonary embolism during vascular surgery

M. Massá Castro¹, J. Moniz², P. Conde¹, Â. Alves¹¹Unidade Local de Saúde de Santa Maria, Department of Anesthesiology, Lisbon, Portugal, ²Instituto Português de Oncologia de Lisboa Francisco Gentil, Dep, Lisbon, Portugal

Background: Postoperative dyspnea is a common complication following surgery, with diverse etiologies involving pulmonary, cardiac, and miscellaneous underlying factors. Therefore, a systematic approach is essential to tackle it.

Case Report: A 57-year-old male, ASA II, previously submitted to a radical prostatectomy for prostate cancer, was admitted for elective excision of a right inguinal lymphocele. Calculated Caprini score was 6, indicating a moderate risk for venous thromboembolism.

The patient underwent a 5-hour complex surgery under balanced general anesthesia. During the procedure, the external iliac vein was accidentally sectioned, requiring a top-to-top anastomosis. Venous clampage lasted 20 minutes and 2000 IU of unfractionated heparin were given. The estimated blood loss was 1700 mL. Hypofibrinogenemia was corrected with 3g of fibrinogen. Anesthetic maintenance and emergence were uneventful.

However, post-extubation, the patient complained of persistent dyspnea despite normal oxygen saturation and an unremarkable ABG. Residual curarization, bronchospasm, pain, and hypoventilation were excluded. Oxygen support was given but did not improve symptoms.

Doppler ultrasound confirmed adequate venous and arterial flow in the operated limb. The patient was then transferred to the post-anesthesia care unit, where 2 episodes of hemodynamic instability and sustained sinus tachycardia occurred.

ABG revealed respiratory alkalosis. Angio-CT scan confirmed a right lobe pulmonary embolism (PE), while the echocardiogram was unremarkable. The patient was started on enoxaparin and later transferred to the ward without further complications.

Discussion: Postoperative dyspnea warrants careful evaluation. A comprehensive patient history, including medical background, surgical details, clinical signs and laboratory tests, is elementary when approaching these situations.

Atelectasis represents the most common cause, but excluding more serious conditions, such as PE, is imperative. Thoughtful management of anticoagulation and diligent monitoring are key, as PE can be silent but lethal.

References:

1. doi:10.1016/j.jvsv.2021.10.0011;

2. doi:10.1213/ANE.0000000000002183

Learning points: Dyspnea can stem from various causes. Despite most being benign, a thorough investigation is essential to exclude life-threatening conditions. PE requires a high level of suspicion. Thromboprophylaxis is vital during the perioperative period, particularly in vascular surgeries.

10AP09-1

Frequency and characteristics of perioperative hypersensitivity reactions: a national study in Brazil

M.A.C. Spindola¹, D. Solé², J.d.S. Nascimento³, J.V.S. Rios⁴, <u>L. Azi</u>⁵

¹Federal University of Santa Catarina, Anesthesiology, Florianópolis, Brazil, ²Federal University of São Paulo, Department of Pediatrics, São Paulo, Brazil, ³Santa Izabel Hospital, Anesthesiology, Salvador, Brazil, ⁴Faculty of Medicine - Federal University of Bahia, Department of Anesthesiology, Salvador, Brazil, ⁵Faculty of Medicine -Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil

Background and Goal of Study: In Brazil, the data on the frequency and characteristics of perioperative hypersensitivity reactions (PHRs) are scarce. This study aims to map the frequency of PHRs reported by anesthesiologists.

Materials and Methods: This observational, cross-sectional study was conducted via a questionnaire distributed to all members of the Brazilian Society of Anesthesiology.

The survey asked anesthesiologists to report the frequency of PHRs they had encountered in the perioperative period through all their lives, focusing on clinical signs, timing, risk factors, and management strategies.

Results and Discussion: A total of 390 anesthesiologists (3.16% of invited participants) responded to the questionnaire, reporting 775 PHRs. The most common clinical signs of suspected hypersensitivity were hypotension (27.07%), cutaneous rash (64.22%), and broncho-spasm (10.47%).

The majority of reactions occurred after induction (38%), with fewer cases after incision (38%) and postoperatively (4.8%). In most cases, surgeries were not interrupted, and the majority of reactions were mild to moderate in severity, with few cases resulting in life-threatening outcomes.

The management strategies were below international standards, with only 7% of patients having blood samples taken for tryptase measurement, 56.5% receiving adrenaline and 61.94% receiving vigorous hydration, which contrasts with higher treatment rates seen in international studies (Mertes et al., 2019; Harper et al., 2018).

Conclusion(s): This national study on PHRs in Brazil reveals important gaps in the recognition, diagnosis, and management of these events.

Further studies and the establishment of a national registry are crucial and should be thinking by both Anesthesiology and Allergy Societies.

Enhancing preoperative CXR appropriateness in a quaternary medical centre: implementing the choosing wisely de-implementation framework with the 4E's model

R. Ng^{1,2}, J.X. Yeo³, P.-S. Au-Yong¹, Y. Ke^{1,2}, K.L. Ng¹, H.R. Abdullah^{1,2,3}

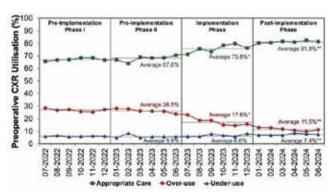

¹Singapore General Hospital, Anaesthesiology & Perioperative Medicine, Singapore, Singapore, ²Duke-NUS, Singapore, Singapore, ³Singapore General Hospital, Office of Value Based Healthcare, Singapore, Singapore

Background and Goal of Study: Medical overuse, such as routine preoperative chest X-ray (CXR) with limited clinical benefit, leads to inefficiencies and unnecessary healthcare costs. The Choosing Wisely (CW) campaign promotes evidence-based practice, but recommendations alone often fail to change clinical practice. The Choosing Wisely De-implementation Framework (CWDIF), enhanced by the 4E's model—Educate, Embed reminders, Empower interprofessionals, and Enforce stewardship—is a promising but untested approach to drive meaningful change.

Therefore, we aimed to implement the CW preoperative CXR bundle using CWDIF and 4E's to evaluate its impact on CXR appropriateness, underuse, mid-term sustainability, and cost avoidance.

Materials and Methods: Our quasi-experimental study at Singapore General Hospital (July 2022–June 2024) included 29,103 adult patients undergoing elective non-cardiac surgeries and preanaesthetic evaluations. The CW preoperative CXR bundle was implemented using CWDIF, incorporating educational initiatives, workflow reminders, staff empowerment, and enforcement via updated electronic forms. Continuous monitoring and feedback were facilitated by data visualisation tools. The primary outcome was CXR appropriateness using clinical criteria. Secondary outcomes included CXR underuse, mid-term sustainability, and cost avoidance.

Results and Discussion: Our CW preoperative CXR bundle increased CXR appropriateness from 67.6% to 75.8% (*p*<0.001), with sustained improvement at 81.8% (*p*<0.001). Underuse rose slightly from 6.6% to 7.4% (*p*<0.001). The intervention achieved a 36.1% cost avoidance. These results suggest that CWDIF, enhanced by the 4E's model, is an effective strategy for driving clinical change, although refinement is needed to address CXR underuse.

Conclusion(s): The CW preoperative CXR bundle, implemented using CWDIF and 4E's, improved CXR appropriateness, ensured mid-term sustainability, and achieved significant cost avoidance. The slight rise in underuse highlights the need for ongoing moni-

toring and feedback. These findings suggest that similar de-implementation strategies could enhance efficiency and sustainability in other clinical settings.

Association between bone mineral density T-score and intraoperative bleeding during spine fixation surgery: a retrospective cohort analysis

T. Shimada^{1,2,3}, Y. Ono^{2,4}, Y. Yanai⁵, I. Takamatsu⁶, Y. Yato⁵, T. Ikeda¹

¹National Defense Medical College, Department of Anesthesiology, Saitama, Japan, ²St. Luke's International University, Graduate School of Public Health, Tokyo, Japan, ³National Health Organization, Murayama Medical Center, Clinical Research Center, Tokyo, Japan, ¹Institute of Physical and Chemical Research, Nishina Center for Accelerator-Based Science, Saitama, Japan, ⁵National Health Organization, Murayama Medical Center, Department of Orthopaedic Surgery, Tokyo, Japan, ⁵National Health Organization, Murayama Medical Center, Department of Anesthesiology, Tokyo, Japan

Background and Goal of Study: Patients with osteoporosis are reported to be associated with postoperative complications after spinal surgery. In contrast, whether the severity of osteoporosis is related to the amount of intraoperative bleeding during spinal surgery remains unknown.

We thus tested the primary hypothesis that perioperative bone mineral density is associated with intraoperative bleeding during spine fixation surgery.

Materials and Methods: After ethical board approved the study, we performed a single center retrospective cohort analysis. We included female patients over 75 years of age having spine fixation surgery between January 2017 and December 2023. Our exposure of interest is bone mineral density T-score assessed by Dual Energy X-ray Absorptiometry within 6 months before surgery or 30 days after surgery.

The primary outcome is the probability of intraoperative bleeding exceeding 500 ml during surgery. The association between the T-score and log odds of intraoperative bleeding were found to be neither linear nor continuous. Furthermore, the association differs in terms of potential confounders.

Therefore, we performed logistic regression using the spline function and nonlinear smoothing to estimate the risk of intraoperative bleeding. The beta regression was also conducted to assess the risk factor of the intraoperative blood loss.

Results and Discussion: Among 481 patients analyzed, 11.6% experienced intraoperative bleeding exceeding 500ml. After smoothing, we found the negative association between perioperative bone mineral density T-score lower than -2.5 and intraoperative bleeding. The risk factors associated with the increased risk of intraoperative blood loss were the number of vertebrae fixed (1.07, 95%Cl: 0.95-1.12, p <0.001), non-cervical surgery (0.21, 95%Cl: 0.03-0.39, p=0.024), and the past medical history of ischemic heart disease (0.26, 95%Cl: 0.07-0.45, p=0.007). Further studies will be needed to find out whether the association is causal.

Conclusion: The bone mineral density T-score lower than -2.5 is negatively associated with the risk of intraoperative bleeding exceeding 500ml during spine fixation surgery.

10AP09-5

Compliance with haemodynamic targets in patients post oesophagectomy for oesophageal cancer

S. Prescott^{1,2}, H. Tayeb^{1,2}, S. Dyson², B. Johnston^{1,2}, J. Colfar^{1,2}, I. Welters^{1,2}

¹University of Liverpool, Institute of Life Course and Medical Sciences, Faculty of Health and Life Sciences, Liverpool, United Kingdom, ²Liverpool University Hospitals Group, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background and Goal of Study: Oesophagogastric cancers are commonly detected at late stages, and have the third lowest five-year survival rate¹, and just over a third are deemed curable at diagnosis². Surgical resection plays a key role in curative treatment, however, oesophagectomies are associated with complication rates of up to 63%. Up to one in five patients develop an anastomotic leak as a complication³. Haemodynamic protocols aim to maintain perfusion within the anastomosis to prevent breakdown. Our protocol recommends targeting a MAP80mmHg for the first six postoperative days⁴. We aimed to audit compliance with these targets in relation to complications.

Materials and Methods: In this retrospective audit, we collected data on patient demographics, complications (e.g., anastomotic leak, pneumonia), and haemodynamics over six post-operative days in all patients admitted to Critical Care after oesophagectomy. Data was captured using RedCAP and statistical analysis tests (Mann-Whitney U and Pearson's χ^2 test/Fisher's Exact Test) alongside descriptive statistics were used to analyse associations between haemodynamic parametres, requirements for vasoactive drugs and post-operative complications.

Results and Discussion: 31 patients were included, four of whom developed an anastomotic leak. 185 days of data was collected with only 47 days (25%) meeting the guideline target MAP. 11 patients developed pneumonia (35.4%), and 30-day mortality rate was 9.7%. There was no significant relationship between compliance and anastomotic leaks. Patients with anastomotic leaks had a significantly higher Comprehensive Complication Index (CCI)⁵ compared to those who did not develop an anastomotic leak (median:59.9 vs 20.9).

Conclusion(s): In this small sample, compliance with the local guideline, while poor, was not associated with anastomotic leaks. Larger cohorts and randomised controlled trials are required to define best haemodynamic targets for patients undergoing oesophagectomy.

Impact of a multimodal prehabilitation program in robotic oncological surgery: a randomized controlled pilot trial

P. 's Hertogen^{1,2}, J. Vandenbrande¹, K. Nijs¹, J.-P. Ory¹, B. Stessel¹

¹JESSA Ziekenhuis, Anaesthesia, Hasselt, Belgium, ²UZ Leuven, Anesthaesia, Leuven, Belgium

Background and Goal of Study: Prehabilitation has recently gained increasing interest as a strategy to begin the rehabilitation process before surgery. It aims to actively prepare patients through exercise, nutritional support, psycho-cognitive training, or a combination of these interventions.

The goal of this study is to evaluate the physical fitness of patients before and after surgery.

Materials and Methods: In this prospective, observer-blinded, randomized controlled pilot study, patients undergoing elective robotic oncologic urological surgery were allocated in a 1:1 ratio to an interventional group (n=10) receiving a multimodal prehabilitation program (including physical, stress reduction, nutritional, and cognitive components) for 2–4 weeks preoperatively, or a control group (n=11) receiving standard care. Physical fitness was assessed before and six weeks after surgery using the 6-minute walking test (6MWT), which measures the maximal distance (meters) a patient can walk in 6 minutes, and the Timed Up and Go (TUG) test, which measures the time required to stand, walk 10 feet, turn around, walk back, and sit down.

Outcome measures were analyzed using the Mann-Whitney U test for non-normally distributed data. A p-value <0.05 was considered statistically significant, and a p-value <0.01 was interpreted as a trend toward significance.

Results and Discussion: A total of 21 patients were included between January 17, 2023, and August 22, 2023. Baseline characteristics of the included patients are presented in Table 1.

A trend toward better 6MWT results was observed six weeks after surgery in the prehabilitation group compared to the control group (720 [570–735] vs. 570 [480–660] m, p=0.08). The TUG test results were significantly faster in the prehabilitation group compared to the control group six weeks after surgery (6 [6–6.5] vs. 8 [7–10] seconds, p=0.01).

Conclusion: The implementation of a multimodal prehabilitation program in elective robotic oncologic urological surgery improves physical fitness six weeks after surgery compared to standard care.

One-year outcomes of high-risk patients discussed in preoperative multidisciplinary team meetings: a multicenter prospective observational study

R. Boerlage^{1,2,3}, J. Vernooij¹, E. Hobrink¹, B. Preckel³, C. Doggen^{2,4}, N. Koning¹

¹Rijnstate Hospital, Anaesthesiology, Arnhem, Netherlands, ²University of Twente, Health Technology and Services Research, Enschede, Netherlands, ³Amsterdam University Medical Centers, Anaesthesiology, Amsterdam, Netherlands, ⁴Rijnstate Hospital, Clinical Research Center, Arnhem, Netherlands

Background and Goal of Study: Surgical patients with a high-risk of serious adverse events (SAE's) are increasingly selected for preoperative multidisciplinary team (MDT) discussions. The aim of the MDT discussion is to optimize the treatment plan by weighing risks and benefits, alternatives in treatment and patients' preferences.

The goal of this study was to assess long-term outcomes at one year for high-risk noncardiac surgical patients following discussion in a preoperative MDT meeting.

Materials and Methods: A prospective multicentre observational study was conducted in the Netherlands in nine hospitals. Each hospital included 25 consecutive high-risk noncardiac surgical patients selected for discussion in preoperative MDT meetings. Data on patient characteristics and outcomes were collected from electronic health records.

The primary outcome was mortality at one year postoperatively (surgical management) or post-MDT meeting (nonsurgical management).

Secondary outcomes included time to SAE or death (event-free-survival), occurrence of SAE's (Clavien Dindo classification \geq 3 or requiring hospital admission) and hospital admissions.

Results and Discussion: A total of 175 patients with complete follow up (175/225) were included in the current analyses. After MDT discussion, 52 (30%) patients received nonsurgical management and 123 (70%) underwent surgery. Of nonsurgical patients, 7 (13%) received palliative care versus 3 (2%) of surgical patients. Mortality at one-year was 42% for nonsurgical patients, of which the majority of deaths occurred within 3 months.

Patients undergoing surgery had a one-year mortality of 20% with over one-third of deaths occurring within 3 months. During the first year, almost half of patients discussed in an MDT were readmitted to hospital at least once.

Patients were readmitted on average twice at one year follow up (nonsurgical IQR 1-2; surgical IQR 1-3). SAE's occurred for 60% of nonsurgical patients and 46% of surgical patients. Nonsurgical patients with SAE's had a median event-free survival of 62 days (IQR 16-135) versus 21 days (IQR 6-78) in surgical patients.

Conclusion(s): Of non-cardiac surgical patients selected for preoperative MDT discussion, one-third received nonsurgical management after discussion.

In both surgical and nonsurgical patients the risk of mortality and SAE's at one year is high. Frequently, patients discussed in MDT meetings had hospital readmissions.

10AP09-8

Comparison of buprenorphine as adjuvant to intrathecal bupivacaine vs no adjuvants for lower limbs peripheral vascular disease reconstruction surgeries

A. Masoodi^{1,2}, O. Rumiantseva², D. Dziuba^{2,1}, O. Loskutov¹ Shupyk National Healthcare University of Ukraine, Department of Anesthesiology and Intensive Care, Kyiv, Ukraine, ²Kyiv Regional Clinical Hospital, Anesthesiology, Intensive Care and ED, Kyiv, Ukraine

Background and Goal of Study: Regional anesthesia techniques are commonly used for many surgical procedures. Unfortunately,these techniques are partially limited by the time of anesthetics action. One method of overcoming this limitation is adding to the anesthetic adjuvant.

Among many adjuvants to local anesthetics tested so far one seems to be interesting-buprenorphine. Prolonging the pain-free interval is crucial for enhancing postoperative recovery and patient satisfaction.

Materials and Methods: Patients posted for Lower Limbs Peripheral Vascular Disease Reconstruction Surgeries in the age 65,3±10,03 years with ASA III and IV. Patients were divided in 2 Groups of 30 each. Group A (GA): 0.5% Bupivacaine 15 mg, group B (GB):0.5% Bupivacaine 15 mg with 60 mcg Buprenorphine. Duration of analgesia, onset of sensory and motor block, VAS, hemodynamic parameters and adverse effects were noted.

Results and Discussion: The duration of analgesia was significantly prolonged in GB ($381,63\pm47,23$ min) than GA ($238,33\pm32,27$ min) (p < 0,002). Onset and duration of sensory and motor blockade was not significantly different (SD).

Regression of motor block in GA (202,11 \pm 30,07min) and prolonged regression in GB (346,35 \pm 54,92 min) (p < 0,011).

Time of surgery GA (142,25 \pm 58,50 min) and with no SD with GB(151,37 \pm 51,48 min). VAS score was before surgery was not SD.GA (8,26 \pm 1,55),GB (7,86 \pm 1,96) (p <0,589). SD changes ware observed in VAS 24 hours after surgery GA (6,23 \pm 1,60), GB (5,20 \pm 11,57) and 48 hours GA (5,20 \pm 1,70),GB (5,13 \pm 1,69) (p<0,020).

Hemodynamic parameters were well preserved and SD changes ware observed only 6hrs after surgery GA (146,1 \pm 11,89), GB (139,1 \pm 12,24) (p <0,047). Drop of BP to 20% was in GA 6 (20%) compare to GB 4 (13,33%).

Higher incidence of PONV was in GB 4(13,33%) compare to GA 3 (10%) and was not SD. Urinary retention level was greater in GB 3 (10%) than in GA 2(6,67%).

Conclusion(s): Addition of 60mcg of buprenorphine to intrathecal bupivacaine prolonged the duration and quality of postoperative analgesia after Lower Limbs Peripheral Vascular Disease Reconstruction Surgeries with minimal adverse effects like urinary retention and PONV which were not significant to hinder recovery.

Cardiac output and carotid flow time as major contributors to cerebral oxygenation in patients undergoing recruitment maneuver during one-lung ventilation

M. Grynovska^{1,2}, M. Granell Gil^{3,4}, I. Vakaliuk⁵
¹University of Valencia, Department of Surgery, Valencia, Spain, ²Ivano-Frankivsk National Medical University, Anesthesia and Intensive Care Department, Ivano-FrankivskUkraine, Ukraine, ³Consorcio Hospital General Universitario de Valencia, Anesthesia, Critical Care and Pain Relief, Valencia, Spain, ⁴University of Valencia, Department of Surgery, ValenciaSpain, Spain, ⁵Ivano-Frankivsk National Medical University, Internal Medicine, Ivano-Frankivsk, Ukraine

Background: The brain, a vital organ, disproportionately receives about 12% of cardiac output (CO)¹. In healthy awake humans CO is an independent regulator of cerebral blood flow (CBF). However, in surgical population the relationship between CO and CBF is not well characterized².

Near-infrared spectroscopy (NIRS) monitors regional tissue oxygenation (rSO $_2$) and is widely utilized as a surrogate of CBF 3 . We decided to investigate if cerebral oxygenation would be affected by recruitment maneuver (RM) - a key component of intraoperative protective ventilation strategy during one-lung ventilation (OLV). RM is associated with transient hemodynamic compromise due to decrease in venous return and CO. It is known to cross-influence the heart, lungs and brain, but its impact on the latter is not studied in detail 4 .

We hypothesized that cardiorespiratory changes induced by RM would decrease cerebral oxygenation during OLV. Our study aimed to identify factors contributing to intraoperative regulation of CBF during OLV.

Methods: 30 patients undergoing elective lung resection were enrolled into the study. NIRS was used to monitor rSO₂. Carotid artery parameters (cFT) were obtained using with portable ultrasound device. Lung RM (35 cmH₂O) was performed after start of OLV. CO and MAP were recorded by pulse contour. Hemodynamic data and ABGs were collected at three timepoints: awake (baseline), before RM, at the end of RM. Statistical analysis was performed.

Results: Hemodynamic and NIRS values were analyzed in correlation and regression model to examine individual predictors and their effect on cerebral oxygenation. CO and carotid cFT were independently associated with mediated change in rSO $_2$ The average significant decrease in CO was 5.9 to 4.5 l/min, cFT 370 to 355 ms, rSO $_2$ 0.6%/min. In contrast, patient age, MAP and paCO2 were not associated with significant change in rSO $_2$.

Conclusion(s): Cerebral oxygenation significantly decreased during RM under one-lung ventilation, which is a solid indicator of RM impact on cerebral dynamics. cFT declined in close association with reduction in CO and rSO₂. We found clinical evidence that intraoperatively cerebral oxygenation, a surrogate parameter of CBF, is regulated by CO.

Further studies are warranted to determine whether cerebral oxygenation-guided interventions can potentially improve clinical outcomes.

Perioperative cardiac arrest and the chain of survival

F. Karami Tireh Shabankareh¹, B. Verma², D. Kumar¹
¹North Middlesex University Hospital NHS Trust,
Anaesthetics, London, United Kingdom, ²North Middlesex
University Hospital NHS Trust, Acute Medicine, London,
United Kingdom

Background: Diabetes is the most common metabolic disorder, affecting 6–7% of the UK population and associated with higher perioperative morbidity and mortality in emergency surgeries!. This is due to co-existing microvascular and macrovascular complications!

Case Report: A 51- year- old male patient with poorly controlled diabetes was found exhausted and immobile at home after a fall on his right knee four days before admission. Initial investigations revealed glucose >27 mmol/L, HbA1c >200 mmol/mol, ketones 6.0 mmol/L and severe metabolic acidosis. He was diagnosed with diabetic ketoacidosis (DKA), which resolved within 54 hours of treatment.

He underwent an emergency arthroscopic washout for septic arthritis under general anaesthesia with Propofol and Alfentanil. Turbid fluid positive for Staphylococcus aureus was identified.

In the PACU, he developed hypotension and cardiac arrest. Return of spontaneous circulation (ROSC) was achieved after one CPR cycle but a second cardiac arrest occurred 15 minutes later. A prolonged downtime of 90 minutes followed with ROSC achieved after two doses of Alteplase. Haemodynamic stabilised and oxygenation improved temporarily.

Further ICU investigations revealed anteroseptal myocardial infarction and severely impaired left ventricular systolic function. Additional cardiac arrests occurred on days 1, 6, and 9 of admission, each achieved with ROSC. Persistent bradycardia complicated by sepsis precluded pacing. He succumbed on day 37 due to multiple organ failure with sepsis, AKI and recurrent cardiac arrests contributing.

Discussion: This case highlights severe cardiovascular complications in poorly controlled diabetes exacerbated by emergency surgery and infection.

Atherosclerotic cardiovascular disease is the leading cause of morbidity and mortality for diabetes patients.

References:

- 1. Levy N, and et al. Perioperative management of the patient with diabetes requiring emergency surgery. BJA Education 2017; 17(4):129-136.
- M.J. Jackson and A.S.Mockridge. prognostication of patients after cardiopulmonary resuscitation. BJA Education 2018; 18(4):109-115.

Learning Points: Emergency diabetic surgical patients require meticulous assessment, management and risk factor optimisation¹.

Post-cardiac arrest investigations including echocardiography, coronary angiography, and CT imaging are critical².

This case underscores the need for an integrated multidisciplinary approach in managing high-risk diabetic surgical patients.

Factors influencing postoperative serum magnesium levels in adult patients undergoing major abdominal surgery

P. Apputhura¹, D. Meyer¹, B. El-Behesy²³, A. Wu²³, A class of statistical undergraduate students, including Polkinghorne A, Fazio A, Findlay J, Chua M, Thai J, Khabbaz S, Carigiet O, Rishika Bhatnagar R. ¹Swinburne University of Technology, Department of Health Sciences and Biostatistics, Melbourne, Australia, ²Eastern Health, Anaesthetics, Melbourne, Australia, ³Monash University, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia

Background: Hypomagnesemia is a common yet under-recognised complication of surgical procedures, including major abdominal surgeries, and is associated with increased morbidity and mortality. Despite its clinical significance, limited research has explored its contributing factors.

This study aimed to assess how patient and perioperative factors influence serum magnesium levels after major abdominal surgery.

Methods: Adult patients scheduled for major abdominal surgery were recruited via preadmission clinic lists. After obtaining informed consent, data were collected on patient demographics, comorbidities, medication or supplement use, and perioperative variables such as bowel preparation, surgical details (e.g., type and duration), and pre- and postoperative serum magnesium levels. Binary logistic regression was employed to calculate odds ratios (OR), and model reliability was assessed using the area under the curve (AUC).

Results: Of 244 eligible patients, 196 were included in the analysis (mean age 59 ± 16 years; 51% female). Postoperative serum magnesium levels decreased significantly from 0.86 ± 0.08 mmol/L to 0.83 ± 0.11 mmol/L (t(195) = 4.91, p < 0.001, d = 0.35).

Significant associations were identified for male gender, reducing odds by 50% after adjustment for confounders (OR = 0.50, 95% CI [0.26, 0.99], p = 0.048) and prolonged surgical duration, with each additional minute increasing odds by 0.4% (OR = 1.004, 95% CI [1.000, 1.008], p = 0.069).

Trending but non-significant associations were observed for bowel preparation, which appeared to reduce odds by 44% (OR = 0.56, 95% CI [0.26, 1.21], p = 0.140) and fluid administration, where each additional litre increased odds by 29% (OR = 1.29, 95% CI [0.95, 1.76], p = 0.106).

Other factors, including age, comorbidities, surgery type, and medication use, showed no significant impact. The model demonstrated moderate reliability (AUC = 0.68).

Conclusions: This study confirms a significant decrease in serum magnesium levels after major abdominal surgery, particularly in females and those undergoing prolonged procedures. While most evaluated factors did not significantly affect magnesium concentrations, bowel preparation and fluid administration warrant further investigation as potential modifiable factors for maintaining perioperative magnesium homeostasis.

Further studies are needed to confirm these findings and explore targeted interventions.

Retrieval augmented generation for 10 large language models and its generalizability in assessing medical fitness

K. Yuhe¹, C.R. Soh¹, H.r. Abdullah¹
¹Singapore General Hospital, Department of Anaesthesia, Singapore, Singapore

Background and Objective: Large Language Models (LLMs) have the potential to support medical tasks, yet they often lack the specific knowledge required for accurate clinical decision-making. Retrieval Augmented Generation (RAG) offers a solution by enhancing LLMs with specialized information, making them more applicable for healthcare needs.

This study aims to evaluate the effectiveness, accuracy, and reliability of RAG-based LLMs in determining a patient's readiness for surgery and providing essential preoperative instructions.

Materials and Methods: We developed RAG-based LLM models using 58 preoperative guidelines from both local and international sources. We tested these models against human responses in a total of 3682 evaluations. Document management and retrieval were handled by Llamaindex. Ten different LLMs, including GPT3.5, GPT4, GPT4-o, Gemini-1.5-Pro, Claude-3-Opus, and versions of Llama2 and Llama3, were evaluated in three ways: as native models, integrated with local guidelines, and integrated with international guidelines. We compared the model outputs to responses from four junior and four senior anesthesiologists from Singapore, the USA, and Taiwan.

The study examined six other important aspects of preoperative instructions in addition to assessing readiness for surgery. Based on established guidelines and expert clinical judgment, we checked model responses for accuracy. We used Fisher's exact statistical analysis test and measured agreement between human and model responses.

Results and Discussion: The LLM-RAG models showed impressive efficiency, generating responses within 25 seconds, much faster than the estimated 10 minutes typically taken by clinicians. Among the models, the GPT4-based LLM-RAG achieved the highest accuracy in assessing surgical fitness, outperforming human-generated responses (96.4% accuracy vs. 86.6%, with p=0.016). The RAG models performed consistently well across local and international guidelines, showing reliable and generalizable results.

Notably, the GPT4 model did not produce "hallucinations" (incorrect information) and provided preoperative instructions that closely matched those from clinical experts.

Conclusions: This study demonstrates that LLM-RAG models can effectively support preoperative tasks in healthcare. Their quick, accurate, and adaptable responses make them promising tools for use in clinical settings. These models could play an essential role in enhancing patient care.

10AP10-2

Is Mini-Mental Sate Examination a useful tool for early recognition of cognitive decline after cardiac surgery: a prospective cohort study?

S. Glumac¹, G. Kardum², L. Sodic³, C. Bulat⁴, M. Carev¹, N. Karanovic¹

¹University Hospital of Split, Department of Anaesthesiology and Intensive Care, Split, Croatia, ²University of Split, Faculty of Humanities and Social Sciences, Department of Psychology, Split, Croatia, ³University Hospital of Split, Department of Neurology, Split, Croatia, ⁴University Hospital of Split, Department of Cardiac Surgery, Split, Croatia

Background and Goal of Study: Postoperative cognitive decline (POCD) is a frequent complication following cardiac surgery with a significant adverse repercussion on patient health and health-care system. Diagnosis of POCD is difficult and it is based on the results of neuropsychological tests. A major obstacle in POCD diagnosis is represented by an absence of unique neuropsychological test battery among investigators.

Thus, the aim of the current study was to assess the sensitivity of Mini-Mental State Examination (MMSE) to detect POCD in comparison with most other commonly used neuropsychological tests

Materials and Methods: This prospective cohort study enrolled 62 patients scheduled for elective cardiac surgery with or without cardiopulmonary bypass. We performed neuropsychological analysis at 3 time points; preoperatively, 7 days and 4 years after surgery.

For cognitive assessment we used 10 following tests: MMSE, Rey Auditory Verbal Learning Test (immediate and delayed recall), Wechsler Memory Scale and its three subscales (visual memory span, digit span forward and backward), Symbol Digit Modalities Test, Trail Making Test (A and B) and computerized PsychE test (simple reaction time). The independent-samples t test was applied for comparisons of preoperative and postoperative neuropsychological test results.

Results and Discussion: MMSE determined POCD at both postoperative time points (P < 0.001) with more sensitivity than other applied tests. Moreover, a number of tests did not reveal POCD at all.

Our results suggest global cognitive decline during four years of follow-up, given that MMSE measures 5 areas of cognitive functions: orientation, registration, attention and calculation, recall and language. In addition, our search of the PubMed database disclosed a massive confusion among neuropsychological tests used in published studies for establishing POCD diagnosis (i.e., over 100 different tests).

Cognitive domains of memory, attention and psychomotor speed are commonly impaired following cardiac surgery; thus, selected tests must have an adequate sensitivity and specificity to cover different domains without overlapping but must also not exhaust the patient in the early postoperative period.

Conclusion: MMSE is a very sensitive and easy to use test for cognitive evaluation and it should be a part of neuropsychological test battery for early detection of such important postoperative issue, as POCD.

Preoperative uric acid levels and postoperative delirium in spine surgery: findings from the Safe Brain Initiative (SBI) - preliminary results

E. Koselerli Akyüz¹, M.B. Akyüz¹, Ç. Yıldırım Güçlü¹, B.C. Meço^{1,2}, F. Radtke³

¹University of Ankara School of Medicine, Department of Anaesthesiology and ICU, Ankara, Turkey, ²University of Ankara, Brain Research Center (AUBAUM), Ankara, Turkey, ³Nykøbing Falster Hospital, Department of Anaesthesia, Nykøbing Falster, Denmark

Background and Goal of Study: Postoperative delirium (POD) is associated with poor outcomes, including prolonged hospitalization, increased costs, and higher mortality rates, highlighting the importance of identifying its risk factors and prevention strategies. Uric acid, a natural antioxidant, may provide neuroprotection; however, recent studies suggest it may also predispose individuals to POD by contributing to white matter atrophy or modulating tau protein levels in cerebrospinal fluid.

Some studies report lower uric acid levels as a risk factor for POD, while others present contradictory findings. This study aims to investigate this relationship within the context of SBI.

Materials and Methods: This retrospective, single-center study investigated spine surgery patients from January 2023 to June 2024, following the SBI protocol at Ibn Sina Hospital, Ankara University, Turkey. Collected data included demographics, postoperative Nu-DESC scores, surgery time, and preoperative levels of uric acid, hemoglobin, neutrophils, lymphocytes, and neutrophilto-lymphocyte ratio (NLR). Patients with renal impairment, gout, neurological disorders, age under 18, or undergoing emergent surgeries were excluded. Data analysis was performed using SPSS Statistics, Version 17.0.

Results and Discussion: We enrolled 150 patients and, after excluding those ineligible or with missing data, analyzed 89. The prevalence of delirium was 12% (n=11), predominantly in women (n=9 vs. n=2). Most patients were classified as ASA II (n=57), and no significant correlation was observed between delirium and ASA status (p=0.79). The delirium group exhibited higher BMI, lower hemoglobin, and elevated inflammation-related parameters, though none reached statistical significance (p>0.05).

However, surgery time and preoperative uric acid levels were significantly higher in the delirium group (220 vs. 143 minutes, p=0.002; 5.84 vs. 4.77 mg/dL, p=0.007), suggesting a potential association.

Conclusion(s): These preliminary findings indicate a possible link between prolonged surgery duration, elevated preoperative uric acid levels, and an increased risk of postoperative delirium. While other factors, such as age, BMI, hemoglobin, and inflammatory markers, did not reach statistical significance.

The results underscore the need for more comprehensive studies to validate uric acid as a biomarker and its role in POD risk assessment and management.

10AP10-4

Dexamethasone, postoperative delirium and the role of hyperglycemia

S. Riesemann¹, T. Tenge², E. Ahrens¹, D. von Wedel¹, L.J. Wachtendorf¹, M.S. Schaefer¹.² ¹Beth Israel Deaconess Medical Center, Harvard University, Anesthesia, Critical Care and Pain Medicine, Cambridge, United States, ²Uniklinik Düsseldorf, Universität Düsseldorf, Klinik für Anästhesiologie, Düsseldorf, Germany

Background: Postoperative delirium (POD) may be precipitated by perioperative systemic inflammation (1). Dexamethasone is a corticosteroid commonly used to prevent postoperative nausea and vomiting and can attenuate perioperative inflammation.

However, a critical side effect of dexamethasone is hyperglycemia, which is an independent risk factor of POD (2).

We assessed whether intraoperative dexamethasone administration is associated with POD and whether this association is modified by postoperative hyperglycemia.

Methods: 92,832 adult hospitalized patients undergoing non-cardiac, non-neurosurgical, and non-transplant procedures between 2008 and 2024 at an academic medical center in Massachusetts, USA, were included.

Multivariable logistic regression models, adjusted for a priori-defined confounding variables, were used to assess the association between intraoperative dexamethasone administration and POD, identified by discharge note reviews, diagnostic codes, and confusion assessment scores.

Figure 1B - Dexamethasone, hyperglycemia and postoperative delirium - a 4-way mediation analysis

BOR 1.43 ### BOR 1.71 ### BOR 1.45 ### B

Figure 18. In 4-way effect decomposition analysis, dexamethasone was associated with a lower relative risk of 7-day postoperative delivium. Dexamethasone was abse-dependently associated with 24-hours postoperative hyperglycemia, which, in turn, was associated with higher odds of postoperative delivium. The proportion of the effect of dexamethasone on delivium that could be avoided by hypothetically preventing postoperative hyperglycemia was estimated to be -11.5%. This means that by setting the mediator (postoperative hyperglycemia) to zero, we would avoid both its mediating and interactive effects, resulting in an increase of 11.5% in the protective association between dexamethasone and delivium.

Abbreviations kgBW kilogram actival body weight, aOR: adjusted odds ratio. Ct. confidence interval. ERR: excess relative risk.

Results: 41,983 (45.2%) patients received dexamethasone and 2,294 (2.5%) developed POD (Figure 1A). In adjusted analysis, dexamethasone was associated with a lower risk of POD independent of dosing (applied median dose 0.09 mg/kg body weight [0.07–0.12]; adjusted odds ratio 0.63 [0.56–0.71], p<0.001). Dexamethasone was dose-dependently associated with postoperative hyperglycemia (Figure 1B), which modified the association between dexamethasone and POD (p-for-interaction<0.001). 4-way effect decomposition analysis (3) suggested that if postoperative hyperglycemia could be avoided, the protective effect of dexamethasone on POD would be further increased by 11.5% (p=0.001, Figure 1B).

Conclusion: Intraoperative dexamethasone administration is associated with lower odds of POD. Higher postoperative blood glucose levels in patients receiving dexamethasone can compromise this association. Based on the 4-way effect decomposition, future studies should investigate if optimized blood glucose control can minimize POD risks and maximize the protective effects of dexamethasone.

Multimodal prehabilitation: impact of anaemia management on postoperative complicactions in patients scheduled for radical cystectomy due to bladder cancer

<u>J. Riu</u>¹, E. Moret¹, I. Penagos¹, A. González², J.L. Gago³, J. Climent⁴

¹University Hospital Germans Trias i Pujol, Anaesthesiology, Postoperative ICU and Pain Treatment, Badalona/Barcelona, Spain, ²Institut Català d'Oncologia/ Institut de Recerca Germans Trias i Pujol, Statistics, Badalona/Barcelona, Spain, ³University Hospital Germans Trias i Pujol, Urology, Badalona/Barcelona, Spain, ⁴University Hospital Germans Trias i Pujol, Immunology, Badalona, Spain

Background and Goal of Study: Multimodal prehabilitation (MP) programs have been developed to enhance patients' physical and mental status before surgery, aiming to minimize postoperative complications and improve outcomes. Most patients with bladder cancer are anaemic and have poor physical baseline status.

The aim of this study was to analyse the prevalence and preoperative treatment of anaemia and its impact on postoperative complications and outcomes in prehabilitated patients scheduled for radical cystectomy due to bladder cancer.

Materials and Methods: Over a 4-weeks period before surgery, patients received personalized physical training, nutritional, and psychological support from a multidisciplinary team. Anaemia was defined and treated if the haemoglobin level was < 13 g/dL. Type of anaemia, its preoperative treatment, intraoperative bleeding, and transfusion needs were analysed.

The functional capacity of all patients was measured using the 6-Minute Walk Test (6MWT), handgrip strength, International Physical Activity Questionnaire (IPAQ), and maximal inspiratory pressure (MIP) measurements. Postoperative complications within 90 days were recorded.

Results and Discussion: A total of 28 consecutive prehabilitated patients scheduled for radical cystectomy were enrolled over a period of 8 months (75% male, mean age 71.6 years, all ASA III, 29.6% non-smokers). Of these, 16 patients (57.1%) were preoperatively anaemic (68.8% male); in 56.25% of the cases, anaemia was due to iron deficiency, and all of them were treated with IV iron. 43.8% of anaemic patients were frail (p=0.010). Intraoperative blood loss, transfusion rates (10.5%) and functional scores post-MP were similar among groups. 55.6% of anaemic patients developed a urinary tract infection (p=0.034). At discharge, 62.5% of the patients were anaemic. No statistical differences in LOS and postoperative complications were found. One anaemic patient died.

Conclusions: The prevalence of anaemia among our patients was 57.1%, with most being iron-deficient and treated with IV iron. Anaemic patients with bladder cancer who underwent radical cystectomy did not show statistical differences in terms of functional capacity compared to non-anaemics at MP-end. Postoperative urinary tract infection was more frequent in anaemia. Anaemia at discharge should be improved. No differences in postoperative complications were found among groups after anaemia correction and training during multimodal prehabilitation.

10AP10-7

Introducing ProphAbby: artificial intelligence-powered platform for surgical antibiotic prophylaxis recommendation

S.L. Ong¹, Y.H. Tan¹, <u>Z.Y. Leow</u>¹, Y.H. Ke¹, A. Lee KY¹, J. Cheng MH¹

Singapore General Hospital, Anaesthesiology and Surgical Intensive Care, Singapore, Singapore

Background and Goal of Study: Surgical antibiotic prophylaxis (SAP) is essential in reducing surgical site infections (SSI) across various surgeries. However, SAP guidelines are often lengthy and periodically updated, posing challenges for clinicians in referencing the latest guidance efficiently.

We designed an Al-powered assistant, named "ProphAbby," to recommend appropriate SAP in alignment with Singapore's national and institutional guidelines efficiently, with the aim to lessen cognitive burden on clinicians.

Materials and Methods: ProphAbby was subjected to testing with six hypothetical cases with complex patient profiles or special considerations such that standard antibiotics prophylaxis may not be suitable and its recommendations were validated internally for appropriateness.

In addition, ProphAbby was tested on 100 real-world surgical cases with its recommendations compared against Singapore National Surgical Antibiotic Prophylaxis Guidelines and the results were studied using Cohen's Kappa analysis model.

To assess ProphAbby's reliability, 2 independent raters evaluated the 100 cases 3 times each using S.C.O.R.E. Evaluation Framework and the mean score for each component of S.C.O.R.E between the 2 raters were compared using Weighted Cohen's Kappa for inter-rater reliability.

Results and Discussion: Amongst the 100 real-world surgical cases, 95 SAP recommendations by ProphAbby were accurate when compared against national guidelines. Using Cohen's Kappa analysis, a score of 0.7403 was obtained, suggesting substantial agreement between local national antibiotic guidelines and

ProphAbby. Based on Weighted Cohen's Kappa used to evaluate the scores of S.C.O.R.E. Evaluation Framework between the two independent raters, there was substantial agreement (k = 0.67), with a mean score of 4.78 and 4.85 respectively.

Conclusion(s): Our results indicate that ProphAbby is able to provide recommendations that were in substantial agreement with existing guidelines with high accuracy. This analysis underscores ProphAbby's potential as a reliable tool to aid clinicians in SAP decision-making, and will be particularly useful given its readily adaptable approach in dynamic clinical setting.

Nonetheless, limitations include the risk of Al hallucination and the necessity for clinician oversight. Future studies should focus on large-scale validation and enhanced functionality incorporating patient-specific microbiology data.

10AP10-8

Opioid-free anesthesia vs opioid-based anesthesia without remifentanil on postoperative nausea and vomiting and additional analgesic use: a propensity score-matched study

T. Nagaoka¹, T. Shiga²

¹Shin-Yurigaoka General Hospital, Anesthesiology, Kanagawa, Japan, ²International University of Health and Welfare Ichikawa Hospital, Anesthesiology, Chiba, Japan

Background and Goal of Study: Recent studies suggest opioid-free anesthesia (OFA) may reduce postoperative nausea and vomiting (PONV) and improve postoperative analgesia compared to opioid-based anesthesia (OBA). Since 2015, we have maintained a database to track PONV and analgesic outcomes in patients undergoing laparoscopic gynecological surgery, implementing propofol-based anesthesia, intraoperative dexamethasone, and IVPCA with droperidol and hydroxyzine (PCA-DH). This protocol has reduced the incidence of PONV to approximately 13%. While adopting OFA, we found OBA without remifentanil yielded similar PONV rates and reduced postoperative additional analgesic use. Therefore, the purpose of this study is to compare these approaches.

Materials and Methods: We first identified risk factors for PONV and postoperative additional analgesic use in patients with PCA-DH (Population A, n=3816) using logistic regression analysis (p<0.01). PONV-related factors included body weight, smoking, motion sickness history, and previous PONV; analgesic-related factors included age, body weight, surgical approach, fentanyl dose, intraoperative cholinesterase inhibitors, NSAIDs, and antihistamines. OFA group and OBA without remifentanil group were extracted from the Population A and propensity-matched by these factors in a 1:1 ratio. Matched-pair analysis using chisquared tests then compared PONV incidence and additional analgesic use between groups. P<0.05 is considered as significant. Results and Discussion: Of the 1,029 patients who met the study selection criteria, 585 received OBA without remifentanil, and 445 received OFA. Following propensity score matching, 442 matched pairs were analyzed for PONV, and 396 matched pairs were analyzed for postoperative additional analgesic use.

In matched pairs, all covariates achieved a standardized mean difference (SMD) <0.1. PONV incidence was comparable between groups (11.1% vs. 12.5%, p=0.60), but postoperative additional analgesic use was lower in the OBA group (20.2% vs. 31.6%, p<0.001).

Conclusion(s): In a setting with significantly reduced PONV, OBA without remifentanil shows similar PONV rates and significantly lower postoperative additional analgesic use than OFA.

10AP10-9

Regional anesthesia for surgical management of incomplete miscarriage in a patient with hereditary angioedema: a safe and effective approach – a case report

A. De Oliveira¹, <u>C. Cunha da Silva</u>¹, M.R. Silva¹, A.S. Coutinho¹, S. Santos Rodrigues¹ ¹Hospital Senhora da Oliveira Guimarães - Unidade Local de Saude do Alto Ave, Serviço de Anestesiologia, Guimarães. Portugal

Background: Hereditary Angioedema (HAE) is a rare autosomal dominant disorder characterized by recurrent episodes of angioedema, with significant mortality risk, especially when upper airway obstruction occurs. Surgical procedures, even minor ones, are well-known triggers for these episodes.

This case report illustrates the successful perioperative management of a patient with HAE undergoing surgical evacuation for an incomplete miscarriage.

Case Report: A 41-year-old woman, ASA II, 51 kg, with a history of HAE, presented for ultrasound-guided curettage after an incomplete miscarriage. She had prior episodes of angioedema involving the eyelids and lips, occasionally accompanied by skin rash and oropharyngeal tightness. Complement studies showed normal levels of C1, C1 inhibitor (C1-INH), C3, and C4, with normal C1-INH functional activity. She was not on regular prophylactic treatment.

Preoperative prophylaxis with 1000 IU of intravenous C1-INH (Berinert®) was administered 1 hour before the procedure. In the operating room, anxiolysis was achieved with 2 mg of IV midazolam, and a subarachnoid block was successfully performed with 8 mg of 0.5% isobaric bupivacaine. C1-INH concentrate and subcutaneous icatibant (Firazir®) were available in case of an acute crisis. The 35-minute surgery proceeded smoothly with excellent patient tolerance.

Postoperatively, she was monitored in the HDU for 24 hours without complications.

Discussion: This case demonstrates the effective management of a procedure typically performed under general anesthesia, using regional anesthesia to avoid airway manipulation in a HAE patient. It underscores the importance of careful preoperative planning and a multidisciplinary team to ensure proper prophylaxis and monitoring.

References:

- Rodrigues, C., Adrego, T., & Vieira, H. (2018). Perioperative Approach to Patients with Hereditary Angioedema. *Journal of the Portuguese Society of Anesthesiology*, 27(1), 70–77. https://doi.org/10.25751/rspa.14816
- Maynard, A. A., Burger, C. F., & Schlesinger, J. J. (2017).
 Angioedema: Perioperative management. SAGE Open Medical Case Reports, 5, 2050313X1771391. https://doi. org/10.1177/2050313x17713912

Learning Points: HAE patients require meticulous preoperative planning involving a multidisciplinary team to ensure proper prophylaxis and minimize risks like airway obstruction. Regional anesthesia is an effective and safe option, reducing procedural triggers while ensuring patient comfort.

10AP10-11

Dose-dependent association between intraoperative dexmedetomidine administration and postoperative delirium: a retrospective cohort study

E. Ahrens¹, L.J. Wachtendorf¹, M.J. Robitaille¹, S.E. Neves¹, H. Ma¹, M.S. Schaefer¹

¹Beth Israel Deaconess Medical Center, Department of Anesthesia, Critical Care and Pain Medicine, Boston, United States

Background: The use of dexmedetomidine can reduce risks of delirium in critically ill patients, but evidence on supplemental intraoperative dexmedetomidine administration and delirium in surgical patients remains equivocal [1,2]. We hypothesized that the risk of delirium after intraoperative dexmedetomidine depends on the dose administered.

Methods: 114,786 hospitalized adults undergoing general anesthesia for non-cardiac procedures at a tertiary academic medical center in New England, USA, between 2008 and 2024 were included. The primary exposure was intraoperative, supplemental administration of dexmedetomidine in mcg/kg body weight (BW), dichotomized based on the median in our cohort (0.49 mcg/kg BW). The primary outcome was delirium within 7 days, identified from discharge notes using a keyword-based search strategy paired with manual chart review, Confusion Assessment Method assessments, and International Classification of Diseases diagnostic codes [3]. Adjusted multivariable logistic and fractional polynomial regression analyses were applied.

Figure 1A. Patient characteristics.

Data are presented as mean (standard deviation (SDI), median (interquartile range (IQRI)) or number (frequency in 1%). ASA: American Society of Anesthesiologists. Desmedetomidine dose was dichotomized and classified as low or high based on the median in our cohort (0.49 mog/kg body weight). "Excerpt."

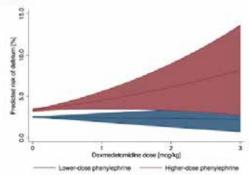

Figure 1B. Exploratory effect modification analysis.

The association between dexmedetomitine dose and risk of delirium was modified by the cadministration of higher doses of phenylephrine (3" tertile, p-5e-interaction=0.035).

Results: 4,804 (4.2%) patients received dexmedetomidine intraoperatively (Figure 1A), with a median (interquartile range) cumulative dose of 0.49 mcg/kg BW (0.28 to 0.84 mcg/kg BW). Postoperative delirium occurred in 3,227 (2.8%) patients, 39 (1.6%) among those receiving lower, and 97 (4.0%) in patients receiving higher dexmedetomidine doses.

Compared to no dexmedetomidine, the risk of delirium was lower in patients receiving lower doses of dexmedetomidine (ORadj 0.61; 95%Cl 0.44-0.85; p=0.004), which was not observed among those receiving higher doses (ORadj 1.06; 95%Cl 0.84-1.34; p=0.62).

This association was modified by the co-administration of higher phenylephrine doses (p-for-interaction=0.035), where dexmedetomidine dose-dependently increased the delirium risk (ORadj 1.42; 95%Cl 1.07-1.88; p=0.014 per mcg/kg BW increase, Figure 1B).

Conclusion: Low- but not high-dose dexmedetomidine administration was associated with lower odds of delirium, depending on intraoperative hemodynamic management.

Real-world deployment and evaluation of PErioperative Al CHatbot (PEACH) - a large language model chatbot for perioperative medicine

K. Yuhe¹, H.r. Abdullah¹, C.l. Tan¹, <u>J. Gao</u>¹, V. Tay¹
¹Singapore General Hospital, Department of Anaesthesia, Singapore, Singapore

Introduction: Preoperative assessment errors can lead to inefficiencies, increased healthcare costs, and surgical cancellations. The PErioperative AI CHatbot (PEACH) integrates local perioperative guidelines within a secure Retrieval-Augmented Generation (RAG) framework to assist clinicians in making accurate and consistent preoperative decisions.

This study evaluated PEACH's accuracy, safety, and user acceptability in real-world clinical settings.

Methods: A silent co-pilot model was implemented in a tertiary hospital's preoperative evaluation clinic, involving 80 clinical scenarios analyzed across 240 interactions. PEACH outputs were compared to institutional guidelines, international standards, and consultant decisions.

Deviations, hallucinations, and inter-rater reliability (IRR) were assessed. Usability was evaluated using the Technology Acceptance Model (TAM). A distinct n-gram analysis assessed response consistency and linguistic diversity.

Results: PEACH achieved an accuracy of 97.5% in its first iteration and 96.8% across three iterations, demonstrating consistent performance (93.8% agreement across iterations).

Hallucination and deviation rates were low, at 1.7% and 0.4%, respectively. Agreement with consultants showed substantial reliability (Kappa 0.73).

There was high internal consistency among PEACH iterations (Kappa 0.89 and 0.77). TAM ratings reflected high user satisfaction, with 95% of users agreeing that PEACH improved clinical decision-making efficiency.

Distinct n-gram scores averaged 0.309 (1-gram) and 0.592 (2-gram), indicating a balance between linguistic diversity and consistency suitable for clinical applications.

Conclusion: PEACH demonstrates high accuracy, reliability, and user acceptability, supporting its use as a clinical adjunct for preoperative decision-making. Its ability to integrate local and international guidelines, ensure data security, and maintain low hallucination rates underscores its potential to enhance clinical workflows, reduce variability, and alleviate clinician workload. Future work will focus on optimizing guideline integration and refining adaptive retrieval mechanisms to enhance its scalability and continued relevance.

Contrast induced acute kidney injury (CI-AKI) in lower limb percutaneous transluminal angioplasty: a machine learning approach for preoperative risk prediction

D.Y.Z. Lim¹, Y. He², R. Koniman³, H. Yap⁴, <u>K.Y. Fong</u>², H.R. Abdullah²

¹Singapore General Hospital, Data Science and Artificial Intelligence Laboratory, Singapore, Singapore, ²Singapore General Hospital, Anaesthesiology, Singapore, Singapore, ³Singapore General Hospital, Renal Medicine, Singapore, Singapore, ⁴Singapore General Hospital, Vascular Surgery, Singapore, Singapore

Background and Goal of Study: Contrast-induced acute kidney injury (CI-AKI) is a frequent complication of lower limb percutaneous transluminal angioplasty (PTA). Existing risk models, developed for cardiology cohorts undergoing percutaneous coronary intervention, omit key predictors like inflammatory markers and preoperative medications. Additionally, these models do not leverage machine learning. This study aimed to develop a preoperative risk model for CI-AKI in lower limb PTA using machine learning and compare its performance with conventional logistic regression.

Materials and Methods: A retrospective cohort of 456 patients who underwent isolated lower limb PTA from 2015 to 2019 was analyzed, excluding those with an Estimated Glomerular Filtration Rate (eGFR) <15 mL/min/1.73 m². Logistic regression and multiple machine learning models were trained using five-fold cross-validation and hyperparameter optimization. Performance metrics, including area under the receiver operating curve (AUROC), area under the precision-recall curve (AUPRC), F1 score, sensitivity, and specificity, were evaluated. Variable importance was analyzed using SHAP (SHapley Addictive exPlantations) plots.

Results and Discussion: The K Nearest Neighbours algorithm demonstrated the best performance (AUROC = 0.914, AUPRC = 0.809). Key predictors included Modification of Diet in Renal Disease (MDRD) eGFR, hemoglobin levels, and inflammatory markers such as neutrophil-to-lymphocyte ratio and red cell distribution width, as identified through SHAP plots.

Conclusion(s): Machine learning models, using exclusively preoperative variables, accurately predicted CI-AKI risk in patients undergoing elective lower limb PTA. These models can aid in preoperative risk counseling and identifying high-risk patients for enhanced monitoring or preventive interventions.

The ascending reticular activating system and its implications in neuraxial anesthesia: coma secondary to epidural anesthesia: a case report

F.M. Colás Borrás¹, C. Izquierdo Perez¹, J.C. Meza Arrigui¹, R.V. Ghidini¹, F.J. Añez Barrera¹, K.G. Albiger Arias¹¹Consorci Sanitari del Maresme, Anaesthesiology, Barcelona, Spain

Background: Epidural anesthesia is a common technique for surgical and chronic pain management, but it carries rare risks, including coma. This case details an unusual prolonged coma following epidural anesthesia, emphasizing the importance of recognizing and addressing such complications, particularly in elderly patients with comorbidities.

Case Report: An 85-year-old woman underwent revision surgery for a periprosthetic femur fracture under subarachnoid anesthesia. Her history included chronic kidney disease, hypertension, diabetes, hypothyroidism, and anticoagulated atrial fibrillation.

Despite multimodal postoperative analgesia, severe pain persisted, prompting the initiation of epidural anesthesia via a lumbar catheter (L2/L3). A 2% lidocaine test dose (3 cc) was negative, followed by 0.125% levobupivacaine (fractioned 10ml).

Shortly after, the patient exhibited transient unresponsiveness initially attributed to vasovagal syncope. However, 25 minutes later, her neurological status deteriorated, presenting a Glasgow Coma Scale (GCS) of 3, unreactive pupils, and no response to naloxone, excluding opioid overdose.

Laboratory results and imaging, including a thoracic CT showing an incidental pulmonary embolism, failed to explain her condition. Differential diagnoses considered included subdural block, ischemic stroke, and rare anesthetic complications.

Transferred to intensive care, the patient regained full consciousness within 7 hours without deficits and was discharged from the ICU after 36 hours.

Discussion: Epidural analgesia, although effective, can cause rare complications such as transient coma. This case highlights the possible involvement of the ascending reticular activating system (ARAS), responsible for cortical arousal. Epidural anesthesia may disrupt sensory input to the ARAS, leading to temporary consciousness impairment.

Prompt recognition and intensive care support were critical in ensuring the patient's full recovery. This case underscores the importance of understanding the neurological effects of epidural anesthesia, thorough monitoring, and timely intervention for managing unexpected postoperative events.

Further research into ARAS-related mechanisms in neuraxial anesthesia is essential to improve perioperative safety.

Learning Points: Epidural anesthesia poses rare risks such as transient coma. ARAS involvement in consciousness regulation highlights the need for further investigation into neuraxial anesthesia's neurological impacts.

10AP11-3

The effect of adding intrathecal Ketamine to spinal anaesthesia on post operative pain in patients undergoing major colorectal surgical procedures

M. Campher ¹, <u>T. Kirkwood</u> ¹

¹The Tweed Valley Hospital, Anaesthesia, Kings Cliff, Australia

Background: Enhanced Recovery After Surgery (ERAS) protocols advocate spinal anaesthesia in laparoscopic colorectal surgery, highlighting it's potential to reduce systemic opioid consumption in combination with intrathecal opioids.^{1,2}

Ketamine, recognized for its analgesic properties, may enhance the effectiveness of opioid analgesia when administered intrathecally.³

This study investigates the impact of adding intrathecal ketamine to spinal anaesthesia for post-op pain management in patients undergoing major colorectal surgical procedures, with a focus on postoperative opioid consumption.

Methods: A retrospective chart review was conducted on patients who received either intrathecal bupivacaine and morphine or a combination of intrathecal bupivacaine, morphine, and ketamine, June 2023 to September 2024.

The analysis included 20 patients, with outcomes measured in terms of oral morphine equivalent (OME) usage in the 48-hour postoperative period, time to breakthrough analgesia, self-reported pain scores, complications, and length of hospital stay.

Results: The mean OME usage in the 48 hr post-op period for the intrathecal morphine group was 106 mg (95% CI 64.7 to 147.9), while the group receiving ketamine in addition to morphine had a mean OME of 52.5 mg (95% CI 26.5–78.6), yielding a statistically significant difference of 53.5 mg (p 0.0463).

Self-reported pain scores showed minimal differences between the two groups, the ketamine group reporting slightly lower scores at 24- and 48-hrs post-op.

Adverse effects were minimal, minimal postoperative nausea and hypotension were noted. The mean length of hospital stay was significantly reduced in the ketamine group (3.7 days) compared to the morphine group (6.3 days).

Discussion: This audit proposes that intrathecal ketamine significantly reduces postoperative opioid requirements and may improve analgesia in patients undergoing laparoscopic colorectal surgery.

However, limitations include the small sample size and variability in post-op analgesic regimes, necessitating further research, supporting these findings, and optimize pain management strategies in major colorectal surgery.

Conclusion: The addition of intrathecal ketamine to spinal anaesthesia may offer a valuable adjunct in postoperative pain management, aligning with multimodal analgesia principles and ERAS protocols. Future prospective studies are warranted to validate these results to enhance outcomes in colorectal surgery patients.

Evaluation of diaphragm excursion with ultrasonography in the perioperative period in laparoscopic surgeries and its association with pain

G. Öncü¹, E. Ozayar¹

¹Ankara Sanatoryum Training and Research Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background and Goal of Study: Pneumoperitoneum created in laparoscopic surgery (LC) causes postoperative ventilation dysfunction associated with a combination of reflex diaphragm inhibition and pain. Diaphragm movement may be reduced due to prolonged pneumoperitoneum and severity of postoperatif pain.

We aimed to evaluate the change of diaphragm movement in the perioperative period by investigating the change of diaphragm excursion (DE) that measured by ultrasonography (USG) and whether DE could be used as a more objective form of visual analog scale (VAS).

Materials and Methods: In this prospective observational study, we included 106 adult patients with ASA I-III who underwent elective LC after ethics committee approval and patient consent. Demographic variables, preoperative and postoperative DE values and vital signs, duration of surgery and anesthesia and postoperative VAS scores of the patients were recorded. DE was measured in the subcostal region with an M mode convex probe. Three consecutive measurements were taken from the right diaphragm and recorded.

Results and Discussion: While the mean preoperative DE was 18.91±2.90 mm, this value was 16.31±3.64 mm in the postoperative period. Initial DE values were shown to be significantly correlated with body mass index, height and age (P<0.001). The mean DE was significantly higher in males compared to females (P<0.001). It was determined that the decrease in the postoperative mean DE (%13.9) compared to the preoperative mean DE of the cases was statistically significant (p<0.001).

We showed that mean postoperative DE was lower in patients with higher VAS scores(P<0.001). Patients with VAS≥5 were considered as having "severe pain".

It was observed that the area under the curve (AUC) calculated for the presence of pain in the postoperative DE parameter of the patients was statistically significant (p<0,001). A cut-off value was determined for VAS≥5. This value was calculated as 15.9 mm in females (AUC:0,715; p<0,001) and 18.9 mm in males (AUC:0,761; p<0,001).

Conclusion(s): In our study, it was objectively shown that LC and postoperative pain restricted diaphragm movements. This relationship between the postoperative DE and VAS; it has led to the conclusion that DE is an objective measurement that can be useful of predicting pain, and it can provide information about the VAS scores, especially in the patient group with limitations in understanding or expressing themselves.

10AP11-5

Evaluation of the qNOX index performance during propofol sedations in endoscopic retrograde cholangiopancreatographies (ERCP)

D. Neira Cedron¹, F.M. Colas Borras¹, R. Torruella Turro¹, E. Reñe De Antonio², I. Fabregas Blanco²
¹Consorci Sanitari del Maresme, Anaesthesiology and Intensive Care, Mataro, Spain, ²Consorci Sanitari del Maresme, Anaesthesiology, Barcelona, Spain

Background and Goal of Study: Excessive sedation and analgesia during endoscopies can lead to cardiovascular and respiratory issues, whereas low levels, pain and discomfort for both the patient and the physician.

The aim of this study is to assess the qNOX performance during ERCP as a tool to safely manage sedations.

Materials and Methods: After IRB approval, 21 patients scheduled for ERCP were enrolled. Sedation used 1 mg midazolam plus continuous propofol at 4–7 mg/kg/h. Surgical stimuli were classified as positive response (PR) if ≥15% increase in heart rate, blood pressure, or movement occurred, followed by a propofol bolus. Patients were monitored with qCON2000(R), an EEG device providing qCON (anesthesia depth) and qNOX (responsiveness to pain). Anesthesiologists were blinded to index values.

Stimuli were categorized as PR or no response (NR). Pre-stimulus qNOX/qCON were averaged 90–30 seconds before stimuli to exclude artifact. Lilliefors and t-student tests (p < 0.05) compared both groups of stimuli.

Results and Discussion: Patients were ASAI-III adults from both genders, aged 72 ± 16 years, weight 77 ± 17 kg and height 166 ± 9 cm (mean \pm standard deviation). Average perfusion rate was 5.74mg/kg/h and bolus administered after PR ranged from 20 to 70mg (30mg/bolus in average). Data from 49 stimuli were recorded, 31 presenting patient response. Table 1 shows the values obtained for the t-test performed to the qNOX values of PR and NR, as well as to the qCON values.

Conclusion(s): Provided that no analgesics were used, deep propofol sedation was responsible for reducing reactions to nociceptive stimuli. No qCON differences were found between PR and NR, suggesting that both had a similar level of consciousness, while nociception balance assessed by qNOX appeared to be different, correlated to responsiveness.

Therefore, qCON and qNOX might be two complementary EEG based indexes useful to manage sedation and pain during ERCP. **References:**

Effects of discontinuation versus continuation of renin-angiotensin system inhibitors before non-cardiac surgery: a systemic review and meta-analysis of randomized controlled trials

Y.T. Kao1, Y.H. Tai1,2, J.T. Chen1,2

¹Department of Anesthesiology, Shuang Ho Hospital, Taipei Medical University, New Taipei City, Taiwan, ²School of Medicine, College of Medicine, Taipei Medical University, Department of Anesthesiology, Taipei, Taiwan

Background and Goal of Study: The optimal strategy for continuing or discontinuing renin-angiotensin system inhibitors in surgical patients remains uncertain. This meta-analysis aims to clarify whether a continuation strategy versus a discontinuation strategy of angiotensin-converting enzyme inhibitors (ACE-Is) and angiotensin receptor blockers (ARBs) before surgery reduces postoperative mortality and myocardial injury after non-cardiac surgery.

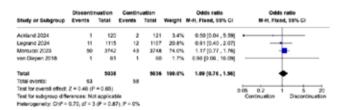

Materials and Methods: We conducted a search of the PubMed, Embase, and Cochrane databases for randomized controlled trials (RCTs) comparing the continuation versus discontinuation of ACE-Is and ARBs from inception to October 15, 2024.

The primary outcome was all-cause mortality at 30 days. Secondary outcome was the incidence of myocardial injury after non-cardiac surgery (MINS).

Meta-analyses were performed using Cochrane RevMan software version 7.12.0 to calculate odds ratios (ORs) and 95% confidence intervals (CIs) using a random-effects model.

Results and Discussion: Four studies were analyzed, involving 10,074 patients receiving ACE-I or ARB therapy prior to non-cardiac surgery. Of these patients, 5,038 discontinued their ACE-I/ARB therapy on the morning of surgery, while 5,036 continued their treatment. The pooled odds ratio (OR) for all-cause mortality was 1.09 (95% CI: 0.76–1.56; I-squared index: 0), indicating no significant difference between the two groups.

Similarly, there was no difference in the rate of MINS between the discontinuation and continuation strategies (pooled OR: 1.00, 95% CI: 0.89–1.14; I-squared index: 0).

Conclusion(s): Our results suggest that the continuation of ACE-Is or ARBs prior to non-cardiac surgery is not associated with the rates of all-cause mortality or myocardial injury compared to a discontinuation strategy. Individualized hypotensive management should be considered during the perioperative period. Further studies are needed to determine the optimal strategy for high-risk patients or surgical procedures.

10AP11-9

Patients' understanding and recollection of information about anaesthesia after attending pre-operative assessment clinic

M. Spiteri Zammit1

¹Mater Dei Hospital, Department of Anaesthesia & Intensive Care, Imsida, Malta

Background and Goal of Study: Effective communication of anaesthetic information in the Preoperative Assessment Clinic (POAC) is vital to empower patients to make informed decisions and consent for their anaesthetic care.

We carried out a telephone questionnaire to assess the patients' understanding and recollection of the anaesthetic information provided during their POAC visit, including the risks and the complications discussed.

Materials and Methods: The local ethics board approved this study. Consent for participation was obtained from 227 adult patients attending POAC over a four week period. The patients were contacted by phone a few days after their appointment. They were asked a set of predetermined, simple and specific questions about the anaesthesia and risks discussed during their visit with the foundation year doctors.

Results and Discussion: Out of 227 patients, 203 completed the questionnaire. 81 patients were unaware of the anaesthetic type they would receive. 125 patients were told about complications, but 28 could not recall any. Commonly recalled complications included nausea, vomiting, non-specific cardiac/respiratory problems and death. 91 patients felt uninformed about anaesthesia risks related to their comorbidities. Although 89 patients wanted more information, only 31 sought further clarification during their visit.

Patients were either not fully informed, did not understand or did not retain information, highlighting a gap, which does not meet the standards outlined in the *AAGBI: Consent for Anaesthesia 2017* guidelines. Contributing factors include insufficient knowledge by junior doctors, time constraints, and complex medical jargon.

Conclusion(s): We came up with the following recommendations to inform and aid retention:

- 1. Distribution of patient-friendly short leaflets in various languages about anaesthesia and its complications,
- 2. Slide show presentation in the waiting area,
- 3. Train young doctors in basic information about anaesthesia,
- 4. Encourage time for questioning and provide a contact email and phone number,
- 5. Provide written information about common co-morbidities and their implications during the peri-operative period.

We are hoping that these small steps lead the patients towards a truly informed consent for anaesthesia.

Effect of preoperative carbohydrate loading on perioperative blood glucose levels and preoperative gastric volume in diabetic patients undergoing elective major surgery - a randomised controlled trial

S.M. Ipe¹, P.S. Thomas¹, R. Sathi¹, R. Mathew¹, S. Philip¹, S. Ipe¹

¹M.O.S.C Medical College, Anesthesiology, Kolenchery, India

Background and Goal of Study: The ERAS protocol recommends liberal fasting and preoperative carbohydrate ingestion 2-3 hours prior to surgery, with proven benefits of decreasing metabolic response, preoperative hypoglycemia, postoperative insulin resistance, and better patient wellbeing. However, there is dearth of evidence for the success of preoperative carbohydrate loading in diabetic patients.

The aim of the study was to compare perioperative blood glucose levels, preoperative gastric volume and patient comfort between carbohydrate and clear fluids loaded group in diabetic patients undergoing elective major surgery.

Materials and Methods: This was a single blinded randomised controlled trial done in 134 diabetic patients undergoing elective major surgery. Patients were randomized into groups - C & F. Group C received carbohydrate drink night before [400mL of 100g] and 2 hours [200mL of 50g] prior to surgery and Group F received plain water 400ml and 200mL respectively. Perioperative glycemic levels, preoperative gastric volume and patient comfort [thirst and hunger], PONV, and duration of hospital stay were assessed

Results and Discussion: The study revealed higher blood glucose levels 1hour postdrink (175.19±44.195 vs 113.19±18.337) (p<0.001) and intraoperatively (133.49±19.147 vs 119.84±19.861) (p<0.001), in carbohydrate group, but within acceptable levels in majority of patients. The mean postoperative blood glucose level was higher in the clear fluids group (140.66±21.575 vs 133.35±36.478) (p 0.161). The carbohydrate loaded group had a higher preoperative gastric residual volume (56.17±24.05 vs 45.9±23.078) (p 0.008), without any increased risk of aspiration (GRV not >1.5mL/kg). PONV was comparable (p 0.680). Carbohydrate group experienced reduced preoperative thirst(p<0.001) and hunger (p<0.001) making the patients more comfortable pre-induction.

Conclusion(s): Preoperative carbohydrate loading demonstrated positive outcome in terms of better patient comfort with acceptable pre and intraoperative blood glucose levels and no increased risk of postoperative hyperglycemia, pulmonary aspiration or PONV. Hence, it may be recommended in well controlled diabetic patients undergoing major elective surgeries. FUTURE STUDIES 1. study with a single type of surgery may have a comparable surgical stress.2. Studies assessing the ideal volume and time interval of carbohydrate drink to be loaded without increasing gastric volume in diabetic patients.

Neuromuscular turmoil: unmasking a postoperative myasthenic crisis

P. Gaspar¹, <u>I.S.M. Carrapatoso</u>¹, T. Estevens¹

¹Hospital Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Myasthenia gravis (MG) is a rare autoimmune disorder of the neuromuscular junction characterized by fluctuating skeletal muscle weakness. Perioperative management, especially during emergency surgeries, presents challenges.

Interruption of MG therapy and inadequate neuromuscular blockade monitoring can precipitate myasthenic crisis, a life-threatening complication.

Case Report: A 75-year-old man with a medical history of diabetes mellitus, hypertension, ischemic cardiomyopathy, and MG underwent emergency thromboembolectomy for acute mesenteric ischemia. MG treatment had been discontinued two days prior to surgery.

General anesthesia was used with rocuronium (100mg) without intraoperative neuromuscular blockade monitoring and reversed using sugammadex (400mg). The surgery proceeded without complciations, and the patient was transferred to the Intensive Care Unit (ICU) for continuous monitoring and postoperative care. Upon ICU admission, the patient exhibited respiratory distress and acidemia (pH 7.20), unresponsive to non-invasive ventilation

A myasthenic crisis was suspected, likely precipitated by the interruption of MG therapy and surgical stress. The patient required reintubation, and a neurology consult advised intravenous immunoglobulins (IVIG, 30 g over 5 days) and prednisolone (10 mg/day). Pyridostigmine was also reintroduced postoperatively. The patient's recovery was gradual and prolonged.

After nine days, he was successfully extubated and placed on 2 L/min of nasal cannula oxygen. No additional neurological complications occurred.

Discussion: This case highlights the risk of MG crisis in the perioperative period, emphasizing the crucial need for neuromuscular monitoring and continuation of MG therapy whenever feasible. Prompt recognition and initiation of immunomodulatory treatments were pivotal to recovery.

Reference:

1. Watanabe A, Watanabe T, et al. Perioperative management in myasthenia gravis patients: A review. *Ann Thorac Cardiovasc Surg.* 2019;25(2):1-8.

Learning Points:

- 1. Surgical stress and interruption of MG therapy are significant risk factors for postoperative myasthenic crisis.
- 2. Neuromuscular blockade in MG patients must be carefully monitored to avoid underestimation of residual paralysis.
- 3. Early intervention with IVIG and corticosteroids can prevent severe complications and improve outcomes in postoperative myasthenic crises.

Anesthetic challenges in Ehlers-Danlos syndrome: a multidisciplinary approach for perioperative management

<u>A. Moreno</u>¹, B. Martínez lozano¹, C. Garcia Albares¹, I. Pérez Fernández¹, I. Rodríguez Martínez¹, G. Romero Martí¹

¹Hospital Granollers, Anesthesia, Granollers, Spain

Background: Ehlers-Danlos syndrome (EDS) is an inherited connective tissue disorder with an incidence of 1/5000, characterized by hyperlaxity of the skin, tissues, trachea, larynx and vascular fragility. The hypermobile type, the most common, is often associated with dysautonomia manifest as postural orthodontic tachycardia syndrome (POTS) and hypotension episodes.

These patients present significant anesthetic risks including bleeding, airway complications, abnormal autonomic responses, and resistance to local anesthetics(1).

Case report: A 43-year-old male with hypermobile EDS and Addison's disease, fibromyalgia and POTS who underwent joint fixation surgery for chronic foot instability. Spinal anesthesia was performed at the L3-L4 level using 7.5 mg of bupivacaine, combined with an ultrasound-guided femoral nerve block with 20 ml of 0.75% ropivacaine. Perioperative stress-dose hydrocortisone was administered in order to prevent adrenal insufficiency.

Discussion: This case illustrated the complexity of anesthetic management in EDS patients, who require individualised care. Chronic pain, neuropathy, and resistance to local anesthetics complicate perioperative pain control. Current evidence does not support a position between general and regional anesthesia. the approach should depend on comorbidities and previous anesthetic experiencies.(2)

Complications such as dysautonomia, tissue fragility, or difficulties with airway must be anticipated. Dysautonomia and POTS, requires careful fluid management and hemodynamic monitoring. Adrenal insufficiency, often secondary to hypothalamic-pituitary-adrenal axis dysfunction, is another critical concern.

Surgical stress can precipitate adrenal crises, which highlights the importance of preoperative evaluation and glucocorticoid supplementation.

References: Wiesmann, T., Castori, M., Malfait, F., & Wulf, H. (2014). Recommendations for anesthesia and perioperative management in patients with Ehlers-Danlos syndrome(s). Orphanet Journal of Rare Diseases, 9, 109. https://doi.org/10.1186/s13023-014-0109-5. Chopra, P., Tinkle, B., Hamonet, C., et al. (2017). Pain management in the Ehlers-Danlos syndromes. American Journal of Medical Genetics Part C, 175(1), 212–219. https://doi.org/10.1002/ajmq.c.31554

Learning points: Screen for poor local anesthetic response and anesthetic risks. Manage dysautonomia with fluid optimization. Assess adrenal function and provide stress-dose hydrocortisone if needed.

10AP12-1

Intra-operative care in uterine transplantation: a case report of a living-donor procedure

<u>A. Macedo</u>¹, D. Negrini¹, B. Araujo¹, F. Pinto¹, C. Fraga¹, J. Rocha¹

¹Universidade do Estado de São Paulo (USP), Surgery/Anesthesia, São Paulo, Brazil

Background: Uterine transplantation is a promising solution for uterine factor infertility, with advancements in surgical techniques and immunosuppressive medications enhancing its feasibility. It is most commonly performed in patients with Mayer-Rokitansky-Küster-Hauser (MRKH) syndrome¹, and only a few institutions worldwide have experience with living donors.

Case Report: This case involved sisters aged 31 (donor) and 34 (recipient), both classified as ASA I. The recipient had MRKH syndrome. An identical anesthetic protocol was used for both surgeries, with minimal bleeding reported. Spinal anesthesia was performed using morphine, fentanyl and sufentanil for postoperative analgesia, while general anesthesia induction included propofol, sufentanil and succinylcholine. Maintenance consisted of sevoflurane (2–3%, MAC 1–1.3), remifentanil infusion (0.1–0.3 μ g/kg/min), and cisatracurium (0.1 μ g/kg/min). Monitoring included BIS, cerebral oximetry, central venous line and temperature.

In the donor procedure, a Flowtrack/Hemosphere monitor was employed to manage hemodynamics and fluid balance. The surgery lasted 12 hours, with the donor successfully extubated in the operating room.

The recipient's surgery began 8 hours later. Before uterine implantation, basiliximab (20 mg) and methylprednisolone (500 mg) were administered, and 5,000 U of heparin was given before arterial and venous anastomoses were released. The total ischemia time was 265 minutes, and no hemodynamic changes occurred during the procedure. Ultrasonography confirmed adequate blood flow through uterine vessels.

Discussion: Experience with living donor uterine transplantation is limited in Latin America. Living donors offer advantages such as reduced cold ischemia time and better surgical planning but raise ethical concerns. This case demonstrated minimal hemodynamic fluctuations, absence of reperfusion syndrome and negligible bleeding, suggesting uterine transplantation may elicit unique physiological responses compared to other solid organ transplants ².

References:

- 1. Brännström M, et al. Transplantation. 2018;102(4):569-77 2. Manning MW, et al. J Cardiothorac Vasc Anesth. 2020;34(2):501-
- 3. Kisu I, et al. Transplant Proc.2018;50(9):2783-8.

Learning Points: Living donor uterine transplantation is a significant advancement for uterine factor infertility³.

However, limited studies and reviews challenge the establishment of standardized protocols, emphasizing the need for further research

10AP12-2

Comparing adherence to Procedure Specific Postoperative Pain Management (PROSPECT) guidelines in Median Sternotomy (MS), Total Hip Arthroplasty (THA) & Total Knee Arthroplasty (TKA)

S.F. Zulquernain¹, M. McCarthy¹, G. Iohom^{2,3}, B. O'Donnell^{2,3}

¹University College Cork, School of Medicine, Cork, Ireland, ²University College Cork, School of Medicine, Department of Anaesthesiology and Intensive Care Medicine, Cork, Ireland, ³Cork University Hospital, Department of Anaesthesia, Cork, Ireland

Background and Goal of Study: Adequate perioperative pain management leads to overall better patient outcomes¹. This research study compared adherence to the ESRA PROSPECT pain management guidelines for MS, THA & TKA in two elective care hospitals in Cork, Ireland. The primary objective was to assess if trends in perioperative adherence to international pain management guidelines translate across different procedures.

Materials and Methods: A prospective chart review was conducted on the first 41, 34 and 30 patients who had elective THA, TKA and MS respectively in June 2024. Pre-, intra- and postoperative analgesia were recorded, benchmarking against each respective PROSPECT guideline. Data were recorded and analysed using Microsoft Excel, comparing adherence across the three disciplines.

Results and Discussion: Intraoperatively, for THA & TKA, the weakest adherence were the use of dexamethasone (68.3% and 73.5% respectively) and NSAIDs/COX inhibitor (94.1% and 82.9% respectively). In terms of MS, only 1 (3.3%) patient received paracetamol/NSAID while 2 (7%) patients received magnesium sulphate, resulting in opioids being the primary choice for pain management during surgery. All MS patients received IV morphine and 28/30 (93%) received IV fentanyl. Surgical wound infiltration, dexmedetomidine and parasternal block were not utilized during any MS, whereas adductor canal/femoral nerve block was performed in 33/34 (97%) TKA patients.

Postoperatively, all THA & TKA received short acting oxycodone, while 82.9% and 79.4% received long acting oxycodone respectively. All MS received paracetamol, aspirin (NSAID) and a morphine infusion while intubated, with short acting oxycodone charted as rescue analgesia post extubation.

	Satisfactory Pre/Intra Operative Adherence	Satisfactory Postoperative Adherence	Pre/Intra-Operative: Post-Operative Ratio (number of patients:number of patients)
THA (n = 41)	51.2% (n = 21)	92.7% (n = 38)	1 : 1.81
TKA (n = 34)	55.8% (n = 19)	91.1% (n = 31)	1 : 1.63
MS (n = 30)	3.3% (n = 1)	100% (n = 30)	1:30

Conclusion(s): Post-operative adherence was higher across all three procedures. The lack of intra-operative adherence may be due to guideline unawareness, reluctancy to use new techniques such as parasternal block or distrust in non-opioid forms of analgesia, particularly in MS. To investigate this, anaesthetist attitudes to guidelines, department-wide discussions and education will be carried out, with a plan to re-audit after.

Takotsubo syndrome in the perioperative setting: the crucial role of POCUS in rapid diagnosis and management

M. Donga¹, M. Matos¹, J. Magalhães¹, E. Figueiredo¹, E. Seguro¹, S. Sacramento¹
¹Unidade Local de Saúde Viseu Dão-Lafões,
Anesthesiology, Viseu, Portugal

Background: Point-of-care ultrasound (POCUS) in anesthesia has grown significantly enabling rapid diagnoses and influencing clinical management in perioperative settings¹.

Stress-induced cardiomyopathy, or Takotsubo syndrome, is a rare nonischemic cardiac condition that mimics acute coronary syndrome. Surgical procedures, due to emotional and physical stress, can act as a trigger for this syndrome².

Case report: 77y female patient, ASA III, with history of atrial fibrillation, ischemic stroke 30 years prior and anxiety disorder, who underwent total thyroidectomy due to a non-toxic multinodular goiter. Prior to induction, she presented anxious with hypertension and tachycardia.

Intraoperatively there was a need of intermittent boluses of ephedrine due to hypotension, with no other events reported. Upon extubation, patient presented with shock. POCUS examination revealed severe biventricular dysfunction.

A transthoracic echocardiography confirmed right ventricular mid-distal free wall and left ventricular mid-apical akinesia with basal hypercontractility and an ejection fraction of 15% consistent with Takotsubo syndrome.

Additionally, a thrombus was identified in the right chambers, prompting administration of 5000 units of unfractionated heparin and initiation of aminergic support. EKG revealed T wave inversion in precordial and inferior leads and QTc prolongation. The patient was transferred to the coronary intensive care unit for further care. Serial echocardiograms demonstrated progressive cardiac function recovery, allowing the gradual weaning of vasopressors. Coronary angiography revealed coronary artery disease without critical ischemia confirming takotsubo syndrome diagnosis (InterTAK score 76).

Discussion: POCUS is increasingly recognized as a valuable tool in perioperative anesthesia, offering rapid diagnostic insights that guide clinical decision-making.

In this case, the use of POCUS was instrumental in identifying the underlying cause of shock and initiating appropriate treatment, including cardiac thrombus management.

- 2. Seretis K, Bounas. Takotsubo Syndrome in the Perioperative Period: A Case Report and a Comprehensive Review of Pertinent Literature. Ann Plast Surg. 2022;88(6):e33–e37.

Learning points: POCUS is a rapidly growing and impactful technique in anesthesia. Perioperative stress is an important risk factor for Takotsubo syndrome.

10AP12-4

Perioperative euglycemic diabetic ketoacidosis induced by SGLT2i: a challenging diagnosis

R. Calaia¹, <u>T. Rocha</u>¹, N. Araújo¹, R. Oliveira¹, P. Antunes¹, A. Guedes¹

¹Unidade Local de Saúde Viseu Dão-Lafões, Anaesthesiology Department, Viseu, Portugal

Background: Euglycemic diabetic ketoacidosis (eDKA) induced by sodium-glucose co-transporter inhibitors (SGLT2i) is rare but potentially life-threatening!. SGLT2i stimulate glucagon production and inhibit renal glucose reabsorption!.

In perioperative settings, their use combined with fasting synergistically reduces glucose levels and increases ketogenesis. Failure to discontinue SGLT2i preoperatively can lead to eDKA².

Case report: A 48yo male, ASAIII, was scheduled for laparoscopic vertical gastrectomy for grade 2 obesity (BMI:38.7Kg/m²). His history included obstructive sleep apnea, and poorly controlled type 2 diabetes managed with insulin, metformin, and dapagliflozin. Surgery was under general anesthesia with desflurane.

Post-pneumoperitoneum, the patient developed persistent tachycardia (HR:-120bpm). In the PACU, he remained tachycardic, with stable blood pressure and no pain. 1h later, he developed diaphoresis and epigastric pain. EKG and cardiac markers ruled out ischemia. Shortly after, he presented with polyuria.

Arterial blood gas analysis revealed metabolic acidosis (pH:7.27, pCO $_2$:40, HCO $_3$:18, glucose:148mg/dL), with worsening acidosis in subsequent tests (pH:7.26 \rightarrow 7.25, HCO $_3$:16 \rightarrow 14), glucose consistently <200mg/dL.

Reviewing his history and medication revealed inadequate preoperative discontinuation of dapagliflozin, suggesting eDKA and urine dipstick confirmed ketonuria (>16mmol). He was treated with IV bicarbonate at 1.4%, insulin infusion with 5% dextrose and 20mEq KCI supplementation.

After 6h the metabolic acidosis was resolved. The patient was referred to diabetes care team and discharged 6 days later without complications.

Discussion: Bariatric surgery patients on SGLT2i have higher eDKA risk, with symptoms appearing from hours to weeks post-operatively². Early onset often results from delayed drug discontinuation; later cases relate to insulin withdrawal, dietary changes, or SGLT2i reintroduction.

In this case, early symptom recognition, exclusion of cardiac causes, and thorough medication review enabled timely treatment. Further studies are needed to identify other risk factors that may lead to eDKA in the perioperative period, as well as scientific evidence to support recommendations regarding the suspension time of SGLT2i².

References:

- 1. Thir. V, Perioperative diabetic ketoacidosis associated with SGLT2i: a systematic review. BrJAnaesth.2019Jul
- 2. Seki H. SGLT2i associated perioperative ketoacidosis: a systematic review. JAnesth.2023Jun

Learning points: SGLT2i should be discontinued at least 72h before surgery.

Prolonged fasting and inadequate SGLT2i discontinuation are triggers for perioperative eDKA.

10AP12-5

Enhanced recovery compared to conventional intensive care following aortic valve replacement: a retrospective analysis

C. Erskine¹, T. van Bos², S. Coppens^{2,3}, D.F. Hoogma^{2,3}
¹University of Glasgow, College of Medical, Veterinary
and Life Sciences, Glasgow, United Kingdom, ²University
Hospitals Leuven, Department of Anaesthesiology,
Leuven, Belgium, ³University of Leuven, Biomedical
Sciences Group, Department of Cardiovascular Sciences,
Leuven, Belgium

Background and Goal of Study: Enhanced recovery after cardiac surgery (ERACS) is a multidisciplinary clinical protocol comprising specific perioperative interventions that aim to reduce the surgical stress response, promote early organ function and decrease hospital length of stay (LOS). Currently there is limited evidence as to the efficacy of ERACS in the literature.

The aim of this study is to evaluate the effect of a post-anaesthesia care unit (PACU)-centric ERACS program compared to a conventional intensive care unit (ICU) program on patients undergoing aortic valve replacement (AVR) surgery.

Materials and Methods: This was a single-centre, retrospective study of patients undergoing isolated AVR surgery between 2011 and 2020. All patients had a EuroSCORE II <3 and a BMI <40. All preoperative and intraoperative care was uniform. An ERACS program was initiated in the PACU in 2011. PACU or ICU admittance was dependent on logistical factors.

Postoperative care data was compared to patients receiving conventional care in the ICU. The primary outcome was hospital LOS, with secondary outcomes including postoperative complications and removal of invasive devices such as catheters, drains and IV lines.

Results and Discussion: Overall, 751 patients were included in the study, comprising 345 with PACU-centric ERACS care and 406 with conventional ICU care, with a median [IQR] hospital LOS of 7 [6-9] and 9 [7-11] days (p<0.0001) respectively. Compared to ICU care, patients admitted in the PACU-centric ERACS program had a significantly higher risk of early discharge (hazard ratio 1.68, 95% CI: 1.46-1.92, p<0.0001).

Regression analyses demonstrated significant reductions in time to removal of invasive devices between groups (Figure). Differences in reintervention rate between groups were negligible (ICU vs ERACS; 5% vs 4%, p=0.39), as too were mortality rates (1% in both, p=0.51).

Conclusion(s): The use of a PACU-centric ERACS program significantly reduced hospital LOS and time to removal of invasive devices. We conclude that the integration of ERACS protocols into perioperative care should become standard practice in the management of AVR patient

10AP12-6

Evaluation of postoperative recovery in patients undergoing thoracic aortic aneurysm surgery: a study using Postoperative quality of Recovery Scale (PQRS)

M. Kajitani¹, K. Takahashi², W. Takayama³, Y. Morita¹
¹Kawasaki Municipal Hospital, Anesthesiology, Kawasaki, Japan, ²Institute of Science Tokyo Hospital, Anethesiology, Tokyo, Japan, ³Kawasaki Saiwai Hospital, Anesthesiology, Kanagawa, Japan

Background and Goal of Study: Postoperative neurological complications, including stroke and postoperative cognitive dysfunction (POCD), impair quality of life (QOL)^(f).

Total arch replacement (TAR) surgery carries a high risk of brain injury due to ischemia and inflammation⁽²⁾.

Despite cerebral protection strategies such as deep hypothermic circulatory arrest (DHCA) and selective cerebral perfusion (SCP), studies on POCD in TAR patients remain limited.

This study evaluated postoperative recovery, including cognitive function, using the Postoperative Quality of Recovery Scale (PQRS)⁽³⁾.

Materials and Methods: This study included 58 TAR patients between June and December 2016 after ethical approval and informed consent (approval no. 28-8). Exclusion criteria included prior thoracotomy, psychiatric disorders, and Mini-Mental State Examination (MMSE) scores ≤21.

PQRS assessed five domains: physiological, nociceptive, emotive, activities of daily living (ADL), and cognitive recovery. Assessments were conducted preoperatively and at 3 hours, 1 day, 3 days, and 7 days after extubation.

Results and Discussion: Of 58 patients, 24 were excluded due to incomplete data or complications, including two patients (3.4%) with delirium and one (1.7%) with stroke. The final cohort included 34 patients (median age 68.4 years, 91.2% male).

Physiological recovery reached 85.0% on day 3, reflecting effective postoperative care.

Nociceptive recovery remained below 50%, with 42.4% on day 7, indicating inadequate pain management.

Emotive recovery peaked at 94.1% on day 3, while ADL recovery improved from 7.1% on day 1 to 84.8% on day 7.

Cognitive recovery was unstable, starting at 17.6% on day 1, rising to 61.8% on day 3, but dropping to 36.4% on day 7, suggesting POCD in some patients.

The occurrences of delirium and stroke, while infrequent, emphasize the need for comprehensive perioperative neurological care to address potential impacts on recovery, particularly cognitive outcomes.

Conclusion(s): The PQRS demonstrated rapid physiological and emotive recovery but identified delays in nociceptive and cognitive recovery in TAR patients. The findings highlight the need for optimized perioperative management and further research on long-term outcomes.

Enhancing temperature management in the post-anesthesia care unit: insights from an audit

C. Pereira¹, V. Katerenchuk¹, D. Rosinha¹, B. Matias¹, A. Batista¹, I. Ferreira¹

¹Unidade Local de Saúde da Arrábida, Anesthesiology, Setúbal, Portugal

Background and Goal of Study: Monitoring body temperature is essential for safe perioperative care, as hypothermia and hyperthermia can lead to significant complications. This audit aims to evaluate the incidence of hypothermia and hyperthermia, assess adherence to perioperative and the post-anesthesia care unit (PACU) temperature documentation, and identify areas for improvement.

Materials and Methods: The audit was conducted in January 2024 at a district hospital in Portugal. All patients undergoing surgical procedures under all types of anesthesia (other than local anesthesia) were included, except those transferred directly to the ICU or day surgery recovery phase II.

Recorded variables included demographic data, type and duration of surgical procedure and anesthesia, perioperative temperature, and values on arrival and discharge from the PACU. Body temperature was measured in the recovery room using an infrared thermometer and intraoperatively using an esophageal thermometer.

Results and Discussion: A total of 343 patients were included in the audit. Of these, 179 (52%) were male, with 49% aged between 18 and 65 years. 333 (97%) and 310 patients (90%) had temperature measured on admission and discharge from the PACU, respectively. Hypothermia, defined as a temperature below 36°C, was observed in 22 patients (6%) on arrival and in 6 patients (2%) at discharge, with the lowest recorded temperature being 35.3°C.

No patients presented with hyperthermia, defined as a temperature above 38°C, on either admission or discharge from the PACU. 88% had no intraoperative temperature record. Among the 22 patients presenting with hypothermia on admission to the PACU, 14 were female and 11 were over 65 years old.

A notable correlation was found between anesthesia duration and hypothermia incidence, with the highest rates in patients whose anesthesia exceeded 3 hours and in those receiving combined anesthesia. The audit results align with the risk factors for perioperative hypothermia identified in the literature.

Conclusion: Temperature is grossly under-monitored perioperatively, as demonstrated by our audit, despite the association of numerous adverse events.

Our findings highlight the need for system-level changes to enable proactive temperature monitoring and documentation throughout all phases of perioperative care to enhance patient outcomes.

10AP12-9

The importance of calcium release-activated calcium channels in inhibitory neurons for perioperative neurocognitive disorders

R. Watanabe¹, K. Hori¹, S. Tsujikawa¹, H. Hino¹, T. Matsuura¹, T. Mori¹

¹Osaka Metropolitan University Graduate School of Medicine, Department of Anaesthesiology, Osaka, Japan

Background and Goal of Study: Perioperative neurocognitive disorders (PND) are serious complications in current perioperative practice, with general anaesthesia playing a major role in their onset. Disruption of neuronal calcium homeostasis, potentially involving calcium release-activated calcium (CRAC) channels, has been proposed as one of the underlying mechanisms.

The study aimed to investigate the role of CRAC channels in inhibitory neurons in the development of PND using a knockout (KO) mouse model.

Materials and Methods: We genetically deleted the channel pore protein in inhibitory interneurons and compared behavioural data between wild-type (WT) and KO mice before and 1h after exposure to general anaesthesia (1 minimum alveolar concentration for 30 min). Electrophysiological experiments were conducted using hippocampal slices to examine the underlying mechanisms.

Results and Discussion: In the Y-maze test, WT mice showed a significant reduction in success rates following sevoflurane anaesthesia (p < 0.001), whereas no significant reduction was observed in KO mice (p=0.1).

These findings were consistent with results under isoflurane or extended sevoflurane anaesthesia (1 h). Similarly, hippocampal long-term potentiation (LTP) was significantly reduced in WT mice after sevoflurane exposure (p < 0.001) but not in KO mice (p=0.2).

Whole-cell patch-clamp recordings from CA1 interneurons revealed a sevoflurane-induced increase in the frequency of spontaneous inhibitory postsynaptic currents in WT mice, which was not observed in KO mice. This frequency increase in WT mice was suppressed by tetrodotoxin, indicating that it was action potential dependent.

Furthermore, pharmacological inhibition of CRAC channels in WT mice prior to anaesthesia resulted in similar improvements in the Y-maze test following sevoflurane exposure.

Conclusion(s): CRAC channels in inhibitory interneurons may play a critical role in the development of PND. These channels appear to regulate the excitatory/inhibitory activity balance by controlling anaesthesia-induced action potentials, potentially contributing to LTP suppression.

10AP12-10

Analgesia in minimally invasive esophagectomy: a case series

J. Vigo Garay¹, J. Silva García¹, F. López Lence¹, A. Heras Ramos¹, E. Conesa López¹, L. Tisner Yagüe¹ ¹Hospital Universitario 12 de Octubre, Anestesiología, Reanimación y Terapeútica del Dolor, Madrid, Spain

Background: Thoracic epidural analgesia (TEA) remains the gold standard for perioperative pain management in open esophagectomy. However, in minimally invasive esophagectomy (MIE), fascial plane blocks, such as the erector spinae plane block (ESPB), offer a potentially effective and safer alternative.

Case report: We reviewed several cases of patients who underwent MIE at our center between January 2022 and June 2024. Variables analyzed included the analgesic technique employed, pain control during the first 3 postoperative days (POD), postoperative opioid consumption, vasoactive drug (VAD) requirements, postoperative complications, and length of ICU and hospital stays. Pain control was categorized using subjective assessments documented in electronic medical records and simplified into the following scale:

• 1 (good control): VAS 1-3

• 2 (moderate control): VAS 4-6

• 3 (poor control): VAS 7-10

Discussion: 24 patients were included, with 4 excluded due to ICU intubation.

Analgesic Technique	Number of Pati- ents	ASA	POD 1	POD 2	POD 3	Postope- rative Opioids	VAD	Postope- rative Complica- tions	UCI Stay	Hos- pital Stay
IV Anal- gesia	11	2,45	1,45	1,27	1,09	3/11 (27%)	2/11 (18%)	4/11 (36%)	6,45	20,27
TEA	6	2,66	1,67	1,33	1	2/6 (33%)	1/6 (17%)	1/6 (17%)	3	14
ESPB	3	2	1	1	1	1/3 (33%)	0/3 (0%)	1/3 (33%)	2,33	13,33

- IV Analgesia: The most commonly used technique, despite
 not being the standard. Pain control was comparable to other
 methods. ICU and hospital stays were longer, likely due to a
 higher number of postoperative complications.
- TEA: This approach demonstrated poorer pain control in the early postoperative period. TEA has a failure rate of up to 12%, primarily due to catheter misplacement or suboptimal dosing. It carries risks associated with insertion and potential adverse effects, including hypotension and urinary retention (1).
- ESPB: Although limited to a small sample size (n = 3), ESPB provided the best pain control during the first 3 PODs, comparable opioid consumption, reduced VAD requirements, and no significant differences in anastomotic leak rates or ICU/hospital stays. These findings align with prior studies (2).

References:

- Carney A, Dickinson M. Anesthesia for esophagectomy. Anesthesiol Clin. 2015;33(1):143-63.
- Feenstra ML et al. Analgesia in esophagectomy: a narrative review. J Thorac Dis. 2023;15(9):5099-5111.

Learning points:

- ESPB represents a promising option for perioperative pain management in MIE.
- Larger randomized controlled trials are required to establish the optimal analgesic strategy for MIE.

10AP12-12

Assessing the impact of pre-assessment communication on elective surgery outcomes in a district general hospital

H. Kaur¹, Y. Serry², S. Seeburuth³, C. Dipura⁴
¹Queen Elizabeth Hospital, London, Anaesthetics, London,
United Kingdom, ²Queen Elizabeth Hospital, Anaesthetics,
London, United Kingdom, ³Queen Elizabeth Hospital,
Clinical Site Management team, London, United Kingdom,
⁴Queen Elizabeth Hospital, Anaestheics, London, United
Kingdom

Background and Goal of Study: Providing high-quality, evidence-based information empowers patients, helping them understand their treatment and associated processes. Studies, including the Sprint National Anaesthesia Project (SNAP-1), highlighted anxiety as a significant concern for patients undergoing surgery. Clear, well-written information can alleviate anxiety, set realistic expectations, and improve patient satisfaction.

This audit was undertaken at QEH London, aimed to Identify the adequacy of information provided to patients during pre-assessment and assess patient comprehension/satisfaction.

Materials and Methods: A total of 50 patients included in this audit and questionnaire consisting of six questions was given to patients undergoing elective surgeries at two time points: before they met the anaesthetist on the day of surgery and postoperatively before discharge. CEPOD cases and obstetric patients were excluded from this study.

Results and Discussion: Before surgery, 14% of patients felt they did not receive adequate explanations regarding anaesthesia choices, which improved to 100% after seeing the anaesthetist. One fourth of patients initially did not understand the side effects of the anaesthetic procedure (this improved to 98% post-consultation).

Majority of patients understood the side effects of pain relief. Only 16% of patients reported not receiving any written or online information regarding the risks and side effects of anaesthesia. Documentation of conversations between nurses or anaesthetists regarding risks and side effects was completed 100% of the time.

Conclusion(s): This audit underscores the importance of clear, thorough communication during the pre-assessment process in enhancing patient understanding, reducing anxiety, and improving satisfaction. The development of concise and informative patient leaflets for Pre-assessment Clinic (PAC) visits for patients could be helpful.

10AP13-1

Identifying patient-related factors for respiratory complications during deep sedation catheter ablations in patients with atrial fibrillation: a single centre retrospective study

M. Homberg¹, K. Betz^{2,3}, D. Linz^{2,4,5,6,7}, K. Vernooy^{2,4}, W. Buhre⁸, E. Bouman¹

¹MUMC+, Anesthesiology and Pain Management, Maastricht, Netherlands, ²Maastricht University, Cardiology, Cardiovascular Research Institute Maastricht (CARIM), Maastricht, Netherlands, ³Eifelklinik St. Brigida GmbH & CO KG, Internal Medicine, Simmerath, Germany, ⁴Radboud University Medical Center and Radboud Institute for Health Sciences, Cardiology, Nijmegen, Netherlands, ⁵Centre for Heart Rhythm Disorders, University of Adelaide and Royal Adelaide Hospital, Adelaide, Australia, ⁵Flinders University, Caring Futures Institute, College of Nursing and Health Sciences, Adelaide, Australia, ¬Maastricht UMC+, Maastricht Heart+ Vascular Center, Maastricht, Netherlands, ³University Medical Center Utrecht, Anesthesiology, Utrecht, Netherlands

Background and Goal of Study: Catheter ablations (CA) in patients with atrial fibrillation (AF) are performed either under procedural sedation and analgesia (PSA) or under general anaesthesia (GA). Patient selection is needed to outweigh the risk benefits related to PSA as compared to GA.

The identification of patient-related factors, in particular in view of respiratory complications during moderate or deep sedation, is known to be very limited.

The aim of this study was to identify predictive factors for development of per-procedural respiratory complications.

Materials and Methods: This single center retrospective cohort study was conducted in a tertiary teaching hospital in The Netherlands from October 2020 and July 2023. It involved adult, consecutive patients for a CA under PSA for AF. The ISOLATION cohort study and ISOLATION 'light' registry were approved by the ethical review boards MUMC⁺ (METC numbers 19-052 and 2019 1022).

This study was conducted in compliance with the Declaration of Helsinki and the Good Clinical Practice guidelines. Per-procedural respiratory complications were defined as the use oral/nasal airway, or an indication for a non-rebreathing mask or high flow oxygen, or a hypoxemic event (a saturation <90% ≥120 seconds) or a conversion to GA with laryngeal mask airway (LMA) or tracheal intubation.

Results and Discussion: A longer sedation duration (OR 1.01 per minute, 95%CI: 0.99-1.00, p-value 0.006) was associated with respiratory complications. Patient factors as a higher percentage of visceral fat (OR 1.11 per percentage, 95%CI: 0.86-0.97, p-value 0.004), a higher Body Mass Index (BMI) (OR 1.12 per point, 95%CI: 1.03-1.23, p-value 0.01), an age >50 years (OR 3.99, 95%CI: 1.27-17.6, p-value 0.03) and a neck circumference > 40cm (OR 2.01, 95%CI: 1.14-3.58, p-value 0.02) resulted in a significant increase of respiratory complications.

The multiple logistic regression model included sedation duration, an age > 50 years, a neck circumference >40cm, visceral fat percentage, tiredness, apnea-hypopnea-index (AHI), the diagnoses obstructive sleep apnea syndrome (OSAS) and chronic obstructive pulmonary disease (COPD) The AUROC of the model with all retained variables was 0.72, 95% CI: 0.65-0.78.

Although the retrospective design of the study might affect the generalizability of the outcome, our results reveal possible predictors for respiratory complications for PSA in CA.

Nevertheless it is obvious that a follow-up study based on a prospective design is needed to further optimize and validate the prediction model.

Conclusion: Predictive patients characteristics factors for development of per-procedural respiratory complications were identified and included an age > 50 years, a neck circumference >40cm, visceral fat percentage, tiredness, AHI and a medical history of OSAS and COPD. An important procedure related predictive factor is the duration of the PSA.

10AP13-2 Multifactorial non-traumatic compartment syndrome: a rare postoperative case

<u>I. Reis Ferreira</u>¹, C. Pinto Campos², B. Silva¹, G. Pereira¹ ¹Unidade Local de Saúde Estuário do Tejo, Serviço de Anestesiologia, Vila Franca de Xira, Portugal, ²Faculdade de Medicina da Universidade do Porto, Anestesiologia, Porto, Portugal

Background: Acute compartment syndrome (ACS) occurs when increased pressure in an osteofascial compartment impairs tissue perfusion, causing irreversible damage to muscles and nerves. While usually linked to trauma, rare non-traumatic cases may result from factors like prolonged surgical positioning, blood loss, vascular insufficiency and intraoperative hypotension.

Case Report: A 39yo male with obesity, hepatic steatosis and prior right femoral subtrochanteric fracture repair underwent a 6h procedure for osteosynthesis revision and bone graft application. The procedure was performed under general anesthesia and femoral and lateral femoral cutaneous nerve block, with standard ASA monitoring, processed EEG, neuromuscular monitoring and invasive blood pressure.

The patient was supine, with the right leg tractioned and the left elevated with gel padding underneath his calves. He remained hemodynamically stable throughout the procedure. Estimated blood loss was 1L.

2 hours postoperatively, he developed left leg pain and tense calf sweling. Doppler ultrasound excluded deep vein thrombosis. Symptoms progressed with severe pain and paresthesia with preserved pulses.

Analytically, with acute kidney injury and rabdomyolisis. Intracompartmental pressures confirmed ACS, requiring urgent fasciotomy. Postoperative recovery was uneventful, with symptom resolution.

Discussion: This case highlights the multifactorial nature of non-traumatic ACS, with contributing factors including limb elevation, compression, prolonged immobility/surgical positioning and blood loss. Young males are more predisposed to ACS due to greater muscle mass. Non-traumatic ACS presents diagnostic challenges, as symptoms may mimic deep vein thrombosis or ischemia. Early pressure measurement is critical for timely diagnosis. Preventive strategies, such as intraoperative limb mobilization and adequate blood pressure are essential during prolonged surgering.

References:

- 2. Hopkinson-Woolley J, Shearer JR. *British Journal of Anaesthesia* 1998;81(4):702-704
- 3. Rorabeck CH, Macnab I. Clinical Orthopaedics and Related Research 1975:113:52-57

Learning Points:

- 1. Non-traumatic ACS can result from prolonged positioning, compression, and blood loss during surgery.
- 2. Preventive strategies, including intraoperative limb mobilization, may reduce ACS risk.
- 3. Early diagnosis and fasciotomy are crucial to avoid irreversible complications.

10AP13-3

Airway warming devices and associated warming strategies for preventing intraoperative hypothermia: a systematic review and network meta-analysis

J.J. Lee1, H. Kang1, G.J. Choi1

¹Chung-Ang University College of Medicine, Department of Anesthesiology and Pain Medicine, Seoul, Korea, Republic of

Background and Goal of Study: Preventing intraoperative hypothermia is an essential element of improving the quality of perioperative care. Active airway warming via heated humidifier (HH) has beneficial effect in maintaining the intraoperative core temperature and supports respiratory physiology during general anesthesia.

However, considering that respiratory heat loss is relatively limited, the application of HH alone may be insufficient to prevent hypothermia, and combining it with other warming devices would be more effective.

Therefore, we performed a network meta-analysis (NMA) to assess the relative efficacy of airway warming devices and associated warming strategies to prevent intraoperative hypothermia.

Materials and Methods: We searched MEDLINE, Embase, CENTRAL, and Google Scholar to identify all randomized controlled trials (RCTs) up to September 2024 that compared the effects of two or more warming strategies especially including airway warming devices in preventing hypothermia in patients under general anesthesia.

The primary outcome was the intraoperative core temperature at the end of surgery. We performed both frequentist and Bayesian NMA and used the surface under the cumulative ranking curve (SUCRA) values to establish a rank order of the warming strategies evaluated.

Results and Discussion: A total of 25 RCTs involving 1404 patients were included in the systematic review and NMA. At the end of surgery, HH, HH + intravenous fluid warmer (IV), HH + IV + water mattress, and the Mega Acer Kit (MAK), which combines an heated-humidified breathing circuit with a fluid warming device, showed significantly higher core temperature than the control. According to the SUCRA values, the core temperature at the end of surgery was highest in MAK, followed by HH + IV + WM, heat and moisture exchanger (HME) + passive insulation + IV, and HME + forced air warmer.

MAK also had the highest SUCRA value for intraoperative core temperature at all other analyzed time points. The SUCRA values from the Bayesian model were similar to those from the frequentist model, demonstrating the robustness of our analysis. Howev-

er, due to the limited quality and quantity of the evidence involved, additional studies are needed to ascertain the relative effects of the various warming strategies.

Conclusion(s): MAK was most effective in preventing intraoperative hypothermia among various warming strategies involving airway warming devices in patients under general anesthesia.

10AP13-4

Prediction of Perioperative Myocardial Injury with the Surgical Apgar Score in non-cardiac high-risk surgery

J. Goff¹, L. Borgstedt², B. Ulm², M. Blobner², B. Jungwirth³, C.A. Bubb³ ¹TUM University Hospital, School of Medicine and Health, Anaesthesiology and Intensive Care, Munich, Germany, ²TUM University Hospital, School of Medicine, Anaesthesiology and Intensive Care, Munich, Germany, ³University of Ulm, Faculty of Medicine, Anaesthesiology

and Intensive Care, Ulm, Germany

Background and Goal of Study: Perioperative myocardial injury after non-cardiac surgery (PMI) is a postoperative troponin (TnT) increase¹ and associated with higher 30-day morbidity and mortality. This study aimed to investigate whether the Surgical Apgar Score (SAS) can predict PMI in non-cardiac high-risk surgery. The SAS assigns points based on intraoperative maximum or minimum of hypotension, blood loss and tachycardia², which are associated with PMI.

Materials and Methods: After ethics approval, a perioperative database with prospective data collection in non-cardiac highrisk surgical patients (ASA status > II or cardiac high-risk procedure) with at least two perioperative high-sensitive TnT (hsTnT) values was prospectively set up [3]. The database includes 1473 patients for whom the primary endpoint, incidence of PMI, was determined based on a difference between pre- and postoperative TnT values (Δ hsTnT > 14 ng/I). SAS quality and its combination with other preoperative scores (RCRI, ASA, POSPOM, CCI, Orion) were evaluated with AUROC and AUPR curves.

Results and Discussion: 222 patients (15.1%) developed PMI. Compared to the cohort without PMI, patients with PMI were older, had higher prevalence of prior cardiovascular disease, were more often ASA class IV/V (3.6% vs. 8.1%, P=0.030), and to undergo high cardiovascular risk surgery more frequently (49.5% vs. 59.9%, P=0.017). PMI occurred more often in thoracic interventions (9.0% vs 6.3%, P<0.001). The SAS was lower in the PMI group (5 [4;7] vs. 6 [5;7], P<0.001) and predicted PMI incidence with an AUROC of 0.630 [0.539 to 0.721]. Combining the SAS with preoperative risk scores did not improve PMI prediction (Table 1).

	RCRI & SAS	ASA & SAS	CCI & SAS	POSPOM & SAS	ORION & SAS
AUROC	0.626	0.611	0.631	0.639	0.662
	[0.535 to 0.717]	[0.518 to 0.705]	[0.541 to 0.722]	[0.551 to 0.727]	[0.578 to 0.745]
AUPR	0.244	0.223	0.269	0.249	0.284
	[0.199 to 0.297]	[0 179 to 0 274]	[0.222 to 0.323]	[0.203 to 0.301]	[0.235 to 0.338]

Table 1: Predictive performance of combined perioperative risk scores for PMI.

Limitations: Most PMI were diagnosed within 24 hours due to frequent blood sampling during this period, potentially overlooking PMI occurring later.

Conclusion: Our study suggests that SAS is not a useful predictive score for PMI, whether alone or combined with commonly used preoperative risk scores. Further studies are needed to allow prediction of PMI based on pre- and intraoperative parameters.

Efficacy and safety of intrathecal morphine in major abdominal surgery: do peripheral nerve blocks add value?

N. Sheffy¹, A. Safo¹, K. Azem¹, S. Fein¹¹Rabin Medical Center, Department of Anestehsiology, Petah Tikva, Israel

Background and Goal of Study: Intrathecal morphine (ITM) provides effective pain control in major abdominal surgeries but is associated with dose-dependent respiratory depression.

Our study compares pain scores, opioid use, and respiratory depression among patients receiving standard care (SC), ITM, peripheral nerve blocks (PNB), or ITM + PNB.

Materials and Methods: A retrospective analysis of patients undergoing major abdominal surgeries (e.g., hepatic, pancreatic) was conducted. Patients were divided into 4 groups: SC, SC + PNB, SC + ITM, and SC + ITM + PNB. Pain scores (Numeric Pain Rating Scale - NRS), opioid use (Oral Morphine Milligram Equivalent - MME), and respiratory depression episodes (Respiratory Rate <6) during the first 24 hours in the post-anesthesia care unit were collected.

Results and Discussion: 319 patients were observed. ITM, with or without PNB, resulted in significantly lower pain scores and opioid use compared to SC or PNB alone. Median NRS was 4 (IQR: 2–5) for ITM, 4 (IQR: 1–6) for ITM + PNB, versus 6 (IQR: 5–7) for SC and 6 (IQR: 3–7) for SC+ PNB (p < 0.001).

Median oral MME was 20 (IQR: 14–40) for ITM and 20 (IQR: 5–36) for ITM + PNB, compared to 50 (IQR: 30–55) for SC and 43 (IQR: 30–58) for SC+ PNB (ρ < 0.001). PNB alone offered no significant pain relief over SC.

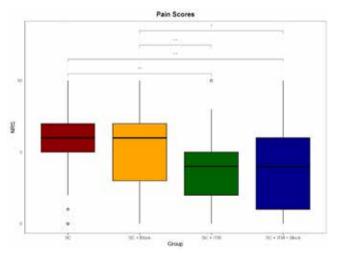

Figure.

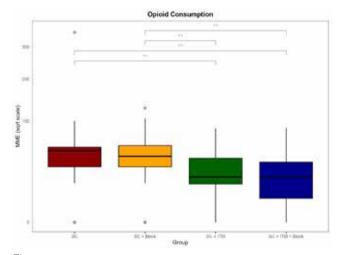

Figure.

Respiratory outcomes were similar across groups; the median number of respiratory depression episodes was zero. BMI and OSA were identified as predictors of desaturation , but ITM was not linked to increased respiratory depression.

Conclusion(s): ITM was highly effective in reducing pain and opioid use compared to SC or PNB alone, with no increase in respiratory risks. Adding PNB to ITM did not significantly improve pain relief. These findings suggest ITM is sufficient for effective pain control in major abdominal surgeries, supporting its use as a safe analgesic approach.

10AP13-6 Perioperative management of a patient with hemophilia A with inhibitors to Factor VIII: a case report

A. Machado Borges¹, <u>C. Fernandes Marques</u>², S. Farraposo², M.d.L. Castro²

¹Hospital do Divino Espírito Santo, Área de Anestesiologia, Ponta Delgada, Portugal, ²Unidade de Saúde Local de São José, Área de Anestesiologia, Lisboa, Portugal

Background: Haemophilia A (HA) is a rare X-linked recessive disorder caused by a deficiency of coagulation factor VIII (FVIII), leading to impaired clotting.¹ Severe cases, defined by FVIII levels below 1%, are associated with higher bleeding risks.¹ Some patients develop FVIII inhibitors, antibodies that further complicate management by increasing bleeding risk and reducing the efficacy of FVIII replacement therapy², requiring agents like activated prothrombin complex concentrate or recombinant activated factor VII (rFVIIa).¹²

Preoperative planning requires inhibitor screening, evaluation of bleeding and thrombosis risks, and medication review. 2

Collaborative efforts are essential to optimize outcomes.^{1,2}

Case report: A 76-year-old male, ASA III, with severe HA (FVIII < 0.5%), an FVIII inhibitor (11.14 UB), reduced mobility from haemophilic arthropathy, and hepatitis C proposed for unilateral cataract surgery. Despite the procedure's low bleeding risk, the patient required meticulous perioperative management. After pre-anesthetic and coagulopathy consultations it was decided to administer prophylactic rFVIIa before surgery. Close perioperative monitoring for bleeding and thrombosis was planned.

Discussion: This case illustrates the challenges of managing severe HA with inhibitors in the perioperative setting. Despite the low bleeding risk, comprehensive preparation was essential. Key aspects included coordination among anesthesiology, hematology, and ophthalmology teams; thorough preoperative assessment of bleeding, thrombosis, comorbidities, and therapies; and hemostatic management with rFVIIa, ensuring bleeding control without excessive thrombotic risk.

This case highlights the importance of individualized perioperative planning for hemophilic patients with inhibitors and provides a model for similar cases.

References:

1. Poston JN, Kruse -Jarres R. Perioperative hemostasis for patients with hemophilia. *Hematology Am Soc Hematol Educ Program*. Published online December 9, 2022:586-593.

2. Lowell AE, Calgi MP, Caruso JJ, Man LM, McNeil JS. Perioperative Management of Hemophilia Patients. *Curr Anesthesiol Rep.* 2024;14(3):354-365.

Learning points: The perioperative management of HA patients with inhibitors requires careful planning, risk assessment, and interdisciplinary communication. Individualized hemostatic strategies are critical even for low-risk procedures to ensure safety and optimal outcomes.

10AP13-7

Surgery cancellation rate after visiting preanesthetic evaluation Clinic Khon Kaen Hospital

A. Pulnitiporn¹, <u>S. Thanasriphakdeekul</u>¹, N. Chitpreeda² ¹Khon Kaen Hospital, Khon Kaen Simulation Training and Education Center, Khon Kaen, Thailand, ²Sawang Daen Din Crown Prince Hospital, Department of Anesthesiology, Sawang Daen Din District, Thailand

Background and Goal of Study: The Pre-anesthetic Evaluation Clinic at Khon Kaen Hospital has been established since 2019, to evaluate patients with comorbidity prior to surgery. The benefit to this clinic has not been evaluated previously.

Objective: To evaluate the rate of surgical cancellation in patients visiting the pre-anesthetic evaluation clinic before surgery.

Materials and Methods: After the ethical committee's approval, the retrospective descriptive study was conducted from October 1, 2021 to September 30, 2022. The pre-anesthetic evaluation form, anesthesia record and medical record of patients who underwent non-cardiac surgery were reviewed after visiting the pre-anesthetic evaluation clinic. Demographic data, underlying disease, surgical cancellation on surgery day and reasons were recorded.

Results and Discussion: 2,701 cases were included. Surgery for 115 patients was cancelled due to the patient's status changed 52.2% (60 patients), treatment plan changed 15.6% (18 patients), patient refusal 12.2 % (14 patients), further investigation or consultation needed 5.2 % (6 patients) and others 14.8% (17 patients).

The 14 patients out of patient's status change were the COVID-19 infection. The cancellation rate on surgery day was 4.3 %.

Conclusion(s): Even though the surgical cancellation of the preanesthetic evaluation clinic patient visit prior to surgery was quite low, the additional improvements can be made by correcting preventable cancellation reasons.

Cardiopulmonary resuscitation in prone position during bone cement-augmented pedicle screw instrumentation in complex spine surgery: a rare presentation of sudden hypotension and Bezold-Jarisch vasovagal reflex

A. Bataller¹, C. Ramírez-Paesano¹, Y.A. Colina-vargas¹, D. Tresandí¹, C. Morgenstern², J. Rodiera¹¹Centro Médico Teknon, Grupo QuirónSalud, Anaesthesiology Department, Barcelona, Spain, ²Centro Médico Teknon, Grupo QuirónSalud, Neurosurgery Department, Barcelona, Spain

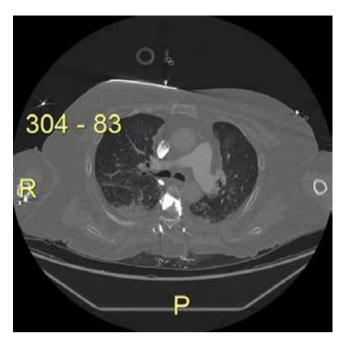

Background: Bone cement implantation syndrome (BCIS) related to polymethylmethacrylate (PMMA) in complex spine surgeries is rare¹. While vascular cement leakage occurs in -9% of cases involving cement-augmented pedicle screw instrumentation (CAPSI), BCIS symptoms are uncommon, with an incidence of 0.2%–1.4% .93% of leaks are perivertebral and asymptomatic². This report describes a severe BCIS case necessitating cardiopulmonary resuscitation (CPR) in the prone position during spine surgery.

Case report: A 76 y.o hypertensive woman(BMI 31.5) with severe osteoporosis and multiple comorbidities underwent thoracolumbar CAPSI. Anesthesia was managed using total intravenous opioid-free anesthesia. During thoracic PMMA cementation, she developed sudden hypoxemia, hypotension, and asystole.

Advanced CPR in prone restored circulation. TEE showed no features of VD dilatation or dysfunction. CT angiography revealed PMMA leakage into intrathoracic veins but no conclusive image of pulmonary embolism (PE). Post-surgery,she recovered in the ICU. One year follow-up, she was fully able to walk and pain-free.

Discussion: BCIS pathophysiology involves mechanical embolization and vasodilatory immunohumoral responses to PMMA. Contributing factors include severe osteoporosis, rheumatic arthritis, extensive screw placement, and prior PMMA exposure. Sudden vasoplegia and Bezold-Jarisch vasovagal reflex can explain the symtoms with no evidence of severe PE.

This case highlights the importance of identifying BCIS risk factors, particularly in spine surgeries involving cement augmentation to reduce complications.

References:

1. Al-Husinat L et al.Bone Cement and Its Anesthetic Complications: A Narrative Review.J Clin Med 2023;12:2105.
2. Mueller J.U. et al.Cement leakage in pedicle screw augmentation:a prospective analysis of 98 patients and 474 augmented pedicle screws.J Neurosurg Spine.2016;25(1):103-9.

Learning points: This case underscores the complexity of BCIS in spine surgeries with CAPSI. Sudden vasoplegia and bradycardia progressing to asystole were likely due to hypersensitivity to polymethylmethacrylate (PMMA), triggering immunological vasodilation and a vasovagal response via the Bezold-Jarisch reflex.

10AP13-10

Evaluation of modified early warning score (MEWS) in Perioperative Medicine: A Pilot Study in a French Military Teaching Hospital

<u>C. Pernod</u>¹, Q. Mathais¹, H. De Malleray¹, J. Schmitt¹, E. Meaudre¹, J. Bordes¹

¹Military teaching hospital of Toulon, Intensive Care Unit, Toulon, France

Background and Goal of Study: The Modified Early Warning Score (MEWS) (1-3) is a is a simple bedside scoring system used to identify clinical deterioration. Yet its application in perioperative medicine remains underexplored. This pilot study aims to describe the implementation of MEWS-based surveillance in perioperative care, focusing on its role in early detection and management of complications.

Materials and Methods: We conducted a retrospective, singlecenter study at a French military teaching hospital, using a database comprising data from 3,968 patients and 59,087 MEWS measurements, covering the period from April 2021 to September 2024. The study focused on postoperative monitoring using the MEWS to assess its impact on patient outcomes in thoracic, visceral, and gastrointestinal surgical units.

Results and Discussion: Out of the 3,968 patients, 99 (2.5%) required unscheduled intensive care unit (ICU) admissions. The MEWS score distribution was as follows: score 0 (46.7%), score

1 (30.5%), score 2 (13.2%), score 3 (5.7%), score 4 (2.3%), and scores >4 (1.6%). Patients with a MEWS score >4 were flagged for immediate medical assessment.

Conclusion(s): Our results suggest that in perioperative period the majority of patients had low MEWS scores, while higher scores were less frequent but potentially associated with the need for ICU care. The MEWS score could be a useful tool for triaging patients in perioperative medicine. It may help identify patients at risk of deterioration, potentially reducing non-scheduled ICU admissions or allowing for earlier and more appropriate intensive care intervention.

However, further research would be needed to confirm these findings and better understand the clinical benefits of routine MEWS monitoring in this setting.

10AP13-11 Magnesium sulphate: a game changer in postoperative analgesia

P. Vaz Salvador¹, <u>J. Santos</u>¹, D. Ramos², D. Afonso¹, E. Lima¹

¹ULS Entre Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal, ²Universidade de Aveiro, Matemática, Aveiro, Portugal

Background and Goal of Study: In bariatric surgery, opioid-free analgesia and reduction of post-operative complications are critical. This study evaluated the efficacy of intraoperative magnesium sulphate (MgSO₄) compared to its use exclusively in the Post- Anaesthesia Care Unit (PACU) and the absence of its use. The primary endpoint was pain intensity at PACU admission. Secondary endpoints included pain at PACU discharge, at 6, 12, and 24 hours postoperatively, and the incidence of overall and pain-related complications.

Materials and Methods: This retrospective study analysed 324 patients who underwent bariatric surgery between 01/2023 and06/2024. Patients with incomplete records were excluded. Non-parametric tests (Kruskal-Wallis and Dunn) assessed differences in pain scores, while logistic regression evaluated complications. Sociodemographic variables, comorbidities, and concurrent analgesics were examined.

Results and Discussion: Patients receiving intraoperative $MgSO_4$ reported the lowest pain scores at PACU admission (1.29±1.62) compared to PACU-only administration (1.96±1.65; p=0.0073). Pain at PACU discharge was similarly low across all groups (p=0.259) - in the PACU- only group, there was asignificant reduc-

tion in pain from admission to discharge (p=9.16x10-7). However, patients receiving MgSO₄ onlyin the PACU required more ketamine than the ones receiving it intraoperatively.

No significant differences were observed between groups in nonpain-related or overall complications (p>0.9). Pain-related complications were fewer in the MgSO₄- using groups (<3%) compared to the non-magnesium group (6.9%).

The analysis confirmed no confounding effects of intraoperative analgesics or sociodemographic differences.

These findings underscore the efficacy of this drug, particularly used intraoperatively, its safety regarding postoperative complications, and the importance of further research into its role in multimodalanalgesia and potential to minimise opioid use and complications.

10AP13-12

Intraoperative EEG reflects the stress-reducing effects of audiovisual sedation, showing its comparability to conventional propofol sedation in regional anesthesia

 I.S. Grüner¹, L. Trinh¹, J. Ostertag¹, G. Schneider¹,
 K. Wagner¹, M. Kreuzer¹
 ¹Technical University Munich, Department of Anesthesiology, München, Germany

Surgery using regional nerve blocks allows for safe and cost-effective procedures while avoiding the risks commonly associated with general anesthesia. Still, many patients opt for a light propofol sedation to mitigate perioperative anxiety.

We hypothesized that utilizing immersive video glasses to calm patients as a form of non-pharmacological sedation is comparable in its anxiety and stress-reducing effects.

We analyzed preliminary data from 90 patients undergoing surgery with regional anesthesia. Subjects were assigned to either the control group receiving propofol or the intervention group receiving video glasses for sedation.

We evaluated physiological markers (frontal EEG low/high beta ratio) and subjective measures (Hospital Anxiety and Depression Scale, HADS; Positive and Negative Affect Schedule: Negative Affect, PANAS NA) as indicators of stress and anxiety.

For comparison, the beta ratio and the relative change between pre-and post-surgery questionnaire scores were calculated, and we performed the Mann-Whitney-U- and the Wilcoxon-Signed-Rank-Test and computed the complementing effect sizes Cohen's d and Cohen's U3.

The EEG analysis depicted in Figure 1A demonstrated a significant increase and small effect in the beta ratio in the intervention group over the first 40 minutes (p= 0.036; Cohen's U3, 0.58 [0.32 0.74]), which correlates with relaxation and reduced anxiety.

This reduction was also present in self-reported anxiety and stress levels after surgery, with a statistically significant decrease in the intervention group (HADS: p<0.001; PANAS NA: p<0.001) and the control group (HADS: p<0.001; PANAS NA: p<0.001). As shown in Figure 1B and C, no significant differences and only small effects were found in the relative changes between the

groups (HADS: p = 0.3118, Cohen's d, -0.19 [-0.62 0.24]; PANAS NA: p = 0.328, Cohen's d, -0.22 [-0.65 0.21]).

Subjective stress and anxiety significantly decreased in both groups; the increase in relaxation-related brain activity further supported the success of audiovisual sedation. These results show similar outcomes and present audiovisual sedation as a promising alternative for clinical use.

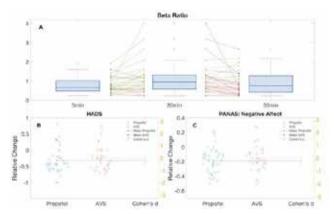

Figure 1.

Anaesthetist-led perioperative transthoracic echocardiography service - a clinical audit

C.F. Yim1, K.C. Tse1

¹Tseung Kwan O Hospital, Department of Anaesthesia & Operating Theatre Services, Hang Hau, Hong Kong, SAR of China

Background and Goal of Study: The growing enthusiasm for transthoracic echocardiography (TTE) among non-cardiac specialties has led to development of a number of focused TTE protocols. In Hong Kong, anaesthetist-led perioperative echocardiography clinic is gaining popularity and rapidly developing. Our hospital is one of the first in the territory to establish an anaesthetist-led TTE service, with a primary aim of fast-tracking patients who require focused TTE in the perioperative period. This audit aims to assess whether TTEs done by anaesthetists are of comparable standard as formal TTEs done by cardiologists.

Materials and Methods: Data were collected from the past 5 years (November 2019-October 2024). All patients who have attended the anaesthetist-led TTE clinic from the period were traced on the electronic patient record(CMS). Focused TTEs done by anaesthetists with formal or so-called "full" TTEs (performed or reported by cardiologists) within the 1-year timeframe were included in order to assess the agreement (or concordance). A total of 405 patients were traced and 34 patients met the set criteria. Cohen's kappa analysis is used to measure inter-observer agreeability for binary/categorical variables e.g. presence of valve pathology, while Bland-Altman plot and Intraclass correlation coefficients (ICC) are used for continuous data.

Out of all the measurements in the TTE studies, left ventricular ejection function (LVEF) and the presence of any stenotic valvular pathologies especially mitral or aortic stenosis are of clinical significance perioperatively.

Results and Discussion: 20 male/14 female patients with average age of 71 (33-91) were examined. There was good agreement for LVEF with little to no systematic bias (ICC 0.61, p<0.001). The

Cohen's Kappa for diagnosing mitral stenosis (κ = 1, p<0.001) and aortic stenosis (κ = 0.87, p<0.001) showed that there was excellent agreement.

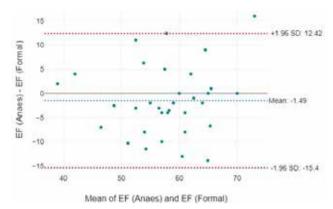

Figure. Bland-Altman plot for left ventricular ejection fraction (LVEF) measurement between TTE done by anaesthetists and by cardiologists.

Conclusion(s): There was a high agreement between TTE done by anaesthetists and by cardiologists for clinically significant cardiac conditions perioperatively.

Severe intraoperative hypertension due to unknown ectopic pheochromocytoma surgical removal

G. Huti¹, A. Abdyli¹, F. Coniglione¹, R. Domi¹, K. Lilaj², D. Hoxha¹

¹American Hospital Tirana, Anesthesia and Intensive Care, Tirana, Albania, ²University of Medicine Tirana, Anesthesia and Intensive Care, Tirana, Albania

Background: Pheochromocytomas are rare endocrine tumors, secreting large amounts of endogenic catecholamines. We reported a 63-year-old woman undergoing unknown ectopic pheochromocytoma surgical removal.

Case Report: A 63-year-old woman with type II diabetes and hypertension was scheduled for surgery to remove a giant intraabdominal tumor of unknown origin. Angio CT revealed a 12.3 x 10.7 cm heterogeneous mass in the hepatic hilum, suggesting an abscess or hydatid cyst. MRI suggested a benign tumor. Preoperative tumor markers were elevated (AFP: 33.81 ng/ml, CEA: 14.5 ng/ml), but serological tests for Echinococcus antibodies were negative.

The patient, classified as ASA 2, underwent preoperative evaluation revealing hypertension and mild palpitations, but no arrhythmias. Standard monitoring was supplemented with central venous and radial artery cannulation. Severe hypertension (200/130 mmHg) was noted initially, decreasing to 145/95 mmHg after induction.

During surgery, exposure attempts led to severe hypertension and tachycardia (270/150 mmHg) with bilateral mydriasis. Hypertension was managed with deepened anesthesia, nitroglycerin, and nicardipine. The lowest recorded blood pressure was 150/70

mmHg. After tumor removal, hypotension required noradrenaline. A postoperative brain CT was normal. The patient was extubated one hour after surgery with no neurological deficits. Noradrenaline was discontinued after 12 hours, and the patient remained stable (120-140/65-78 mmHg, sinus rhythm). She was transferred to the ward on the second postoperative day and referred to an endocrinologist for further care

Discussion: Unknown pheochromocytomas are rare, but with increased perioperative mortality. The patient was scheduled for intraabdominal tumor removal but resulted intraoperatively to be clinically pheochromocytoma. The pathology report confirmed the diagnosis. Adequate monitoring and good communication with surgeons can guarantee success and patient safety.

- 2. DiMaria CN, Rasquin LI, Hung Pinto WA. The Highs and Lows of an Unknown Pheochromocytoma in an Elderly Patient. Case Rep Endocrinol. 2019; 2019:5707968.

Learning Points:

- 1. A thorough preoperative evaluation is essential to identify potential signs of undiagnosed pheochromocytoma.
- 2. Close intraoperative collaboration with the surgical team is crucial.

11AP10-8

Impact of intravenous iron administration to patients with iron deficiency anemia before major abdominopelvic cancer surgery

T. Guyot¹, <u>J. Elmawieh</u>²

¹Université de Paris - Sorbonne, Médecine, Paris, France, ²Gustave Roussy Cancer Campus, Anesthesiology, Villejuif - Paris, France

Background and Goal of Study: Perioperative iron deficiency anemia (IDA) is associated with significant morbidity. Delta-hemoglobin (Δ Hb), defined by the difference between preoperative and discharge hemoglobin values, is described in the literature and seems associated with postoperative outcomes. Discharge anemia in cancer patients can limit tolerance to further cancer therapies.

This study aims to test the variation in ΔHb according to intravenous iron administration in patients with IDA having major abdominopelvic cancer surgery.

Materials and Methods: We included retrospectively adult patients with abdominopelvic cancer and preoperative IDA who had undergone major surgery for tumor resection between September 2019 and August 2022. Anemia was defined as hemoglobin<12g/dL, and iron deficiency as ferritin<100 ng/mL or ferritin<300 ng/ml with transferrin saturation coefficient<20%. Participants received 1g intravenous ferric carboxymaltose at least 7 days before the procedure (D-7 group), or upon admission the day before the surgery (D-1 group), or did not receive any intravenous iron (control group). The primary endpoint was ΔHb defined by the difference of hemoglobin level between preoperative and discharge values. A multivariable analysis was conducted using a linear regression model to analyze ΔHb according to iron supplementation group, blood loss and blood transfusion. Secondary endpoints were blood transfusion and postoperative complications (Clavien-Dindo classification).

Results and Discussion: 99 patients were included: 36 patients in D-7 group, 29 in D-1 group and 34 in control group. There was a significant difference in Δ Hb between the group receiving intravenous iron (D-7 and D-1, mean Δ Hb=0.34) and the untreated group (control, mean Δ Hb=0.97) with a p-value=0.036. No difference in Δ Hb between D-7 and D-1 groups.

In multivariable analysis, blood loss, transfusion, and intravenous iron were independently associated with changes in Δ Hb (p-value=0.011, 0.004, 0.013, respectively). Secondary endpoints were all non-statistically different.

Conclusion(s): Preoperative administration of intravenous iron in patients with IDA before major abdominopelvic cancer surgery was associated with reduced delta hemoglobin from the preoperative value to that at discharge.

Threshold heterogeneity of perioperative hemoglobin drop for acute kidney injury after noncardiac surgery: a propensity score weighting analysis. BMC Nephrol 2022

General Anaesthesiology

11AP01-1

Interdisciplinary action of an anaesthesiologist: a case report of an active oropharyngeal bleeding with no identified focus

A.S. M. Fernandes¹, <u>T. Silva</u>¹, A. Araújo¹

¹Unidade Local de Saúde de Santo António, Department of Anaesthesiology, Porto, Portugal

The anaesthesiologist plays a fundamental role in promoting the best surgical outcome for the patient. We present a clinical report of an active bleeding patient and the multidisciplinary approach necessary to identify its source.

A 72-year-old male patient with a personal history of peripheral arterial disease, dyslipidemia, smoking, and an aorto-bifemoral bypass surgery. He presented at the Emergency Department with an acute ischaemia of the right lower limb, grade Ilb, and underwent a thromboembolectomy of the bypass right branch.

An intravenous general anaesthesia was performed, with placement of an i-Gel® 4. Preoperative haemoglobin was 14.4g/dl, blood loss was 600ml and no surgical complications arose. During the emergence from anaesthesia, a large oropharyngeal bleeding was noted, with no identified focus. A bolus of vasopressors was needed due to transient hypotension.

Re-induction of anaesthesia and orotracheal intubation were performed, followed by bronchofibroscopy, which excluded the presence of blood in the trachea. Gastric aspiration of 400ml of blood. The upper GI endoscopy showed a large, fresh, adherent clot occluding the duodenum lumen.

A review of the CT scan previously obtained led to the suspicion of an aorto-enteric fistula and the patient underwent percutaneous aortic expander placement. Anticoagulation was reversed with protamine sulfate (aPTT ratio 2.94) and tranexamic acid was given. Due to a revised haemoglobin of 9.2g/dl and 1.16 aPTT ratio, it was requested 1 unit of RBCs and fresh frozen plasma. No further need for vasopressors.

The patient was admitted to the ICU, sedated and mechanically ventilated. Postoperative lactate levels peaked at 2.1mmol/L and then steadily decreased.

Four re-interventions were required due to rethrombosis of the branch in the context of septic shock, including a bi-axillary bifemoral bypass and D4 duodenal resection, culminating in a transfemoral amputation because of irreversible right inferior limb ischaemia. After a 94-day hospitalization, the patient was discharged to a Rehabilitation Unit.

Anaesthesiology focuses on patient safety in the perioperative period. This case highlights the diagnostic and therapeutic role of the anaesthesiologist in the management of an active bleeding patient, leading to a swift resolution of an otherwise possibly fatal condition.

- Active participation of the anaesthesiology team is essential to the differential diagnosis in cases of oropharyngeal haemorrhage.

11AP01-2

Case report: anesthetic challenges and strategies in a patient with pulmonary hypertension

A. Aly1, A. Abdelaal1

¹Princess Alexandra Hospital, NHS Trust, Anaesthesia, Harlow, United Kingdom

Background: Pulmonary Hypertension (PHT)

Case Report: A 37 years old female presented with right iliac fossa pain, diagnosed with ectopic pregnancy. The scan showed ruptured sac in right fallopian tube. Because of intra-peritoneal collection evidence, surgical decision was for emergency oophorectomy.

Anaesthetic review revealed that she is known idiopathic pulmonary hypertension on taladenfil 40mg, selexigap 200mcg, Macitentan 10mg. Medical records traced diagnosis in 2022, showed evidence for dilated right atria and ventricle. Along with limited exercise tolerance with history of chest pain and fainting < 20 seconds.

At time of examination, patient was haemodynamically stable, as no tachycardia and blood pressure were maintained, however, surgical decision was for urgent intervention for likely possibility for further deterioration based on scan assessment.

At briefing, surgical team was advised to adopt open surgical approach rather than laparoscopic one to avoid complications expected. Spinal anaesthesia was chosen as best modality, along with continuous invasive blood pressure monitoring. Spinal drugs used bupivacaine 0.5% 3.5 ml and diamorphine 500mcg. Before starting spinal anaesthesia, infusion of vasopressor (metaraminol) commenced.

Intraoperatively, target was to keep mean arterial blood pressure (MAP) at 65mmHg. During operation, no adverse events were recoded. Minimal blood loss was estimated.

At recovery, patient continued metaraminol as to achieve target MAP. Later, transferred to HDU of closer monitoring. Later after 2 days, Discharged uneventfully.

Discussion: PHT is defined as mean pulmonary pressure equal or > 25 mmHg. Despite being on 3 agents, moderate pulmonary pressure on ECHO was detected. Initially, surgical technique was proposed as laparoscopic approach, however, after MDT meeting, accepted to be open one as increased intra-abdominal pressure reduce venous return and cardiac output.

In addition, with CO2 insufflation, this increases the end-tidal CO2, which affects negatively pulmonary vascular resistance (VR). In agreement, anaesthetic technique preferred was spinal block to avoid complication associated with general anaesthesia as most of anaesthetic drugs being negative inotropic.

Also, positive pressure ventilation can affect small pulmonary vessels can precipitate RV failure. In addition, spinal anaesthesia known to have a minimal or neutral effect on pulmonary VR.

The reason for metaraminol infusion was to counteract predictable decrease in systemic vascular resistance to maintain vital organs perfusion pressure including right ventricle.

- 2. British Journal of Anaesthesia, Volume 126, Issue 4, 774 790

Learning Points: Central axial block (spinal anaesthesia) is considered as a safe alternative when applicable to avoid complications associated with general anaesthesia in cases of pulmonary hypertension.

11AP01-3

Anaphylactic shock induced by the combination of midazolam and patent blue dye

B. Lagarteira¹, <u>M. Flor</u>¹, J. Rego¹, M. Bento¹
¹Unidade Local de Saúde do Tâmega e Sousa, Anesthesiology, Penafiel, Portugal

Background: Perioperative anaphylaxis during anesthesia is a rare, but life-threatening condition. (1) The diagnosis can be challenging, as classic symptoms like rash are absent in severe cases. (1)

We report a case of anaphylactic shock following the administration of midazolam, a rare anaphylaxis trigger (2), and patent blue dye during breast cancer surgery.

Case Report: A previously healthy 30-year-old woman scheduled for a left mastectomy developed cardiovascular collapse unresponsive to vasopressors, shortly after general anesthesia induction and patent blue dye injection.

Although there were no respiratory or skin manifestations, the situation was interpreted as a possible anaphylactic shock. She was treated with epinephrine boluses and fluids, followed by a continuous epinephrine infusion due to partial response; rash and edema appeared 20 minutes later. She was stabilized and the surgery was postponed.

Elevated tryptase levels at 2 hours supported the diagnosis, with skin testing four weeks later confirming midazolam and patent blue dye as allergens. The surgery was safely performed five weeks later, omitting these agents.

Discussion: This case highlights the diagnostic challenges of perioperative anaphylaxis. The onset of cardiovascular collapse, unresponsive to vasopressors following the administration of patent blue dye and induction agents, strongly indicated anaphylaxis. Typical cutaneous symptoms emerged only 20 minutes after resuscitation, aligning with other reports of severe cases (2).

Tryptase levels supported the diagnosis, and skin tests identified midazolam and patent blue dye as causative agents. While patent blue dye is a relatively common trigger, midazolam is not; however, it can still provoke severe hypersensitivity in rare cases such as this. (2)

This case underscores the need to identify triggers for future management.

Neurologic alterations following cerebral angiography: serotonin syndrome or the butterfly effect

S. Tavares¹, <u>J. Assuani Mang</u>i¹, I. Tomé¹, D. Andrade¹ ¹*Unidade Local de Saúde de São José, Anesthesiology, Lisboa, Portugal*

Background: Serotonin syndrome (SS) is a relatively rare clinical condition that can arise in the perioperative period. The clinical picture can be life-threatening, and comprises a triad of changes in mental status, neuromuscular abnormalities and autonomic hyperreactivity.¹

Interventional Neuroradiology procedures have the potential for neurologic complications in the postoperative period.²

This can make more difficult the adequate diagnosis of SS.

Case Report: A 30-year-old woman with no known previous illnesses or usual medication was admitted for an elective endovascular embolization of a cerebral arteriovenous malformation (AVM). She was submitted to general anesthesia with a propofol infusion and an initial bolus of fentanyl and rocuronium.

The procedure lasted for 2.5 hours, but was unsuccessful in treating the AVM. Ondansetron was administered at the end of the procedure, and the patient emerged uneventfully. In the following 24h, she presented with worsening of her mental status, muscle spacity, clonus in her left hand and hyperreflexia. She became progressively hypertensive, and mild hyperthermia was identified (38.2°C).

A hypothesis of SS secondary to propofol, fentanyl and ondansetron was advanced, and the patient managed accordingly. Complete resolution of symptoms was achieved under the course of the next three days.

The patient ended up needing a second cerebral angiography for better treatment planning. Conscious sedation with dexmedeto-midine infusion was implemented, and no adverse events were observed.

Later, she was successfully treated with radiosurgery.

Discussion: SS is a challenging diagnosis to make in the perioperative period, and is usually caused by multiple drug interactions. Concurrent use of antidepressants is a strong association, which this patient lacked!

In fact, other causes were proposed during her stay, including possible grand mal and contrast-induced encephalopathy. Nevertheless, the initial hypothesis was taken in account in the anesthetic approach for the second procedure.

Considering the patient's age, it is reasonable to assume that she will likely develop other health problems during her life, making unpredictable how this diagnosis might affect future care.

References:

1. BJA Education. 2020; 20(1): 10e17 2. BJA Education. 2016; 16 (5): 147–152

Learning Points: SS is a challenging diagnosis in the perioperative period. This case raises awareness to the impact of clinical decisions in patients' future care.

11AP01-5 Improving trauma theatre efficiency: a quality improvement project implementing a "golden trauma patient" initiative in Scarborough Hospital, UK

S. Khaliq¹, B. Chandler², C. Wong³, N. McWhirter², A. Tamburini²

¹Hull University Hospitals, Anaesthesia, Hull, United Kingdom, ²Scarborough Hospital, Anaesthesia, Scarborough, United Kingdom, ³Hull University Hospitals, Emergency, Hull, United Kingdom

Background and Goal of Study: Significant inefficiencies, characterized by substantial delays in theatre start times, plague emergency orthopaedic services at Scarborough Hospital. These delays contribute to elevated operational costs and potentially compromise patient care. This quality improvement (QI) project aimed to mitigate these inefficiencies and enhance theatre efficiency by implementing a structured "Golden Trauma Patient" (GTP) initiative.

Materials and Methods: Baseline data (January-May 2024) established existing inefficiencies. A "Golden Trauma Patient" (GTP) initiative, involving pre-operative preparation and anaesthetist assessment, was implemented using a standardized operating procedure (SOP). Two PDSA cycles evaluated the intervention's impact on theatre start and turnaround times.

Figure. Golden Trauma Patient: Orthopedics lists Start date: 28 May 2024

Results and Discussion: PDSA cycle 1 yielded a significant reduction in theatre start times, although turnaround times increased. While PDSA cycle 2 maintained the improved start times (p=0.07), consistent improvement in turnaround times was not observed. These findings highlight the need to address challenges of communication and staff engagement to achieve sustained improvements in start and turnaround times.

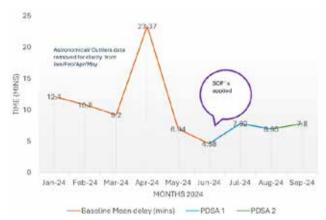

Figure. Monthly delay start times (minutes).

Figure. Turnaround times (mins).

Conclusion(s): The GTP initiative reduced emergency orthopaedic theatre start times. However, sustained improvement necessitates addressing protocol adherence, communication, and staff engagement to optimize start and turnaround times. Further refinement and robust implementation strategies are crucial for long-term efficiency gains.

11AP01-7

Use of transesophageal echocardiography in radical nephrectomy with inferior vena cava tumor thrombectomy: a case series

E. Lacoba¹, C. Ibañez Esteve², B. Tena Blanco¹, G. Urquijo Fernández¹, M. Magaldi Mendaña¹ ¹Hospital Clínic of Barcelona, Department of Anaesthesia, Pain Management and Critical Care, Barcelona, Spain, ²Hospital Clínic of Barcelona, Department of Cardiothoracic Anesthesiology, Barcelona, Spain

Background and Goal: Renal cell carcinoma is a type of kidney cancer that can spread locally, forming a tumor thrombus within the renal vein. This thrombus may extend into the inferior vena cava (IVC) or even reach the right atrium, complicating surgical management and increasing the risks of thrombus migration and cardiovascular complications.

The use of transoesophageal echocardiography (TOE) is increasing in radical nephrectomy with IVC tumour thrombectomy. TOE provides detailed characterization of thrombus extension, facilitating optimal selection of the venous clamp site and enabling real-time detection and prevention of potential complications. The recommendations for TOE use according to different guidelines are ambiguous and evidence is limited.

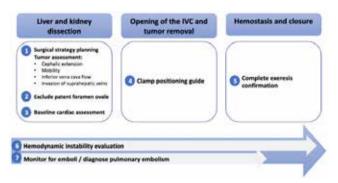

The goal of the study is to describe our experience with the TOE implementation during this type of surgery.

Methods: We conducted a retrospective review of 5 patients scheduled for open resection of renal cell carcinoma with level III-IV IVC invasion between January 2019 and December 2024. An specific TOE protocol for this surgery (figure 1) had been previously implemented. TOE was performed by an expert anaesthesiologist in echocardiography.

Results: In Table 1 we present a total of 7 findings in the 5 registered patients. All findings led to specific early interventions that significantly modified clinical management.

Patient	Findings	Further actions and management / impact
1	Supplemental morphologic information (Right Atrium tumour extension)	Reassessment of the need for cardiopulmonary bypass
	Hypovolemia	Fluid therapy administration
2	Incomplete resection	Reclamping and new resection
	Refractory hypotension secondary to systolic anterior motion	Fluid therapy administration, control of heart rate and optimisation of mean blood pressure
3	Pericardial effusion	Surgical drainage
4	Right atrial emboli	Echographic monitoring for right ventricular dysfunction
5	Refractory hypotension secondary to systolic anterior motion	Fluid therapy administration, control of heart rate and optimisation of mean blood pressure

Table 1. TOE findings and further management.

Conclusions:

- In this case series, the use of TOE has provided useful information in all patients. Specific interventions were conducted and successfully resolved clinical problems.
- Developing specific TOE protocols could address knowledge gaps in non-cardiac anesthesia teams, optimizing patient management and enhancing clinical outcomes.

11AP01-8

Enhancing total intravenous anesthesia monitoring with bispectral index (BIS) and patient state index (PSI): a prospective randomized comparison of remimazolam and propofol on depth, recovery, and haemodynamics

M. Cindric¹, L. Lijović¹, M. Grzelja¹, N. Kovač¹, T. Radočaj¹ ¹University Hospital Centre Sestre Milosrdnice, Department of Anaesthesiology and Intensive Care, Zagreb, Croatia

Background and Goal of Study: Remimazolam, an ultrashort-acting benzodiazepine, has recently been approved for general anesthesia in Europe, expanding its clinical applications. Despite its growing utilization, the comparative effects of remimazolam and propofol on anesthesia depth, as measured by bispectral index (BIS) and patient state index (PSI), remain underexplored. This study aims to compare the effects of total intravenous anesthesia with remimazolam and propofol on BIS-PSI correlation, as measures of anesthesia depth, along with recovery profiles, haemodynamics and side effects.

Materials and Methods: This prospective, randomized, singleblinded study included ASA II and III patients undergoing laparoscopic cholecystectomy. Participants were randomized into a remimazolam group, receiving remimazolam (0.25 mg/kg induction dose), and a propofol group, receiving propofol (2 mg/kg induction dose). Both groups received remifentanil, with continuous drug doses titrated to maintain target BIS values 40–60 and PSI values 25–50, defining general anesthesia. BIS and PSI monitors were placed simultaneously on each patient.

The primary outcome was the correlation between BIS and PSI during anesthesia.

Secondary outcomes included times to achieve adequate anesthesia depth (BIS<60, PSI <50), recovery times (BIS > 80, PSI > 50 and > 75, extubation), haemodynamic parameters (systolic and diastolic BP).

Results and Discussion: Data from 20 patients revealed a strong, statistically significant correlation between BIS and PSI values in both groups. Repeated measures correlation were r=0.938 (p < 0.001, 95% CI: [0.910, 0.960] for remimazolam (n=9) and r=0.937 (p < 0.001, 95% CI: [0.910, 0.960]) for propofol (n=11). Propofol demonstrated faster induction than remimazolam with shorter times to achieve BIS < 60 (30.0 \pm 16.5 seconds vs. 49.0 \pm 44.0 s, respectively, p = 0.017) and PSI < 50 (73.0 \pm 18.0 s vs. 155.9 \pm 73.6 s, respectively, p = 0.010).

Recovery was also faster in the propofol group, with shorter times to BIS > 80 (411.7 \pm 178.1 s vs. 611.1 \pm 201.7 s, p = 0.031) and extubation (448.2 \pm 191.2 s vs. 675.9 \pm 182.6 s, p = 0.015). Linear-mixed effects model observed no statistically significant differences between groups for hemodynamic parameters.

Hypotension occurred more frequently in the propofol group (36.4%) than in remimazolam group (22.2%), but the difference was not statistically significant. No significant differences were observed in PSI > 50 and > 75 recovery times or total anesthesia duration.

Conclusion(s): Both remimazolam and propofol demonstrated strong positive BIS and PSI correlations, reinforcing the reliability of these agents for monitoring anesthesia depth. Propofol facilitated faster induction and recovery, while remimazolam's characteristics may offer advantages for prolonged procedures. These findings highlight the utility of BIS and PSI in monitoring anesthesia depth with both agents.

11AP01-9

The objective evaluation on facial flushing through a laparotomy by a pocket-sized color sensor; a multicenter observational study

Y. Ikki¹, T. Tamura²

¹Handa City Hospital, Anesthesiology, Handa, Japan, ²Nagoya University, Anesthesiology, Nagoya, Japan

Background and Goal of Study: Mesenteric traction syndrome (MTS) is associated with facial flushing, hypotension and tachycardia. Facial flushing is a subjective assessment whose diagnostic criteria is ambiguous. We hypothesized that quantifying the color tone would allow us to evaluate facial flushing objectively in undiagnosed MTS patients.

Materials and Methods: This study was a multicenter observational study. Patients scheduled for pancreaticoduodenectomy or distal pancreatectomy for laparotomy surgery were enrolled. Patients taking NSAIDs or antihistamines were excluded. Using a Nix color sensor (Nix Sensor Ltd., Ontario, Canada), we measured the value of redness (Lab color system a- value) at four points of face periodically before and 90 minutes after skin incision.

Simultaneously, pulse rate and arterial blood pressure were recorded. An anesthesiologist at each case diagnosed with MTS and assessed the degree of facial flushing on a three-point scale (Level 0; no flushing, Level 1; slight flushing, Level 2; complete flushing).

We classified patients into two groups. Patients diagnosed with MTS were assigned to MTS group and the others were assigned to non-MTS group. In non-MTS group, we evaluated the ratio of change in a-value in patients with tachycardia and decreased blood pressure with a subjective rating of less than Level 2. The ratio of change was defined as the ratio of the difference between the maximum value (a-value and heart rate) or minimum value (blood pressure) and base value. This base value meant the average value 5 minutes before and after skin incision. EZR software was used for the statistical analyses.

Results and Discussion: Thirty-eight patients were included, 14 in the MTS group and 24 in the non-MTS group. The median ratio of change in a-value [interquartile range] for the four facial points was 0.45 [0.43-0.49] vs. 0.25 [0.12-0.55] (p=0.02) in the MTS and non-MTS groups. The ratio of change in heart rate was 0.45 [0.38-0.52] vs. 0.23 [0.17-0.27] (p<0.01) and the ratio of change in mean arterial blood pressure was -0.26 [-0.41-(-0.20)] vs. -0.14 [-0.24-(-0.09)] (p=0.01). In the non-MTS group, only 1 out of 24 cases met the threshold value of the ratio of change in heart rate and mean arterial blood pressure calculated from the MTS group and the subjective evaluation was less than Level 2.

Conclusion: The demand of objective evaluation for MTS diagnosis was rare, therefore conventional subjective evaluation can be enough.

11AP01-10 Pediatric patients with Autism Spectrum Disorder (ASD): what anesthetic management?

<u>G. Montenero</u>¹, G. Sfregola¹, A. Ragone¹, M. Ciuffreda², C. Piangatelli², D. Galante¹

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, ²Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Pediatric patients with Autism Spectrum Disorder (ASD) present unique challenges in anesthesia management due to sensory sensitivities, communication difficulties, and behavioral issues. Both general anesthesia (GA) and regional anesthesia (RA) are commonly used for pediatric surgeries, but their application in children with ASD may lead to distinct complications.

This study aims to evaluate the complications and challenges encountered in 18 pediatric patients with ASD who underwent various surgical procedures requiring either GA or RA.

Materials and Methods: A survey was conducted in 10 hospital anesthesia departments on 35 pediatric patients diagnosed with ASD who underwent surgery between 2020 and 2023. The patients received either GA or RA (spinal, epidural, or peripheral nerve blocks) depending on the surgical procedure. Data on patient demographics, anesthetic techniques, intraoperative management, complications, and postoperative recovery were collected. Special attention was paid to challenges related to anesthesia induction, intraoperative issues, and recovery, particularly focusing on how ASD-related characteristics affected anesthetic management.

Results and Discussion: Of the 35 patients, 26 received GA, and 9 received RA. Common challenges included difficulty with preoperative communication and anxiety, with 60% of patients exhibiting resistance to induction or difficulty remaining still. For GA, complications included delayed emergence (30%) and increased agitation during recovery (40%). In patients receiving RA, difficulties included challenges in maintaining cooperation during block placement (42%) and postoperative pain management (35%). No severe adverse events were reported, but several patients required additional sedation for anxiety or sensory overload during the perioperative period.

Conclusion(s): Anesthesia in pediatric patients with ASD requires careful planning and individualized strategies. Both GA and RA can be safely used in this population, but complications such as anxiety, difficulty with sedation, and sensory sensitivities are common. Tailored anesthetic approaches, preoperative education, and close postoperative monitoring are essential to minimize risks and improve outcomes. Further studies are needed to optimize anesthesia protocols for children with ASD.

11AP01-11

The comparison of the incidence of postoperative delirium and emergence agitation between remimazolam and propofol in general anesthesia: a systematic review and meta-analysis

C.-H. Ho¹, C.-Y. Chang¹, C.-W. Lu¹²¹
¹Far Eastern Memorial Hospital, Department of
Anesthesiology, Banqiao Dist, New Taipei City, Taiwan,
²Yuan Ze University, Taoyuan, Taiwan, Department of
Mechanical Engineering, Taoyuan, Taiwan

Background and Goal of Study: Postoperative delirium (POD) is a common neurocognitive complication following surgery, and associated with an increased risk of postoperative complications and mortality. (1) Guidelines currently discourage the use of benzodiazepines perioperatively, which is linked to an elevated risk of developing POD. (2)

However, evidence regarding the risk of POD and emergence agitation associated with remimazolam, an ultra-short-acting benzo-diazepine used for procedural sedation and general anesthesia, remains limited.

Materials and Methods: We perform a comprehensive literature search across 2 electronic databases, PubMed and the Cochrane Central Register of Controlled Trials. The search strategy utilizes the keywords "remimazolam" AND "propofol" AND ("delirium" OR "emergence agitation"), supplemented by MeSH terms for enhanced precision.

We include all randomized controlled trials (RCTs) that compared the incidence of postoperative delirium and emergence agitation between remimazolam and propofol in patients undergoing general anesthesia. Data extraction, synthesis, and risk of bias assessment are conducted.

Results and Discussion: A total of 6 articles that meet the inclusion criteria. The pooled data indicate no significant difference in the incidence of postoperative delirium (OR, 1.06; 95% CI, 0.75 to

1.49; n = 1270; p = 0.63; I^2 = 0%, Figure 1A) or emergence agitation. (OR, 0.72; 95% CI, 0.40 to 1.30; n = 468; p = 0.28; I^2 = 79%, Figure 1B). The findings indicate that the use of remimazolam during surgery does not lead to a higher incidence of postoperative delirium or emergence delirium within the initial three days following the procedure compared to propofol.

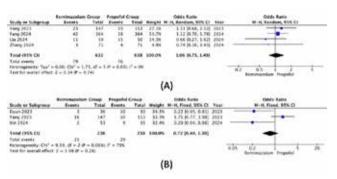

Figure 1. The forest plot of the incidence of postoperative delirium (A) and emergence agitation (B)

Conclusion(s): Compared to propofol, intraoperative administration of remimazolam demonstrates a comparable risk of postoperative delirium within the initial three days after surgery.

Unexpected hyperkalaemia in robot assisted radical prostactectomy

Y.X. Chin¹, Q.J. Tong², N. Lim³

¹Singapore General Hospital, Anesthesia, Singapore, Singapore, ²Changi General Hospital, Anesthesia, Singapore, Singapore, ³Changi General Hospital, Anaesthesia and Intensive Care Medicine, Singapore, Singapore

Background: A 68 year old gentleman with a background of hypertension, hyperlipidemia, diabetes and chronic kidney disease underwent robot assisted radical prostatectomy (RARP) and developed unexpected hyperkalaemia intraoperatively.

Case Report: A 68 year old gentleman presented to the hospital for RARP, the surgery took a total of 5 hours and 22 minutes in the steep Trendelenburg position. 2.5 hours into the surgery, an ABG showed unexpected hyperkalaemia: pH 7.33 paCO2 42 K 6.2 glucose 12.9 base excess -4 bicarbonate 22. Insulin-dextrose therapy was initiated, further investigation revealed normal serum ketone (pre-existing diabetes) and stable renal function.

Post-extubation, he complained right arm muscle pain, which was an old injury. Creatine kinase was checked and found to be elevated at 166 U/L. The patient was kept on IV fluids postoperatively to maintain urine output, he was discharged uneventfully on postoperative day 2.

Discussion: RARP is a prolonged surgery performed in the steep Trendelenburg with lithotomy position. Hypoperfusion of the lower limbs can lead to complications such as muscle injury, rhabdomyolysis and lower limb compartment syndrome. Creatine kinase often rises in the postoperative period even in asymptomatic patients

When hyperkalaemia develops intraoperatively, potential causes include renal impairment, metabolic acidosis, medication such as suxamethonium or red blood cell transfusion, or cellular injury such as rhabdomyolysis. In our patient, hyperkalaemia was unexpected and on investigating, metabolic acidosis and renal impairment were ruled out. After extubation, the patient mentioned muscle pain in his arm (likely incidental given that it was an old injury) and the creatine kinase was found to be high. Thus, hyperkalaemia in our patient was likely due to intraoperative position-related muscle injury. In surgeries requiring Trendelenburg position, if unexpected hyperkalaemia develops, the creatine kinase should be checked to investigate for muscle injury and rhabdomyolysis.

Reference:

J Endourol. 2013 Jan;27(1):45-51. doi: 10.1089/end.2012.0169. Epub 2012 Sep 10. PMID: 22770120.

Learning Points: Patients undergoing robot assisted radical prostatectomy or any surgeries in steep trendelenburg can develop unexpected intraoperative hyperkalaemia, causes include renal impairment and metabolic acidosis, however it is also important to check creatine kinase to look for muscle injury and rhabdomyolysis.

11AP02-2

Evolution of gender equity among authors in anaesthesiology and paediatric anaesthesiology research articles: a comparative scientometric analysis

<u>A. Dejaco</u>¹, J. Rosenberger¹, A. Sablewski², M. Nemeth³, C. Miller^{3,4}

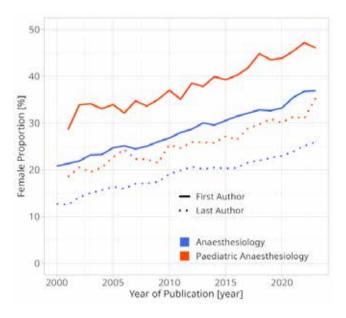

¹University Hospital Regensburg, Department of Anaesthesiology, Regensburg, Germany, ²University Hospital Schleswig-Holstein, Department of Anaesthesiology, Kiel, Germany, ³University Medical Center Göttingen, Department of Anaesthesiology, Göttingen, Germany, ⁴Children's Orthopaedic Hospital Aschau im Chiemgau, Department of Anaesthesiology, Aschau im Chiemgau, Germany

Background: Females are still underrepresented in academic medicine. This gender disparity in leading authorship positions may also be observed in the field of paediatric anaesthesiology. We hypothesised notable differences in female authorship patterns in paediatric anaesthesiology when compared to overall anaesthesiology. To test this, we conducted a scientometric analysis.

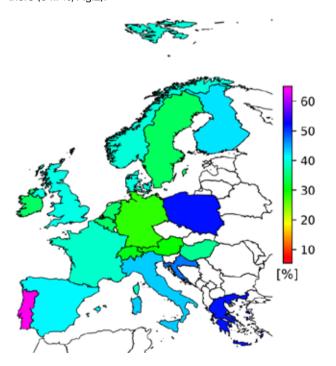

Methods: The MEDLINE/PubMed 2024 Baseline database was converted to PostgreSQL, and anaesthesiology-related articles were extracted using a comprehensive regular expression applied to affiliation strings. Paediatric anaesthesiology articles were filtered using an existing database [Miller et al. 2024]. Author gender was inferred via GenderAPI and Genderize online services, applied to forenames. Countries were identified through text-mining of affiliation strings.

Results and Discussion: We identified 374,978 anaesthesiology articles (2,249,636 authorships) and 34,426 paediatric anaesthesiology articles (218,219 authorships) from 1987 to 2023. The pro-

portion of female authors in anaesthesiology was 38.2% among first authors and 25.7% among last authors, compared to 30.7% and 20.7%, respectively, in paediatric anaesthesiology.

Although trends in gender distribution were similar, female authorship was higher in paediatric anaesthesiology compared to overall anaesthesiology articles, with a difference of approximately 8% among first authors and 5% among last authors (Fig.1). Among countries, Portugal had the highest share of female authors (64.7%, Fig.2).

Conclusions: Despite the persistence of a gender gap in paediatric anaesthesiology and anaesthesiology overall, recent trends indicate a reduction in this disparity. Paediatric anaesthesiology exhibits a higher proportion of female lead authors than overall anaesthesiology. However, targeted efforts are necessary to advance gender equity.

11AP02-3

Effectiveness of short prehabilitation program in a mix group of frail patients

C.J. Tan¹, A. Au Yong², J. Sim², K.L. Ng³, <u>X.M. Wong</u>², H.R. Abdullah²

¹Singapore General Hospital, Department of Physiotherapy, Singapore, Singapore, ²Singapore General Hospital, Anaesthesiology, Singapore, Singapore, ³Singapore General Hospital, Pre-Operative Services, Singapore, Singapore

Background and Goal of Study: Prehabilitation aims to enhance functional capacity to better manage surgical stress perioperatively. Singapore General Hospital's "Prehabilitation for Elderly Frail Patients Undergoing Elective Surgeries" (PREPARE) targets frail patients undergoing major surgery to optimize physical fitness through physiotherapy education and individualized exercise programs.

Evidence suggests prehabilitation should be supervised, targeting moderate to vigorous intensity over at least three weeks. However, frail patients are typically scheduled for surgery within 2-4 weeks, presenting a significant challenge.

This study evaluates the PREPARE program's impact on physical fitness pre- and post-prehabilitation with a shortened intervention

Materials and Methods: Patients aged >50 years undergoing major surgery were screened for frailty using the Edmonton Frail Scale. Frail patients received routine preoperative physiotherapy, education, home exercises, and inspiratory muscle training (if Maximal Inspiratory Pressure [MIP] < 100 cmH2O). Patients with >2 weeks before surgery were offered supervised sessions, including aerobic and resistance exercises targeting a Borg rate of perceived exertion of 3-5/10.

Baseline and post-program measures included MIP (digital manometer), handgrip strength (HGS, Jamar® dynamometer), 30-second and 1-minute Sit-to-Stand (STS), usual gait speed (GS), and 6-minute walk test (6MWT). Data were analyzed using paired t-tests with SPSS v22.

Results and Discussion: Between 2023 and 2024, 19 patients completed 2-4 supervised sessions, limited by surgical lead time. Improvements were observed in HGS (18.39kg \pm 6.27 to 19.20kg \pm 7.37), GS (0.70m/sec \pm 0.43 to 0.78m/sec \pm 0.37), 6MWT (172.19m \pm 110.43 to 173.38m \pm 109.83), and MIP (91.33cmH2O \pm 40.07 to 103.00cmH2O \pm 57.82). However, none were statistically significant.

Conclusion(s): Prehabilitation trends indicate improved physical fitness with supervised sessions, even with a shortened duration. Minimal improvements suggest potential for meaningful change, warranting further studies with larger samples and program adjustments to fully evaluate efficacy.

Acknowledgements (optional): Staff at preadmission clinic for the primary frailty screening and the physiotherapy team for their effort in prehabilitating the patients

Improved Perioperativ Risk assessment and EDucation with Interactive Consultation Tool (iPREDICT) – Assessment of patients' knowledge about anaesthesia related risks after preoperative face-to-face consultation visit

<u>A. Puskarevic</u>¹, M. Wittmann¹, H. Ehrentraut¹, A. Kunsorg¹, I. Abulizi²

¹University Hospital Bonn, Department of Anesthesiology and Intensive Care, Bonn, Germany, ²University Hospital Bonn, Institute of Medical Biometry, Informatics and Epidemiology, Bonn, Germany

Background and Goal of Study: Preoperative anaesthetic assessment is often time-limited in routine clinical practice. An essential part of this process is patient empowerment, which includes patient education and involvement in decisions related to their anaesthetic care pathway.

The overall goal of this prospective, randomized, placebo-controlled clinical study is to investigate the feasibility of using an Interactive Consultation Tool (ICT) during the pre-operative period, thereby improving patient's knowledge and awareness of the risks associated with anaesthesia.

Materials and Methods: Patients scheduled for elective surgery under general or combined anaesthesia (n=246) were randomly assigned to either the ICT group or the control group. The ICT group was informed about anaesthesia procedures and risks by video and text, while the control group received patient safety but not anaesthesia-related video content.

All participants took part in the routine preoperative face-to-face consultations and were surveyed about 15 items immediately after the consultation and again 2 days later (risk recall) via an online questionnaire to assess retained information.

Results and Discussion: Demographic analysis of the initial study results showed an average participant age of 54.1 years, with 66 % male and 34 % female participants. At baseline, participants expressed a moderate level of need for knowledge about the anaesthesia.

After the premedication visit, the ICT group showed a higher, but not significant tendency to remember more anaesthesia risks. At the risk recall visit two days later after premedication visit, a significant higher number of risks could be correctly remembered by patients of the ICT group (p < 0.05).

These results indicate a greater improvement in the anaesthesia risk recall in the experimental group compared to the control group.

Conclusion(s): The findings of this study suggest that the use of an ICT during the preoperative period can significantly enhance patients' retention of anaesthesia-related risk information.

By supplementing routine face-to-face consultations with interactive video and text content, the ICT promotes better patient understanding and recall of critical information, potentially contributing to improved patient empowerment and shared decision-making. Further research is warranted to explore the long-term impact of such tools on patient outcomes and satisfaction.

11AP02-5

Comparative analysis of lactate clearance as a predictor of adverse postoperative events in patients with cardiovascular-kidney-metabolic syndrome in non-cardiac surgery

<u>A. Grazhdankin</u>¹, P. Mironov¹, A. Lifanova¹, I. Lutfarakhmanov¹

¹Bashkir State Medical University, Anesthesiology and Intensive Care, Ufa, Russian Federation

Background: Recently introduced cardiovascular-kidney-metabolic syndrome (CVKMS) is defined as a health disorder associated with obesity, diabetes mellitus, chronic kidney disease, and cardiovascular disease. Patients with CVKMS are at risk for adverse perioperative events.

Postoperative hyperlactatemia is independently associated with an increased risk of complications after major non-cardiac surgery.

Goal of Study: To conduct a comparative analysis of the dynamic parameters of blood lactate levels with postoperative complications and the length of stay in patients with CVKMS and metabolic syndrome (MetS) after non-cardiac surgical interventions.

Materials and Methods: 51 patients were divided into the CVKMS group (n = 17) and MetS group (n = 34). Both the peak concentration and clearance of blood serum lactate in the first 0, 6, 12, 18, 24 and 48 hours after surgery were calculated. Lactate concentration greater than 2.0 mmol/L was defined as hyperlactatemia. Endpoints were the severity of complications according to the Clavien-Dindo classification and the length of stay.

Results and Discussion: Peak lactate concentrations were statistically significantly higher and lactate clearance was significantly lower in the CVKMS group in comparison with MetS group. 53% of patients developed hyperlactatemia.

Lactate clearance after surgery was significantly lower in patients with hyperlactatemia. In patients with CVKMS, the degree of severity of postoperative complications and the length of stay were significantly bigger.

Conclusions: Peak lactate concentration and lactate clearance 12 hours postoperatively are significantly higher in patients with CVKMS. Postoperative hyperlactatemia over 2.0 mmol/l is associated with the occurrence of complications and prolongation of treatment.

Keywords: cardiovascular-kidney-metabolic syndrome, lactate, postoperative complications, outcomes

Effectiveness of multimodal analgesia in Robot-assisted laparoscopic Radical Prostatectomy (RALRP): comparison with conventional analgesia

M. Vall Navés¹, A. Pardo Bedia¹, P. Ferrer Segarra¹, S. Beltran de Herredia Marrodan¹, A. Vilches Garcia¹, M. Corcov Bidasolo¹

¹Parc Salut Mar - Hospital del Mar, Anesthesiology, Critical Care and Pain Medicine, Barcelona, Spain

Background and Goal of Study: Multimodal analgesia (MA) combines various analgesic medications to enhance pain management. Its benefits include better pain control, reduced opioid use, fewer side effects, and quicker recovery. MA is particularly effective in improving patient comfort and overall recovery, making it a recommended approach in Enhanced Recovery After Surgery (ERAS) protocols.

This study aims to evaluate the effectiveness of MA compared to conventional analgesia (CA) in managing pain and improving patient outcomes in RALRP.

Materials and Methods: A retrospective observational cohort study was conducted with patients undergoing RALRP, comparing those receiving CA (fentanyl or sufentanyl) to those treated with MA (lidocaine, dexmedetomidine, and magnesium sulfate). Both groups received postoperative analgesia with dexketoprofen, paracetamol, and morphine as needed.

Primary outcomes included intraoperative opioid use (measured in morphine sulfate equivalents) and postoperative pain levels assessed via the Visual Analog Scale (VAS). Side effects, such as the need for vasopressors, antihypertensives, and the incidence of nausea and vomiting, were also recorded.

Statistical analysis was performed with T-student test for quantitative variables and Fisher or Chi-squared tests for qualitative dichotomic variables. Significance was set at p-value < 0.05.

Results and Discussion: This study included 133 patients (55 in CA and 78 in MA). No significant demographic differences were observed. Intraoperative opioid use was significantly lower in the MA group (19.88 \pm 7.33) compared to the CA group (30.97 \pm 8.72, p < 0.01).

Postoperative pain levels showed no significant differences in the first 6 hours (CA: 1.57 ± 2.09 vs. MA: 1.77 ± 2.10 , p = 0.58), but a trend towards higher pain scores in the MA group at 24 hours (CA: 0.33 ± 1.34 vs. MA: 0.78 ± 1.34 , p = 0.06) was observed.

The need for additional morphine and the incidence of nausea and vomiting were similar between groups. Intraoperative requirements for vasopressors and antihypertensives showed no significant differences.

Conclusion(s): Our findings suggest that while MA significantly reduces intraoperative opioid use, it does not appear to improve postoperative pain control as indicated by VAS scores and morphine rescue. CA group need higher requirements for antihypertensives. Our results should be confirmed in larger prospective studies.

11AP02-7

Anaesthesia for awake spine surgery in high-risk patients using opioid-free conscious sedation without spinal or regional anaesthesia

H.Y. Tan¹, S. Selvaraj¹, J. Wong¹, V.K. Ho¹, J. Malanjum¹, J. Cheng¹

¹Singapore General Hospital, Anaesthesiology, Singapore, Singapore

Background: Spine surgeries, typically performed under general anesthesia, pose risks for patients with severe comorbidities like COPD or ischemic heart disease (IHD), often excluding them from surgery and leaving them in pain. Awake spine surgeries reduce perioperative risks, opioid use, and costs, specifically in lumbar procedures!

Spinal and regional techniques like erector spinae or thoracolumbar interfascial plane blocks employed by some centres can target dorsal rami but may risk respiratory compromise.

This case highlights opioid-free awake spine surgery in a patient with GOLD E COPD.

Case Report: A 71-year-old male (BMI 22) with COPD (FEV1 39% predicted), IHD, rheumatic heart disease (metallic valves), Stage 2 CKD, and cervical spondylosis underwent L4/5 lateral recess stenosis endoscopic decompression under opioid-free sedation without regional or spinal techniques.

He self-positioned prone with protected pressure points. Standard monitors were applied. IV glycopyrrolate (0.2 mg) controlled secretions.

Oxygen at 2L/min was delivered via nasal prongs. Sedation was initiated with a propofol-ketamine infusion (1% propofol 50ml:50 mg ketamine) at 2 mcg/ml (TCI Marsh model). Once ketamine dose 0.5 mg/kg was achieved, sedation continued with propofol alone.

The surgical site was infiltrated with 10 ml of 0.5% bupivacaine. The patient remained awake, comfortable, and hemodynamically stable.

Recovery was uneventful; he reported mild calf cramping (pain score: 2), mobilized the next day, and was discharged well.

Discussion: Opioid-free conscious sedation provides a safer option for high-risk patients, minimizing respiratory, cardiovascular, and opioid-related risks².

Conscious sedation enables real-time neuromonitoring, symptom recreation, and self-positioning, reducing prone-positioning risks and avoiding airway instrumentation. This technique facilitates hemodynamic stability, early mobilization, and potential sameday discharge, making surgery feasible for medically complex patients.

Learning Points:

- 1. Opioid-free sedation minimizes perioperative risks for high-risk patients.
- 2. Awake patients provide real-time feedback, ensuring surgical precision.
- Self-positioning and avoidance of general anaesthesia enhances safety.

Anaesthesia in a patient with anti-N-methyl-D-aspartate receptor encephalitis

S. Ker¹, S. Kumar Reddy Challa¹
¹KK Women's and Children's Hospital, Paediatric Anaesthesia, Singapore, Singapore

Background: Anti-N-methyl-D-aspartate (NMDA) receptor encephalitis is immune-mediated, caused by production of IgG antibodies against the NMDA receptor in the nervous system. Anti-NMDA encephalitis is often associated with ovarian teratomas and resection of the tumour can facilitate earlier functional recovery. Many anaesthetic agents have interactions with NMDA receptors.

There is no definite recommendation of anaesthesia technique for patients with anti-NMDA receptor encephalitis currently.

Case Report: A previously well 14 year old female was diagnosed with anti-NMDA encephalitis after being admitted for seizures and psychosis. She was treated with IVIG and methylprednisolone and although the seizures resolved, her psychosis did not. Further scans revealed an ovarian lesion which is often associated with anti-NMDA encephalitis.

She was then listed for emergency laparoscopic cystectomy for removal of the likely ovarian teratoma. We conducted general anaesthesia using a target controlled infusion of propofol with Sed-line monitoring.

Multimodal analgesia with a regional technique, paracetamol, and ibuprofen was used in combination with fentanyl boluses. The following day her psychosis had resolved and the patient was back to her normal cheerful demeanour.

Discussion and Learning Points: Commonly used anaesthetic agents that inhibit NMDA receptors include ketamine, nitrous oxide, and volatile anaesthetics. Anaesthetic agents with effects on NMDA receptors become unpredictable in patients with anti-NMDA receptor encephalitis.

Therefore we avoided the use of anaesthetic agents with effects on the NMDA receptor by employing total intravenous anaesthesia. Pain management may also be challenging due to alterations in pain perception or the ability of patients to communicate their pain. Hence multimodal analgesia was utilised.

Anti-NMDA encephalitis may have cardiovascular and respiratory involvement, as well as autonomic dysfunction and temperature dysregulation. Hence the patient should be thoroughly assessed for these complications and managed accordingly.

Systematic review and meta-analysis of high fraction of inspired oxygen for surgical site infection prevention

R. Hulskes¹, R.P. Weenink¹, M.A. Boermeester², M.W. Hollmann¹, S.W. de Jonge²

¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Surgery, Amsterdam, Netherlands

Background and Goal of Study: Increasing the fraction of inspired oxygen (FiO₂) may reduce the rate of surgical site infection (SSI) by optimising tissue oxygenation.¹

Several new studies have been published on the use of high (0.8) ${\rm FiO_2}$ and the possible association with lower rates of SSI after the WHO guideline update found less effect and weaken their recommendation of high ${\rm FiO_2}$.²

This systematic review and meta-analysis of randomised controlled trials updates the current literature on the effect of high ${\rm FiO_2}$ compared with standard ${\rm FiO_2}$ on SSI incidence in patients undergoing surgical procedures.

Materials and Methods: The databases Medline (OVID) and Embase (Embase.com) were searched with relevant search terms up to 18th of August 2023. Randomised controlled trials were selected based on high ${\rm FiO_2}$ compared with standard ${\rm FiO_2}$ to prevent postoperative wound infections.

Subgroup analysis was performed on the incidence of SSI in patients in which high ${\rm FiO_2}$ or standard ${\rm FiO_2}$ was administered via endotracheal intubation versus a face mask without endotracheal intubation

Results and Discussion: Twenty-seven studies were included after title and abstract screening and reading the full text. The results were pooled in a meta-analysis.

The pooled number of SSI in the high ${\rm FiO_2}$ treatment group was 885/8402 (10.5%), compared to 1039/8364 (12.4%) in the standard FiO2 treatment group, and resulted in a pooled relative risk ratio of 0.84 (95% CI 0.73 to 0.96), in favour of high ${\rm FiO_2}$ treatment. SSI in patients who received high or standard ${\rm FiO_2}$ administered via endotracheal intubation were reported in 22 trials.

The pooled number of SSI in the high FiO2 treatment group, administered via endotracheal intubation, was 789/7491 (10.5%), compared to 956/7434 (12.9%) in the standard ${\rm FiO_2}$ treatment group, administered via endotracheal intubation, and resulted in a pooled relative risk ratio of 0.79 (95% CI 0.68 to 0.91), in favour of high ${\rm FiO_2}$ treatment.

Conclusion(s): High ${\rm FiO_2}$ results in less SSI than standard ${\rm FiO_2}$ in patients undergoing surgical procedures. Our results justify a stronger recommendation for the use of high ${\rm FiO_2}$ via endotracheal intubation.

Total intravenous general anaesthesia in a Glucose-6-Phosphate Dehydrogenase deficiency child

C. Martins¹, M.M. Pereira Campos Mugeiro¹, I. Portela¹, N. Carrilo-Alfonso¹, S. Gestosa¹, A. Lares¹ ¹Unidade Local de Saúde do Algarve, Serviço de Anestesiologia, Faro, Portugal

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is the most common enzymatic disorder of red blood cells (RBCs), inducing an inability to protect them against oxidative stresses, triggering haemolytic crisis. In these patients is crucial to avoid drugs that can precipitate haemolysis.¹

This case report describes the management of total intravenous general anaesthesia in a paediatric patient with G6PD deficiency.

Case report: A 6-year-old male with G6PD deficiency, ASA II, presented for endoscopic treatment of vesicoureteral reflux. He had no history of acute hemolytic episodes, comorbidities, previous hospitalizations, or allergies and was not on any medication. Preoperative evaluation revealed normal laboratory analysis and no evidence of infection or hemolysis.

A total intravenous general anesthesia (TIVA) was induced with fentanyl, propofol and rocuronium and maintained with propofol under pressure-controlled ventilation. We did not administer any local anesthetics. The procedure was uneventful.

After adequate recovery, the patient was discharged on the same day. At the one-week postoperative follow-up, no adverse events were reported.

Discussion: In G6PD deficiency, RBCs are unable to defend against oxidative stress, leading to loss of function and haemolysis. While most individuals are asymptomatic, factors like infection, metabolic conditions, certain drugs and specific foods can trigger haemolysis. The anaesthetic risk depends on the severity and onset of anaemia.

The main perioperative goal is to minimize the risk of haemolysis, by avoiding oxidative drugs such as non-steroidal anti-inflammatory drugs and sulphonamides. Local anaesthetics that may cause methemoglobinemia should also be avoided, since methylene blue may trigger haemolysis.¹

In this case, the patient had normal blood tests and no clinical signs of infection, limiting pre-operative oxidative stressors before elective surgery. TIVA has no documented association with haemolytic crisis, revealing a safe and effective choice.

References:

Cicvarić A, et al. Management of Anesthesia and Perioperative Procedures in a Child with Glucose-6-Phosphate Dehydrogenase Deficiency. *Journal of Clinical Medicine*. 2022; 11(21):6476.

Learning points:

- The anaesthetic aim is to reduce oxidative stress and monitor signs of haemolysis.
- 2. TIVA proved safe and effective in the management of a child with G6PD deficiency.

11AP02-11

Postoperative anisocoria after general anesthesia: A cause for concern – a case report

A. De Oliveira¹, <u>C. Cunha da Silva</u>¹, A.S. Coutinho¹, S. Silva¹, S. Santos Rodrigues¹ ¹Hospital Senhora da Oliveira Guimarães - Unidade Local de Saude do Alto Ave, Serviço de Anestesiologia, Guimarães, Portugal

Background: Postoperative anisocoria (PA) after general anesthesia (GA) can signal life-threatening conditions, such as intracranial pathologies or ocular injury.^{1,2} Prompt evaluation is crucial to rule out serious causes.

We present a case of unilateral mydriasis after a routine septoplasty and inferior turbinate reduction, highlighting the need for timely assessment.

Case Report: An 18-year-old healthy male, ASA 1, underwent GA for nasal septoplasty and bilateral turbinectomy. Preoperatively, he had stable vital signs, a Glasgow Coma Scale of 15, normal pupil size and reactions, and no neurological deficits.

After anesthesia induction, his eyes were taped closed, and surgical compresses soaked in phenylephrine and cocaine paste were used for nasal mucosal vasoconstriction.

The surgery was lengthy but uneventful. Upon awakening, anisocoria was detected, with the left pupil more dilated than the right (~4-5mm).

There were no associated symptoms, pupillary light reflexes were normal and neurological examination revealed no other abnormalities. The anisocoria resolved within four to six hours, and the patient was discharged on the second postoperative day without complications.

Discussion: PA following nasal surgery under GA can be concerning due to potential serious causes, including oculomotor nerve injury or central nervous system damage.

In this case, after a thorough evaluation and the spontaneous resolution of anisocoria, it is likely caused by sympathomimetic agents like phenylephrine and cocaine, which may have entered the eye through the nasolacrimal duct, as reported in other cases. Cocaine may also enhance mydriasis by anesthetized the short ciliary nerve.

References:

1. Kaushal, A., Andleeb, R., Gupta, P., Talawar, P. (2023). Postoperative Anisocoria-need not be Concerned Always. *Turkish Journal of Anaesthesiology and Reanimation*, *51*(3), 278–279. https://doi.org/10.4274/TJAR.2022.221013

2. Azhdam, A., Liu, G., Lee, M. K. (2021). Unilateral mydriasis following septoplasty with inferior turbinate reduction. American Journal of Otolaryngology - Head and Neck Medicine and Surgery, 42(2), 102881. https://doi.org/10.1016/j. amjoto.2020.102881

Learning points: PA, while typically benign, can sometimes indicate serious complications. During sinus surgery, a dilated pupil may suggest intraorbital injury, but it is crucial to recognize that common nasal decongestants can also cause mydriasis, helping to reduce concern for the medical team.

Unexpected hypertensive episode following a dural tear in endoscopic spine surgery: a case report

M. Azevedo¹, M. Monteiro¹, N. Pereira Coutinho²¹Hospital Lusíadas Lisboa, Anesthesiology, Lisboa, Portugal, ²Hospital Lusíadas Lisboa, Orthopedics, Lisboa, Portugal

Background: Endoscopic spine surgery (ESS) is a minimally invasive treatment for spinal conditions, with dural tears (DT) occurring in 1.07-3.95% of cases^{1,2}.

Irrigation fluid entering via the DT has been linked to rare but significant neurological and cardiovascular manifestations^{2,3}.

Case report: V.M.M., a 58-year-old female (ASA II), underwent ESS under total intravenous general anesthesia with Propofol and Remifentanil. Mid-surgery, an hypertensive crisis (BP > 190/120 mmHg) without tachycardia, coincided with a DT requiring repair. Hypertension persisted despite increased Remifentanil doses. It partially resolved with Dexmedetomidine, allowing extubation. Post-extubation, the patient presented with severe agitation, hypertension, and tachypnea. Arterial blood gas revealed hypocapnia and lactate of 2.7 mg/dL.

Stabilization was achieved with Furosemide and Labetalol. The patient was monitored in the postanaesthesia recovery unit, and discharged the next day hemodynamically stable, without neurological deficits.

Discussion: This case highlights a differential diagnosis of an hypertensive crisis, particular to ESS. Management requires recognition of a DT and communication between surgeons and anesthesiologists. When suspected, treatment includes minimizing irrigation fluid pressure and timely surgery completion³.

Antinociceptive drugs, antihypertensives (diuretics, corticosteroids, dexmedetomidine), and fluid management are appointed in the literature as strategies to control the physiological impact of intraspinal pressure changes³.

Learning points: This case contributes to the understanding of a rare complication in minimally invasive spinal surgery. It highlights a differential diagnosis of an ESS-related hypertensive crisis, and reviews treatment and strategies to improve intra and postoperative management.

11AP03-1

Management of a patient with Wolff-Parkinson-White (WPW) syndrome in open abdominal surgery: Case report

A. Porto Soto¹, O. Martinez¹, E. Vilardell¹, F. Munar¹, S. Manrique¹

¹Hospital Universitari Vall d'Hebron, Anesteshiology Department, Barcelona, Spain

Background: Wolff-Parkinson-White (WPW) Syndrome is a rare congenital cardiac conduction disorder, where electrical impulses are conducted via accessory pathways between the atrium and ventricle. This results in an increased risk of arrhythmias such as paroxysmal reentry tachycardias.

Case Report: A 56-year-old woman with asymptomatic WPW Syndrome and an ECG typical of pre-excitation underwent laparotomy for retroperitoneal liposarcoma. A propofol-based TIVA (total intravenous anaesthesia) was performed for its cardiostability.

For perioperative pain management, a T9-T10 thoracic epidural block was performed with ropivacaine 0.2% without adrenaline. Invasive monitoring was carried out with the FloTrac®/Vigileo® system to maintain goal-directed fluid therapy.

An intravenous fluid warmer was used to avoid hypothermia and a defibrillator was available. The surgery ended without arrhythmogenic events. Given her good evolution, the patient was discharged home a week later.

Discussion: Patients with WPW syndrome may require some form of surgery in their lifetime, so it is important to understand their pathophysiology: 80% of tachycardias are due to atrioventricular reentry arrhythmias and 20% are due to atrial fibrillation or flutter. During the preoperative period, a thorough cardiological history should be taken, as some patients are asymptomatic.

The anaesthetic management consists of an adequate maintenance of the balance between vagal and sympathetic tone, stable haemodynamics, avoiding stimuli produced by pain, anxiety, hypovolaemia and the superficial plane of anaesthesia, as they may increase conduction through the accessory pathway and produce arrhythmias. Although most drugs used in anaesthesia are safe in these patients, drugs with a sympathomimetic effect should be avoided or used with caution.

The urgency of treatment of these arrhythmias depends on: if the patient is stable, pharmacological treatment with antiarrhythmics should be considered as the first option; whereas in case of haemodynamic instability, synchronised cardioversion should be performed.

Reference:

Yeap, Tat Boon et al. (2021). "Anaesthetic challenges in a patient with Wolff-Parkinson-White syndrome for orchidectomy." *BMJ case reports* vol. 14,3 e241176.

Learning points: The anaesthetic management of patients with WPW syndrome is a challenge. Proper invasive monitoring, avoidance of sympathomimetic drugs, as well as consideration of possible associated complications are essential.

Perioperative management of patients with ventricular assist devices in non-cardiac surgery

S. Cuervo Escribano¹, P. García Robledo¹, M. Guerrero Diez¹, A. García Campos¹, M. Boned García¹, C. López Ponce¹

¹Hospital Universitario 12 de Octubre, Anestesiología y Reanimación, Madrid, Spain

Background: Ventricular assist devices (VAD) are a key therapeutic alternative in patients with end-stage heart failure. An increasing number of patients with VAD will require non-cardiac surgery, which represents a challenge for anesthesiologists.

Case Report: A 71-year-old male, with Heart Mate III for dilated cardiomyopathy and history of bladder adenocarcinoma, underwent elective transurethral resection of the bladder due to an episode of hematuria and a low-flow VAD alarm in the previous days. Monitoring included electrocardiogram, non-invasive blood pressure (NIBP), pulse oximeter, invasive blood pressure (IBP), central venous pressure, capnography, BIS, INVOS and transesophageal echocardiography (TEE).

Intravenous induction was performed with fentanyl, etomidate and rocuronium, with low-dose norepinephrine support. Maintenance, with sevoflurane.

The patient was connected to mechanical ventilation in volume control mode, programming a FiO2 of 0.5, a PEEP of 5 and a tidal volume of 7 ml/kg. During surgery, the patient remained stable. Extubation was carried out without complications, and the patient was discharged home on the sixth postoperative day.

Discussion: Preoperative optimization of patients with VADs should be multidisciplinary, with device interrogation, echocardiogram update, discontinuation of anticoagulation with bridging therapy and infection prevention.

Pulse oximetry and NIBP may give erroneous readings due to the continuous flow of the VAD; therefore, monitoring IBP, cerebral oxygenation and serial blood gases are recommended. TEE may also be considered. General anesthesia is preferred, being able to use conventional drugs as long as hemodynamic stability is guaranteed. High doses of fentanyl are recommended at induction to prevent sympathetic discharge during laryngoscopy.

Severe hypovolemia and acute right ventricular failure may progress to potentially fatal suction events. Vasopressors with minimal effects on pulmonary vascular resistance are recommended in cases of hypotension.

Reference:

1. Min, J.-J. et al. (2023) Anesthetic management for non-cardiac surgery in patients with left ventricular assist devices, KJA.

Learning points: Optimal perioperative management of patients with VAD requires anesthesiologists to understand the preload-dependent and afterload-sensitive physiology of these patients, a multidisciplinary approach and the optimization of systemic and pulmonary vascular resistance for proper VAD function.

11AP03-4

From myotonia to the operating table: Crafting care for a complex condition

M. Moreira das Neves¹, <u>C. Fernandes Marques¹</u>, M.d.L. Castro¹, L. Lijnzaat¹ ¹ULS São José, Anesthesiology, Lisbon, Portugal

Myotonic dystrophy type 1 (DM1) is a multisystemic disorder characterized by progressive muscle weakness and associated complications, including cardiac and respiratory involvement. Anesthesia management in these patients can be challenging and regional anesthesia is preferred.

This report presents a case of a 38-year-old female patient with DM1 affecting distal muscle groups, cognitive impairment, anxiety, and minimal cardiac involvement. She was scheduled for an elective total abdominal hysterectomy with bilateral salpingectomy. Given her neuromuscular disorder, anesthesia was carefully tailored to minimize risks, with reassurance provided throughout. Upon arrival in the operating room (OR), standard ASA monitoring was applied, and multifunction defibrillation pads were placed for rapid access if needed.

Sedation was initially avoided, and an arterial radial line was placed with local anesthesia for blood gas analysis. Preanesthetic administration of 10 mg metoclopramide IV was given to reduce the risk of pulmonary aspiration, and active forced air warming was used to maintain normothermia.

A combined spinal-epidural anesthesia technique was successfully employed with 10 mg of 0.5% hyperbaric bupivacaine intrathecally. Block level was assessed using a pinprick test, achieving a T11 level. Subsequently, 3 mL of 0.75% ropivacaine was administered through the epidural catheter for an adequate block, and propofol TCI was initiated for conscious sedation.

Goal-directed fluid therapy with saline (NaCl 0.9%) was used. Despite these measures, the patient became anxious and uncomfortable due to positioning, prompting the initiation of general anesthesia with propofol and remifentanil TCl for induction and maintenance.

Intubation was performed without the need for muscle relaxants, and no complications occurred. Serial blood gas tests revealed no significant electrolyte imbalances. Postoperatively, the patient recovered from anesthesia without significant complications, although mild shivering occurred, which was controlled with IV metamizole magnesium.

She was transferred to the intensive care unit (ICU) for monitoring and recovery. This case highlights the complexities of managing DM1 patients undergoing surgery.

Careful perioperative planning is essential for a safe outcome. Despite stable cardiac function, the patient's neuromuscular condition required precise attention to anesthesia and recovery protocols to minimize complications and ensure optimal care.

Effect of methadone compared to morphine on the quality of anesthetic recovery after abdominoplasty

V. Corradi¹, A. Keng Wei Hsu¹, C. Furtado Beller¹, J. Ribeiro dos Santos Junior¹, J.C. Dorneles Zanin¹, C.R. Urmann¹

¹Universidade Regional Integrada do Alto Uruguai e das Missões, Medicina, Erechim, Brazil

Background and Goal of Study: This study aimed to analyze the effect of methadone compared to morphine as a component of multimodal analgesia during the intraoperative period regarding the quality of postoperative recovery in patients undergoing abdominoplasty.

The objective was to demonstrate that methadone, although underutilized in surgical settings, offers potential benefits for these patients.

Materials and Methods: This prospective, parallel, randomized, double-blind, controlled clinical trial included 40 patients undergoing abdominoplasty surgery. Participants were divided into two groups of 20 individuals each: one group received methadone, and the other received morphine during the intraoperative period as part of the anesthetic protocol.

All surgeries were performed by the same surgical team using a standardized technique. The anesthetic protocol was identical for all, differing only in the opioid used.

Twelve hours post-surgery, participants completed the QoR-40 questionnaire to assess aspects of comfort, emotions, pain, physical independence, and support. Medical record data were also analyzed.

This study was approved by an Independent Ethics Committee (protocol number: 67775323.7.0000.5351). Data normality was analyzed using the Shapiro-Wilk test, followed by the appropriate t-test based on the data's normality.

Results and Discussion: The global QoR-40 score 12 hours postsurgery was higher in the methadone group (mean: 181.6) compared to the morphine group (mean: 171.4). The methadone group also showed higher mean scores across all subdomains of the questionnaire except for the support subdomain.

Nausea and vomiting rates were significantly lower in the methadone group. Specifically, 5% of methadone participants experienced vomiting and 50% experienced nausea, compared to 40% vomiting and 70% nausea in the morphine group.

When vomiting was scored on a scale from 1 (never) to 5 (all the time), the methadone group had an average score of 1.050, while the morphine group scored 1.950 (p = 0.0074).

In the post-anesthesia care unit, methadone patients showed a shorter average length of stay and required a lower cumulative dose of rescue morphine. No cases of respiratory depression were observed in either group.

Conclusion(s): Methadone, when compared to morphine, is associated with better postoperative recovery outcomes, particularly in reducing the incidence of nausea and vomiting.

11AP03-6

Successful anaesthetic management with remimazolam under thoracoscopic subtotal esophagectomy: two case reports

K. Kawano¹, H. Fujiii¹, Y. Watanabe¹, S. Ohtani¹, M. Watanabe¹, T. Fujimura¹

Okayama City Hospital, Anesthesiology, Okayama, Japan

Background: Esophagectomy typically requires a prolonged anaesthetic duration, leading to increased consumption of volatile anaesthetics, which contributes to global warming. To our knowledge, no reports in English have documented the use of remimazolam (RMZ) for esophagectomy.

Here, we present two successful cases of anaesthetic management using RMZ during thoracoscopic subtotal esophagectomy. Case report:

Case 1. A man in his 70s was diagnosed with thoracic oesophageal cancer. He underwent esophagectomy with lymph node resection. To minimise invasive effects on the recurrent nerves, a nerve integrity monitor tube was inserted, and RMZ was administered to reduce its impact on evoked potentials. The operation lasted 577 min. RMZ was transitioned to propofol upon admission to the intensive care unit (ICU). The patient was extubated the next day after confirming an adequate cough reflex using bronchoscopy. On postoperative day (POD) 5, he was discharged from the ICU with no respiratory complications.

Case 2. A woman in her 40s underwent a total gastrectomy for gastric cancer. A subsequent pathological diagnosis revealed residual cancer in the lower oesophagus, necessitating additional esophagectomy. The patient was extubated in the operating room because lymph node resection around the recurrent nerves was not indicated. The operation lasted 530 min. After 20 min of discontinuation of RMZ, prompt awakening was achieved, and the patient was extubated in the operating room after reversal with 0.25 mg of flumazenil. She was discharged from the ICU on ROD 2

In both cases, epidural anaesthesia was administered. General anaesthesia was induced using RMZ, fentanyl, and rocuronium, with maintenance achieved through continuous RMZ and remifentanil infusions. Bispectal Index monitoring was maintained between 40 and 60. A bronchial blocker was used for one-lung ventilation after intubation. Neither patient experienced post-operative delirium or agitation.

Discussion: RMZ is a short acting benzodiazepine that facilitates rapid awakening with flumazenil. Additionally, a case series suggests that RMZ use may result in slightly higher motor-evoked potential amplitudes compared to propofol anaesthesia [1].

References:

1. Yamada S, et al. The intraoperative motor-evoked potential when propofol was changed to remimazolam during general anesthesia: a case series. J Anesth. 2023;37(1):154-159.

Learning points: RMZ can be a viable alternative anaesthetic for esophagectomy.

What to expect when you are not expecting: a case report of sciatic neuropraxia after Total Knee Replacement

S. Faria¹, M.M. Gomes¹, C. Monteiro¹, J. Paulo¹, T. Sousa Branca¹, S. Ramos¹ ¹Unidade Local de Saúde de Vila Nova de Gaia e Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: Intraoperative iatrogenic nerve injury can be multifactorial. Sciatic nerve injury, although rare, is a significant complication following total knee replacement (TKR), requiring prompt diagnosis and management due to its critical role in lower limb function.

Case Report: A 77-year-old female was admitted for a left TKR due to severe osteoarthritis without previous neurological deficits. She had asthma and systemic hypertension and was graded American Society of Anesthesiologists class III.

Spinal anesthesia was administered at the L4-L5 level using a 27G Whitacre needle, with intrathecal administration of 9 mg of 0.5% bupivacaine and 1.5 mcg of sufentanyl. Intra-articular infiltration with 300 mg of ropivacaine, 1 mg of adrenaline, and 30 mg of ketorolac in 100 ml saline was performed for analgesia besides multimodal analgesia. The surgery lasted 90 minutes and was uneventful. The tourniquet remained in place for 70 minutes.

On postoperative day 1, the acute pain team observed reduced knee flexion and extension, plantar flexion, and absence of dorsiflexion, inversion, and eversion in her left foot. A neurological evaluation confirmed sciatic neuropathy, and electromyography (EMG) was recommended in 2-3 weeks.

One month later, EMG revealed no abnormal resting activity or dysfunction in the peroneal and tibial nerves, suggesting sciatic neuropraxia with a good prognosis. At her 2-month follow-up, the patient showed significant improvement of neurological deficits. The sciatic neuropathy was likely caused by a combination of stretching, compression and ischemic injury.

Discussion: Sciatic neuropathy is a rare complication of knee replacement surgery. It may arise from inflammatory, mechanical, ischemic, or anesthesia-related factors (such as peripheral nerve blocks), often linked to positioning, surgical manipulation and prolongued tourniquet time.

Although uncommon, understanding the pathophysiology, risk factors, and preventive measures for nerve injuries in TKR is crucial for optimal management and patient care.

References:

Yoon, S. J. (2018). https://doi.org/10.1186/s12891-018-2091-x Yacub, J. N. (2009). https://doi.org/10.1097/ PHM.0b013e3181ae0c9d

Learning points: This case provides insights into the potential complications of TKR, reminding healthcare providers to consider uncommon but significant complications and encouraging early intervention for better outcomes.

11AP03-9

Evaluation of opioid free and opioid based anesthesia techniques for super-obese patients

<u>P. Ratajczyk</u>¹, K. Wasiak¹, B. Szmyd², M. Szczurek¹, T. Gaszynski¹

¹Medical University of Lodz, Anesthesiology and Intensive Therapy, Lodz, Poland, ²Medical University of Lodz, Department of Neurosurgery and Neuro-Oncology, Lodz, Poland

Background and Goal of Study: We presented a hypothesis that opioid-free anesthesia (OFA) is equally good as fentanyl anesthesia (FNT) for super-obese patients undergoing bariatric surgery under general anesthesia.

Materials and Methods: The research included 129 patients with BMI of >50 kg/m² undergoing the same surgery, randomly divided to the group receiving FNT or OFA + sevoflurane (OFA+s). The FNT group was randomly divided into receiving sevoflurane (FNT+s) or propofol (FNT+p).

Measurements taken: systolic blood pressure (SBP), diastolic blood pressure (DBP), mean blood pressure (MBP), heart rate (HR), end-tidal carbon dioxide (EtCO₂), blood oxygen saturation (SpO₂).

Test applied for analysis: the Mann-Whitney U test for independent data and the Wilcoxon signed-rank test for paired data.

Results and Discussion: SBP values significantly decreased between induction and the first measurement across all groups: FNT+s from 150.0 to 100.0 mmHg, FNT+p from 155.0 to 121.0 mmHg, and OFA from 137.5 to 120.0 mmHg.

A similar decrease was observed in the FNT+s group as in the OFA+s group. Significant disparities were noted between the FNT+s and FNT+p groups: 50.0 vs. 28.0 mmHg.

The OFA+s group presented the most stable SBP. FNT+s and OFA+s groups had greater DBP stability, as the FNT+p group had larger fluctuations. MBP presented a similar trend. HR decreased significantly in all groups after anesthesia induction. It was lowest in the FNT+p group: 81.0 vs. 79.0 (/min). In the FNT+s group it dropped from 83.0 to 70.0, and in the OFA+s group it lowered from 90.0 to 80.0.

HR stability across two following measurements after induction had the smallest difference in the OFA+s group (2 beats/min), a moderate difference in the FNT+p group (3.5 beats/min), and the largest in the FNT+s group (6 beats/min). SpO $_2$ increased between induction and the first measurement (largest in the FNT+p group, smallest in the FNT+s group), then decreased in the next two measurements. OFA group had higher SpO $_2$ values compared to both FNT groups. EtCO $_2$ had more stable values in the OFA group than in the FNT groups. Patients of FNT+s group required a lower dose of fentanyl compared to FNT+p group: 0.037 vs. 0.047 $\mu g/kg/min$.

Conclusion(s): OFA+s provides stable conditions for bariatric surgery in super-obese patients. Fentanyl-based anesthesia gives more stable conditions with sevoflurane compared to propofol. Moreover, sevoflurane significantly reduces fentanyl consumption.

Post-operative Atypical Carcinoid Crisis: a rare but critical complication

A. Vieira Ferreira¹, <u>H. Azevdo Duarte</u>¹, G. Nascimento Almeida¹, P. Mariano Pereira¹ ¹ULS São José, Anestesiologia, Lisboa, Portugal

Background: Carcinoid syndrome (CS) is a rare paraneoplastic condition caused by the release of hormones like serotonin by Neuroendocrine Tumors (NET). It typically presents with diarrhea, flushing, and hypotension. Carcinoid crisis (CC), a life-threatening form of CS, is triggered by sudden mediator release, often due to tumor manipulation, stress, or anesthesia.

There is a wide array of associated features ranging from flushing and labile tension to bronchospasm and life-threatening arrhythmias. We present an atypical CC case to raise awareness about its diagnosis, treatment, and prevention.

Case Report: A 46-year-old man with known stage IV intestinal NET was admitted for bowel obstruction and underwent urgent enterectomy and partial colectomy under TIVA and thoracic epidural anesthesia.

Surgery proceeded without complications, and the patient emerged stable. In the PACU, he developed refractory hypertension, hyperthermia, and abdominal pain. Suspecting atypical CC, a bolus of octreotide (500ug) was administered. A subsequent perfusion of octreotide was initiated and clinical stabilization was achieved.

He was then transferred to the ICU, where CC was confirmed, and treatment with octreotide and antihypertensives continued. By day 3, BP normalised, and he was moved to the ward, later being discharged home.

Discussion: CC is a rare and critical event, with limited data available. This case is especially unusual, as CC manifested postoperatively with hypertension and hyperthermia rather than hypotension. This case highlights the wide array of CC presentations, underscoring the importance of prompt recognition and management.

Anesthetic care is challenging due to unpredictable perioperative behavior, emphasizing the need for thorough monitoring (invasive BP, temperature), maintaining normothermia, avoiding triggering drugs, and using additional octreotide prophylactically or therapeutically.

In this case, earlier octreotide use may have prevented CC, as it effectively stabilized BP when administered.

Learning points: Anesthetic management of patients with associated NET can be quite challenging and should include a thorough preparation of all the perioperative settings.

Specific protocols guiding the management of these patients should be available and early suspicion is of the utmost importance.

Non-cardiac urgent surgery in patients with partial repaired atrioventricular canal defect: a case report

<u>G. Urquijo</u>¹, D. Revuelta¹, J.M. Sanahuja¹, R. Pujol¹, X. Morales², E. Rivas¹

¹Hospital Clínic de Barcelona, Anaesthesiology Department, Barcelona, Spain, ²Hospital Clínic de Barcelona, Urgent surgycal department. Surgery Department, Barcelona, Spain

Background: The survival rate of people born with congenital heart defects has increased with nearly 90% of patients reaching adulthood and requiring non-cardiac surgeries throughout their lives. We present a patient with a complete atrioventricular canal defect (AVCD) who underwent an urgent appendicectomy.

Case Report: A 24-year-old woman proposed for urgent laparoscopic appendectomy. The patient had a history of visceral heterotaxy and a complete AVCD with a single atrium and a large ventricular septal defect, which has been partially corrected: a pulmonary binding and a connection between the superior vena cava and the right pulmonary vein during her first year and at 13 years old a connection between the inferior vena cava and the right pulmonary vein (Fontan).

Arriving to the operating room, the patient was hemodynamically stable with 92% oxygen saturation on ambient air, proBNP 176pg/mL with hepatic congestion on the CT scan and a recent cardiac hemodynamic without signs of pulmonary hypertension.

Before induction, the left radial artery was catheterized and filters were placed in all intravenous access to minimize air embolism. General anesthesia was performed with rapid sequence induction. Pneumoperitoneum was maintained at low pressure rates (9-11cmH2O) with a PEEP of 5cmH₂O and a Vt of 420mL.

During surgery, ventricular function and blood volume were monitored using transesophageal echocardiography (TEE). The surgery and postoperative period in PACU proceeded without complications.

Discussion: Adults with congenital heart disease are at potential risk for cardiac complications. Before surgery, it is important to exclude signs of congestive heart failure and pulmonary hypertension.¹

Single ventricle patients rely on volume and high heart frequencies to keep a normal cardiac output. Intraoperatively, it is crucial to adjust monitoring as well as anesthesic and analgesic drugs to prevent changes in blood pressure and use filters to deair intravenous lines.

The TEE plays a major role providing a non-invasive cardiac function information although it might be difficult in patients with altered anatomy.Low intrathoracic pressure is important to avoid left-right shunt, working with low PEEP and intraabdominal pressure.

Communication with the surgical team helps to prevent avoidable complications.

Do the neuromonitoring depth of anesthesia and neuromuscular monitoring have impact on the quality of recovery after general anesthesia?

K. Atlagic¹, N. Kovac¹, D. Stranic¹, T. Radocaj¹, S. Babic¹, N. Vratan¹

¹UHC Sestre milosrdnice, Dep. of Anesthesiology, Intensive Care and Pain Therapy, Zagreb, Croatia

Background and Goal of Study: Quality of recovery after general anesthesia are complex, multi-dimensional parameters. This study aimed to compare the overall quality of recovery following general anesthesia after major abdominal operations guided by advanced monitoring techniques-bispectral index (BIS) and Train of Four (TOF) for neuromuscular monitoring and without that monitoring. The Quality of Recovery-40 (QoR-40) questionnaire was used as a psychometric instrument designed to quantify postoperative recovery with validate Croatian version and its correlation with hand grip strength.

Materials and Methods: An observational comparative study was conducted on two groups. Patients were randomly assigned in Group A and B. Group A underwent anesthesia guided by BIS and TOF, while Group B was guided by hemodynamic parameters. Hand-grip muscle strength was measured with a dynamometer: before general anesthesia and 24 hours after extubation. The quality of patient recovery was assessed with a Qor-40 questionnaire 24 hours after extubation.

Results and Discussion: The study included 50 participants, age 37-86, ASA 1-3. Female made 46% of the participants and men 54%, average BMI was 27 in both groups. The average duration of the operation was 3 h and 20 min.

Figure 1. shows the responses to the QoR questionnaire and figure 2. shows the results of grip strength measurements.

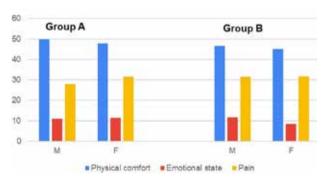

Figure 1. QoR-40 questionnaire among groups.

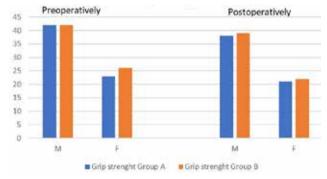

Figure 2. Grip strength.

Conclusion(s): Quality of recovery after general anesthesia and surgery is wide concept that seeks to assess recovery from the patient's perspective and is a patient-reported measurement. Hand grip strength is commonly used to measure voluntary muscle function as an indicator of muscle strength and postoperatively recovery after different surgeries.

This study did not show a significant difference between groups in the quality of recovery after general anesthesia despite BIS and TOF monitoring.

11AP04-1

Optimizing anesthetic management in latex-allergic patients: a case report of urethroplasty with a latex-free protocol

I. Sousa Braga¹, <u>C. Dantas de Oliveira</u>¹, T. Barreto¹, H. Machado¹

¹Unidade Local de Saúde de Santo António, Departamento de Anestesiologia, Porto, Portugal

Background: Latex allergy, an immunological reaction to natural rubber proteins, remains a critical challenge in perioperative care. While its incidence is declining due to better identification of at-risk patients, latex in surgical materials remains a significant risk ¹.

Ensuring a latex-free environment is paramount to prevent hypersensitivity reactions, especially in high-risk settings like urologic surgery.

Case Report: A 57-year-old male with confirmed latex allergy, obstructive sleep apnea, and grade I obesity underwent oral mucosa graft urethroplasty. After detailed risk assessment using a validated screening questionnaire, a latex-free protocol based on hospital guidelines was implemented. Preparations included patient isolation, removal of latex-containing materials, and substitution with latex-free alternatives such as silicone catheters and nitrile gloves.

The procedure was scheduled as the first of the day to reduce latex aeroallergen exposure. Anesthesia equipment was adapted, including latex-free airway devices, and precautions were taken with medication preparation to avoid cross-contamination.

The patient was closely monitored perioperatively for hypersensitivity reactions. The surgery was completed successfully without allergic or anesthetic complications, underscoring the protocol's effectiveness.

Discussion: This case highlights the effective application of an institutional latex-free protocol. Early identification of allergy risk, strict operating room preparation, and team coordination were key. Literature supports such protocols as essential for reducing hypersensitivity risks and ensuring patient safety.

Premedication with antihistamines or corticosteroids can attenuate mild reactions but is not a substitute for preventive measures².

Learning points: The successful management of this case validates the efficacy of the hospital's latex-free protocol in addressing the challenges of latex-allergic patients in perioperative set-

tings. The approach highlights the importance of standardized, evidence-based practices to optimize safety and improve outcomes in high-risk surgical scenarios.

11AP04-2

Autistic adult with pneumonia and suspected radial nerve injury: an anesthesic challenge

A. Pedroso¹, <u>Z. Ouzounova</u>¹, A.F. Correia¹, I. Martins¹¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Autism, usually viewed as a pediatric condition, affects 1-2% of adults. The authors describe a case of an autistic uncooperative adult with extreme agitation, pneumonia and an upper limb fracture with suspected radial nerve injury in need of urgent surgery.

Case Report: 34-year-old autistic man with psychomotor agitation and community-acquired pneumonia was admitted due to a humeral fracture with radial nerve paralysis. The patient was agitated and uncooperative, with self-aggressive behaviour upon arrival at the operating theater.

An intramuscular injection of 1mg/kg ketamine + 1 mcg/kg dexmedetomidine was administered to sedate the patient and minimize the risk of airway compromise during transport to the operating room.

Upon arrival, the patient was monitored according to ASA standards, BIS and TOF, peripheral catheterization was possible and a general balanced anesthesia was administered, combined with a multimodal analgesia.

Ventilation parameters were carefully chosen for a protective ventilation and SpO2 >95%. Two recruitments were made, one after induction and one before extubation. The surgery was uneventful, and the patient woke up calm, maintaining 92-94% SpO2 with 28% O2 supply.

Discussion: Autism affects interaction, communication, and perception, often coexisting with other medical conditions.

In this case, regional anesthesia was not an option due to a high suspicion of radial nerve injury with need for intraoperative electrostimulation. So, although a general anesthesia could substantially worsen the respiratory condition due to the presence of community-acquired pneumonia, with need for prolonged invasive airway management, it was a necessary risk to take.

The authors believe that this case highlights the importance of knowing how to adapt the anesthetic strategy to the challenges that arise, always considering the risks and how to minimize them. **References:**

1. Anesthesiology, 92(5), 1467–1472. doi:10.1097/00000542-200005000-00037.

2. *BMC* anesthesiology, 19(1), 153. doi:10.1186/s12871-019-0804-9. **Learning Points:** Autism affects all ages and influences medical decisions. It is essential to use pre-anesthetic medication that can adequately sedate a patient reducing anxiety and trauma and maintaining patient safety.

Protective ventilation and recruitment maneuvers are fundamental for managing acute or chronic lung disease intraoperatively.

11AP04-3

Case Report of a Post-Right Pneumonectomy Patient undergoing Laparoscopic Cholecystectomy

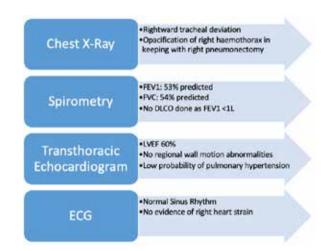

T.W.C. LIEW1, E. Tan2

¹Tan Tock Seng Hospital, Anaesthesiology, Singapore, Singapore, ²Ministry of Health, Anaesthesiology, Singapore, Singapore

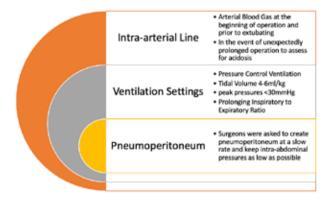

Background: Pneumonectomies significantly impact respiratory and cardiovascular systems. Right pneumonectomies cause greater reduction in lung volume with mortality rates thrice that of left. There are limited reports on these patient undergoing laparoscopic surgeries. Laparoscopic approaches reduce pain and length of hospital stay but capnoperitoneum causes further compromise to the cardiorespiratory system.

This case report discusses anaesthesia considerations of a postpneumonectomy patient undergoing laparoscopic cholecystectomy

Case Report: 69 year-old female required laparoscopic cholecystectomy 23 years after a right pneumonectomy. Pneumonectomy was done due to post-tuberculosis bronchiectasis and recurrent infections complicated by complete bronchial occlusion. Pre-operative assessment of her cardiorespiratory status are summarised:

Intra-operative considerations included use of invasive monitoring, lung protective ventilation strategies and minimization of pneumoperitoneum pressure.

She was sent to high dependency for aggressive chest physiotherapy and recovered uneventfully. **Discussion:** With improved healthcare and life expectancy, there are more post-pneumonectomy patients presenting for laparoscopic cholecystectomies. There is a need for more reports on perioperative management for this patient group.

Impact of pneumoperitoneum and extreme Trendelenburg position in laparoscopic anterior rectal resection: a case report

F. Santos¹, <u>T. Barros</u>¹, I. Macedo¹, M.H. Lima¹, E. Valente¹ Local Health Unit of the Leira Region, Anesthesiology, 2410-197, Portugal

Background: Laparoscopic anterior rectal resection (LARR) risks include pneumoperitoneum-induced increased intra-abdominal pressure (IAP), causing cardiovascular, respiratory, and neurological changes, worsened by extreme Trendelenburg positioning (1). Case Report: A 57-year-old female (65 kg, 160 cm), ASA II, with hypertension and dyslipidemia, was proposed to LARR under balanced general anaesthesia and epidural analgesia. ASA monitoring standards were followed, as well as neuromuscular blockade (NMB), invasive blood pressure, and core temperature monitoring. Epidural catheter was placed at L4-L5 and 20 mL 0.375% ropivacaine plus 2.5 mcg sufentanil was given in boluses, with a final 5 mL bolus of 0.2% ropivacaine. The 7-hour procedure required extreme Trendelenburg and left-side positioning, with a maximum IAP of 12 mmHg. No pauses for positioning or pneumoperitoneum relief were made. Hemodynamic stability was maintained with goal-directed fluid therapy. Following NMB reversal, the patient began spontaneous ventilation but regained consciousness 1 hour after halogenated agent suspension. She was extubated and transferred to the PACU with mydriatic photoreactive pupils and motor blockade in all limbs. Arterial blood gas showed mixed acidosis and type II respiratory failure. Chest X-ray showed obliterated costophrenic angles. Epidural catheter was removed and motor function gradually returned. She was transferred to the ICU and recovered without complications.

Discussion: We attributed the delayed emergence from anaesthesia, neurological findings, and arterial blood gas alterations to prolonged extreme Trendelenburg positioning combined with pneumoperitoneum insufflation. This assumption is supported by the literature, which documents cases of peripheral neuropathy associated with similar conditions (2).

2. No MY, Shin JM, Choi WJ. Two cases report of brachial plexus injury in laparoscopic colorectal surgery. Korean J Anesthesiol. 2013;65(6 Suppl):S149-50.

Learning points: Strategies such as limiting IAP and implementing pauses during surgery are important to improve anaesthetic and surgery outcomes.

11AP04-7

The effect of opioid-free anesthesia on the haemodynamic response during laryngoscopy and intubation. a randomized double-blind study

C. Orfanou¹, M. Mavromati¹, K. Theodoraki¹
¹Aretaieion Hospital, National and Kapodistrian University of Athens, Anesthesiology, Athens, Greece

Background and Goal of Study:Laryngoscopy and endotracheal intubation can provoke a significant haemodynamic response and opioids are commonly used in order to mitigate this. The goal of this study was to assess the effect of opioid-free anesthesia on haemodynamic response parameters during laryngoscopy and intubation

Materials and Methods:This randomized controlled doubleblind prospective study included 70 patients of both sexes, ASA I-II, that were assigned to two groups: OFI (opioid free induction) group received a combination of dexmedetomidine, ketamine and lidocaine prior to laryngoscopy and intubation and OBI (opioid-based induction) group received fentanyl during induction in anesthesia. Haemodynamic parameters were assessed in six different timepoints from baseline up to 5 minutes after intubation.

Results and Discussion:Both groups displayed a significant increase in heart rate (HR) after intubation as compared to pre-intubation values (p<0.001 for both groups). However, in group OFI, this increase persisted only up to 3 min after intubation, whereas, by 5 min after intubation, heart rate had returned to pre-intubation values

In contrast, in the OBI group, the increase in HR was longer lasting since it was still evident 5 min post-intubation. In direct comparison between the two groups, the increase in HR was more prominent in the OFI group in comparison to the OBI group immediately post intubation as well as 1, 3 and 5 min post-intubation (p=0.001, 0.002, 0.033 and 0.043 respectively). Mean arterial pressure (MAP) in group OFI was not affected throughout the study observation period. In contrast, in group OBI, MAP increased immediately post intubation in comparison to pre-intubation values (p=0.007).

Conversely, at 3 and 5 min post intubation, MAP in the OBI group decreased significantly as compared to pre-intubation values (p=0.001 and <0.001, respectively). In direct comparison between the two groups, group OBI displayed lower MAP values 3 and 5 min post intubation as compared to group OFI (p=0.046 and<0.001, respectively).

The incidence of clinically significant hypotension (systolic arterial pressure<70% of baseline) was higher in the OBI group throughout the whole observation period (48.5% vs 17%, p=0.011). **Conclusion:**The increase in heart rate post intubation is of greater magnitude and more pronounced with an opioid-based technique. Additionally, an opioid free technique helps maintaining a more stable MAP in the peri-intubation period.

11AP04-8

The impact of preoperative waiting time on patient safety and outcomes in hip fracture surgery: a retrospective observational study

B. Peralta-Carretero¹, B. Martinez-Moreno¹,
R. Navarro Pérez¹, J. Ripolles-Melchor²,
B. Del Blanco-Narciso³, L. Sante-Serna³
¹Hospital Clinico San Carlos, Anaesthesia, Madrid,
Spain, ²Universidad Complutense Madrid/Hospital
Infanta Leonor, Anaesthesia, Madrid, Spain, ³Universidad
Complutense Madrid/Hospital Clinico San Carlos,
Anaesthesia, Madrid, Spain

Background and Goal of Study: Hip fractures in older adults pose significant safety challenges due to their association with high morbidity and mortality. Preoperative waiting time has been identified as a critical factor influencing patient safety, particularly regarding complications and hospital outcomes.

This retrospective observational study investigates the impact of preoperative waiting time on safety-related outcomes in hip fracture surgery, aiming to inform strategies to optimize care for this vulnerable population.

Materials and Methods: This study included patients aged 65 years or older who underwent hip fracture surgery at a tertiary hospital over the past year. Patients were categorized by preoperative waiting time: <24 hours, 24-48 hours, and >48 hours. Safety-related outcomes, including 30- and 90-day mortality, postoperative medical complications, and hospital length of stay, were analyzed.

Multivariable regression was performed to evaluate the independent effect of waiting time, adjusting for confounding factors such as age, ASA score, fracture type, and surgical technique.

Results and Discussion: The study analyzed 99 patients (77% women, mean age 85.7 years). The average waiting time was 62 hours. Patients with waiting times >48 hours experienced significantly longer hospital stays (20.8 days vs. 13.4 days for <24 hours, p=0.021) and increased postoperative complications (p=0.008), particularly respiratory and urinary issues.

However, no significant association was found between waiting time and mortality (p=0.260). Age was a significant predictor of complications (p=0.002) and extended hospital stays (p=0.022), highlighting its role in safety outcomes. These findings underscore the importance of timely surgery to enhance patient safety (1).

Conclusion(s): Prolonged preoperative waiting times compromise patient safety by increasing the risk of postoperative complications and extended hospital stays, though they do not significantly impact mortality. Early surgery emerges as a key strategy to improve safety in hip fracture management.

While spinal anesthesia is the predominant technique, its impact on safety outcomes remains neutral. Optimizing preoperative processes is essential to safeguarding outcomes in this high-risk population.

A customized protocol for anesthetic management in TORS

G. Piras¹, F. Cantaluppi¹, B. Milan¹, D. Cigolini¹, K. Donadello¹², R. Nocini³ ¹University Hospital Integrated Trust of Verona, Anaesthesia and Intensive Care Unit B, Verona, Italy, ²University of Verona, Department of Surgery, Dentistry, Gynecology and Paediatrics, Verona, Italy, ³University Hospital Integrated Trust of Verona, Otolaryngology-Head and Neck Surgery, Verona, Italy

Background and Goal of Study: Transoral robotic surgery (TORS) combines precision and minimal invasiveness, addressing benign and malignant oropharyngeal pathologies. This study aimed to develop and validate an anesthetic protocol for TORS, focusing on airway management, safety, and complication reduction.

Materials and Methods: The protocol involved preoperative fiberoptic evaluation in high-risk cases, total intravenous anesthesia (TIVA) with propofol and remifentanil, videolaryngoscopy-guided intubation, and dexamethasone for edema prevention. Statistical tests included Fisher's exact and logistic regression ($p \le 0.05$).

Results and Discussion: 22 TORS patients (March–September 2024) were analyzed. Airway management was successful in all cases, with three difficult intubations resolved using advanced techniques (fiberoptic intubation).

A predictive score was created to identify patients requiring protected awakening in the intensive care unit. Non-significant correlation was found between preoperative fiberoptic evaluation and intubation difficulty (p = 0.5534), but a trend toward improved outcomes was observed.

Specifically, 25% of patients who did not undergo preoperative fiberoptic evaluation had difficult intubation, compared to 7.14% of those who had the procedure. Dexamethasone reduced post-operative edema, and tranexamic acid managed bleeding in selected cases.

Bleeding during intubation occurred in 1 out of 3 patients with malignant lesions and in 1 out of 3 patients on antiaggregant therapy, underlining the challenge in managing these cases. TIVA minimized postoperative nausea and vomiting (PONV), enhancing recovery. The predictive score accurately identified patients needing ICU-protected awakening, optimizing patient safety.

Conclusion(s): Our evaluation highlighted the importance of careful patient selection, especially for high-risk patients. The protocol improved safety, reduced complications, and addressed complex airway challenges.

The ICU awakening score provides a step toward personalized anesthetic strategies. Future research should validate findings in larger cohorts and refine high-risk patient management.

11AP04-10 BIS monitoring in deranged cerebral autoregulation

A. Karavaev¹, V. Glushchenko¹, S. Rozengard¹, A. Marin¹ National Medical Research Centre of Oncology named after N.N. Petrov, Anaesthesiology and Intensive Care, Saint-Petersburg, Russian Federation

Background: In our case of BIS monitoring we are demonstrating an unusual relationship between mean arterial blood pressure (BP) and BIS index which could have an impact on correct decision making.

Case Report: The ASA III 75 year old, 70 kg male patient was scheduled for an elective laparoscopic gastrectomy due to cancer. His past medical history was complicated by an ischemic stroke 6 years ago without consequent neurological deficit, chronic arterial hypertension with BP 140/70 mmHg and a congenital absence of the left frontal lobe of the brain. No distinct behavioral, cognitive and emotional disorders were noted on examination.

The surgery was performed under combined general and epidural anaesthesia. Invasive arterial BP monitoring and central venous line were established; CVP was 6 cmH2O. BIS monitoring was also utilized to prevent cognitive impairment. The electrodes were applied according to a manufacturer's manual.

At the start of the surgery, BIS was 60, arterial BP 110/80 (mean 95) mmHg and end-tidal (Et) sevoflurane concentration 2.5%. Aiming for BIS=40, Et concentration of the anaesthetic was increased to 3%. BP became 107/76 (mean 91) mmHg and BIS leveled off at 60. It became obvious that in order to obtain adequate depth of anaesthesia not Et concentration but mean arterial BP should have been raised.

After initiation of norepinephrine infusion at 0.02 mcg*kg-1*min-1 BP was elevated to 130/90 (mean 100) and BIS decreased to 30. Sevoflurane Et concentration was then lowered to expected 1.4 and BIS eventually figured at 40. Further course of action was uneventful.

Discussion: In one study, BIS declined along with hypotension [1]. In our case, however, there was a decrease in BIS with higher mean BP. Most probably, despite non-acute state, autoregulation of cerebral blood flow in this particular patient was impaired, and delivery of not only sevoflurane but also oxygen was linearly dependant upon mean arterial BP.

Reference:

1. Liu X, Nakano M, Yamaguchi A, Bush B, Akiyoshi K, Lee JK, Koehler RC, Hogue CW, Brown CH 4th. The association of bispectral index values and metrics of cerebral perfusion during cardiopulmonary bypass. J Clin Anesth. 2021 Nov;74:110395.

Learning Points: In our opinion, this case highlights the importance of BIS in patients with cerebral blood flow derangement as a tool for monitoring depth of anaesthesia as well as preventing new ischemic events in the brain.

11AP04-11

Identifying and overcoming barriers to pre-operative fasting in adults: a quality improvement project

A. Mandrekar¹, S. Johar¹, R. Ghosh¹, S. Patel²
¹Watford General Hospital, Anaesthesia and Intensive
Care Medicine, Watford, United Kingdom, ²Watford
General Hospital, Anaesthesia, Watford, United Kingdom

Background: Prolonged fasting is associated with negative perioperative outcomes. Our Trust's 2022 audit showed that average fluid fasting times varied 8- 12 hours.

Primary Aims:

- Monitor compliance with national/ local guidelines for preoperative fasting.
- · Identify potential contributors to prolonged fasting.

Secondary Aims:

- Identify areas for improvement in preoperative fasting/ hydration.
- Identify potential events related to prolonged preoperative fasting

Materials and Methods: We did a single centre observational study at Watford General Hospital, by using a 27-point question-naire for data collection over 6-week period. All adults undergoing elective procedures under anaesthesia/ sedation were included. We collected preoperative details from patients, while intra/ post-operative data were extracted retrospectively from the Electronic Patient Records and analysed using Excel spreadsheet.

We also surveyed our Consultants to understand their practice and recommendations for improvement.

Results and Discussion:Observations: - Our Consultant survey showed that although we followed local policies [Stop fluids 2 hours prior to surgery], the median fluid fasting duration 7 hours. Despite offering water to some patients, we did record unfavourable preoperative events in about 40% of patients.

Implementing changes: Based on the Survey, we amended our Trust Preoperative fasting policy. We are now educating patients and their attending nurses/ peers to encourage having clear fluids, i.e., we have introduced 'Sip Till Sent For' policy.

Conclusion(s): Despite following the national guidelines, there is still prolonged fluid fasting duration with unfavourable preoperative events. We have initiated 'Sip Till Sent For' policy and plan to reanalyse once fully implemented.

Perioperative management of an adult patient with Prader-Willi syndrome

M. Pereira¹, <u>J. Pereira</u>¹, L. Oliveira¹

¹North Lisbon University Hospital Centre (CHULN), Department of Anaesthesia, Lisbon, Portugal

Background: Prader-Willi Syndrome (PWS) is a rare disease caused by a deletion on the paternal chromosome 15q11.2-q13 and represents the most common syndromic cause of obesity. Clinically, it is characterized by short stature, hypogonadism, growth hormone deficiency and muscle hypotonia. Behavioral alterations such as hyperphagia lead to severe obesity and associated comorbidities, including obstructive sleep apnea, cardiovascular dysfunction and insulin resistance with type 2 diabetes mellitus as consequence.

Despite the scarcity of reported cases in the literature¹, these factors present unique challenges in the perioperative period, especially in patients with morbid obesity.

Case Report: Here we report the case of a 26-year-old patient with a BMI of 85 and a diagnosis of PWS who underwent endoscopic sleeve gastroplasty and argon plasma coagulation.

Discussion: The surgical procedure was performed under general anesthesia. Induction was achieved with fentanyl, propofol, and rocuronium, with orotracheal intubation facilitated using a videolaryngoscope due to an anticipated difficult airway. A pulmonologist was present to assist with fibroscopy if necessary.

Anesthesia maintenance was achieved with sevoflurane, fentanyl and rocuronium, under standard ASA monitoring. Intraoperative blood glucose monitoring revealed hyperglycemia which was promptly corrected with insulin administration. Antagonism of neuromuscular blockade was achieved with sugammadex, ensuring complete reversal, essential due to the patient's basal hypotonia.

The patient remained hemodynamically stable throughout the procedure and immediately afterwards, with no signs of airway obstruction or delayed emergence from anesthesia.

Postoperative management included close monitoring for respiratory and metabolic complications which exacerbate perioperative risks. The patient was discharged on the first postoperative day following an uneventful recovery.

References:

1. Aravindan A, Singh AK, Kurup M, Gupta S. Anaesthetic management of paediatric patient with Prader-Willi syndrome for bariatric surgery. *Indian J Anaesth*. 2020;64(5):444-445

Learning points: This case highlights the complex interplay of PWS-associated features in the perioperative setting, including severe obesity, altered neuromuscular physiology and metabolic dysregulation.

Careful preoperative evaluation, tailored anesthetic techniques and vigilant postoperative monitoring are critical in optimizing outcomes for these patients.

11AP05-1

Inhalation anesthesia for congenital Steinert Myotonic Dystrophy: two approaches in the same patient

R. Pinto de Sá¹, <u>S. Vieira</u>¹, J. Barbosa¹, C. Gomes¹ ULS de Braga, Anesthesiology, Braga, Portugal

Background: Myotonic Dystrophy Type 1, the most common of the myotonic syndromes, is an autosomal dominant disorder. Also known as Steinert's Disease, it can represent a serious challenge to the anesthesiologist.

Case Report: A 2-year-old girl, diagnosed with Steinert's dystrophy, was proposed for otolaryngology surgery. Her preoperative assessment revealed generalized hypotonia and a small patent foramen ovale

She first underwent bilateral myringotomy. Anesthesia induction used fentanyl and sevoflurane, without neuromuscular blocking agents. Intubation was successful after an uneventful laryngoscopy. Anesthesia was maintained with sevoflurane, and emergence was uneventful, with extubation after the procedure.

Four months later, she underwent analysis of auditory function using brainstem evoked potentials and myringotomy, with fentanyl and sevoflurane induction, and a supraglottic device placed for maintenance od spontaneous ventilation throughout the surgery. Both surgeries included previous warming of the operating room, analgesia, nausea, and vomiting prophylaxis, and the patient was monitored in the PACU before discharge.

Discussion: Neuromuscular disorders have particularities that concern anesthesiologists.

Firstly, a risk for difficult endotracheal intubation has been described in this syndrome. It is current practice to use intravenous anesthesia due to concern about malignant hyperthermia (MH). However, recent studies show the risk of developing MH is similar to the general population.

Hence, induction and maintenance of general anesthesia with sevoflurane, performed in both surgeries, can be advantageous, enabling spontaneous ventilation until the airway is secured.

Additionally, increased sensitivity to neuromuscular blocking agents and opioids can lead to postoperative respiratory muscle insufficiency, making preoperative muscle disability assessment crucial, which may be challenging in the pediatric population.

Hence, a prolonged PACU stay for monitoring is essential.

Fortunately, the physiological stress leading to hypotonia was not an issue, as these were two short surgeries with minimal blood loss and pain stimuli, where hypothermia could be easily prevented.

Learning Points: Congenital Steinert's disease is a rare myotonic syndrome. This case report demonstrated that, for this syndrome, the use of volatile anesthesia is a possibility. Perioperative monitoring for ventilatory failure is required.

11AP05-2

A novel online monitoring scheme of propofol – rapid evaluation of anesthetic effects via exhaled propofol

P. Chang¹, J. Wang²

¹Sichuan University, Anesthesiology, Chengdu, China, ²Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Anesthesiology, Chengdu, China

Background and Goal of Study: Exhaled propofol monitoring has not been widely adopted to assess anesthesia depth or guide dosing due to a lack of efficient methods for real-time evaluation of its pharmacodynamic effects, including sedative and cardiovascular responses.

This study evaluates a non-invasive approach using ultraviolet-photoionization time-of-flight mass spectrometry (UV-TOF-MS) to rapidly determine anesthesia depth and hemodynamic effects via exhaled propofol concentrations.

Materials and Methods: Thirty-six mechanically ventilated beagle dogs were anesthetized with propofol administered either as a single bolus group (3, 5, or 10 mg/kg) or continuous infusion group (0.3, 0.5, or 0.7 mg/kg/min). UV-TOF-MS was used to measure exhaled propofol concentrations in real-time, with bispectral index (BIS), mean arterial pressure (MAP), and heart rate (HR) as pharmacodynamic indicators. The correlations between exhaled propofol and bispectral index (BIS), mean arterial pressure (MAP) and heart rate (HR) were evaluated.

Results and Discussion: UV-TOF-MS demonstrated ultra-fast response and high-resolution spectrograms. Moderate to strong negative correlations were observed between exhaled propofol and BIS under single bolus groups (3, 5, or 10 mg/kg) with r reached -0.3847 to -0.7069 (all p < 0.0001) and continuous infusion groups (r = -0.7237 to -0.5322, all p < 0.0001, except r = -0.1474 for the highest dose).

Similar correlations were noted between exhaled propofol and MAP (r = -0.6444 to -0.9178) and HR (r = -0.4413 to -0.8343). However, weak associations with r= -0.1463 (P <0.0001) were observed at the highest continuous infusion rate (0.7 mg/kg/min). **Conclusion(s):** UV-TOF-MS has emerged as a promising technology for real-time monitoring of exhaled propofol. The observed correlations of exhaled propofol levels not only with BIS (Bispectral Index) values but also with blood pressure highlights its potential for efficiently tracking anesthesia depth and hemodynamic effects. This advancement provides a promising pathway for personalized anesthesia management of propofol in clinical settings.

11AP05-3

Preoperative Anxiolysis and Treatment Expectation (PATE Trial): Open-label placebo treatment to reduce preoperative anxiety in female patients undergoing gynecological laparoscopic surgery – A bicentric, prospective, randomized-controlled trial

<u>J. Aulenkamp</u>^{1,2}, J. Wessels³, R. Tillmann¹, S. Benson⁴, T. Brenner¹, S. Elsenbruch^{5,2}

¹University Hospital Essen, University of Duisburg-Essen, Department of Anesthesiology and Intensive Care Medicine, Essen, Germany, ²University Hospital Essen, University of Duisburg-Essen, Department of Neurology, Center for Translational Neuro- and Behavioral Sciences (C-TNBS), Essen, Germany, ³University Medical Center Hamburg Eppendorf, Department of Anaesthesiology, Hamburg, Germany, ⁴University Hospital Essen, University of Duisburg-Essen, Institute for Medical Education, Center for Translational Neuro- and Behavioral Sciences (C-TNBS), Essen, Germany, ⁵Ruhr University Bochum, Bochum, Germany, Department of Medical Psychology and Medical Sociology, Essen, Germany

Background and Goal of Study: Preoperative anxiety affects nearly half of all surgical patients and often leads to poorer outcomes, including delayed recovery. While sedatives are often used to address anxiety, they have side effects and debateable efficacy, leaving a gap for alternative approaches. Open-label placebos (OLPs) provide a way to harness placebo effects by enhancing positive treatment expectations, where patients consent to taking a placebo¹.

This study aims to determine whether OLPs can effectively reduce preoperative anxiety and to investigate whether their effects can be amplified through social learning.

Materials and Methods: This ongoing bicentric randomized controlled trial (see study protocol²) plans to enroll 120 gynecological patients undergoing laparoscopic surgery.

In this interim analysis, 65 participants were randomly assigned to one of three groups: (1) a control group receiving treatment as usual (TAU, n=21), (2) an OLP group (n=21), and (3) an OLP+Video group (n=23), which added a video featuring a patient perspective about OLPs.

Anxiety was measured preoperatively using a numeric rating scale (NRS, 0 = not anxious to 10 = very anxious).

Secondary outcomes included postoperative pain and patients' acceptance of OLPs.

Results and Discussion: Preliminary findings reveal that anxiety levels were lowest in the OLP group (3.5 \pm 1.9), followed by the OLP+Video group (4.1 \pm 3.1), and highest in the TAU group (5.2 \pm 3.2). While these differences are not statistically significant, the current sample size is likely insufficient to detect small-to-moderate effects.

Notably, patient acceptance of OLPs was very high: 74% indicated they would use OLPs again in a similar situation, and 86% would consider them for other conditions, such as pain or sleep disturbances. The results suggest the potential acceptability of leveraging targeted placebo effects in perioperative care.

Conclusion(s): OLPs offer a novel and patient-centered approach to addressing preoperative anxiety. While awaiting final results, this trial aims to contribute to the evidence base for OLPs, potentially supporting their integration into perioperative care, particularly for patients with contraindications to sedatives.

11AP05-4

Retrospective observational study comparing the combination of granisetron and dexamethasone vs. ondansetron and dexamethasone as prophylaxis in patients at high risk for PONV undergoing orthopedic surgeries

P. Makwana¹, R. Deshmukh²

Mubadala Health Dubai, Anesthesia, Dubai, United Arab Emirates, ²Medcare Orthpedic and Spine Hospital, Anesthesia, Dubai, United Arab Emirates

Background and Goal of Study: Postoperative nausea and vomiting (PONV) is the 2nd most common complaint following surgery. According to the 4th Consensus Guidelines for the Management of Postoperative Nausea and Vomiting the literature on combination of 2 or more antiemetics for the prevention of PONV is robust and shows superiority over single agents for most studies (evidence A1). Granisetron is considered a more effective and potent antiemetic than Ondansetron.

Our aim of conducting this study was to compare the subgroups of Ondansetron vs Granisetron in combination with Dexamethasone

Materials and Methods: A retrospective study was conducted on 60 patients undergoing an orthopaedic surgical procedure under general anaesthesia. Main inclusion criteria was Apfel score 3 or above. Patients were divided into two groups of 30 individuals each. Just after induction of general anaesthesia, each patient received Inj. Dexamethasone 4 mg iv plus at the end of surgery approximately 30 minutes before extubation, they received either Ondansetron 4 mg iv or Granisetron 1 mg iv. A balanced anaesthetic technique was used for all patients.

Patients were assessed for episodes of nausea, retching, vomiting, and the need for rescue antiemetics at intervals of 1, 6 and 24 hours after surgery. Incidence of complete response and adverse effects were assessed at 24 hours postoperatively. Data was tabulated and subjected to statistical analysis using the chi-square test, unpaired t-test, or the Mann-Whitney U-test as appropriate. A P-value less than 0.05 was considered statistically significant.

Results and Discussion: There was no statistically significant difference between the two groups for incidence of PONV or the need for rescue antiemetic.

Conclusion(s): Combination therapy should consist of drugs from different classes, using minimum effective doses, and the choice of drugs will be determined by patient factors as well as institutional policy and drug availability. However, larger studies are needed on this subject.

11AP05-5

A case report of Kounis syndrome type I triggered by sugammadex administration

<u>K. Kuwahara</u>¹, T. Sugiura¹, S. Sato¹, S. Nagamatsu¹, I. Shiroh², J. Okazaki¹

¹Kimitsu Chuo Hospital, Anesthesiology, Kisarazu-shi, Japan, ²Chiba unibersity, Respiratory Molecular Medicine, Chiba, Japan

Background: Kounis syndrome (KS) is a rare type of anaphylaxis involving acute coronary syndrome triggered by allergic reactions. It occurs when inflammatory mediators from an allergic response affect coronary arteries and is classified into four types based on the underlying mechanism. Type I is characterized by coronary artery spasm without pre-existing coronary artery disease.¹

Case Report: We report a case of Type I KS following the administration of sugammadex, a reversal agent for rocuronium-induced neuromuscular blockade. The patient, a 66-year-old male, 161cm, 54kg, was under treatment for hypertension, hyperlipidemia, and hyperuricemia. His medical history included a valacyclovir allergy and a smoking history of 20 cigarettes/day for 15 years but no evidence of coronary artery disease, electrocardiogram (ECG) abnormalities, or exercise intolerance.

He was scheduled for transurethral resection of a bladder tumor. General anesthesia was induced and maintained under deep neuromuscular blockade with rocuronium to prevent adductor muscle contraction. Neuromuscular reversal was achieved with 250 mg of sugammadex, and extubation was performed.

Shortly after extubation, the patient's systolic blood pressure dropped to 50 mmHg, followed by a marked ST-segment elevation on ECG. The patient's consciousness is clear, showing no skin or respiratory symptoms indicative of anaphylaxis.

However, he remained unresponsive to vasopressors, including phenylephrine and norepinephrine, and progressed to complete atrioventricular block.

Preparations for temporary pacing and circulatory support were initiated. Based on the presence of suspected drugs and hypotension, KS was considered. Administration of adrenaline, antihistamines, and corticosteroids led to rapid improvement in hemodynamic and ECG parameters.

Coronary angiography revealed no abnormalities, and intradermal testing confirmed hypersensitivity to sugammadex, resulting in a diagnosis of Type I KS.

Discussion: The incidence of anaphylaxis associated with sugammadex is reported to be 0.0029-0.039%, with cardiac arrest in KS cases occurring in 6.3%²⁾, highlighting the importance of prompt and effective management.

In this case, rapid diagnosis and therapeutic intervention ensured a favorable outcome.

Reference:

1. J. Clin. Med, 13, 1647. 2024 2) Int J Car, 232p1-4, 2017

Learning points: Clinicians should consider the possibility of KS when anaphylaxis occurs and adjust management strategies accordingly.

11AP05-6

Comparison of epidural morphine versus epidural dexamethasone for postoperative analgesia following lumbar discectomy: a double blinded, randomised control study

S. Verma¹, N. Kaloria¹, M. Kaur²
¹Postgraduate Institute of Medical Education and Research, Anaesthesia and Intensive care, Chandigarh, India, ²All India Institute of Medical Sciences, Anaesthesia and intensive care, Jodhpur, India

Background and Goal of Study: Effective postoperative pain management is critical for recovery following lumbar discectomy. Intravenous opioids, though effective, are associated with delayed recovery and prolonged hospital stays.

This study evaluates the comparative analgesic efficacy and safety of gelfoam soaked with epidural morphine versus dexamethasone.

Materials and Methods: This prospective, double-blinded, randomized controlled trial included 60 patients undergoing singlelevel lumbar discectomy. Participants were randomized into two groups: Group M (gel foam soaked with 3 mg of morphine) and Group D (gelfoam soaked with 8 mg of dexamethasone).

The primary outcome was the time to first rescue analgesia within the first 48 hours postoperatively. Secondary outcomes included pain intensity assessed via Visual Analogue Scale (VAS), total rescue analgesic requirement, and adverse events. Pain and sedation scores were recorded at predetermined intervals (0, 6, 12, 18, 24, 36, and 48 hours).

Results and Discussion: Group M showed a longer mean time to first rescue analgesia (26 ± 12 hours) compared to Group D (19 ± 6 hours), though this difference was not statistically significant (p=0.3). Pain scores were significantly lower in Group M at 48 hours (p=0.006), with a trend toward lower scores at earlier time points. The need for rescue analgesia was significantly lower in Group M at 18 hours (p=0.049).

The proportion of patients with complete response (minimal/no pain and no rescue analgesia) was higher in Group M (83%) compared to Group D (57%; p=0.02). Both groups showed minimal adverse effects, with only one episode of nausea in Group M.

Conclusion(s): Gelfoam soaked with epidural morphine provides superior analgesia compared to dexamethasone, evidenced by lower pain scores, reduced rescue analgesia requirements, and higher complete response rates over 48 hours postoperatively. This method is safe and demonstrates a sustained analgesic effect, making it a valuable option for postoperative pain management in lumbar discectomy patients.

Case report: Cervical subcutaneous emphysema and hypercarbia as complications of laparoscopic surgery – Challenges in recognition and management

M.I. Silva Carvalho¹, <u>G.L.R. Freitas Pinto</u>¹, J. Paulo¹ ¹Unidade Local de Saúde Gaia e Espinho, Department of Anesthesiology, Vila Nova de Gaia, Portugal

Background: Subcutaneous emphysema (SE) is a rare complication of laparoscopic surgeries, with an incidence of 0.43%–2.3%¹. It occurs when gas escapes into soft tissues during pneumoperitoneum. Although often benign, massive SE can be life-threatening.

Case Report: A 59-year-old female, ASA II, underwent elective laparoscopic subtotal gastrectomy. Preoperative vital signs were stable: SpO_2 99%, pulse 76/min, and blood pressure 126/85 mmHg. Total intravenous anesthesia was performed with rapid sequence induction.

Protective lung ventilation was used (tidal volume of 6 mL/kg, with permissive hypercapnia, PEEP of 6 cmH20), reaching peak inspiratory pressure of 19 mmHg, and EtCO₂ of 34-36 mmHg.

After one hour, EtCO₂ progressively increased to 62 mmHg. Hypercarbia led to immediate surgical team notification and a procedure pause. CO₂washout measures included increasing respiratory rate and oxygen flow to 10 L/min with FiO₂ at 100%.

The ventilatory system was inspected and found intact. Physical examination revealed extensive crepitus from mid-face to chest. Respiratory acidosis was confirmed via arterial blood gas analysis.

Despite interventions, EtCO₂only decreased to 50 mmHg after 20 minutes. Due to the predicted duration and recurrence risk, the team converted to an open approach, completing it without complications

The patient recovered with stable vitals and EtCO₂ below 45 mmHg. A postoperative chest radiograph ruled out pneumothorax, and SE resolved spontaneously within 24 hours without additional treatment.

Discussion: This case highlights the importance of early detection and management of SE. Intraoperative hypercarbia and crepitus are key indicators. Preventive measures include maintaining low intra-abdominal pressures, optimizing ventilation, and closely monitoring EtCO₂². Prompt conversion to open surgery may be necessary when SE compromises respiratory status.

References:

- 1. Ito K et al. Subcutaneous emphysema associated with laparoscopic or robotic abdominal surgery: a retrospective single-center study. *Surg Endosc. 2024*.
- Aldakhil SK et al. Subcutaneous emphysema and hypercarbia in laparoscopic procedures: case report. J Surg Case Rep. 2020.
 Learning points: Subcutaneous emphysema during laparoscopy can escalate to airway or respiratory compromise if unrecognized.

Vigilance in intraoperative monitoring and early recognition of hypercarbia and crepitus are critical.

Proactive measures and conversion to open surgery may prevent severe complications.

11AP05-8

Electroconvulsive therapy in patient with ascending aortic aneurysm: a case report

J. Groenewald¹, M. Finnegan², R. Fenton¹, V. McMullan¹, C. Frith-Keyes¹, C. O'Connor¹

¹Tallaght University Hospital, Anaesthesiology, Dublin, Ireland, ²Tallaght University Hospital, Psychiatry, Dublin, Ireland

Background: Electroconvulsive therapy (ECT) is widely accepted as one of the most effective therapeutic interventions for a wide range of psychiatric disorders1.

Activation of the autonomic nervous system, triggered by the administration of an electrical current to the brain under general anaesthesia, can precipitate a tachycardia and hypertension as much as 20-40% above its baseline².

Case Report: We present the case of a 65 year old patient with severe depression who presented for ECT treatment in our institution with a known ascending aortic aneurysm of 4.4cm.

While the risk of aneurysmal rupture during the sympathetic surge was recognised, multidisciplinary meetings between cardiothoracic surgeons, perioperative anaesthesiologists and clinical psychiatrists established no precedent amongst our collective clinical expertise.

During this time, the patient's clinical condition worsened significantly and it was decided to proceed. Good blood pressure control was established pharmacologically in the preoperative phase and during treatment with non-invasive blood pressure monitoring. The patient received 8 ECT treatments in total, after which time her clinical condition improved and the treatments were ceased.

Discussion: There is a published review of ECT in 8 patients with unrepaired abdominal aortic aneurysms3 and a case report of successful ECT after an ascending aorta replacement4.

However, there are no published guidelines or case reports of patients with ascending aortic aneurysms undergoing ECT.

Our experience demonstrates that ECT can be a treatment offered to this cohort of patients where life-threatening psychiatric illness persists.

11AP05-10 **Multidisciplinary consultation after** hospitalization in the burn unit - A new direction

L. Spencer¹, I. Tomé Ribeiro¹, M.J. Salsinha², M.E. Silva², F. Vaz¹. A.L. Jardim¹

¹Unidade Local de Saúde São José, Anesthesiology, Lisboa, Portugal, ²Unidade Local de Saúde São José. Nurse department Burn Unit, Lisboa, Portugal

As critically ill patients, burn patients are at increased risk of developing disorders after hospitalization in the Burn Unit (BU). In this context, a new multidisciplinary evaluation was created in 2023 at the São José Local Health Unit, by Anesthesiology and Nursing team, the Post-hospitalization consultation in the Burn

Its objectives are: to identify sequelae in the various domains, that condition changes in quality of life: to refer to the necessary clinical areas, and to coordinate with Primary Health Care, in order to optimize recovery, reduce morbidity and re-hospitalization rates. Since the start of this pioneering consultation, 176 patients admitted to the BU between April 2023 and April 2024 were analyzed. The adopted inclusion criteria were: Transfer from the BU > 6m, possible consultation of the clinical file, previous telephone contact. Seventy-one patients were excluded according to the following criteria: Deceased; current hospitalization in long-term care, rehabilitation or hospital; Non-resident foreigners; Patient refusal; 3 failed attempts of contact; neurological condition that prevented assessment and patients transferred to other BU.

Of the 63 patients evaluated in the first consultation, 46 still presented complaints related to the burn, as illustrated in figure 1.

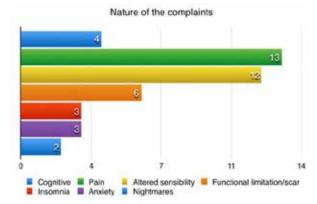

Figure 1. Nature of the identified sequelae complaints.

At the time of the assessment, 13 patients had not received any clinical follow-up, 10 of whom still had complaints associated with the burn and hospitalization. There were 38 patients without clinical referral, the referrals were mostly to chronic pain consultation, psychiatry, neurology and primary care.

The changes resulting from hospitalization lead to a decrease in quality of life and greater difficulty in re-adapting to society. Identifying and monitoring these situations is essential for resolving them and reintegrating the patient into an active and independent lifestyle.

Given the shortage of scientific resources that document the monitoring of this specific population, this is also a crucial opportunity to better adapt and adapt the individualized clinical situation of hospitalized patients to the pharmacological and methodological choices currently used.

11AP05-11

Are there differences in the outcomes of the ERAS colorectal pathway based on the level of compliance?

L. Cortes Pacheco¹, <u>M. David Cardiga</u>¹, M. Brízido¹, J. Costa Mendes¹, J. Oliveira¹ ¹Hospital da Luz de Lisboa, Anesthesiology, Lisboa, Portugal

Background and Goal of Study: Enhanced recovery after surgery (ERAS*) pathways have been proven to improve postoperative recovery, reduce morbidity and length of stay (LOS) after colorectal surgery. It is well-established that compliance above 70% is associated with better outcomes compared to compliance below 70%. However, it remains debated whether outcomes further improve with increasing compliance among already compliant patients (>70%).

This audit aimed to analyze whether higher compliance levels correlate with progressively better outcomes.

Materials and Methods: The audit included 749 patients enrolled in our institution's colorectal ERAS* program from April 2018 to October 2024, all with ≥70% compliance.

Patients were divided into three groups: group 1, 2 and 3 for overall compliance between 70-79%, 80-89%, and ≥90%, respectively. Descriptive statistics was used to compare the groups.

Outcomes analyzed included hospital length of stay (LOS), complications, 30-day mortality, unplanned intensive care unit (ICU) admissions, and readmissions. Linear and logistic regressions of the outcome variables were later used to adjust for possible confounders.

Results and Discussion: Of the 749 patients, 23,4% were in group 1, 41,4% in group 2, and 35,3% in group 3. Groups were generally balanced, except for ASA performance status, severe heart disease prevalence, intraoperative blood loss (lower with higher compliance), and laparoscopic surgery rates (higher with higher compliance).

Outcomes improved along with higher compliance: in group 1, 2 and 3, median LOS decreased from 6 to 5 to 4 days (p=0,001); 30-day mortality dropped from 3,0% to 1,0% to 0% (p=0,014); complication rates decreased from 55,4% to 36,5% to 17,8% (p<0,001); and ICU admissions fell from 12,0% to 5,5% to 1,9% (p<0,001), respectively.

These differences were statistically significant and remained robust after adjusting for confounders. Hospital readmission rates remained similar across groups.

Conclusion(s): Increased compliance with the ERAS® program correlates with progressively better outcomes, including reduced LOS, complications, and mortality.

Full adherence to ERAS® protocols enhances outcomes even in already compliant patients, reinforcing the value of maximizing compliance.

11AP05-12

Effect of dexmedetomidine versus subanaesthetic ketamine infusions on postoperative cognitive function in patients undergoing major abdominal surgeries: a randomized controlled trial

P.K. Das¹, P.B. Rao¹, K. D S¹
¹AIIMS, Bhubaneswar, Anaesthesiology & Critical Care, Bhubaneswar, India

Background and Goal of Study: Cognitive dysfunction is a common neurological complication after major surgeries, affecting 25-40% of patients¹. First identified by Bedford in 1955², post-operative cognitive dysfunction (POCD) can present as memory loss, impaired concentration, or delirium, with an incidence of 25.8% after one week and 9.9% three months post-surgery³. Risk factors include advanced age, prolonged surgery, pre-existing cognitive impairment, and certain medications^{3,4}.

The Mini-Mental State Examination (MMSE) is often used to assess cognitive function.

The study aims to compare the effects of dexmedetomidine and ketamine, both known for their neuroprotective properties, on POCD and MMSE scores, after major abdominal surgeries.

Materials and Methods: The study was a prospective, randomized trial conducted at AIIMS Bhubaneswar from Sept 2020 to May 2022. Patients aged 18-80 years, undergoing elective major abdominal surgeries with ASA 1 or 2, were randomised into three groups:

Group A received dexmedetomidine infusion (0.5 mcg/kg/hr), Group B received ketamine infusion (0.1 mg/kg/hr), and:

Group C received placebo (normal saline at 6 ml/hr).

Standardized anesthesia and postoperative analgesia protocols were followed, and the MMSE score was assessed preoperatively and 6 hours post-extubation.

Results and Discussion: Postoperative MMSE scores were significantly higher in the Dex group (26.88±1.9) compared to the ketamine (24.88±1.68) and placebo groups (25.76±2.04) (p=0.02). The time to extubation and recovery room Modified Aldrete scores were significantly better in the Dex group. Additionally, intraoperative hemodynamics were lower in the Dex group.

Conclusion(s): Dexmedetomidine significantly preserves cognitive function better than subanesthetic ketamine and placebo after elective major abdominal surgeries. It reduces the incidence of cognitive dysfunction, particularly in abdominal surgeries.

Extremely low BIS levels during robotic radical prostatectomy: an intraoperative case report

P. Vieito¹, E. Tavares¹, M.E. Amadeu¹, H. Machado¹ ¹Unidade Local de Saúde de Santo António. Departamento de Anestesiologia, Porto, Portugal

Background: Monitoring anesthesia depth is critical for patient safety during surgery. The Bispectral Index (BIS) is commonly used to assess the hypnotic effects of anesthetics on the brain. Maintaining BIS values between 40 and 60 is essential to prevent awareness and reduce long-term neurological damage.

Case report: A 68-year-old male with hypertension and diabetes underwent robotic prostatectomy for prostate cancer. He received general anesthesia with Target-Controlled Infusion (TCI) of Propofol (20mg/mL) using the Schnider model, maintaining BIS values between 40 and 60.

The patient was intubated and blood pressure was monitored non-invasively. He was placed in a 17° Trendelenburg position for the surgery. After 3.5 hours, as the resection neared completion, the BIS dropped to 18, prompting a reduction in the Propofol dose. BIS continued to decline and TCI infusion was stopped.

Despite 25 minutes without anesthetic, the BIS remained between 1 and 17, with very low density of waves in the Density Spectral Array (DSA), almost flat electroencephalography (EEG) activity and suppression rates of 80-100%. The sensors and signals were checked and no dysfunction was found.

Prior Mean Arterial Pressure (MAP) was 83 mmHg and the heart 85 bpm, both varying less than 20% during this period. Ventilation was unaffected as Rocuronium perfusion was maintained. Arterial CO2 was 55 mmHg.

Cerebral oximetry sensors were placed and showed no significant asymmetry (80% right, 84% left), despite the reference value for this patient not being known. Cerebral edema was suspected and Mannitol 2g was administered intraoperatively.

Propofol infusion was resumed at lower doses as the BIS began to slowly rise. Anesthetic emergence was unexpectedly rapid and the patient was immediately oriented in time and place.

No neurological deficits or signs of awareness were found upon awakening, in the Post-anesthesia Care Unit (PACU) or in the infirmary.

Discussion: Trendelenburg position, pneumoperitoneum and hypercapnia can increase intracranial pressure (ICP), which may lead to cerebral edema, potentially reducing EEG amplitude below the BIS detection threshold.

This case underscores the importance of early identification and management of cerebral edema to prevent complications, from mild cognitive impairment to death.

Learning points:

- Trendelenburg, pneumoperitoneum, and hypercapnia can increase ICP.
- · Cerebral edema should be promptly addressed to avoid postoperative complications.

11AP06-2

Patient centred outcomes and resource utilisation (PACORUS-D) - Validation of "Days alive and out of hospital" in noncardiac surgery a prospective multicenter cohort study

A. Stroda¹, C. Bußhoff¹, M. Rallis¹, O. Aydemir¹, T. Schüssler¹, G. Lurati Buse¹, PACORUS-D Investigators ¹University Hopital Duesseldorf, Department of Anaesthesiology, Duesseldorf, Germany

Background and Goal of Study: In the perioperative setting, "days alive and out of hospital" (DAOH) has been proposed as patient-centred outcome [1].

Nevertheless, this recently endorsed endpoint still suffers from limited validation across health care systems. Our aims were:

- 1. Quantifying DAOH after noncardiac surgery in Germany;
- 2. Assessing the impact of preoperative risk factors and postoperative complications on DAOH;
- 3. Evaluating the criterion (predictive) validity of DAOH for patient-reported disability at 365 days.

Materials and Methods: prospective multicenter cohort study (PACORUS-D; NCT: NCT04675905; Main endpoints: DAOH at 30 and 365 days; secondary endpoints: disability after 1 year (WHO-DAS 2.0 score), 1-year mortality; main exposures:

- 1. Preoperative risk (ACS NSQIP);
- 2. Postoperative complications (Clavien-Dindo class);
- 3. DAOH; We conducted descriptive analysis, multivariate quantile and logistic regression analysis.

Results and Discussion: Out of 1474 patients, 1030 with complete case and follow up after 1 year were analyzed (67% male, age: 67 [60-74] years). Median DAOH was 24 [Interquartile range (IQR): 18-27] after 30 days and 357 [IQR: 341-361] after 365 days. 1-year mortality was 6.4% and "new onset clinically significant disability" at 365 days was 12.6%. Quantile regression analysis showed significant independent association of preoperative risk and postoperative complications with DAOH (s. Figure 1).

Odds ratio (OR) for the association of 30 days DAOH with new onset 1 year disability was 0.94 [95%CI: (0.92-0.96)].

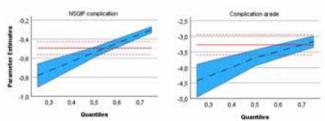

Figure 1.

Conclusion(s): This cohort confirms the construct validity of DAOH in the German health care systems and the predictive ability of DOAH at 30 days for new 1-year disability, i.e. the predictive ability of the patient-centred outcome DAOH for the patient-reported outcome disability.

11AP06-3

Acute myocardial damage in a young patient with no risk factors after epidural catheter insertion

M. Diaz Rueda¹, M.J. García Cebrián¹, A. Martin Arrabal¹, D. Diaz Perez¹, J.C. Callejas Rodelas¹, M.R. Pretel Lara¹ ¹Hospital Clínico San Cecilio, Anesthesia Service, Granada, Spain

Background: Myocardial injury after non-cardiac surgery (MINS) is defined as myocardial injury due to ischemia occurring during or within 30 days after a non-cardiac surgery. Risk factors include: age ≥65 years, coronary or peripheral arterial disease, diabetes, renal insufficiency, elevated pro-BNP, ST-segment changes.

Case Report: 40-year-old female scheduled for laparotomic hysterectomy. Medical history: smoking, epilepsy, and depression. In the operating room she was in good general condition.

Decision was made to place an epidural catheter with easy single puncture, no cerebrospinal fluid or blood return upon aspiration, and negative test doses.

Prior to induction, she experienced hypotension and bradycardia, episodes of agitation and decreased consciousness level while maintaining spontaneous ventilation. Electrocardiogram (previously normal) showed ST-segment depression in the inferior leads and precordial leads.

Surgery was suspended, and the patient transferred to the ICU where echocardiography showed no segmental alterations. The patient improved favorably. Serial troponin tests peaked at 1270 ng/mL with normalization of the ECG. Coronary angiography found no significant coronary lesions.

Discussion: MINS is a rare but potentially fatal complication in patients without risk factors, has prognostic implications, and should be recognized for its possible occurrence and management.

The special scope of our case and our aim to emphasize the possibility of occurrence in unsuspecting patients; also to delve into the broader definition of myocardial damage in perioperative period and not just the purist diagnosis of infarction, as we are not accounting for a high number of patients.

Learning points: Diagnosis based on two criteria:

- Non-cardiac surgery within the last 30 days with an elevated troponin level
- · Exclusion of non-ischemic causes of troponin elevation

The diagnosis of MINS is broader than that of perioperative myocardial infarction; it includes not only myocardial infarction but also other causes of perioperative myocardial injury of prognostic importance due to ischemia.

MINS incidence is estimated around 8% (though studies with patients <45 years without associated risk factors are still inconclusive). It is more frequent within the first 48 hours post-surgery and increases the risk of non-fatal cardiac arrest, heart failure, and stroke compared to patients without MINS. Troponin elevation is an independent predictor of 30-day mortality.

11AP06-4

Patient centred outcomes and resource utilisation (PACORUS-D) – Disability after noncardiac surgery: a prospective multicenter cohort study

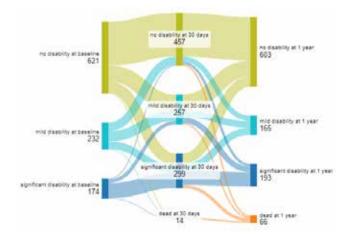

A. Stroda¹, C. Bußhoff¹, M. Rallis¹, O. Aydemir¹, T. Schüssler¹, G. Lurati Buse¹, PACORUS-D investigators ¹University Hopital Duesseldorf, Department of Anaesthesiology, Duesseldorf, Germany

Background and Goal of Study: Recently, the 12-items WHODAS 2.0 has been proposed as preferred tool for the measurement of impaired functional status (disability) after surgery [1]. Nevertheless, epidemiology of disability in unselected patients after non-cardiac surgery is underexplored. Thus, we aim at:

- 1. Quantifying disability after noncardiac surgery
- 2. Describing the flow of disability from preoperative status to 365 days after surgery;
- 3. Assessing the impact of preoperative risk factors and postoperative complications on postoperative disability.

Materials and Methods: prospective multicenter cohort study (PACORUS-D; NCT: NCT04675905); Main endpoint: "new onset clinically significant disability" at 30 and 365 days (WHODAS 2.0 ≥ 35% with increase of at least 5% compared to baseline; Main exposures: 1) preoperative risk (ACS NSQIP); 2) postoperative complications (Clavien-Dindo class). We conducted descriptive analysis including Sankey diagram and multivariate logistic regression analysis.

Results and Discussion: Of 1474 patients, 1030 with complete follow up at 1 year were analyzed (67% male, median age: 67 [Interquartile range (IQR): 60-74] years). At 30 and 365 days, respectively, 21.5% and 12.6% reported a new significant disability. Figure 1 shows the flow of disability from preoperative status to 365 days after noncardiac surgery. The Odds ratio (OR) for the independent association of preoperative risk with disability after 30 and 365 days was 1.06 [95% CI: (0.96-1.17)] and 1.08 [95% CI: (0.97-1.20)], respectively. The OR for the independent association of postoperative complications with disability after 30 and 365 days was 1.46 [95%CI: (1.28-1.65)] and 1.40 [95%CI: (1.23-1.59)].

Conclusion(s): This prospective multicenter cohort indicated that while at 30 days disability was increased, by one year, disability returned to levels comparable to baseline. In contrast to postoperative complications, the preoperative risk has no impact on new postoperative disability.

11AP06-5

Nitrous oxide added at the end of sevoflurane anesthesia hastens early recovery - SEVONATE trial

B. Mraovic¹, D. Gassmayr², T. Šimurina³ ¹The Ohio State University, Department of Anesthesiology, Columbus, United States, 2 Medical University of Graz, Medical School, Graz, Austria, ³University of Zadar, Department of Anesthesiology and ICU, Zadar, Croatia

Background and Goal of Study: ISONATE trial showed when N₂O was administered at the end of isoflurane anesthesia it significantly shortened emergence without increasing the incidence of PONV.1

We investigated effects of N₂O at the end of sevoflurane anesthesia on recovery.

Materials and Methods: Patients aged 18-80 years, ASA PS I - III, undergoing elective laparotomy/laparoscopic surgery with duration of >120 min were randomized into 2 groups according to carrier gasses: GO₂ - air/30% O₂ and GN₂O - same mixture until last 30 minutes of surgery when 70% N₂O/30% O₂ was used. Anesthesia was standardized and maintained with sevoflurane ~1 MAC.

Time to extubation, eye opening, following commands, answering simple questions and orientation were recorded. Simple verbal orders were repeated every 15 seconds.

Results and Discussion: 51 patients in GN₂O and 50 in GO₂ completed the study. There were no differences in characteristics between the two groups. Mean time of N₂O administration in GN₂O was 24.8±9.4 min.

Mean time to extubation was faster in the GN₂O (5.5±2.6 min) than in the GO_a (9.1±4.0 min), mean difference 3.6 min; 95% CI 2.3 to 4.9, P<0.001, also ability to open eyes, follow commands, and being oriented (mean differences 3.6, 3.4 and 3.7 minutes, respectively, P<0.001 in all). (Table 1.)

	GN ₂ O (air/ N ₂ O) n=51	GO ₂ (air) n=50	Р
Open eyes (sec)	258 ±154	476 ±238	<0.001*
Follow commands (sec)	316±167	521 ±234	<0.001*
Tracheal extubation (sec)	330 ±159	543±242	<0.001*
Answering to simple questions (sec)	525±146	632±278	0.042*
Orientation (sec)	520±220	739±318	<0.001*
Complications on emergence (n, %)	9 (18)	11 (22)	0.625

Data presented as mean ±SD, n (%) *P<0.05

Table 1. Early recovery.

There were no differences between the groups in postoperative pain, in early and late postoperative recovery. GN2O group received significantly less pain medications; tramadol (medians 0 vs 100 mg, P=0.037), paracetamol (33% vs 62%, P=0.004) and ketoprofen (16% vs 32%, P=0.054), respectively. GN₂O had higher PONV risk scores and increased incidence of early PONV. The quality of late recovery was not influenced by adding N₂O.

Conclusion: This study showed that adding 70% N₂O in the last 30 minutes of general anesthesia maintained with sevoflurane hastened extubation and early recovery. Moreover, it reduced the overall use of postoperative pain medications.

Pancreaticoduodenectomy for insulinoma in a patient with untreated severe aortic stenosis: a case report

J.F. Landeira Afonso Barata¹,

I. de Portugal Mascarenhas do Amaral Lucas¹, C. Bento¹ ¹Unidade Local de Saúde de Coimbra, Serviço de Anestesiologia, Coimbra, Portugal

Background: Insulinoma is a rare insulin-producing tumor of the pancreas. Definitive treatment requires surgical resection and the anaesthetic approach has important particularities. Furthermore, managing major comorbidities, such as severe aortic stenosis, can pose significant challenges for anaesthetic planning.2

Case Report: A 73-year-old woman with severe hypoglycaemia was diagnosed with insulinoma and offered pancreaticoduodenectomy.

She had a history of atrial fibrillation and severe aortic stenosis. The echocardiogram showed the aortic valve with a mean pressure gradient of 47mmHg, a functional valve area of 0.8-0.9cm² and a systolic ventricular ejection fraction of 60%.

Preoperatively, a continuous infusion of 10% glucose at 40ml/h was started after the beginning of the fasting period, which was maintained intraoperatively until tumour resection. The surgery was performed under balanced general anaesthesia with glycaemic monitoring via Freestyle libre 2® every 15 minutes and hourly blood gas test. Diazoxide 25mg and verapamil 80mg were administered prior to surgery and octeotride 0.2mg intraoperatively. Due to severe aortic stenosis, strict haemodynamic control was carried out using invasive arterial pressures and continuous noradrenaline perfusion. Particular attention was also paid to controlling heart rate and intravascular volume. Due to the risk of arrhythmia, multifunction paddles were applied to the patient and a defibrillator was placed in the operating room.

The procedure and post-operative period were uneventful. Patient was discharged after 7 days.

Discussion: Insulinoma can lead to life-threatening situations due to hypoglycaemia.1 Severe aortic stenosis is associated with an increased risk of peri-operative morbimortality, with valve repair recommended prior to high-risk surgery, such as pancreaticoduodenectomy.2 In asymptomatic patients with severe aortic stenosis and preserved systolic ejection fraction, high-risk surgery may be reasonable with strict haemodynamic monitoring in place.2

2-Rohatgi N, et al. Perioperative Considerations for Patients with Severe Aortic Stenosis Undergoing Elective Noncardiac Surgery. Am J Med. 2023;136(10):960-962

Learning points: The approach to patients with severe aortic stenosis proposed for high-risk surgery should be individualised, considering the risk/benefit of postponing the procedure.

11AP06-7 When the cause isn't obvious: a cardiac arrest event in the operating room

F. Ramos¹, <u>P. Gaspar</u>¹, R. Calhau¹, I. Neri¹

¹Western Lisbon Local Health Unit, Anesthesiology, Lisbon, Portugal

Background: Cardiac arrest (CA) in the operating room (OR) is a rare event with more than 50% mortality. When it happens it's important that all healthcare professionals know how to manage the case and correct reversible causes, even the ones that don't come immediately to our mind.

Case Report: We present the case of a 64-year-old dependent woman with type 1 chronic respiratory insufficiency after bilateral pulmonary embolism, epilepsy, cognitive impairment and left hemiparesis sequelae to meningitis. She was submitted to urgent laparotomy due to intestinal ischemia.

She was in septic shock (blood pressure (BP) 77/42 mmHg) with multiorgan dysfunction. Before induction we initiated invasive monitoring of the BP and started fluid therapy as well as a noradrenaline (NA) infusion.

Then we performed an uneventful rapid sequence intubation with ketamine and rocuronium. A few minutes later, CA occurred (pulseless electrical activity vs ventricular fibrillation).

Advanced life support was initiated with the administration of adrenaline 1mg and there was return of spontaneous circulation (ROSC) after 2 minutes. Two more episodes of pulseless ventricular tachycardia followed with ROSC after defibrillation.

After the stabilization, the surgery began and was successful. Hemodynamic stability was maintained with NA and terlipressin. The patient was then transferred to the intensive care unit (ICU).

Discussion: Further investigation in the ICU showed T wave inversion in DI, DII and aVF and increased Troponin/NT-proBNP. Transthoracic echocardiogram revealed hypokinesia of the anterolateral wall (ejection fraction 20%).

These findings suggested a type I myocardial infarction. However, cardiac magnetic resonance showed normal systolic function without evidence of structural heart disease and hemodynamic compromise.

Reference:

Shahreyar M, Fahhoum R, Akinseye O, Bhandari S, Dang G, Khouzam RN. Severe sepsis and cardiac arrhythmias. Ann Transl Med. 2018 Jan;6(1):6

Learning points: Despite being a rare event, this patient had several predictors: age, elevated ASA classification, septic shock and urgent surgery. It's important to follow the advanced life support algorithm like in any other situation and focus on the reversible causes, even if in some cases, the differential diagnosis isn't possible. Moreover, CA due to sepsis typically occurs in a non-shockable rhythm. This case represents an exception.

11AP06-8

Takotsubo cardiomyopathy during a total hip arthroplasty

M. Guarda¹, <u>P. Branco</u>¹, R. Pato¹, A. Delgado¹, N. Santos¹, T. Seixas¹

¹Hospital Professor Doutor Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Takotsubo cardiomyopathy (TCM) is a rare cardiac complication in the perioperative setting and mortality can be as high as 20% in the 10-year follow-up¹.

Only a few cases have been reported in orthopaedic and surgical literature

Case Report: We present a clinical case of TCM in a 73-yearold woman during an elective total hip arthroplasty. After a total blood loss of 1,5 liters, the patient developed acute chest pain, electrocardiography showed ST segment elevation and laboratory workup revealed an elevation of myocardial biomarkers. Ecocardiography revealed a left ventricular ejection fraction (LVEF) of 35%, apical hypokinesis and compensatory hypercontractile base

The coronary angiogram showed absence of obstructive coronary disease. Resuscitation was achieved with cristalloids and packed red blood cells and vasopressor support was initiated. The patient was discharged on day 7 with normalization of LVEF.

Discussion: TCM is characterized by transient left ventricular dysfunction without evidence of obstructive coronary artery disease. Much evidence suggests that it is precipitated by an excess of circulating catecholamines, leading to microvascular spasm and myocyte injury. Its characteristics are not easily identified in the perioperative environment due to the hemodynamic changes related to surgery and anaesthesia².

Initial management focuses on supportive care and prevention of complications. As far as we know, there are only two case reports of TCM during orthopaedic surgery and injection of pressurized cement was identified as the trigger³.

In our case the triggers were blood loss and psychological stress. The patient was treated initially as a type 2 acute coronary syndrome but key echocardiographic features helped determine the exact aetiology.

References:

- 3. Busse E, Wiater J. Perioperative Takotsubo Cardiomyopathy: A Rare Cardiac Complication Following Orthopaedic Surgery: A Case Report. 2015;5:e64

Learning points: TCM diagnosis and management remains challenging in the perioperative setting. Clinical findings, electrocardiography and imaging are key to an accurate diagnosis.

Further research is needed regarding TCM pathophysiology and effective treatment.

11AP06-9

General anesthesia in a patient with corticobasal syndrome: a rare clinical case

I. Reis Ferreira¹, B. Silva², C. Lemos², G. Pereira¹ ¹Unidade Local de Saúde Estuário do Teio. Servico de Anestesiologia, Vila Franca de Xira, Portugal, 2Hospital CUF Sintra, Anestesiologia, Sintra, Portugal

Background: Corticobasal syndrome (CBS) is a rare neurodegenerative illness characterized by dystonia, cognitive decline, and an asymmetric akinetic-rigid syndrome. Anesthetic management of CBS is challenging due to altered pharmacodynamics, autonomic dysfunction, and potential neuromuscular hypersensitivity.

Literature on perioperative care in CBS is scarce, highlighting the importance of case reports to guide practice.

Case Report: A 74yo woman with CBS, chronic obstructive pulmonary disease, chronic kidney disease, and cervical radiculopathy presented with severe dysphonia attributed to a chord lesion and progression of CBS and was scheduled for laryngeal microsurgery. Balanced general anesthesia was induced with propofol and rocuronium with adequate muscle relaxation. Neuromuscular blockade was reversed with sugammadex, allowing smooth extubation without complications.

The patient was closely monitored overnight due to her neurodegenerative and comorbid conditions and was discharged the next day. A month later the patient remained without neurological complications.

Discussion: Reporting the anaesthetic management of patients with CBS is scarce. Challenges include sensitivity to anesthetic drugs, potential autonomic instability, altered responses to neuromuscular relaxants and postoperative complications such as dysautonomia and respiratory depression.

Neuromuscular blockade reversal with sugammadex was effective and avoided the complications associated with anticholinesterase agents.

A tailored approach to CBS, including careful perioperative monitoring and judicious selection of anesthetic agents, is critical to mitigate these risks.

This case adds to the limited body of knowledge demonstrating the feasibility of general anesthesia in such patients.

References:

Van den Berg ME et al. Anesthesiology Clinics 2019;37(4):651-664. Schaltenbrand G. Journal of Neurology 2018;265(2):563-575. Ball N et al. British Journal of Anaesthesia 2020;125(1):e150-e153.

Learning points:

- · CBS requires individualized anesthetic strategies due to its rarity and complex symptomatology.
- · Neuromuscular blockers can be used effectively with appropriate reversal agents such as sugammadex.
- · Reporting such cases enriches the evidence base, aiding clinicians in managing perioperative risks in rare neurodegenerative conditions.

11AP06-11

Colombia

Intraoperative management of a patient with complex multi-valve disease and atrial fibrillation undergoing non-cardiac surgery. Back to basics: approaches when unable to measure cardiac output

N. Molina¹, J.S. Valderrama-Mendoza¹, M.C. Bautista-González² ¹National University of Colombia, Anesthesiology Department, Bogota, Colombia, 2National University of Colombia Hospital, Anesthesiology Department, Bogota,

Background: Patients with mitral or aortic regurgitation have a higher mortality rate in the postoperative period (1).

Case Report: A 46-year-old female patient in whom multi-valvular disease secondary to aortic and mitral valve endocarditis was documented resulting in moderate aortic stenosis and severe regurgitation, severe mitral regurgitation and severe tricuspid regurgitation.

Additionally, she had valvular paroxysmal atrial fibrillation and severe pulmonary hypertension. Subsequently, a pseudoaneurysm of the left common iliac artery was found and then scheduled for a femoral artery bypass.

Invasive arterial pressure plus standard ASA monitoring was decided. Induction was conducted with fentanyl, propofol and cisatracurium with maintenance using remifentanil and sevoflurane. Hemodynamic support was provided with norepinephrine and milrinone.

Postoperative arterial blood gases showed acid-base balance and lactate of 1. The patient was transferred to the ICU with hemodynamic support and spontaneous ventilation.

Postoperative clinical course was uneventful and mitral and aortic valve replacement with tricuspid valvuloplasty was performed three days later. She was discharged home ten days after the procedure.

Discussion: This is a particular case as the patient presented with triple valvular lesions and atrial fibrillation, which posed a challenge for intraoperative monitoring. Atrial fibrillation impeded the proper pulse contour analysis and severe tricuspid regurgitation is considered a relative contraindication for a Swan-Ganz catheter.

Therefore, hemodynamic monitoring was guided by arteriovenous blood gas analysis and understanding of hemodynamic goals for valvular pathologies.

The case was successfully managed, allowing for subsequent surgical intervention of her valvular pathology and posterior discharge home. Hemodynamic monitoring through estimates based on arteriovenous blood gas analysis is an alternative when invasive cardiac output monitoring is not possible due to patient characteristics or availability of such technologies

Reference:

Richter, E. W., et. al (2022). Mitral regurgitation in patients undergoing noncardiac surgery. Seminars in Cardiothoracic and Vascular Anesthesia, 26(1), 54-67.

Learning points: Understanding the physiology of valvular pathologies and their intraoperative management goals for noncardiac surgery is essential, especially when invasive or minimally invasive methods of cardiac output monitoring cannot be used.

11AP06-12

Modified jet ventilation using high oxygen flow and a Mapleson D circuit for transtracheal tumor resection

R. Millán Martínez¹, M.D. Serrano Merlín¹, D.F. de Luna Cerda¹, D. Arizpe Bravo² ¹Hospital Angeles Puebla, Anesthesia, Puebla, Mexico, ²Hospital Angeles Puebla, Anesthesia & Critical Care, Puebla, Mexico

Background: Tracheal tumors are rare, with nonspecific clinical presentations and progressive airway obstruction, typically requiring surgical resection. This involves a shared airway between the anesthesiologist and the surgical team, making ventilation in this context a true anesthetic challenge.

Case Report: A 19-year-old was referred to our hospital for a positron emission tomography (PET) scan due to suspected tracheal tumor. During the procedure, the patient developed hypoxemia and desaturation that did not improve with supplemental oxygen necessitating transfer to the Emergency Department for anesthesiology evaluation. A rapid sequence intubation was performed. A decision was made to resect the tumor via an endotracheal approach using rigid and flexible bronchoscopy.

Total intravenous anesthesia (TIVA) was administered. For ventilation during rigid bronchoscopy, a Bain circuit was used with an oxygen flow rate of 70 liters per minute, connected to an auxiliary oxygen supply.

Discussion: During the perioperative period, rigid bronchoscopy provided the surgical exposure required for resection. Based on the literature, options for patient ventilation include apneic oxygenation, jet ventilation, high-frequency ventilation, assisted spontaneous ventilation, or controlled ventilation with a closed circuit [1].

The last two options were not feasible because a thoracoscopic approach had been considered and this required the patient to be under general anesthesia, and the transtracheal instrumentation prevented closure of the circuit [1,2].

Simulating the concept of jet ventilation, it was decided to maintain a high flow of 100% inspired oxygen to allow for oxygen diffusion through an open circuit due to the working channel of the rigid bronchoscope [2].

References:

- 1. Pathak V, Welsby I, Mahmood K, Wahidi M, MacIntyre N, Shofer S. Ventilation and anesthetic approaches for rigid bronchoscopy. Ann Am Thorac Soc. 2014;11(4):628–34.
- 2. Galway U, Zura A, Khanna S, Wang M, Turan A, Ruetzler K. Anesthetic considerations for bronchoscopic procedures: A narrative review based on the Cleveland clinic experience. Vol. 11, Journal of Thoracic Disease. 2019.

Learning points: Sharing the surgical field and the ventilatory system requires a combined understanding of surgical technique, ventilation options, and timely identification of associated complications.

11AP07-1

Hemodynamic management in abdominal paraganglanglioma surgery

A. García Portero¹, M.E. Agudelo Montoya¹, A.M. Durán Román¹, J. Martín Sopo¹ ¹CHUB, Anesthesiology, intensive care and Pain management., Badajoz, Spain

Background: Paragangliomas are rare neuroendocrine tumors (0.2-1/100,000) arising from chromaffin cells outside the adrenal gland (extra-adrenal). Most sympathetic ganglion-derived tumors are located in the abdomen and produce excess catecholamines; extraadrenal tumors produce noradrenaline.

The risk of these patients is high with intraoperative complications such as: hypertension, tachycardia, arrhythmias, cardiovascular collapse and hypotension after tumor resection.

Case Report: Our management was divided into three phases: induction, tumor manipulation and extraction. We premedicated with midazolam and fentanyl, placed thoracic epidural catheter and cannulated radial artery for invasive monitoring. Induction with lidocaine, fentanyl, Propofol and rocuronium and intubation with McGrath video laryngoscope for less stimulation, without hemodynamic alterations.

Maintenance with sevoflurane and remifentanil. During tumor manipulation, blood pressure and sinus tachycardia increased to 130lpm with the need for continuous perfusion of clevidipine, esmolol and magnesium sulfate.

After tumor resection, hemodynamic instability with the need for phenylephrine, continuous perfusion of noradrenaline and vaso-pressin.

According to the latest guidelines, it is recommended to use target-guided hemodynamic monitoring devices, we use acumen IQ (Edward) with hypotension prediction index (HPI). After completion of surgery, extubation and transfer to hemodynamically unstable resuscitation. During the following 48 hours in resuscitation, vasopressors were decreased without incident.

Discussion: As anesthesiologists we must be aware of the high risk of this surgery with its possible complications such as arrhythmias, hypertension, subsequent hypotension and cardio-vascular collapse, as well as their treatment. We must use drugs with rapid onset and duration due to the variable hemodynamic alterations.

The use of hemodynamic monitoring is very useful in the management of these surgeries. It is essential to choose anesthetic drugs with little sympathetic and histamine-releasing stimulation.

References:

Schäpfer P, Albrecht E, Baumgartner M, Blanc C. Anesthetic management in adrenal gland surgery. EMC- Anesthesia-Resuscitation 2017; 43(2):1-8 [Article E-36-590-A-170].

Learning points: The management of this pathology must be properly understood.

11AP07-2

Role of rare anatomical variation in adapting anaesthesia management in Kartagener's syndrome

A.S. Torres¹, J. Sofia Abreu Henriques¹, F. Correia¹, H. Machado¹

¹Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Clínica de Anestesiologia Medicina Intensiva Emergência e Urgência. Serviço de Anestesiologia, Porto, Portugal

Background: Kartagener's syndrome (KGS) is a rare autosomal recessive disorder characterized by a triad of situs inversus, bronchiectasis and chronic sinusitis resulting from defective cili-

Dextrocardia with complete situs inversus occurs in approximately 2 per 10 000 births.2

Anaesthetic management in KGS focuses primarily on preventing respiratory and cardiac complications, which pose significant perioperative challenges.

Case Report: A 45-year-old female patient, ASA II, was scheduled for tympanoplasty combined with tympanomastoidectomy due to bilateral conductive hearing loss.

Patient's medical history included KGS with situs inversus totalis, asthma, hypothyroidism, grade I obesity, and non-insulin-dependent type 2 diabetes mellitus.

Pulmonary function tests revealed a mixed ventilatory defect with a moderate obstructive component, and an ECG with reversed leads was normal. Standard ASA monitoring was applied, including ECG with reversed leads, neuromuscular blockade monitoring, processed EEG.

Total intravenous anaesthesia (TIVA) with propofol and remifentanil target-controlled infusion was used. After the administration of 60 mg of rocuronium, an attempt at endotracheal intubation was performed using direct larvngoscopy, which revealed a Grade II laryngoscopy (Cormack-Lehane classification) and difficulty in guiding the RAE tube.

After optimization, a second attempt using videolaryngoscopy was successful. The surgery was uneventful, and hemodynamic stability was maintained throughout. Neuromuscular blockade was reversed with sugammadex (2 mg/kg).

After gentle orotracheal suctioning and recovery of spontaneous ventilation, extubation was performed. The postoperative period was uneventful, and the patient was discharged on postoperative day 1.

Discussion: Anaesthetic management in KGS requires strategies to minimize respiratory and cardiac risks. TIVA with propofol and remifentanil may help preserve mucociliary function, reducing pulmonary complications3, while reverse ECG electrode positioning addresses anatomical variations.

Learning points: Anatomical variations in KGS should be considered when monitoring for anaesthesia. Volatile anesthetics may exacerbate ciliary dyskinesia in KGS and predispose patients to respiratory complications; thus TIVA is a safe option in this population.

General anesthesia in a patient with spinal muscular atrophy type III (Kugelberg-Welander disease) with awake fiberoptic intubation: a case report

D. Mendes¹, D. Monteiro¹, S. Ferraz¹ ¹Unidade Local de Saúde de Lisboa Ocidental, Serviço de Anestesiologia, Lisboa, Portugal

Background: Spinal Muscular Atrophy (SMA) type III is a rare autosomal recessive disease characterized by progressive muscle weakness. Perioperative risks may be significant and often related to the respiratory system, namely respiratory failure and difficult intubation.

Neuromuscular blocking agents (NMBA) must be used carefully as the use of succinvlcholine may result in rhabdomyolysis and hyperkalemia and the duration non-depolarizing NMBA's block may be prolonged1.

Case Report: A 62-year-old woman, with SMA type III presented for right breast lumpectomy with sentinel lymph node biopsy because of a stage II invasive carcinoma. She was wheelchairbound, under nocturnal non-invasive ventilation and had dysphagia in relation with disease progression. She also had a multinodular goiter that extended into the mediastinum, with a neck and chest CT scan showing a retrosternal thyroid causing moderate tracheal deviation. The patient had several difficult airway predic-

We performed an awake fiberoptic intubation, with first attempt success. Total intravenous anesthesia with no NMBA was used. A serratus anterior plane block with ropivacaine was performed after induction. The patient was extubated in the operating room and transferred to a surgical intermediate care unit. She was discharged from the hospital 2 days after surgery.

Discussion: Patients with SMA have an increased risk of complications following general anesthesia. There is supporting evidence regarding safe use of non-depolarizing NMBA, however for patients with respiratory impairment the decision not to use NMBA should be considered to prevent postoperative respiratory depression, associated with residual block.

This case also presented the additional challenge of the difficult airway, preventing the use of other NMBA sparing options, such as the use of a supraglottic device.

A careful pre-anesthetic evaluation and planning should be carried and an individualized plan made for each patient considering the stage of the disease.

Reference:

1. Islander G, et all. Anesthesia recommendations for patients suffering from Spinal muscular atrophy. Orphan Anesthesia,

Learning points: Anesthesia plan for patients with SMA must be individualized, considering disease progression, respiratory impairment and difficult airway.

The decision not to use NMBA should be considered when pos-

Awake fiberoptic intubation is a valid option if a difficult airway is present, which also spares the use of NMBA.

11AP07-5

Functional characteristics of malignant hyperthermia variant R174W in the alpha 1 subunit of the dihydropyridine gene (CACNA1S)

T. Ikeda¹, K. Mukaida¹, S. Otsuki¹, S. Narasaki¹, H. Miyoshi¹, Y. Tsutsumi¹

¹Hiroshima University, Anesthesiology and Critical Care, Hiroshima, Japan

Background: Malignant hyperthermia (MH) is an autosomal dominant pharmacogenetic disorder of skeletal muscle calcium (Ca²⁺) homeostasis. MH causative variants have been identified in genes coding for ryanodine receptor (*RYR1*), alpha 1 subunit of the dihydropyridine (*CACNA1S*) and *STAC3*. Most of these pathogenic variants were in *RYR1* and only two in *CACNA1S* (https://www.emhq.org/diagnostic-mutations).

This study aimed to examine the Ca²⁺ kinetics on cultured human myotubes in a pathogenic *CACNA1S* variant R174W and infer the mechanism for MH pathogenesis.

Materials and Methods: We selected 21 patients who underwent MH predisposition test (Ca-induced Ca release [CICR] test) and classified into three groups; R174W: 1 patient (cell count n = 6-15), RYR1 group (variants in *RYR1* identified as the cause of MH): 10 subjects, and N group (normal CICR rate: no pathogenic variants in *RYR1* and *CACNA1S*): 10 patients.

The intracellular Ca²⁺ concentration [Ca²⁺]*i*. of the myotube was determined using fluorescent Ca²⁺ imaging system with fura-2. The 50% effective concentrations (EC₅₀) for caffeine and 4-chloro-m-cresol (4-CmC) were calculated from the dose-response curves

The resting [Ca²+]i and the decreased [Ca²+]i. after 50µM dant-rolene (Dan) loading were examined. The values were expressed as median [interquartile range]. The Kruskal-Wallis test and Dunn's multiple comparisons test were used.

Results and Discussion: The EC $_{50}$ values for caffeine and 4-CmC were 4.50 [4.03–5.86] mM, 226.8 [167.8–285.7] μ M in R174W group, 2.54 [1.92–2.75] mM, 127.4 [84.5–147.9] μ M in RYR1 group, 4.93[4.32–5.85] mM, 278.8 [225.2–302.7] μ M in N group, respectively. EC $_{50}$ was not significantly different between R174W group and N group. The resting [Ca $^{2+}$]i were 93.1 [81.0–109.1] nM in R174W group and 105.4 [103.8–112.1] nM in RYR1 group, significantly higher than 71.2 [65.4–72.7] nM in N group.

The decreased [Ca²⁺]i. after Dan loading were 23.4[17.5–26.6] nM in R174W group and 30.9 [25.7–47.2] nM in RYR1 group, which were significantly higher than in N group (13.3 [11.3–19.6] nM).

Conclusion(s): The development of MH in the patient with R174W variant involves increased [Ca²⁺]i. in skeletal muscle cells by mechanisms other than increased RYR1 sensitivity. We suggested that Dan may be effective in R174W variant.

11AP07-7

Simple techniques, complex outcomes – Sudden cardiorespiratory arrest during jugular central venous catheter placement in a patient with epilepsy: a case report

I. Ferreira¹, <u>D. de Vasconcelos e Sá Pires da Silva</u>¹, H. Seabra¹

¹Unidade Local de Saúde de Santo António, Departamento de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal

Background: Patients with certain pre-existing conditions can complicate otherwise routine procedures. Sudden unexpected death in epilepsy (SUDEP), commonly associated with seizures, is the leading cause of mortality in patients with chronic refractory epilepsy¹.

This case report highlights a sudden cardiorespiratory arrest (CPA) in an epileptic patient during jugular central venous catheter (CVC) placement.

Case Report: A 67-year-old female with a 20-day hospital stay for pyelonephritis, requiring intravenous antibiotics and loss of peripheral venous access, was referred to the anesthetic team for jugular CVC placement.

Her medical history included obesity, cognitive impairment following a hemorrhagic stroke, and chronic epilepsy. During standard ASA monitoring and Trendelenburg positioning, the patient experienced an unnoticed focal seizure with rapid eye movements and apnea. This led to desaturation and subsequent CPA with asystole.

Immediate advanced life support was initiated, including cardiorespiratory resuscitation, laryngeal mask ventilation, and administration of 1 mg of adrenaline via a 22-gauge peripheral line placed by the nursing team. Ventilation and spontaneous circulation were restored within two minutes, and the patient was transferred to the intensive care unit for further monitoring.

Discussion: This case underscores the importance of assessing patient-specific risks, procedural factors, and environmental conditions in anesthetic practice.

An otherwise routine CVC placement became a critical event due to an unexpected epileptic seizure compounded by Trendelenburg positioning and obesity, leading to hypoxia and CPA.

Reference:

Pathak SJ, et al. Sudden Unexpected Death in Epilepsy. [Updated 2022 Dec 19]. In: StatPearls [Internet]. Treasure Island (FL): StatPearls Publishing

Learning points: Routine procedures can pose significant challenges, particularly in patients with complex medical histories. Vigilance and preparedness are essential to address potential complications.

11AP07-8

Influence of aging on clinical presentation of malignant hyperthermia

<u>T. Ikeda</u>¹, K. Mukaida¹, S. Otsuki¹, S. Narasaki¹, H. Miyoshi¹, Y. Tsutsumi¹

¹Hiroshima University, Anesthesiology and Critical Care, Hiroshima, Japan

Background: Malignant hyperthermia (MH) is common in young males. However, there have been no reports on the effect of aging on clinical manifestations in adults.

In this study, we analyzed the database of MH patients collected by our hospital to investigate the differences in clinical findings.

Methods: We compared the clinical characteristics of male patients aged 30-39 years (30s group) with those aged 65 years or older (elderly group) with a Clinical Grading Scale of 35 or higher (MH rank 5 or 6) since 1990.

The values are shown as medians (25-75%), and the χ -square test and Mann-Whitney test were used for statistical analysis. p<0.05 was considered significant.

Results: Thirty-three patients (19 in the 30s group and 14 in the elderly group) were included in the study. There were no significant differences in mortality rates, dantrolene use, or succinylcholine use between the two groups.

The first symptoms that led to the diagnosis of MH were increased EtCO2 (36.8%) in the 30s group and tachycardia of unknown origin (33.3%) in the elderly group.

The incidence of colored urine was higher in the 30s group than that in the elderly group (63.2% vs 11.1%, p=0.016). There were no significant differences in the incidence of muscle rigidity, dysphagia, tachycardia, or arrhythmia between the groups.

The maximum body temperature was 39.0 (38.6-40.1) $^{\circ}$ C in the 30s group and 39.7 (39.1-41.0) $^{\circ}$ C in the elderly group (p=0.17), but the time to maximum body temperature was 115 (80-150) minutes in the 30s group and 225 (165-263) minutes in the elderly group (p=0.017). There were no differences in PaCO2, pH, base excess, or serum potassium levels.

Conclusions: The early symptoms in MH, the incidence of colored urine, and the time to peak temperature were significantly different between the 30s group and the elderly group.

11AP07-10

Intraoperative ultrasound diagnosis by an anaesthesiologist, of an unexpected pregnancy in a surgical patient

E.-l. Tataki¹, P. Mpampali¹, S. Ralli¹, S. Vangelis¹, M. Soumelidou¹, P. Kouki¹ ¹General Hospital of Nikea-Piraeus, Anesthesiology, Athens, Greece

Background:We present a case of a 35-year-old woman, unaware of her pregnancy status, who was scheduled for elective open post-cesarean hernia repair.

Case Report: The patient's medical history included caesarean section 7 months ago, that led to postoperative hernia. She was still lactating and when she was asked about possibility of pregnancy her answer was negative (both to surgeons and anaesthesiologists). Induction of anaesthesia included fentanyl, propofol and rocuronium, sevoflurane for maintenance, and remifentanil in-

fusion. Upon finding a considerably enlarged uterus, the surgeons were concerned, so a blood $\beta\text{-hCG}$ test was performed. While awaiting the result, a trained, in ultrasound use anaesthesiologist, applied a curved ultrasound probe, to scan the enlarged uterus. Scanning clearly visualized a fluid-filled amniotic sac, along with the fetus, with a formed four-chamber beating heart, findings which were later confirmed by an obstetrician. Pregnancy was estimated to be 25 weeks, based on fetal head circumference measurement. The operation was discontinued, and post-extubation the patient was informed about the events (referral to an obstetrician for consultation).

Discussion: As menstrual irregularities are common among lactating mothers, the patient attributed amenorrhea to lactation and had no awareness for possible pregnancy. Intraoperative use of ultrasound by a trained anaesthesiologist, provided immediate, definitive diagnosis and appropriate decision making by the whole team

Learning points: There is need for continuous vigilance by anaesthesiologists for women in child baring age and possible pregnancy. This case report emphasizes the versatile role of ultrasound in the operating room, as an essential tool for anaesthesiologists in contexts beyond its conventional use.

11AP07-11

Attitudes of anaesthetists towards neuromuscular blockade monitoring: An audit in a teaching hospital

X. Spahillari1, T. Hitka1

¹University Hospital Limerick, Department of Anaesthesia and Intensive Care, Limerick, Ireland

Background and Goal of Study: International guidelines advocating for patient safety strongly recommend the use of quantitative neuromuscular blockade monitoring (NMBM) during general anaesthesia where neuromuscular blocking (NMBs) agents are used. An initial audit of practice in our hospital found that only in 24.6% of cases (n=122) were being monitored for adequate reversal of blockade prior to extubation. In view of this low compliance, departmental teaching was delivered to non-consultant hospital doctors (NCHD) with the goal of improving implementation of the

guideline. The result of this intervention was an increase in the percentage of monitored patients (53.8%, n=117). The objective of this project was to reach near 100% compliance in NMBM and improve patient safety by ensuring adequate reversal of NMBs.

Materials and Methods: A questionnaire was given to members of department with the goal of identifying the reasons behind the low compliance.

The questions referred to:

- 1. Frequency of NMB monitoring,
- 2. Preferred mode of monitoring,
- 3. Common reasons for refraining to use quantitative monitoring,
- 4. Reversal drug of choice, and;
- 5. Occurrence of complications.

An infographic was shared among NCHDS and also exhibited in every theatre summarizing the risks of residual blockade and how to use the NMBM device adequately. Teaching sessions were organized for both NCHDS and nursing staff to encourage the use of monitoring device.

Results and Discussion: Twenty anaesthetists initially replied to our questionnaire, reporting rare use of NMBM (1 in 10 cases or less) and listing "happy with clinical assessment" as the most common reason to forego monitoring.

After educational interventions, the practice of our department was re-audited and found no improvement in frequency of monitoring. (52.6% n=131). Despite multiple interventions in education, practitioners won't necessarily change their practice.

The anaesthetists' clinical experience together with the efficiency and affordability of sugammadex, has led to a heightened sense of safety, despite nine of the anaesthetists admitting that they had a complication due to inadequate reversal of muscle relaxants during their practice.

Conclusion(s): Educational interventions might not be sufficient to change clinical practices and further administrative interventions might be necessary.

11AP08-1 Emergency procedural sedation for broken glass ingestion: A case report in a NORA setting

K. Öncü¹, A. Kaynar², Ö. Kömpe², Ş. Alişkan², S. Önem³, C. Genc⁴

¹Sinop Atatürk State Hospital, Anaesthesiology and Reanimation, Sinop, Turkey, ²Samsun Educational and Research Hospital, Anaesthesiology and Reanimation, Samsun, Turkey, ³Samsun Educational and Research Hospital, Gastroenterology, Samsun, Turkey, ⁴Samsun University Faculty of Medicine, Anaesthesiology and Reanimation, Samsun, Turkey

Background: Foreign body aspiration is a high-risk NORA (nonoperating room anaesthesia) procedure that often requires sedoanalgesia. We present a case of emergency esophagogastroduodenoscopy (EGD) due to broken glass ingestion.

Case Report: A 28-year-old male with no known history of chronic illnesses or regular medication use, but with a heavy smoking history, presented at 03:00 AM for procedural sedation during an emergency EGD following the ingestion of broken glass. The patient, with a normal chest CT and hemodynamic parameters within normal limits, had consumed no food or liquids except for glass, and the fasting period was appropriate.

After ASA-required monitoring, including end-tidal carbon dioxide, 1.5 mg/kg propofol (titrated) and 2 mg midazolam were administered for induciton. Propofol was continuously infused at 5–6 mg/kg/h, anticipating that the prolonged duration, to maintain moderate sedation. Intermittent suctioning was used for smoking-related secretions.

The procedure, lasting 90 minutes, involved the removal of nine glass fragments using an overtube. A submucosal stomach laceration was treated with a clip. Apart from that, esophageal laceration, gastric perforation, and any airway injury were not observed. Post-procedure, the patient was monitored in the PACU for 30 minutes and in the ward for one day, with an uneventful discharge.

Discussion: This case emphasizes the importance of following the ASA checklist for all NORA procedures. All pre-procedural evaluations were performed, and non-invasive end-tidal carbon dioxide monitoring was used to improve safety.

Though endotracheal intubation could have been considered, procedural sedation was deemed appropriate based on the patient's prior similar experiences.

In urgent, high-risk airway scenarios outside the operating room, a comprehensive anesthesia management strategy is crucial for ensuring patient safety.

Learning points A thorough preoperative evaluation, preparedness for potential difficult airways and complications, and the use of appropriate and sufficient monitoring techniques are essential for the successful management of NORA procedures.

Priapism and epidural anaesthesia - a case report of multimodal approach for pain management in a case refractory to surgery

N. Torres¹, <u>M. Massá Castro</u>¹, F. Lança¹², A. dos Santos Rocha¹² ¹Unidade Local de Saúde Santa Maria, Anaesthesiology, Lisbon, Portugal, ²Faculty of Medicine, University of Lisbon, University Clinic for Anaesthesiology and Reanimation, Lisbon, Portugal

Background: Priapism, a persistent penile erection lasting four hours or more, occurs independently of sexual stimulation. It results from a dysfunction of the hemodynamic mechanisms regulating penile erection and detumescence. Priapism carries the risk of erectile dysfunction and mandates prompt evaluation and intervention!

We describe a complex case, refractory to three consecutive surgery interventions, requiring epidural analgesia.

Case Report: A 39-year-old male patient, known for smoking history and multiple drug addictions, presented with priapism for the past 36 hours elicited by a recreational injection of a prostaglandin-based compound.

Firstly, a penile shunt procedure was performed. Due to persistence of skeletal rigidity, an intracavernosal injection of adrenaline was administered. Despite these interventions, the skeletal rigidity remained unchanged;

Thirdly, a corporoglandular shunt was conducted under general anaesthesia, leading to a reduction in penile tumescence. After 1h, in the Post-Anaesthesia Care Unit (PACU), the priapism relapsed along with intense pain, despite fentanyl, morphine and ketamine administration.

Epidural analgesia with ropivacaine was performed, providing pain relief but no clinical change in the penile rigidity. Ultimately, the patient was submitted to a saphenous vein bypass surgery resulting in clinical resolution at the expense of permanent erectile dysfunction.

Discussion: Most cases of priapism are promptly solved after surgical treatment and do not require complex analgesia regimens. Epidural anaesthesia has been rarely described in this scenario. On one hand, therapeutic effects have been reported with priapism resolution after local anaesthetic injection in the epidural space².

On the other hand, epidural analgesia has been described as a possible cause for priapism, in rare cases.

In our case, the epidural technique did not affect the clinical presentation of priapism but provided valuable time for decisionmaking and surgical planning.

Reference:

1. PMID: 24314827; 2. PMID: 8122754

Learning points: This case highlights the complex nature of priapism and the role of the anaesthesiologist in providing multimodal anaesthesia and analgesia in refractory cases.

The recurrence of priapism in the PACU underscores the importance of vigilant monitoring and timely intervention.

11AP08-3

Comparison of nerve stimulator-guided obturator nerve block with or without ultrasound real-time visualization in the transurethral resection of non-muscle-invasive bladder cancer

N.A.M. Dragoescu¹, A.D. Stanculescu¹, C. Maria², M.A. Radu³, A. Panus³, P.O. Dragoescu³
¹Craiova University of Medicine and Pharmacy, ICU, Craiova, Romania, ²Craiova Clinical Emergency Hospital, Urology, Craiova, Romania, ³Craiova University of Medicine and Pharmacy, Urology, Craiova, Romania

Background and goal: Transurethral resection of bladder tumours (TUR-BT) is currently the gold standard surgical treatment. Obturator nerve stimulation during the procedure may lead to obturator reflex with severe complications. The obturator block procedure may be performed by nerve stimulator-guided technique or under real-time ultrasound nerve stimulator-guided technique.

Our study aim is analysing the safety and efficacy of the two different techniques: the nerve stimulator-guided or the ultrasound visualisation and nerve stimulator-guided method.

Materials and methods: We conducted a prospective study within the Urology Department of the Craiova Clinical Emergency Hospital. We initially analysed 247 patients admitted for bladder cancer in our hospital between May 2023 and May 2024.

Patients with muscle invasive bladder cancer (62 cases) and those with non-muscle invasive tumours not suitable for obturator nerve block due to location or type of anaesthesia (70 patients) were excluded.

A total of 115 patients that underwent TUR-BT for NMIBC with ASA status II and III were therefore included in the study: 57 patients with the nerve stimulator guided technique nerve block (group S) and 58 patients with ultrasound and nerve stimulator guided block (group US-S). Patients from both groups received 15 ml bupivacaine 0.25%.

Results and discussion: There were no significant differences between the two patient groups regarding sex, age, BMI, tumour number, size and laterality as well as operating time. All TUR-BT procedures were performed under spinal anaesthesia.

The adductor reflex was present in 44 cases (38%) the majority in group S (30 vs 14 cases, p <0.05). The majority were mild and did not require stopping the procedure (21 vs 9 cases, p<0.05). Significant complications, such as bleeding or bladder perforation was recorded for 14 patients (11 from group S and 3 in group US-S, p<0.05). Incomplete resection (3 cases, 5%) and bladder perforation (4 cases, 7%) were all recorded in the nerve stimulator guided technique group. Significant bleeding was recorded in 11 cases (7 vs 3, p<0.05).

Conclusions: Obturator nerve block is generally a valuable tool that ensures the safety and efficacy of transurethral resection of bladder tumours located on the lateral bladder walls.

Both techniques are safe and easy to perform. The nerve stimulator under ultrasound guided approach leads to significantly lower risk of complications with a higher success rate.

Anesthetic management of an adrenalectomy for phaeochromocytoma

M. Sebastian¹, L. Frias¹, <u>J. Gonzalez</u>¹, M. Rodrigues¹ *'ULS Santa Maria, Anesthesiology, Lisboa, Portugal*

Background: Intraoperative management of an elective laparoscopic left adrenalectomy for phaeochromocytoma in a patient with MEN 2A syndrome.

Case Report: A 42-year-old woman, diagnosed with MEN2A syndrome, who had previously undergone a total thyroidectomy for medullary thyroid carcinoma and a right adrenalectomy for phaeochromocytoma, presented in March 2024 with two nodules in the left adrenal gland. Catecholamine levels and their metabolites were in borderline values. Laparoscopic surgical removal was the next step chosen.

The Endocrinology team put the patient on alfa adrenergic blockers before the surgery. From an anesthetic perspective, along with the use of standard anesthetic drugs, we followed a combined approach, including a subarachnoid block with 7.5 mg of bupivacaine and 0.1 mg of morphine and intravenous dexmedetomidine (1ug/kg/h) and magnesium sulfate (20 mg/kg) infusion during maintenance. Blood-pressure was invasively monitored. There was no need of hypotensive agents. After the removal, the expected hypotensive phase followed and vasopressors were given.

At the end of the procedure, the patient was extubated and transferred to a level II care unit under vasopressor support. No complications occurred during and after the procedure. The pathology diagnosis was a catecholamine producing phaeochromocytoma.

Discussion: This case illustrates the importance of a combined anesthetic strategy to successfully manage the removal of a suspected phaeochromocytoma. Noxious stimuli and tumor manipulation are the major contributors to the release of catecholamines and subsequent haemodynamic instability.

The subarachnoid block contributed both to pain and hemodynamic control during the surgery due to the vasodilatory effect of local anesthetics. Magnesium sulfate was infused due to its inhibitory effect in the release of catecholamines from the adrenal gland and peripheral nerve endings. Dexmedetomidine, being an alfa-2-adrenergic receptor agonist, has sympatholytic properties that justified its choice.

Reference:

Connor, David et al. Perioperative care of phaeochromocytoma. BJA Education. 2016 May 1;16(5):153–8.

Learning points: A good management of analgesia and haemodynamic changes during adrenalectomy surgery is essential for patient safety.

11AP08-6

Evaluation of 'Sip Til Send' implementation in a London teaching hospital: Implementation and challenges

<u>H. Kaur</u>¹, J. Qureshi¹, M. Mankaruis¹, M. Ahmed¹, M. Leong¹, H. Bidd¹

¹Guy's and St Thomas Hospital, Anaesthetics, London, United Kingdom

Introduction: The Sip Til Send (STS) protocol was first introduced at NHS Tayside in Scotland and has been adopted by several NHS trusts. Building on this success, we conducted a pilot audit at Guy's and St Thomas' Hospital within controlled settings, initially focusing on patients in the Day Surgery Unit (DSU) and Surgical Admission Lounge (SAL) which was subsequently expanded to all preoperative inpatients.

Methods: A pilot audit was conducted from January to May 2023 for patients undergoing elective surgeries. Following approval by the Surgical Safety team and hospital management, STS guideline was implemented.

Interventions were introduced to raise staff awareness and ensure proper adherence to the protocol, allowing patients to sip unlimited clear fluids until they were called to theatre.

A re-audit was carried out in November 2024 to assess compliance with the guideline and identify any wards or surgical specialties that required further attention.

Results and Discussion: In the initial audit cycle, data from 214 patients was analysed, revealing the longest fluid fasting times in pain management (547 minutes) and shortest fasting durations were seen in orthopaedics (180 minutes) with a median fasting time of 347 minutes. Notably, 118 patients (55.1%) fasted for five hours or longer, with 26.2% exceeding ten hours.

Additionally, more than 60% reported feeling thirsty before transfer to the operating theatre.

After implementing the STS guideline, staff education/ teaching sessions, a snapshot audit involving 42 patients, was conducted in November 2024. The longest fasting time was noted as 658 minutes in trauma patients, and shortest fasting time was only 12 minutes in orthopaedics, with a median of 68.5 minutes.

Encouragingly, 79% of patients received water until their transfer to the operating theatre, and only 16% felt thirsty before surgery. There have been no complications reported; however, the primary challenge remains fostering consistency among nurses in offering water and promoting a cultural shift in practice.

Conclusion: This project showcases the effective implementation of a Trust wide STS policy, resulting in a notable decrease in preoperative fluid fasting durations.

However, there were a few outliers where patients experienced unnecessarily extended fasting periods.

We will continue to oversee the policy's implementation, with ongoing staff education aimed at removing any barriers to effective practice.

Patient satisfaction with postoperative services provided by an anaesthesiologists based acute pain care team, in a tertiary hospital of Greece

R. Saiti ¹, A. Gizli¹, K. Manika¹, E. Iordanidi¹, E. Chrona¹, P. Kouki¹

¹General Hospital of Nikaia-Piraeus, Dept of Anaesthesiology and Pain Medicine, Athens, Greece

Background and Goal of Study: Effective postoperative analgesia is an important metric for evaluating quality of health care services. The goal of this study was to measure patient satisfaction regarding quality of postoperative analgesia services that were provided from an acute pain care team (anaesthesiologists based)

Materials and Methods: After ethical committee approval and written consent, 53 patients who underwent various surgical procedures were recruited. Operation types included: 56% orthopaedics, 23% open abdominal, 6% thoracic, 6% laparoscopic abdominal, 4% gynaecological, and 4% spinal surgery. Postoperatively, 65% of patients received patient-controlled analgesia (PCA), while 35% received epidural analgesia.

An 18-item standardized questionnaire was administered to patients in the ward, on the day that analgesia device was removed. The questionnaire was designed to evaluate three key dimensions:

- 1. Sleep disturbance due to pain and incidence of nausea or vomiting
- 2. Effectiveness of measures taken for pain relief
- 3. Patient satisfaction related to behavior of acute pain care team members.

One question involved possible self-reporting adverse effects and dissatisfaction points on behalf of patients.

Results and Discussion: Concerning dimension (1) 67% of the patients experienced sleep disturbance due to pain, 35% and 15% experienced nausea or vomiting respectively.

As for dimension (2) 86% of the responders were satisfied with the level of postoperative analgesia provided.

Regarding dimension (3) 98% of the responders stated that anesthesiologists did everything possible to alleviate postoperative pain.

Events such as sleep disturbance due to pain and incidence of nausea or vomiting were not statistically correlated with level of patients satisfaction.

However, strong correlation was found between patients' satisfaction and the perception that anesthesiologists were proactive in managing pain (p = 0.012).

Conclusion(s): Patients' satisfaction in the postoperative period can be enhanced by proper and timely pain alleviation. Patients' perception that the anaesthesiologists involved in the acute pain care team did everything possible to alleviate their postoperative pain was the most important parameter for increasing their satisfaction.

Similar studies should be included in order to consolidate these results.

11AP08-8

The hidden threat: Pneumothorax unveiled by abdominal drain migration following thoracoabdominal penetrating trauma

R. Graça¹, M. Massá de Sousa Castro¹, J. Galacho² ¹Unidade Local de Saúde de Santa Maria, Department of Anesthesiology, Lisbon, Portugal, ²Unidade Local de Saúde do Oeste, Department of Anesthesiology, Caldas da Rainha, Portugal

Background: Thoracoabdominal penetrating trauma is a complex, potentially life-threatening condition. Early diagnosis is crucial for survival, as timely surgical intervention may be required.

Case Report: A 29-year-old male, ASA II, was admitted after being assaulted with a curved fishing harpoon that penetrated the left subcostal region.

Upon arrival, he was hemodynamically stable with no signs of respiratory distress. CT imaging revealed a minor ipsilateral pneumothorax and a possible gastrointestinal perforation. An exploratory laparotomy was performed under general anesthesia.

Ventilation and oxygenation were adequate during surgery, using a protective lung ventilation strategy. The harpoon was removed, a gastrorrhaphy performed, and a drain was placed at the injury site

Post-extubation, the patient presented paradoxical breathing and desaturated to 90%. The drain's collection bag inflated and deflated with his breathing, so it was removed and a three-sided occlusive dressing was applied, immediately improving ventilation and oxygenation.

A chest radiograph revealed the drain had migrated into the thoracic cavity, causing a moderate pneumothorax. After removing the drain and inserting a chest tube, the patient recovered and was discharged after four days.

Discussion: Penetrating trauma is particularly challenging due to the difficulty in predicting the extent of injury and structures involved. In this case, the curved object and its entry point between the thorax and abdominal wall created a unique clinical situation.

Pneumothorax is a common complication, typically worsened by positive pressure ventilation; however, that was not the case here. Instead, it was exacerbated by the surgical drain's occlusion, which had unintentionally migrated into the thoracic cavity.

Timely recognition of respiratory distress and prompt intervention to manage the likely pneumothorax was crucial for a successful outcome.

Reference:

Jain, A., Sekusky, A. L., & Burns, B. (2023). Penetrating Chest Trauma. In *StatPearls*.

Learning points: Managing thoracoabdominal penetrating trauma requires a high index of suspicion for occult injuries, even with unremarkable initial clinical findings.

Vigilant assessment and prompt diagnostics are crucial to detect life-threatening injuries.

Inserting the drain through the injury's entry point can pose additional risks due to its unpredictable trajectory, thus is not recommended.

11AP08-9 Anesthetic considerations in myotonic dystrophy: A case report on urgent surgery

C. Pereira¹, <u>D. Fernandes de Carvalho</u>¹, J. Cortesão¹, R. Inácio¹, T. Monteiro¹ ¹Unidade Local de Saúde de Coimbra, E.P.E, Anesthesiology, Coimbra, Portugal

Background: Myotonic dystrophy type 1 (Steinert's) is a multisystemic autosomal dominant disorder, associated with cardiac and pulmonary complications. These patients have an increased sensitivity to most drugs used during anesthesia, making the anesthetic plan and management extremely challenging.

Case Report: We present the case of a 59-year-old woman, with a two-year diagnosis of myotonic dystrophy, proposed for an urgent femoral artery embolectomy due to acute limb ischemia. The patient had hypercapnic respiratory insufficiency, grade II diastolic disfunction, type 1 obesity and was on dual antiplatelet therapy due to a recent stroke (< 3 months). She had a history of hypercapnic respiratory insufficiency with acidosis in the immediate pos-operative period of a laparoscopic surgery under general anesthesia.

This procedure underwent with monitored anesthesia care (midazolam, fentanyl and ketamine) and local anesthetic infiltration (ropivacaine and lidocaine). Hemodynamic stability and spontaneous ventilation (FiO2 28%) were maintained.

No complications occurred during the procedure. The patient was transferred to the post-anesthesia care unit and a few hours later to the vascular surgery ward.

Discussion: Myotonic dystrophy can pose significant challenges to general anesthesia administration. Local or regional anesthesia diminishes some risks such as cardiopulmonary problems and myotonic crisis triggers.¹

Short action agents should be preferred, titrating doses and close monitoring must be assured.²

In an age when tailored anesthesia is increasingly emphasized, this case demonstrates the significance of attending to both personal and surgical demands, reaffirming the necessity of a patient-centered approach.

Learning points: Critical role of preoperative assessment in patients with rare diseases (current symptoms and comorbidities, previous contact with anesthesia, problems anticipation) - leading to an individualized anesthesia preparation and proper complications avoidance/management; Adequate team communication, patient cooperation and understanding of available resources

11AP08-10

Improvising in hostile terrain: Excision of giant goiters under opioid-free anesthesia in a low-resource humanitarian setting

N. Aracil Escoda¹, E.D. Martinez-Hurtado¹, B. Escontrela Rodriguez¹, T. Collazo-Lorduy², A. Zuazua-González², <u>A. Abad-Gurumeta¹</u> ¹Hospital Universitario Infanta Leonor, Servicio de Anestesiología y Reanimación, Madrid, Spain, ²Hospital Universitario Infanta Leonor, Servicio de Otorrinolaringología, Madrid, Spain

Background and Goal of Study: Thyroid surgery in low-resource environments is particularly challenging due to the limited availability of medications and equipment. This case series describes the outcomes of 10 women with advanced thyroid pathology who underwent subtotal or hemithyroidectomy during a humanitarian mission to Benin, Africa.

This was not the original purpose of the mission, however, on the ground these were the needs of the population. Opioid-free anesthesia (OFA) was used due to the absence of opioids.

Materials and Methods: Patients aged 30–55 years were selected for surgery. The pre-operative evaluation was limited to a clinical examination, a laryngoscopy and a basic laboratory test. A management approach with the only available resources was chosen: General anaesthesia was administered to all patients due to lack of cooperation due to language barrier. The analgesia strategy employed was based on the OFA approach using preincisional and post-closure local wound infiltration combined with intravenous nonsteroidal anti-inflammatory drugs (NSAID).

The primary outcome was the feasibility and safety of the OFA protocol. Secondary outcomes included intraoperative hemodynamic stability, postoperative pain scores, and complications.

Results and Discussion: All surgeries were completed according to our plans. Intraoperative haemodynamics parameters were stable in all patients, with no significant adverse events. Postoperative pain was effectively managed with NSAIDs, achieving a mean visual analogue scale (VAS) score of 1 (range 1-2) at 24 hours. There was only one complication due to the loss of a drain, which required repositioning.

In a humanitarian mission, it is possible to change plans and adapt to the environment according to the needs of the target population. The lack of opioids was mitigated by the effective use of local anaesthetics, highlighting the adaptability of anaesthetic strategies in limited settings. Wound infiltration is a viable alternative for humanitarian missions and may reduce reliance on opioids in certain scenarios.

Conclusion: OFA using NSAIDs and local wound infiltration is a safe and effective anaesthetic approach for thyroid surgery in low-resource settings.

This strategy provides a practical solution to the challenges posed by limited drug availability and offers a model for safe perioperative care in similar environments.

Encéphalopathie de Wernicke survenant précocement après une gastrectomie totale: est-il possible de la détecter et de la prévenir?

A. Driouich¹, J. Ouachaou¹, O. Jamil¹, H. Ouchtiti¹, Y. Zarrouki¹

¹ARRAZI HOSPITAL ,UHC Mohammed VI, Anesthesia and Care Intensive, Marrakech, Morocco

Background: Wernicke's encephalopathy is an acute neuropsychiatric complication secondary to thiamine deficiency. The classic triad is frequently reported in this context, associated with unusual signs. Cerebral involvement typically affects the medial regions of the thalamus and the periaqueductal gray matter, appearing on MRI, which is the reference examination, along with vitamin dosage.

Case Report: We report the case of a patient, 62 years in relatively good nutritional status admitted to postoperative intensive care following a total gastrectomy for gastric adenocarcinoma, who developed postoperative neuropsychiatric disturbances in an incomplete table ultimately suggesting Wernicke's encephalopathy, confirmed by MRI and vitamin B1 dosage.

Discussion: Wernicke's encephalopathy (WE) is an acute neuropsychiatric condition primarily caused by thiamine (vitamin B1) deficiency. Although it is most often seen in chronic alcoholics, WE can also be precipitated by other conditions that lead to nutritional deficiencies, such as malignancies, malabsorption disorders, or major surgeries like a total gastrectomy (TG).

This discussion focuses on the potential for detecting and preventing WE after total gastrectomy, as well as the importance of early intervention.

Detecting WE early in the context of a total gastrectomy can be challenging, as its symptoms may overlap with other postoperative complications, such as delirium or metabolic disturbances. The hallmark symptoms of WE-ataxia, confusion, and ophthalmoplegia-

Routine screening for thiamine deficiency post-surgery could help identify those at higher risk.

Prevention of Wernicke's Encephalopathy After Total Gastrectomy

Prevention of WE following total gastrectomy hinges on addressing the nutritional deficiencies that lead to thiamine deficiency. This can be accomplished through a combination of dietary management, supplementation, and regular monitoring.

11AP08-12

Identification of high-risk groups of surgical patients using unsupervised learning from administrative electronic health record data

R. Huf¹, B. Ulm^{1,2}, S. Kagerbauer^{1,2}, B. Jungwirth¹, M. Graessner^{1,2}

¹Universitätsklinikum Ulm, Department of anesthesiology and intensiv care, Ulm, Germany, ²TUM Universitätsklinikum rechts der Isar, Department of anesthesiology and intensiv care, Munich, Germany

Background and Goal of Study: At 4%, the European average for perioperative mortality is relatively high (1). A rapid and correct risk assessment is important to institute appropriate clinical management, and machine learning can help with this task (2). The aim of this study is to identify risk groups of surgical patients purely from preoperative administrative data that can be easily extracted from electronic patient records

Materials and Methods: We included 179.135 patients undergoing planned and emergency non-cardiac surgery at a German university hospital between June 2014 and December 2022 (ethics number 253/19 S-SR). Only administrative data from the EHR was included as input for a k-means clustering algorithm: age, sex, reason for admission, admitting department, type of surgery or intervention, date and daytime of surgery.

Results and Discussion: We obtained 5 clusters: cluster 1 with predominantly older (median age 69) emergency patients (76,6% emergency admissions), cluster 2 containing rather older patients (median age 65) with a high proportion of general surgery, cluster 3 consisting of rather younger patients with a high proportion of trauma and orthopaedic procedures, cluster 4 with predominantly gynaecological (99,9% female patients, median age 35) and cluster 5 with older, urological patients (median age 65) (Table 1). All clusters differed significantly in mortality and the need for postoperative intensive care (Figure 1).

Cluster	·	. 2		and the same	5	p-value
de la companya del companya de la companya del companya de la comp	N=9,218	N = 28,063	N=117,178	N = 8,497	N=16,179	
Sex female	43.5%	51.0%	45.4%	99.9%	16.1%	<0.001
Age (Median, IQR)	69 (54, 79)	65 (53, 74)	55 (36, 70)	33 (30, 36)	85 (54, 74)	<0.001
Emergency admission	76.6%	23.7%	25.5%	1.0%	13.4%	<0.001
Weekend	22.2%	3.1%	4.2%	21.2%	1.6%	<0.001
Standard duty	55.1%	91.0%	88.2%	51.4%	93.8%	<0.001
Admission from external hospital	9.6%	1.5%	2.7%	0.2%	0.6%	<0.001

Table 1. Descriptive statistics of all obtained clusters. Baseline data for all 5 clusters including: age, sex, reason for admission, date and daytime of surgery.

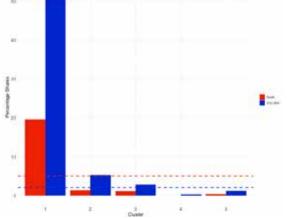

Figure 1. Mortality and ICU-Admission rate after clusterization. The bar chart represents the fraction of postoperative mortality and post-operative ICU admission. ICU = Intensive care unit.

Conclusion(s): Unsupervised machine learning applied to administrative data enables the identification of risk groups in patients undergoing non-cardiac surgery. These methods thus have the potential to be used as automatic triage tools at hospital admission.

11AP09-1

Low opioid anesthesia combined with loco-regional anesthesia: A successful alternative in patients undergoing oncological surgery and allergic to muscle relaxants

L. Bacariza Morillas¹, A. Culebradas¹, V. Ureña¹, A. Juan¹, M. Duart¹, A. Mira¹

¹HU Sant Joan, Anestesiología, reanimación y terapéutica del dolor., Reus, Spain

Background: Patients with a history of anaphylaxis to NMBA can be a challenge to anesthesiologists. Major abdominal surgery is generally carried out under general anesthesia.

Specially those performed by laparotomy due to the substantial insult of the approach and to facilitate organ relaxation and paralysis. Locoregional anesthesia offers a means of providing anesthesia without using NMBAs (1).

Case Report: An 88-year-old male patient (ASA III; 83 kg; 167 cm) who was scheduled for laparotomic hemicolectomy and reparation of an incisional abdominal wall hernia, had a history of anaphylaxis to NMBAs. We planned a multimodal anesthesia with locoregional anesthesia: first, we placed a thoracic epidural catheter; then at L3-4 level, we administered 15mg intradural Bupivacaine.

We administered as in a LOA protocol: Midazolam, Magnesium Sulfate, Dexketoprofen, Dexamethasone, and IV Lidocaine. While preoxygenating for 2 minutes we started Remifentanil TCI. We induced general anesthesia with Propofol and completed 5min mask ventilation with 100% oxygen and 4% Sevoflurane.

After confirming no more self-ventilation, we performed the laringoscopy with an Airtraq device. Intubation condition was good. General anesthesia was maintained with Sevoflurane, Magnesium Sulfate infusion, and Remifentanil TCI. Intervention time was 4h. The surgeon felt no difference from patients under relaxation with NMBAs.

At the end of surgery, gave 1g of Paracetamol. The patient recovered in less than 10min after the cessation of drugs and was extubated without complications. We used an epidural pump of Ropivacaine 48h. He was discharged after 6 days without complications.

Discussion: Combination of general and loco-regional anesthesia would translate into lower metabolic and endocrine responses to stress and better pain control (2).

Laparotomy under locoregional anesthesia resulted safe and feasible. Intradural anesthesia has advantages over epidural anesthesia.

Amongst the drugs at our reach, we chose those which would provide a greater muscle relaxation whilst keeping in sight our goal of an enhanced recovery. Induction without NMBAs was successful under videolaryngoscopy (3).

Coe C. Locoregional Anaesthesia for Laparotomy: A Literature Review and Subsequent Case Series Highlighting the Potential of an Alternative Anaesthetic Technique. Cureus. 2023 Sep 19:15(9):e45529

Learning points: LOA general anesthesia and locoregional anesthesia are an option in allergies.

11AP09-2

Effects on perioperative blood glucose in patients with type 2 diabetes mellitus according to different anesthesia methods: a PRISMA-compliant systematic review and meta-analysis

S.H. Kim^{1,2}, Y.J. Choi³, H. Kang⁴

¹Chosun University Hospital, Department of Anesthesiology and Pain Medicine, Gwangju, Korea, Republic of, ²Chosun University, School of Medicine, Department of Anesthesiology and Pain Medicine, Gwangju, Korea, Republic of, ³Korea University Medical School and Ansan Hospital, Department of Anesthesiology and Pain Medicine, Ansan, Korea, Republic of, ⁴Chung-Ang University College of Medicine, Department of Anesthesiology and Pain Medicine, Seoul, Korea, Republic of

Background and Goal of Study: To evaluate the impact of intravenous and inhalation anesthesia on blood glucose in patients with type 2 diabetes mellitus undergoing surgery.

Materials and Methods:

Design: A systematic review and meta-analysis of randomized controlled trials. Medline, EMBASE, CENTRAL, and Google were searched from inception up to 14 October 2024.

Setting: Operating room, postoperative recovery area, and ward, up to 2 days after surgery.

Patients: patients with type 2 diabetes mellitus undergoing surgery.

Interventions: We used Comprehensive Meta-Analysis version 2.0 to pool the data with fixed or random effects model. The quality of evidence was rated using the Grading of Recommendations, Assessment, Development and Evaluation system. Two researchers in 1 group independently screened literatures with eligibility criteria, extracted information, and used RevMan5.3 software to perform a meta-analysis.

Measurements: The primary outcomes were combined intraoperative blood glucose in patients with type 2 diabetes mellitus at multiple time points. The secondary outcomes included blood glucose at each time point during surgery and after surgery, and inflammation factors and cortisol.

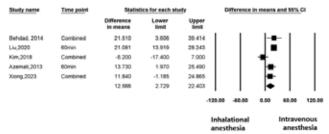

Figure 1. Blood glucose levels comparison by intravenous and inhalation anesthesia.

Results and Discussion: Five studies involving 512 participants were included. The meta-analysis results suggested that compared with inhalation anesthesia, intravenous anesthesia has better glycemic control in combined intraoperative blood glucose levels (WMD 1.26, 95% confidence interval [CI] _1.77 to 0.76). However, there was no evidence of a difference in blood glucose level after surgery (MD_7.379, 95% CI_-34.01 to 48.76).

Conclusion(s): Existing evidence showed that compared with inhalation anesthesia, intravenous anesthesia has better glycemic control in intraoperative blood glucose levels.

Obstructive sleep apnea syndrome resolved by lobectomy: insights from a clinical case

G. Ivanova ^{1,2}, M. Atanasova^{1,2}, G. Ganchev²
¹Medical University Sofia, Anesthesia and Intensive Care,
Sofia, Bulgaria, ²University Hospital of Endocrinology,
Surgery, Sofia, Bulgaria

Background: Obstructive sleep apnea syndrome (OSAS) involves recurrent upper airway obstruction during sleep. Common risk factors include obesity, nasal obstruction, adenoid/tonsil hypertrophy, and hypothyroidism. However, the role of large thyroid goiters, independent of hypothyroidism, in OSAS remains unclear. While thyroidectomy has been reported to alleviate OSAS symptoms, the relationship between goiter size and OSAS, particularly in males, is underexplored.

Case report: A 72-year-old male with a BMI of 37, hypertension, metabolic syndrome, and OSAS (AHI 39 supine, 9 lateral) diagnosed a year earlier presented for thyroid surgery. Despite being euthyroid, he had a left thyroid lobe measuring 4/4.5 cm on ultrasound, fully nodular, with biopsy findings suggestive of malignancy. The right lobe was normal.

Preoperative CPAP therapy had been initiated 11 months earlier. Intraoperatively, the left lobe measured 15/10/12 cm, extended retrosternally, and displaced the trachea rightward. Post-lobectomy, the patient reported improved breathing, with $SpO_2 \ge 93\%$ on room air and an AHI of 13 supine and <5 lateral.

Discussion: This case underscores the potential role of large thyroid goiters in OSAS pathogenesis, even in euthyroid patients. While other risk factors persisted, significant improvement in polysomnographic and clinical outcomes was observed postoperatively.

This highlights the need to consider thyroid enlargement in OSAS evaluation. Discrepancies between ultrasound and actual thyroid size suggest that CT imaging may be more reliable.

Further studies are warranted to clarify the impact of thyroid pathology on OSAS and refine diagnostic protocols.

Learning points: This case suggests a link between thyroid goiters and OSAS, even in euthyroid patients, highlighting the value of CT for accurate thyroid assessment in OSAS diagnosis.

11AP09-4

The role of pharmacogenetics in patients with severe postoperative nausea, vomiting, and pain following general anaesthesia: concept of a pilot study

A.M. Wank^{1,2,3}, G. Bartl^{1,4,5}, F.A. Landsteiner^{1,4,3}, B. Gustorff^{6,3,7}, Vienna Human Pain Research Group ¹Sigmund Freud Private University, Faculty of Medicine, Vienna, Austria, ²Ottakring Clinic, Department of Anaesthesia, Intensive Care and Pain Medicine, Vienna, Austria, ³Ottakring Clinic, Verein zur wissenschaftlichen Forschung am Wilhelminenspital, Vienna, Austria, ⁴Ottakring Clinic, Department of Anaesthesia, Intensive Care and Pain Medicine, Wien, Austria, ⁵Ottakring Clinic, Verein zur wissenschaftlichen Forschung am Wilhelminenspital, Wien, Austria, ⁶Ottakring Clinic, Head of Department of Anaesthesia, Intensive Care and Pain Medicine, Wien, Austria, ⁷Sigmund Freud Private University, Head of the Department of Interdisciplinary Pain Medicine, Vienna, Austria

Background and Goal of Study: Despite advancements in anaesthesiology, postoperative nausea and vomiting (PONV) remain prevalent, affecting over 27% of patients, while severe postoperative pain impacts approximately 32%, even in the implementation of standardized prevention protocols. These outcomes suggest that genetic polymorphisms may play a critical role - although their effect remain unclear. Studies on polymorphisms in gene locations like CYP2D6, crucial for drug metabolism in anaesthesia, reveal deviations of 20–30%. These findings highlight the possible relevance of pharmacogenetics in perioperative care.

The objective of our ongoing proof-of-concept-study is to examine pharmacogenetics as a factor contributing to severe adverse events. We present a pilot study investigating the prevalence of genetic polymorphisms in patients suffering from severe PONV or postoperative pain following general anaesthesia. By analysing specific gene loci associated with anaesthetic and analgesic drug metabolism and pharmacodynamics, this study represents a pioneer study to clinically examine how pharmacogenetic variability influences severe side effects.

Methods: The cohort includes 50 patients treated at a teaching hospital, with recruitment concluding in early 2025. Participants are divided into two groups: 25 patients with severe PONV and 25 patients with intense postoperative pain (NRS \geq 6/10). Defined inclusion and exclusion criteria ensure consistent patient selection. Blood or saliva samples undergo whole-genome sequencing targeting a defined gene panel associated with drug metabolism and pharmacodynamics. The rate of polymorphisms in the study cohort is compared to an Austrian average population using a pharmacogenetic laboratory database.

Results and Discussion: We anticipate a higher prevalence of genetic polymorphisms in patients with severe PONV or postoperative pain compared to an average population. This is used to validate the concept of this pilot study. Preliminary data provide insight into the genetic factors to perioperative side effects and support the development of personalized interventions.

Conclusions: This pilot study introduces a novel approach to understanding the genetic basis of severe postoperative side effects. Findings from 50 patients are presented and provide valuable data for a planned clinical controlled study. We will address the potential of pharmacogenetics in enhancing anaesthetic tolerability and optimising perioperative care.

11AP09-6

Evaluation of lung ultrasound as a screening tool to detect early post operative pulmonary complications following major upper open abdominal surgeries

M. Harjai¹, H. Kumar¹¹Dr. Ram Manohar Lohia Institute of Medical Sciences, Anesthesia and Critical Care, Lucknow, India

Background and Goal of Study: Early, post-operative pulmonary complications have a detrimental effect on the outcomes of all major surgeries, hence their screening through sensitive modalities is very important. The goal of the study is to evaluate usefulness of Lung Ultrasound as a screening tool for detection of early post-operative complications following major upper open abdominal surgeries.

Materials and Methods: In this prospective observational study, a total of 100 patients (20-65 years) were scheduled to undergo major upper open abdominal surgeries. Preoperative Lung Ultrasound (USG) and Chest X-ray were performed in all the patients and were subsequently screened for pulmonary complications on post-op. day 1, 2 and 3 using Lung USG and Chest X-ray. Pulmonary effusion, consolidation and interstitial abnormalities were noted. Cumulative incidence of lung abnormalities was also noted. Statistical analysis- Detection rate for pulmonary complications was compared between Chest X-ray and Lung USG using Chi-square test.

Results and Discussion: As per Lung USG, incidence of pulmonary abnormalities was 48%. Compared to this Chest X-ray screened pulmonary abnormalities in 18% cases only. Pleural effusion, consolidation and interstitial abnormalities were detected in 35%, 22% and 48% using lung USG and 18%, 9% and 0% respectively using Chest X-ray. There was a significant difference in detection rates of pulmonary abnormalities between two modalities (p<0.001

Conclusion(s): Lung USG was a highly sensitive imaging modality, particularly for detection of interstitial pulmonary abnormalities which remained almost undetected on Chest X-ray.

11AP09-7

Incidence of Postoperative Nausea and Vomiting in bariatric surgery

J. Korjas^{1,2,3}, J. Kirss^{3,4}, I. Kaur³, L. Maddison^{1,5}
¹University of Tartu, Institute of Clinical Medicine, Tartu,
Estonia, ²East Tallinn Central Hospital, Department of
Anaesthesiology and Intensive Care, Tallinn, Estonia,
³Bariatric Services AS, Department of Surgery, Viimsi,
Estonia, ⁴The North Estonia Medical Centre, Surgery
Clinic, Tallinn, Estonia, ⁵The North Estonia Medical Centre,
Anaesthesiology Clinic, Tallinn, Estonia

Background and Goal of Study: Postoperative nausea and vomiting (PONV) is a common complication in bariatric surgery. ERAS guidelines¹ and a position statement endorsed by professional societies² recommend implementing universal prophylaxis with two or three antiemetics.

This study implements a universal PONV prevention protocol comprising three agents from different antiemetic classes: a glucocorticoid, a 5-HT3 antagonist, and a butyrophenone.

Materials and Methods: A retrospective analysis was performed on the records of 1,051 patients who underwent bariatric surgery, including laparoscopic sleeve gastrectomy, Roux-en-Y gastric bypass, one-anastomosis gastric bypass, single-anastomosis sleeve-ileal bypass, or revision surgery. All patients received 8 mg of dexamethasone during anesthesia induction, 1 mg of granisetron, and 1 mg of droperidol at the end of surgery. PONV incidence was defined by the need for rescue antiemetics postoperatively. Adjusted logistic regression analysis evaluated risk factors.

Results and Discussion: Most patients were female (84%), with a median age of 42 (range 18–80) and a median BMI of 37.6 (IQR 34.6–42.3). The overall PONV incidence was 38%. Risk factors associated with an increased likelihood of PONV included female sex (OR 2.52, 95% CI 1.69–3.83), type of surgery (laparoscopic sleeve gastrectomy OR 2.20, 95% CI 1.42–3.42), non-smoking status (OR 1.51, 95% CI 1.05–2.18), and postoperative opioid use (OR 1.07, 95% CI 1.04–1.10). Total intravenous anesthesia did not appear to provide additional protective effects when three antiemetics were used (p = 0.347).

Conclusion(s): Clinically significant PONV continues to occur in over one-third of bariatric surgery patients, despite implementing a liberal, universal antiemetic prophylaxis protocol. Further research and efforts to mitigate PONV risk are necessary.

11AP09-8

Association between pre-operative use of selective alpha 1 blockers and intraoperative hypotension

O. Cohen Rosenboim^{1,2}, V. Rabkin^{1,2}, T. Talmy^{1,2}, S. Zarour^{1,2}, B. Cohen^{1,2}

¹Tel Aviv Medical Center Ichilov, Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel, ²Tel Aviv University, Faculty of Medicine, Tel Aviv, Israel

Background and Goal of Study: Selective alpha-1 blockers (SAB) are widely prescribed for lower urinary tract symptoms. While associated with adverse effects of orthostatic hypotension, current literature supports their safe continuation in surgical patients. However, isolated case reports suggest a potential association between selective alpha-1 blockers and intraoperative hypotension (IOH), which in turn is associated with significant postoperative complications. We aimed to investigate the association between preoperative SAB use and the incidence of IOH, as well as its relationship with a composite secondary outcome including myocardial injury after non-cardiac surgery, acute kidney injury, stroke, and 30-day mortality.

Materials and Methods: Single-center retrospective cohort study analyzing data of male patients > 50 years of age who had non-cardiac surgery. Exposure of interest was pre-operative prescription of SAB, and the primary outcome was time-weighted average (TWA) under mean arterial pressure (MAP) of 65 mmHg. IOH was also quantified as minutes under MAP of 65. Multivariable logistic regression was utilized to adjust for potential confounders.

Results and Discussion: Among 28,705 cases analyzed, 6,303 (22%) patients used SAB preoperatively, and 22,402 (78%) did not. The SAB group exhibited lower average MAP (81 mmHg vs. 82 mmHg, p=0.001) and spent more time under a MAP of 65 mmHg (median 4 vs. 3 minutes per hour, p=0.001). The primary outcome (TWA under MAP 65) was significantly greater in the study group (0.30 mmHg, 95% CI 0.00-1.01) compared to the control group (0.22 mmHg, 95% CI 0.00-0.83, p<0.001) and remained so after adjusting for potential confounders. Univariate analysis also demonstrated a crude association with the composite secondary outcome (9% vs 7% p<0.001), However this association became non-significant after adjusting for potential confounders (OR 1.1, 95% CI 0.98 to 1.24, p=0.091).

Conclusion(s): In this large retrospective cohort study, chronic use of SAB was associated with more IOH, lower mean blood pressure, and longer durations of hypotension.

Nonetheless, it was not associated with a composite of adverse postoperative events, which might indicate that SAB serve as markers for higher-risk patients rather than exerting a direct effect on postoperative complications.

Further prospective studies may elucidate the causal relationship between SAB and IOH as well as the clinical significance of these findings.

11AP09-9

Assessing efficacy of intravenous acetaminophen for perioperative pain treatment in spinal surgery

H. Ma¹², B. Lai³, M. Albanese², M. Smith², A. Mueller², J. Wang²

¹The Second Hospital of Jilin University, Department of Anesthesiology, Changchun, China, ²Massachusetts General Hospital, Department of Anesthesia, Critical Care and Pain Medicine, Boston, United States, ³The Second Hospital of Jilin University, Department of Intensive Care Unit, Changchun, China

Background and Goal of Study: Intravenous Acetaminophen (IVA) is an effective medication for primary and adjunctive pain management and has demonstrated reductions in total morphine consumption.

The main objective of this study was to investigate the effectiveness of IVA in relieving pain, reducing opioid use, shortening hospital stay, and improving patient satisfaction.

Materials and Methods: This randomized, quadruple-blinded, controlled, single-site, parallel-arm superiority trial was conducted to investigate the effect of IVA on reducing pain scores and several other secondary outcome measures. 60 consented spinal surgery patients were randomized by the research pharmacy into the placebo or acetaminophen group. Within 30 minutes of surgical closure, participants received either 1-gram IVA or placebo (0.9% saline). There were 3 patients found ineligible and removed from the trial.

Superiority testing was used to examine the differences between the two treatment arms for the primary and all secondary outcomes. Multiple forms of regression analysis conditional on treatment group assignment and several a priori selected prognostic variables, age, sex, preoperative opioid use, and preoperative pain, were used to estimate IVA's effect on the outcomes.

Results and Discussion: Imbalance between the placebo and acetaminophen group was observed in several of these characteristics, including preoperative pain (median 3.0 [2.0, 5.3] vs. 4.0 [2.0, 6.0]; SMD = 0.179), preoperative NSAIDS (14.3 % vs. vs. 27.6 %; SMD = 0.331), and pre-anesthetic medications (10.7 % vs. 25.9 %; SMD = 0.401).

Primary and secondary outcomes estimated from regression models conditional on treatment and prognostic variables are captured. The worst numerical pain score (primary outcome; 0 to 10 scale) was higher in the acetaminophen group compared to the placebo group, adjusted difference: 0.54 (95%Cl: -0.87, 1,97), p = 0.452. Patient satisfaction was estimated to be lower in the acetaminophen group compared to the placebo group (Estimate: -1.11, 95% Cl: -2.06, -0.17; P = 0.021).

Conclusion(s): Our study findings suggest that incorporating IVA into existing opioid-based perioperative pain management strategies may not provide substantial relief for postoperative pain. Thus, adding IVA to existing perioperative pain management strategies is unlikely to meaningfully reduce postoperative pain.

11AP09-10

Assessment of postoperative nausea and vomiting in the early postoperative period

S. Maricic Prijic^{1,2}, J. Crnic², A. Uvelin^{1,2}, R. Popovic^{1,2}, S. Vickovic^{1,2}, T. Tubic^{1,2}

¹University Clinical Center of Vojvodina, Clinic of Anesthesia, Intensive Therapy, and Pain Therapy, Novi Sad, Serbia, ²University of Novi Sad, Medical Faculty, Anestesiology and Perioperative Medicine, Novi Sad, Serbia

Background and Goal of Study: Postoperative nausea and vomiting (PONV) is still a common complication of general anesthesia and a significant cause of preoperative fear in patients. After pain, PONV is the second most frequent complaint in the early postoperative period. It delays recovery room discharge.

The aim of this study is to examine the incidence of PONV in the early postoperative period, risk factors that are most significant in predicting early PONV and the association between acute postoperative pain and early PONV.

Materials and Methods: The research was conducted on Clinic of Anesthesia, Intensive Therapy and Pain Therapy, University Clinical Centre of Vojvodina, Serbia as a cross-sectional observational study that included 150 patients from elective program of abdominal, plastic, maxillofacial, vascular, and neurosurgery. Brief history was taken, and a survey was conducted on early PONV and acute postoperative pain. Necessary data from medical history and anesthesia protocol were recorded in the research protocol.

For primary data analysis there were used descriptive statistical methods, methods for testing correlations and methods for testing predictive abilities.

Results and Discussion: Out of 150 patients, PONV occurred in 36 patients (24%), which correlates with data from the literature. Patients most often rated the severity of nausea as 3 on the numerical rating scale. Risk factors that can be related to the occurrence of PONV are history of motion sickness, use of opioids postoperatively, and antidiabetic medication. The first two are well-known risk factors for the development of PONV, they are even part of the well-known Apfel score. In our study we came to conclusion that motion sickness increases the chance of early PONV by 4.2 times, and the use of opioids by as much as 5.7 times. Regarding diabetes therapy, these results can be explained by delayed gastric emptying due to autonomic neuropathy and hyperglycemia in diabetics.

There is a slight correlation between the severity of acute postoperative pain and PONV, and between Apfel score and PONV.

Conclusion(s): The incidence of postoperative nausea and vomiting is 24%. Most significant factors in prediction of early PONV are presence of motion sickness, postoperative use of opioids, and use of antidiabetic medication. Occurrence and severity of early PONV is related to the severity of acute postoperative pain.

11AP09-12

Caffeine-induced masseter spasm as a controversial risk factor for MH? Internal audit

M. Klincová^{1,2,3}, D. Štěpánková^{1,2}, I. Schröderová^{4,2}, E. Klabusayová^{1,3}, P. Štourač^{1,3,2}

¹Faculty of Medicine, Masaryk University and University Hospital Brno, Department of Paediatric Anaesthesiology and Intensive Care Medicine,, Brno, Czech Republic, ²Masaryk University, Academic Centre for Malignant Hyperthermia, Brno, Czech Republic, ³Faculty of Medicine, Masaryk University, Department of Simulation Medicine, Brno, Czech Republic, ⁴Faculty of Medicine, Masaryk University and St. Anne's University Hospital, Department of Anaesthesiology and Intensive Care, Brno, Czech Republic

Background and Goal of Study: Masseter spasm after triggers is one of the early signs of malignant hyperthermia (MH). Historically, probably because caffeine is used as one of the substances during In vitro contracture test (IVCT), "caffeine intolerance" was believed to be a risk factor for MH in Czechia. After drinking coffee, some patients referred to masseter twitching, spasms or jaw trismus. Caffeine is a stimulant and can increase susceptibility to muscle cramps (1). Although the exact pathophysiological mechanism is still subject to debate, the potentiation of muscle contraction via induction of sarcoplasmic reticulum calcium release is well established (2). The controversy is that we could not find any similarities in other cohorts of MH patients worldwide. To reveal the facts, we conducted an internal audit at the MH centre in Brno, Czechia.

Materials and Methods: In this retrospective observational internal audit, we screened 303 patients referred to our MH centre from 2002 to 2022. Probands were investigated depending on the valid MH diagnostic criteria. Inclusion criteria for further analysis included a caffeine intolerance as a reason for referral. The data were reported descriptively using Microsoft 365. We also performed a literature review to detect the source of "caffeine-induced jaw spasm is an MH risk factor" information.

Results and Discussion: The jaw trismus after drinking black coffee was listed as a possible MH risk factor in the first Czech "modern" textbook of Anaesthesiology from 1981(3) and in the Czech translation of the 5th edition of Larsen's Anaesthesia textbook from 1998. 24 probands were referred to our MH centre based on any form of caffeine intolerance. IVCT was performed in 19, four (21%) were MH susceptible (MHS). None of the MHS patients had other MH risk factors. Genetic screening detected only one variant of unknown significance in the RYR1 gene.

Conclusion(s): With about a fifth MHS probands, our data does not confidently rule out a controversial potential connection between caffeine-induced jaw spasms and MH risk.

Incidence and risk factors of preoperative hyponatremia in patient underwent urgency tracheostomy: a retrospective study

S. Junyatham¹¹¹Mahidol University, Department of Anesthesiology, Bangkok, Thailand

Background and Goal of Study: Hyponatremia is a frequently encountered electrolyte disturbance in surgical patients. It is found to be associated with elevated risks of complication during the perioperative period. Despite its association with poor outcomes in critically ill patients, there was no study on the association between preoperative hyponatremia and urgent tracheostomy.

This study aims to evaluate the incidence of preoperative hyponatremia prior to urgent tracheostomy, identify its risk factors and related complications.

Materials and Methods: We retrospectively reviewed adult patients underwent urgency tracheostomy with confirmed hyponatremia (serum sodium [Na] under 135) within 48 hours preoperatively during 10 years (2014-2023), and identified the risk factors and related complications using chi-square tests and logistic regression models.

Results and Discussion: Among 288 adult patients undergoing urgent tracheostomy, 129 patients presented with preoperative hyponatremia (44.8%), with the severity graded as follows: 29.2% mild (Na; 130-134 mmol/L), 6.6% moderate (Na; 125-129 mmol/L), and 9.0% severe hyponatremia (Na less than 125 mmol/L). The significant risk factors were body mass index (BMI) under 18.5 kg/m² (odds ratio [OR]: 2.24; 95% Confidence Interval [CI]: 1.35-3.70; p=0.002) and American Society of Anesthesiologists physical status of III-IV (OR: 2.15; 95% CI: 1.26-3.65; p=0.005). Factors including old age (OR: 0.69; 95% CI: 0.42-1.14; p=0.146), malignancy (OR: 1.61; 95% CI: 0.91-2.86; p=0.103), or others were not found significantly related. There was no complication significantly found associated with preoperative hyponatremia in patients undergoing urgent tracheostomy.

Conclusion(s): Almost half of the adult patients undergoing urgent tracheostomy had preoperative hyponatremia. Low BMI and advanced ASA classifications significantly increased the likelihood. However, preoperative hyponatremia was not found associated with perioperative complication in patients undergoing urgent tracheostomy.

11AP10-2

Influence of intraoperative nociception guided analgesia on perioperative analgesia consumption in patients undergoing laparoscopic resection of endometriosis

P. Ranner¹, H.-T. Morselli¹, T. Piskor¹, I. Marcolino¹ Spital Limmattal, Institute of Anaesthesiology & Intensive Care, Schlieren, Switzerland

Background and Goal of Study: The absence of objective intraoperative nociception monitoring limits anaesthesia providers to using physiological markers, such as tachycardia and hypertension, as surrogates for nociception. This can lead to suboptimal analgesic administration, affecting postoperative outcomes. Recent innovations, such as the Nociception Level (NOL®) index, allow for a quantifiable measure of nociception, offering a potential solution. Patients being scheduled for endometriosis surgery do have a significant history of chronic pain thus being more prone to difficulties in postoperative pain management and therefore will benefit the most from a tailored analgesic regimen.

This study aims to determine whether nociception monitoring with NOL can optimize perioperative analgesia in patients undergoing laparoscopic endometriosis surgery without exacerbating postoperative pain and minimizing side effects of analgetic medication.

Materials and Methods: This prospective randomized, controlled trial is being conducted at Spital Limmattal (Zurich-Schlieren, Switzerland) between August 2024 and is expected to end in December 2025 and includes patients undergoing laparoscopic endometriosis surgery. Every patient was blinded regarding group assignment.

Both groups received a standardized multimodal analgesic regimen and underwent nociceptive monitoring with the NOL device. In the control group, the NOL monitor was blinded, while in the intervention group, analgesia was adjusted based on real-time NOL values to maintain a target range of 10-25.

The primary outcome was total analgesic consumption. Secondary outcomes included length of stay in the post-anaesthesia care unit (PACU) and PACU pain scores.

Results: Preliminary analysis using standardized statistical methods demonstrated a significant reduction in total intraoperative remifentanil consumption in the intervention group using nociception sensor-guided analgesia. For the examined secondary outcomes, postoperative pain scores and length of stay in the PACU, no significant difference could be shown so far.

Discussion and Conclusion: Nociception sensor-guided analgesia decreases opioid use thus decreasing opioid-related complications and improving patient related outcome.

While the randomized design strengthens the findings, limitations such as sample size and generalizability warrant further research to assess long-term outcomes, cost-effectiveness, and broader applicability in clinical practice.

11AP10-3

Multimodal general anesthesia with dexmedetomidine for endonasal surgery in paroxsysmal nocturnal hemoglobinuria (PNH): a case report

J. Sofia Abreu Henriques¹, C. Mateus¹, H. Machado¹
¹Centro Hospitalar Universitário de Santo António,
Unidade Local de Saúde de Santo António, Clínica de
Anestesiologia Medicina Intensiva Emergência e Urgência,
Serviço de Anestesiologia, Porto, Portugal

Background: PNH is a rare stem cell disorder, in which surgery and anesthesia can trigger complement system activation, hemolysis and thrombosis.¹

We report a case of a successful management of a patient who underwent general multimodal anesthesia with dexmedetomidine for endonasal surgery.

Case report: A 54-year-old woman with PNH was scheduled for endonasal surgery and exodontias due to recurrent sinus and teeth infections that triggered multiple hemolytic crisis. Prior intraabdominal venous thrombosis led to portal hypertension, splenomegaly and thrombocytopenia. Previous surgical history included a uretherorenoscopy, halted due to critical hemorrhage. Current medication included eculizumab, prednisolone and acenocumarol.

Patient was monitored according to ASA standards plus invasive arterial pressure, ToFscan $^\circ$, Sedline $^\circ$ and O $_3$ $^\circ$. General anesthesia was induced with target-controlled infusion of remifentanil, lidocaine (1mg/kg), propofol and rocuronium, and maintained with sevoflurane and an infusion of dexmedetomidine (DEX) at 0.4mcg/Kg/h.

Multimodal analgesia included also paracetamol and tramadol. A maxillary sinusotomy, anterior and posterior ethmoidectomy and multiple exodontias were performed with minimal blood loss.

At the end, laboratory analysis showed similar LDH and bilirubin levels. The postoperative period was uneventful, and patient was discharged on the fourth postoperative day.

Discussion: PNH is a rare acquired hematopoietic stem cell disease caused by a mutation in PIGA gene, that results in chronic complement-mediated intravascular hemolysis and hemoglobinuria. Free hemoglobin predisposes patients to thrombosis, especially venous. Infections and inflammation can trigger hemolysis by activating complement system and, for that, surgery and anesthesia are considered potential risk factors².

The literature is sparse regarding best anesthetic approach. However, the main goal is to avoid a hemolytic crisis. To our knowledge, this was the first case in which DEX was used in PNH. Studies have shown DEX's direct anti-inflammatory effect, reducing the expression of pro-inflammatory mediators and increasing the level of anti-inflammatory mediators³.

We hypothesized that DEX could attenuate complement activation and reduce complications.

Learning points: Anesthetic management of patients with PHN is complex. The use of DEX could be a safe alternative, by reducing surgical stress and possibly complement activation and hemolytic crisis.

11AP10-4

Features of the clinical course of the postoperative period in patients with Cardiovascular-Kidney-Metabolic syndrome

I. Lutfarakhmanov¹, A. Grazhdankin¹, <u>A. Lifanova</u>¹, P. Mironov¹

¹Bashkir State Medical University, Anesthesiology and Intensive Care, Ufa, Russian Federation

Background: Recently introduced concept of Cardiovascular-Kidney-Metabolic Syndrome (CVKMS) is defined as a health disorder associated with obesity, diabetes mellitus, chronic kidney disease, cardiovascular disease, and aims to improve a multidisciplinary approach to the prevention, risk stratification, and treatment of these disorders.

Goal of Study: To substantiate the feasibility for selection of CVKMS within the framework of metabolic syndrome (MetS) in anesthesiologic support of non-cardiac operations in high-risk patients.

Materials and Methods: One hundred and two patients were divided into the CVKMS group (n = 34) and the (MetS) group (n = 68). The severity of postoperative complications was classified according to the Clavien-Dindo definitions. The length of postoperative stay was calculated.

Results and Discussion: Patients with CVKMS had a significantly higher rate of metabolic syndrome components: arterial hypertension, obesity, and diabetes mellitus (p < 0.005 for all comparisons). The total number of patients with complications, the rate of postoperative complications of Clavien–Dindo grade II and III was significantly higher in the CVKMS group (p = 0.005; p = 0.001 and p < 0.001; respectively). The length of postoperative stay was significantly longer in the CVKMS group (p = 0.022).

Conclusion: Compared to patients with MetS, patients with CVKMS have a higher incidence of perioperative adverse events and longer hospitalization after non-cardiac surgery. This indicates the expediency of taking it into account when providing anesthesia support in high-risk patients.

Perioperative management of myotonic dystrophy: tailored approaches to general anaesthesia – a case report

- J. Magalhães Fernandes¹, M. Vaz de Carvalho¹,
- D. Sepúlveda¹, L. Godinho¹, <u>I. Mendes Leitão</u>¹,
- S. dos Santos Rodrigues¹

¹Unidade Local de Saúde do Alto Ave, Anesthesiology, Guimarães. Portugal

Background: Myotonic dystrophy (MD) is a rare (2–14/100,000) autosomal dominant multisystem disorder. It ranges from fatal congenital myopathy to late-onset forms where cataracts may be the only symptom. Classic features include myotonia and progressive muscle weakness, often affecting facial, respiratory, laryngeal, axial, and distal limb muscles, with symptoms worsened by stress, pain, cold, or succinylcholine. MD frequently involves the cardiac and respiratory systems, complicating anesthetic management due to hypersensitivity to hypnotics and paralytics. Case reports suggest a possible link between MD and malignant hyperthermia.¹²

Case Report: A 41yo female, ASA III, was admitted for elective hemithyroidectomy. She had a history of MD type I (Steinert's syndrome) with facial and upper limb diparesis, particularly affecting her hands. She had no prior surgeries or anesthesias and denied dyspnea, dysphagia, or dysphonia.

Anesthesia induction was performed with 2mg midazolam, 100mcg fentanyl, 200mg propofol, and 50mg rocuronium, followed by orotracheal intubation. Maintenance was achieved with propofol infusion, adjusted using Bispectral Index* monitoring, and 20mg boluses of rocuronium as needed.

Analgesia included 1g paracetamol, 100mg tramadol, and 30mg ketorolac. The patient remained normothermic and hemodynamically stable.

At the procedure's end, 400mg sugammadex were administered, achieving a TOF ratio >0.9. She was extubated after recovery of motor strength and airway reflexes and transferred to the post-anesthesia care unit.

Discussion: MD is associated with high perioperative morbidity and mortality, primarily due to cardiovascular and respiratory complications. Hypersensitivity to sedatives and paralytics increases risks of ventilatory dysfunction, delayed muscle recovery, pharyngeal dysfunction, and aspiration. To mitigate these, short-acting drugs are recommended to allow rapid recovery of consciousness and muscle strength.²

Learning Points: Perioperative monitoring and preparation for complications are essential for optimal MD patient outcomes.

11AP11-1

Comparison effectiveness of topical analgesics with and without Entonox® for esophagogastroduodenoscopy - a randomized controlled trial

P. Noitasaeng1

¹Mahidol University, Department of Anesthesiology, Faculty of Medicine Siriraj Hospital, Bangkok, Thailand

Background and Goal of Study: Esophagogastroduodenoscopy (EGD) is vital for diagnosing and treating upper gastrointestinal symptoms, but patient discomfort and anxiety can affect procedural outcomes.

This study aimed to compare the effectiveness of topical analgesics with and without Entonox® during EGD in terms of procedural success, patient tolerance, and satisfaction.

Materials and Methods: A prospective, randomized controlled trial was conducted with 212 patients undergoing elective EGD. Patients were randomly assigned to receive either 10% xylocaine spray alone (Group C) or 10% xylocaine spray combined with Entonox* (Group E). Data on demographics, previous EGD experiences, and side effects were collected. Procedural success and patient comfort were evaluated using the Bath Gastroscopy Toleration Score (GTS) and Patient Comfort Scores (PCS), with scores of 0 or 1 indicating success. Satisfaction was measured using the Numeric Rating Scale (NRS), where scores of 7 or higher indicated high satisfaction.

Results and Discussion: A total of 211 patients underwent EGD successfully (Group C=106, Group E=105). Patients in Group E demonstrated a significantly higher proportion of success rate (76.2% vs 35.9%, P < 0.001), better toleration score (82.9% vs 75.5%, P = 0.004), and better patient comfort score (86.7% vs 39.6%, P < 0.001) compared to Group C. Endoscopists and patients in Group E expressed higher satisfaction levels (9 vs. 8, P < 0.01 and 9 vs. 8, P < 0.01).

Side effects of Entonox® were minimal. Notably, patients in Group E had a lower proportion of high blood pressure and tachycardia during the procedure (*P* < 0.001).

Conclusion(s): Combining Entonox® with topical analgesics significantly improves tolerance, satisfaction, and procedural success during EGD, offering a safe and effective option for managing patient discomfort and anxiety.

11AP11-2 Anaesthesia management in Kennedy's disease. A case report

H. del Pino Soriano¹, G. Fraga Casais¹, S. Gholamian Ovejero¹, <u>A.C.O. Orozco Vinasco¹</u>, M. Vicente Orgaz¹, C. Crespo Gómez¹ ¹Hospital Severo Ochoa, Anaesthesiology, Madrid, Spain

Background: Kennedy's Disease (KD) is a rare condition characterised by bulbar and spinal muscular atrophy, predisposing to laryngospasm and bronchial aspiration. Literature on anaesthetic management is limited. We present the case of a male patient with KD undergoing general anaesthesia (GA).

Case Report: A 69-year-old male, with prior KD diagnosis, presented with a suspected malignant vocal cord lesion. KD symptoms included facial weakness, limited mouth opening, dysarthria, dysphonia, choking episodes, self-limited laryngospasms and a need of a cervical collar for head support.

After multidisciplinary assessment, surgery under GA was planned. The patient fasted for >8 hours and received metoclopramide and atropine for premedication. Monitoring included basic parameters, TOF, and temperature. A rapid sequence induction was performed using fentanyl 1mcg/kg, propofol 2mg/kg, rocuronium 0.8 mg/kg, Sellick's manoeuvre and videolaryngoscopy. Maintenance was achieved with propofol and remifentanil.

The patient was extubated without complications when fully alert, after performing TOF-guided neuromuscular block reversal using sugammadex 4mg/kg and a period of CPAP.

Discussion: KD, an X-linked disorder that leads to neuromuscular toxicity, bulbar weakness (dysarthria, dysphagia), and impaired airway (AW) reflexes. Laryngospasms, glottic oedema, and aspiration risk make GA particularly challenging¹.

There is a potential for prolonged ventilation due to vulnerability to depressive drugs and muscle relaxants. Short-acting agents minimise respiratory depression, with depolarising (succinylcholine) and non-depolarising muscle relaxants being used, though succinylcholine may pose a hyperkalaemia risk².

Reversing neuromuscular block is crucial to prevent later respiratory depression, and extubation is preferred when the patient is awake.

References:

- Case series: anesthetic management of patients with spinal and bulbar muscular atrophy (Kennedy's disease). Canadian Journal of Anesthesia, 2009; 56:136–141.
- 2. Use of sugammadex in a patient with Kennedy's disease under general anesthesia. Saudi Journal of Anaesthesia, 2014; 8(3):418–420.

Learning Points:

- KD causes bulbar and spinal muscular weakness, impairing AW protective reflexes.
- GA poses high risks, requiring strategies for AW patency and to prevent postoperative respiratory depression.
- Literature on anaesthetic management of KD is limited; nondepolarising relaxants are preferred over succinylcholine.

11AP11-3

Pneumothorax after difficult face mask ventilation

A.C. Orozco Vinasco¹, D. Orozco Vinasco², S. Gholamian Ovejero¹, H. Del Pino Soriano¹, M. Sanjuan Alvarez¹, R. Saz Castro¹ ¹Hospital Universitario Severo Ochoa, Anesthesiology, Leganés, Spain, ²Hospital General de Granollers, Anaesthesiology, Granollers, Spain

Background: Pneumothorax is a rare complication during anesthesia, mostly related to trauma, central venous cannulation or regional techniques.

Case Report: A 56 y-o woman was scheduled for knee replacement. She had a history of OSA, COPD and carried a ventriculoperitoneal shunt. The patient underwent an uneventful combined anesthesia (balanced general anesthesia + US-guided femoral nerve block). Intubation was done under Glidescope® vision, as she was a known Cormack III.

After extubation the patient suffered a severe laryngospasm and bronchospasm that required high pressure face-mask ventilation (FMV), during which profound hypotension supervened (MAP 45 mmHq).

The patient was reintubated and cardiovascular stability restored. She was transferred to the surgical ICU. A cardiac-US discarded pulmonary hypertension; chest x-ray and laboratory tests were unspecific, the former showing only subcutaneous emphysema. US-scan was not reliable because of subcutaneous adipose tissue.

Extubation was scheduled the same afternoon after which the patient had mildly desaturation. A new chest x-ray showed a complete pneumothorax. A chest tube was inserted and removed after 48 h. The patient was discharged home after 5 days.

Discussion: In our case the most probable cause of pneumothorax was difficult face-mask ventilation, as a result of air trapping and high airway pressure. During surgery driving pressure was <20 cmH2O, but FMV required very high pressure (>40 cmH2O) in an attempt to ensure oxygenation prior to reintubation. Before FMV it the patient was desaturated (SpO2 78%), but hypertensive (MAP >125 mmHg). Cardiovascular instability was probably due to sudden increase in intrathoracic pressure critically reducing preload. This case is special because the first X-ray showed only subcutaneous emphysema. Pneumothorax must have been minimal immediately after intubation but should have been increasing in size during mechanical ventilation.

References:

- 1. Hoechter DJ et al. Tension Pneumothorax During One-Lung Ventilation An Underestimated Complication? J Cardiothorac Vasc Anesth. 2018 Jun;32(3):1398-1402. doi: 10.1053/j. jvca.2017.07.022.
- 2. Markota A et al. Absence of lung sliding is not a reliable sign of pneumothorax in patients with high positive end-expiratory pressure. Am J Emerg Med. 2016 Oct;34(10):2034-2036. doi: 10.1016/j.ajem.2016.07.032.

Learning Points: An immediate chest X-ray does not rule out pneumothorax, but subcutaneous emphysema can be the only sign. Further investigations might be necessary.

11AP11-4

Evaluating nociception during general anaesthesia: a comparison of the Analgesia **Nociception Index and the Nociception Level** Index

H. Kempe¹, M. Kreuzer¹, G. Schneider¹, P. Gambús^{2,3}, S. Vide^{2,4,5}

¹Technical University of Munich, Department of Anesthesiology and Intensive Care, Munich, Germany, ²Hospital CLINIC de Barcelona, Anesthesiology Department, Barcelona, Spain, 3Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), NeuroImmunology Research Group, Barcelona SpaSpa, Spain, ⁴Unidade Local de Saúde de São João, Serviço de Anestesiologia, Porto, Portugal, Faculdade de Medicina da Universidade do Porto. RISE@Cintesis. PortoPo. Portugal

Background and Goal of Study: Multimodal anaesthesia combines hypnotics, analgesia, and, if necessary, muscle relaxation [1]. Potent opioids maintain the balance between nociception and analgesia, but over- as well as underdosing cause severe side effects. Optimal opioid titration is mainly based on the attending anaesthesiologist's knowledge. To help titrate analgesics and thus individualize analgesia several nociception monitors emerged. Two of these, the Analgesia Nociception Index (ANI) and the Nociception Level Index (NOL), focus on different autonomic reactions as surrogate parameters to estimate the nociception-antinociception balance.

Our primary objective was to compare the ANI and NOL during general anaesthesia to evaluate their (dis-)agreement level.

Materials and Methods: We included all patients with corresponding ANI and NOL recordings undergoing operations under general anaesthesia from a larger dataset. This included 30 patients (25 female, 5 male). Propofol and remifentanil were administered with a target-controlled infusion. Both monitors measure from 0 to 100. We allocated three ranges based on the manufacturer's information.

The ranges were

- i. Nociception, which is likely predominant,
- ii. Optimal analgesic level, and;

iii. Analgesia, which could be reduced as it exceeds nociception. Agreement and disagreement were evaluated across varying levels of remifentanil, propofol, and noxious stimuli. We performed a chi-square test of independence to assess any correlation between the monitors and the range allocated.

Results and Discussion: We analysed 38 hours and 15 minutes of surgery time. A predominance of analgesia was found 37.60% of the time for ANI and 38.99% for NOL, suggesting a potential opioid reduction. The optimal balance was observed in 30.89% for the ANI and in 30.85% for the NOL. A predominance of nociception occurred in nearly 25% for both monitors. The chi-square statistic was 31.79 (3, 55080), p < 0.001, Cramer's V: 0.024. ANI and NOL agreed 43.66% of the time. Disagreement by one score was found in 37.08%, and contrasting information was observed in 8.71%.

Conclusion(s): The overall agreement between ANI and NOL was less than 45%, while the opposite information was seen nearly 10% of the time. These findings demonstrate the need to evaluate nociception monitors to provide better nociception assessment during general anaesthesia.

Mask induction in pediatric patients with autism: is it really a winning strategy?

A. Ragone¹, G. Sfregola¹, G. Montenero¹, C. Di Terlizzi¹, M. Ciuffreda², D. Galante¹

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, ²Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Autism Spectrum Disorder (ASD) is a neurodevelopmental condition that often presents with communication difficulties, sensory sensitivities, and behavioral challenges. The anesthetic management of pediatric patients with ASD undergoing surgery poses unique challenges.

This study aims to evaluate the complications and issues encountered in 18 pediatric patients with autism who underwent various surgical procedures under general anesthesia.

Materials and Methods: A survey analysis was conducted in 10 hospital centers on 23 pediatric patients diagnosed with ASD who were scheduled for surgery between 2019 and 2023. The surgeries included elective and emergency procedures across various specialties.

Data on anesthetic management, perioperative complications, and recovery were collected. Special attention was given to difficulties related to sedation, preoperative preparation, intraoperative management, and postoperative recovery.

Results and Discussion: The study identified several challenges, including difficulties in preoperative communication, with many patients exhibiting heightened anxiety and resistance to routine preparatory procedures.

During anesthesia induction, a significant proportion of patients (72%) required modified approaches, such as the use of alternative sedatives or physical restraint. Intraoperatively, 61% of the patients experienced increased sensitivity to stimuli, requiring adiustments to anesthetic depth.

Postoperatively, 44% of the patients showed signs of confusion or agitation, and 39% required prolonged recovery times due to difficulty with sensory overload or behavioral disturbances.

No severe adverse events were reported, but complications included nausea, delayed emergence, and difficulty in pain management.

Conclusion(s): Anesthesia in pediatric patients with ASD requires careful preoperative planning and individualized management strategies. Special attention to sensory sensitivities, anxiety management, and communication difficulties is essential to minimize perioperative complications.

The results suggest that a tailored approach to anesthetic care can help mitigate risks and improve patient outcomes in this challenging population. Further prospective studies are needed to refine protocols for this cohort.

11AP11-7 Predictive modeling of the anesthetic risk assessment score

M. Oofuvong¹, N. Pongpankhae¹, N. Pattaravit¹, K. Yongyukantorn¹, K. Sutthibenjakul¹, T. Chanchayanon¹ Prince of Songkla University, Anesthesiology, Hat yai, Thailand

Background and Goal of Study: To improve patient safety from anesthesia events such as cardiac arrest or other adverse events during perioperative period, one should understand the causes or various risk factors contributing to those anesthesia adverse events (AAE).

We aim to develop the predictive model of the anesthesia risk assessment score, which has never been reported, in order to mitigate these risks and improve patient outcomes in noncardiac surgery.

Materials and Methods: This retrospective cohort study was conducted after approved by the Institutional Ethics Committee of Prince of Songkla University, Thailand, on July 24, 2023. The retrospective data was retrieved and reviewed between January and December 2022.

We recorded patient-related risk (age, sex, body mass index, underlying disease), anesthesia-related risk (ASA classification, choice of anesthesia, anesthetic agents), and surgery-related risk (duration of surgery, estimated blood loss).

Severity of anesthesia risk assessment score was divided into low (no adverse events), intermediate (score A-D), and high-risk assessment score (score E up). Risk scores of score E up (vs. A-D), adjusted odds ratios (OR), and 95% confidence intervals (CI) were determined. The risk scores were derived from the coefficients of the final multivariate logistic regression model.

Results and Discussion: The incidence of anesthesia incidents (A to D) and AAE (E to I) was 6.2% (n=243) and 59.9% (n=2,353), respectively, among the 3,930 patients. Our risk prediction tool for AAE provided a sensitivity of 64% and a specificity of 69% and was classified into high (>15), intermediate (11–15), or low (<11) risk groups (the area under the curve of 0.74, Fig 1).

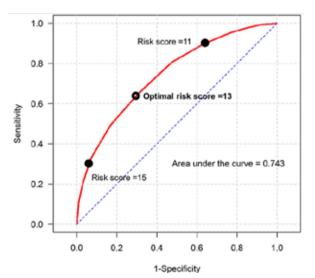

Fig 1.

The patient-related risks were age 10-65 years and >65 years (vs. age <10 years) (OR [95% CI]: 1.9 [1.4, 2.5], score of 2, and 2.9 [2.1, 4.1], score of 3, respectively) and use of preoperative antiar-

rhythmic drugs (2.7 [1.1, 7.0], score of 3). The anesthesia-related risk was ASA classification 3 and 4 (vs. 1) (2.2 [1.5, 3.3], score of 2, and 5.5 [2.4, 12.8], score of 4, respectively), general anesthesia (GA) alone and GA with regional anesthesia (vs. monitor anesthetic care) (7.8 [3.7, 16.6], score of 5, and 6.7 [3.2, 14.5], score of 4, respectively), and etomidate use (2.1 [1.2, 3.8], score of 2). The surgery-related risk was emergency surgery (1.5 [1.1, 2.0], score of 1), duration of surgery 3-4 h and >4 h (vs. <1 h) (2.8 [2.1, 3.8], score of 3, and 5.9 [4.3, 8.0], score of 4, respectively) and estimated blood loss >1000 ml (vs. 100 ml) (3.0 [1.7, 5.3], score of 3). Conclusion(s): Our risk prediction tool for AAE provided a modest predictive ability. The combination of patient-related and anesthesia-related risk factors played an important role in the intermediate to high-risk group of AAE. The modifiable risk factors were ASA classification and choice of anesthesia, which could minimize the risk of AAE.

11AP11-8

When reversal fails: investigating recurarization after sugammadex administration

L. Freixo¹, E. Ribeiro¹, C. Cunha¹, M. Campagnoli¹¹Unidade Local de Saúde Lisboa Ocidental, Anesthesiology, Lisboa, Portugal

Background: Sugammadex, a modified γ-cyclodextrin, has transformed clinical practice by providing rapid and reliable reversal of neuromuscular blockade (NMB) induced by rocuronium and vecuronium, even at profound levels. Unlike acetylcholinesterase inhibitors, Sugammadex reverses NMB without muscarinic side effects. However, cases of recurarization or delayed recovery have been reported. We present a case of recurarization following Sugammadex administration.

Case Report: A 60-year-old female with ovarian cancer underwent laparoscopic hysterectomy and bilateral salpingo-oophorectomy under general anesthesia. Her history included breast neoplasia, fibromyalgia, and smoking. Induction was achieved with fentanyl (2 mcg/kg), lidocaine (1 mg/kg), propofol (2 mg/kg), and rocuronium (0.6 mg/kg). Intraoperative medications included dexamethasone, ondansetron, ketorolac, paracetamol, and metamizole. NMB was monitored using Train-of-Four (ToF) acceleromyography (Dräger ToFscan®), calibrated per instructions. The surgery lasted two hours. At its conclusion, ToF=1. Sugammadex (400 mg) was administered, achieving ToF=4 in six minutes (CONOX®=80). Recurarization occurred after 10 minutes. Anesthetic depth was increased, and 200 mg of Sugammadex was given. ToF=4 returned after 15 minutes, but spontaneous ventilation was absent. At 20 minutes, recurarization recurred, requiring 200 mg Sugammadex. Ventilation resumed at 25–30 minutes, with complete reversal. The patient was extubated 40 minutes post-reversal and monitored without complications.

Discussion: Possible causes of recurarization include monitoring errors, drug batch defects, hypothermia, neuromuscular pathology, organ dysfunction, pharmacological interactions, immune resistance, rocuronium redistribution, or acute-phase protein binding. In this case, the etiology was likely multifactorial, involving pharmacological interactions, immune resistance, and redistribution. Other causes were systematically ruled out. To minimize recurarization risks, clinicians should ensure rigorous monitoring, individualized dosing, drug quality assessment, and extended observation.

Iwasaki, H., Renew, J.R., Kunisawa, T. Preparing for the unexpected: special considerations and complications after sugammadex administration. BMC Anesthesiology. 2017; 17, 140. **Learning points:** Recurarization is a rare serious complication; Importance of Quantitative NMB Monitoring; Clinical preparedness for reversal failure is vital.

11AP11-9

Impact of robotic-assisted colorectal surgery on intraoperative and postoperative pain: a retrospective comparison with conventional laparoscopic surgery

Á. Lucas Iranzo¹, S. Sánchez¹, C. Moreno¹, H. Rivera¹, L. Castelltort¹, M. Sadurní¹

¹Hospital del Mar de Barcelona, Anestesiología, Reanimación y Terapéutica del Dolor, Barcelona, Spain

Background and Goal of Study: The benefits of robot-assisted colorectal surgery compared to conventional laparoscopic surgery remain controversial. There is limited evidence on its effect on perioperative analgesia. The aim of this study is to assess whether robotic surgery is associated with less intraoperative and postoperative pain.

Materials and Methods: After approval by the ethics committee, a retrospective study was designed for patients undergoing elective colorectal surgery in 2022. Patients were divided into 2 groups based on the type of surgical approach: robotic versus conventional laparoscopic. In terms of intraoperative analgesia, all patients were managed with multimodal anesthesia, incluiding lidocaine (2 mg/kg bolus + infusion at 1.5 mg/kg/h), ketamine (0.5 mg/kg after induction), magnesium sulfate (10 mg/kg/h), dexmedetomidine (0.3 µg/kg/h) and fentanyl (on demand according to hemodynamics). Postoperatively, they received paracetamol 1 g/6h and dexketoprofen 50 mg/8h. Demographic variables (sex, age, BMI, ASA) as well as the type (right hemicolectomy, sigmoidectomy, or low anterior rectal resection) and duration of surgery were collected. The outcomes evaluated were intraoperative pain (measured by fentanyl consumption in µg/kg/h) and postoperative pain (measured by the percentage of patients with any VAS>3 or VAS>7 during the first 48 hours post-surgery).

Statistical analysis: Student's t-test for quantitative variables (intraoperative fentanyl consumption) and chi-square for qualitative variables (% of patients with VAS>3 or VAS>7).

Results and Discussion: Seventy-two patients were included (robot group= 41, laparoscopic group= 31). There were no differences between the groups in terms of demographic variables or type of surgery. Surgery duration (mean±SD) was longer in the robot group (273±83 vs. 234±60 minutes, p<0.05). Intraoperative fentanyl consumption was significantly higher in the laparoscopic group compared to the robot group (1.43±0.67 μ g/kg/h vs. 1.13±0.53 μ g/kg/h; p<0.05). In the laparoscopic group, 52% of patients had a VAS > 3 (moderate pain) postoperatively compared to 15% in the robot group (p<0.05). In the laparoscopic group, 9.5% of patients had a VAS>7 (severe pain) postoperatively compared to 2.5% in the robot group (p=0.18).

Conclusion: Although robotic surgery has a longer duration, it requires fewer opioids to maintain adequate intraoperative analgesia. Robotic surgery provides better pain control during the first 48 hours postoperatively.

11AP11-10

Unraveling negative pressure pulmonary edema post-tonsillectomy

P. Gaspar¹, I<u>.S.M. Carrapatoso</u>¹, T. Estevens¹, A. Delgado¹, A. Fernandes¹

¹Hospital Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Negative pressure pulmonary edema (NPPE) is a rare but serious postoperative complication caused by upper airway obstruction, often following head and neck surgeries. Its rapid onset and nonspecific symptoms, such as hypoxemia and respiratory distress, makes early recognition crucial. We report a case of NPPE following a tonsillectomy in a healthy young male patient.

Case Report: A 29-year-old male underwent an uncomplicated tonsillectomy under general anesthesia with orotracheal intubation. Rocuronium was used for neuromuscular blockade and reversed with sugammadex 200mg before extubation with train-of-four monitoring.

He was transferred to the post anesthesia care unit (PACU) on spontaneous ventilation, and 5 minutes later developed agitation, dyspnea, and oxygen desaturation to 88%. There was no airway active bleeding. Arterial blood gas showed normal pH and pCO2 but a low pO2 of 58 mmHg. Examination revealed tachycardia (122 bpm), normal blood pressure, and bilateral coarse crackles and rales.

Oxygen via nasal cannula at 2L/min improved saturation to 96%. Chest X-ray (CXR) and Computed Tomography (CT) confirmed bilateral alveolar infiltrates, and a diagnosis of NPPE was considered. He was monitored for 18 hours in the PACU with progressive symptom resolution.

Oxygen was discontinued after 12 hours, and he remained asymptomatic, eupneic, with normal lung auscultation and normoxic at discharge with no further complications.

Discussion: NPPE is a rare complication of airway obstruction, caused by negative intrathoracic pressure leading to fluid transudation into the lungs and acute hypoxemia. It typically occurs after extubation or airway manipulation. Early diagnosis using imaging, such as CRX or CT, is essential. NPPE is often self-limiting and managed with supportive care, including oxygen and monitoring. Awareness is vital, particularly after surgeries like tonsillectomy, to avoid unnecessary interventions.

Reference:

Yun H, Jeong S, Lee J, et al. "Negative pressure pulmonary edema following extubation: a review of pathophysiology, diagnosis, and management." Korean Journal of Anesthesiology. 2020;73(5):373-381.

Learning Points:

- 1. NPPE is a rare but critical cause of postoperative respiratory distress, often after airway manipulation.
- 2. Early identification, oxygen supplementation, and monitoring are crucial.
- 3. Consider NPPE when bilateral infiltrates appear without infection, aspiration or signs of heart failure.

11AP11-11

Comparison of ramosetron with different doses on hemodynamic influences during total intravenous anesthesia induction with propofol and remifentanil and endotracheal intubation

S.H. Kim^{1,2}, Y.J. Choi³

¹Chosun University, School of Medicine, Department of Anesthesiology and Pain Medicine, Gwangju, Korea, Republic of, ²Chosun University Hospital, Department of Anesthesiology and Pain Medicine, Gwangju, Korea, Republic of, ³Korea University Medical School and Ansan Hospital, Department of Anesthesiology and Pain Medicine, Ansan, Korea, Republic of

Background and Goal of Study: Serotonin (5-hydroxytryptamine; 5-HT) induces the triphasic blood pressure response consisting of early short-term hypotension, a middle pressor phase, and longer-lasting hypotension. Ramosetron, 5-HT3 antagonists, effectively reduced the vasopressor demand for the prevention or treatment of spinal anesthesia-related hypotension.

Therefore, we investigated whether the ramosetron affects the hemodynamic changes during anesthesia induction under total intravenous anesthesia with propofol and remifentanil.

Materials and Methods: This study was approved by the Institutional Review Board, and was prospectively registered with the Clinical Research Information Service.

After obtaining the patient's informed consent, 135 patients aged 20 to 70 years with an ASA Physical Status of I-III were randomly assigned to three groups receiving normal saline (group C, n=43), ramosetron 0.3 mg (group R3, n=49) or ramosetron 0.6 mg (group R6, n=43) once 5 minutes before anesthesia induction.

Anesthesia induction was initiated with 6 mg/kg/h of propofol and 60 μ g/kg/h of remifentanil after a bolus dose of propofol 1 mg/kg. We recorded hemodynamics [systolic arterial pressure (SAP), diastolic arterial pressure (DAP), mean arterial pressure (MAP), and heart rate (HR)], before injecting either ramosetron or normal saline, at loss of consciousness, at 1 min after rocuronium injection, before endotracheal intubation, and 1 min after endotracheal intubation.

We analyzed data using the one-way analysis of variance (ANO-VA) and repeated measures ANOVA, appropriately. p values < 0.05 were considered statistically significant.

Results and Discussion: No significant differences in SAP, DAP, MAP, and HR were observed among the groups. The differences in hemodynamics value from baseline were lesser in group R6 than in groups C and R3 during anesthesia induction and after endotracheal intubation (without significant differences).

Conclusion(s): Ramosetron in the clinical dose range has no significant effect on hemodynamic changes after anesthesia induction and endotracheal intubation. A high dose of ramosetron can be expected to reduce the degree of blood pressure drop that occurs during anesthesia induction and endotracheal intubation.

However, further studies are needed on whether a high dose of ramosetron can satisfy the effectiveness of preventing PONV or drug injection pain simultaneously without clinically significant side effects.

The effect of arthroscopic shoulder surgery on lung, assessed by ultrasonography, in the elderly patients under general anesthesia with mechanical ventilation

S.-W. Hong¹, <u>S.-H. Kim</u>¹

¹Konkuk University, Anesthesiology and Pain Medicine, Seoul, Korea, Republic of

Background and Goal of Study: The study was designed to compare the lung condition, assessed by lung ultrasonography (LUS), after arthroscopic shoulder surgery (ASS) between surgical side and non-surgical side in the elderly patients under general anesthesia with mechanical ventilation.

Materials and Methods: Elderly patients above 65 years old undergoing ASS under general anesthesia with mechanical ventilation were enrolled in the study. Lung condition was assessed by LUS before and after ASS. Intra- and post-operative respiratory events were also evaluated. Chest radiograph was performed twice, just after discharge from post-anesthetic care unit (PACU) and before admission at general ward and on postoperative 2 days.

Results and Discussion: Surgical side significantly had the higher values for the scores of LUS (sitting position at end of ASS, 1.44 \pm 1.87 in surgical side vs. 0.43 \pm 0.75 in non-surgical side, p < 0.001; supine position just before discharge from PACU, 1.48 \pm 1.91 in surgical side vs. 0.43 \pm 0.75 in non-surgical side, p < 0.001). There were no intra-operative respiratory events, including desaturation, and post-operative respiratory events until post-operative 2 days. Any abnormal finding was not observed on twice chest radiograph in all patients.

Conclusion(s): ASS for the elderly patients under general anesthesia with mechanical ventilation had the limited impact on respiratory function, although the significant change of lung condition at surgical side, assessed by LUS, was observed.

Additionally, LUS than chest radiograph showed the better detection of lung change after ASS.

Regional Anaesthesia

A comparative study of Quadratus Lumborum block vs epidural block for post operative analgesia in patients with gynaecological malignancies

A. Gupta¹, K. Prakash¹, S. Shah¹, V. Rewari¹, S. Singhal² ¹All India Institute of Medical Sciences, Department of Anaesthesiology, Pain Medicine and Critical Care, New Delhi, India, ²All India Institute of Medical Sciences, Department of Obstetrics and Gynaecology, New Delhi, India

Background and Goal of Study: Epidural analgesia (EA) is associated with side effects like hypotension and motor block . The effect of a single shot Quadratus lumborum block (QLB) has been found to last for up to 24 to 48 hours. We conducted a randomised controlled study to compare QLB vs EA for postoperative analgesia.

Materials and Methods: After obtaining written informed consent , 52 patients (18-75 years, ASA I/II) scheduled for gynecological onco-surgeries were randomly allocated to receive either lumbar EA (0.1% of Ropivacaine with fentanyl 2mcg/ml: 5 cc bolus + 5cc/ hour for 48 hours) or bilateral USG-guided transmuscular QLB (25ml of 0.2% ropivacaine on each side). Patients with decreased mental ability, BMI > 30kg/m2 or surgeries involving removal of non-gynecological viscera were excluded from the trial. Postoperative analgesia was provided with paracetamol, ketorolac and i/v PCA morphine. The primary objective was to compare postoperative morphine consumption at 24 hours. The secondary objectives were comparison of morphine consumption and NRS (numeric rating scale) scores at 2, 6, 12,24 and 48hours and time to first mobilization). Data was analyzed using SPSS software (Mann Whitney-U/T-test).

Results and Discussion: Morphine consumption was comparable in two groups at 24 hours [1.5 mg (0.5,4.6) in EA vs 2.5 mg (1,4.37) in QLB, p= 0.55]. 12-hour NRS score was lower in epidural group as compared to QLB group [1.0 (1,2)] vs 2.5 (2 - 3), p= 0.05). NRS scores, morphine consumption at all other time points and time to mobilization was comparable between the two groups (table 1).

	EA	QLB	P value
NRS (median, IQR)			
2h	1.0 (1,2)	1.0 (1,2)	0.10
6h	1.0 (0.75,2)	2.0 (1,2.75)	0.10
12h	1.0 (1,2)	2.5 (2,3)	0.05
24h	1.0 (1,2)	2.0 (2,3)	0.65
48h	1.0 (0,1)	1.0 (0,1)	0.40
PCA Morphine consumption (mg) (median, IQR)			
2h	0.5 (0,1)	0 (0,1)	0.71
6h	1.0 (0,2)	1.0 (0.5,1.87)	0.59
12h	1.25 (0.37, 3.12)	1.5 (0.5,2.87)	0.51
24h	1.5 (0.5,4.62)	2.5 (1,4.37)	0.56
48h	2.0 (0.5, 5.62)	3.25 (1,4.37)	0.65
Day of mobilization (mean, SD)	1.19 (0.42)	1.13 (0.34)	0.56

Conclusion: There was no difference between QLB and EA when used for postoperative analgesia in patients with gynecological cancers.

12AP01-3

Comparison of analgesic effects between modified thoracoabdominal nerve block and oblique subcostal transversus abdominis plane block in laparoscopic cholecystectomy: a retrospective study

M. Kurihara¹

¹Sendai City Medical Center, Sendai Open Hospital, Department of Anesthesiology, Sendai City, Japan

Background and Goal of Study: Laparoscopic cholecystectomy (LC) causes significant postoperative pain. Oblique subcostal transversus abdominis plane block (OSTAPB) and the modified thoracoabdominal nerve block through the perichondral approach (M-TAPA) are both trunk blocks used for postoperative

This study compared the analgesic effect of M-TAPA with that of OSTAPB in patients undergoing LC, hypothesizing that M-TAPA would provide superior analgesia.

Materials and Methods: Medical records of 125 patients who underwent LC from 2022 to 2024 were retrospectively analyzed. The primary outcome was the number of analgesic requirements in the first 15 hours postoperatively. All LCs were performed with ports positioned in the right upper quadrant.

Both OSTAPB and M-TAPA groups received blocks in the right abdomen and rectus abdominis sheath block to the umbilical region. The OSTAPB group received an oblique subcostal block in the right transversus abdominis fascial plane.

The M-TAPA group received a modified thoracoabdominal nerve block through a perichondral approach centered over the costal cartilage of ribs 7-9 on the right side. Propensity score matching using genetic matching with replacement and generalized linear model distance estimation was performed to adjust for confounding factors.

Confounding factors included in the propensity score model were age, gender, body mass index (BMI), intraoperative fentanyl dose, administration of flurbiprofen or acetaminophen, type of anesthesia (inhalation versus intravenous), and operative time. Robust standard errors were used for effect estimation due to matching with replacement.

Results and Discussion: 49 patients received M-TAPA and 76 patients received OSTAPB. Propensity score matching showed that 15 M-TAPA patients were matched with 76 OSTAPB patients. In the matched groups, patients received 0-4 rescue doses.

There was no statistically significant difference in the number of analgesics (mean difference: -0.16, 95% confidence interval: -0.52 to 0.21, p = 0.41).

A limitation of this study is that the asymmetrical matching may limit generalizability, necessitating cautious interpretation of re-

Conclusion: There was no significant difference in analgesic effect between the two techniques. These results suggest that both methods of blockade are viable options for pain management in LC.

12AP01-4 BRILMA block for breast oncological surgery

I. Zaragoza García¹, I. Adalid Hernàndez¹,

S. Alonso Pages¹, A.M. Cerro Pérez¹, M. Costa Murtra¹, A. Recasens i Garcia¹

¹Hospital del Mar, Anestesiologia i Reanimació, Barcelona, Spain

Background: The choice of anesthetic plan is critical, especially in balancing safety and efficacy for high-risk patients. The BRILMA block provides anesthesia to the thoracic and mammary region by infusing local anesthetic between the serratus anterior and external intercostal muscles under ultrasound (US) guidance. One of its key uses is in oncological breast surgery, where it minimizes systemic impact and improves outcomes.

This case shows how locoregional techniques can allow non-delayable surgeries in frail patients while maintaining safety¹

Case Report: A 64-year-old man was scheduled for a right mastectomy and selective sentinel node biopsy following a breast cancer diagnosis. He had multiple comorbidities, including permanent atrial fibrillation, chronic heart and renal failure, and severe aortic stenosis with moderate regurgitation.

During preanesthetic evaluation, prioritization was initially given to valve correction, but valvuloplasty proved ineffective. Due to his ongoing valvular disease, the surgical plan was adapted to a right breast lumpectomy and sentinel node biopsy.

Anesthesia was provided through a right BRILMA block under US guidance, combined with midazolam and fentanyl sedation. Mepivacaine and bupivacaine were used for the block, with additional lidocaine infiltration at the surgical site.

The patient remained hemodynamically stable throughout the procedure, with no complications. Postoperative pain was controlled with standard intravenous analgesia. He was discharged the following day.

Discussion: The BRILMA block was an effective alternative in this high-risk patient, unsuitable for general anesthesia due to his severe comorbidities. It allowed for stable hemodynamics, especially relevant in the context of severe valvular disease, while minimizing the risk of decompensation.

The block provided effective pain control and reduced the need for systemic sedatives and analgesics. It optimized postoperative recovery time, hospital stay, patient experience, admission cost and resources.

References:

1. Chin KJ et al. Ultrasound-guided fascial plane blocks of the chest wall: a state-of-the-art review.

Learning Points: Locoregional anesthesia is an invaluable tool for patients with complex comorbidities, which are increasingly prevalent in the surgical population.

Its use requires a thorough preoperative assessment, close interdisciplinary collaboration, and careful consideration of the risks and benefits to optimize patient outcomes.

12AP01-5

Heart rate variability and analgesia effect of transversus abdominis plane block in laparoscopic surgery patients

T.C. Wang¹, <u>W. Lan¹</u>, K.Y. Lu¹

¹MacKay Memorial Hospital, Department of Anesthesia, Taipei, Taiwan

Background and Goal of Study: Monitoring pain and analgesic balance is critical in clinical anesthesia. Traditionally, indirect brainstem reflex signs such as heart rate (HR) and blood pressure (BP) were used to assess pain stimuli. In recent years, modern techniques have applied objective parameters. Heart rate variability (HRV), a measure of autonomic nervous system activity, is closely associated with the balance of analgesia and nociception in anesthetized patients.

However, Common HRV-based commercial tools, such as the analgesia nociception index (ANI), have not effectively demonstrated significant improvements in postoperative pain, resulting in inconsistent outcomes in clinical practice.

Further investigation is warranted to understand the objectivity of HRV in monitoring pain and its underlying physiological significance.

Materials and Methods: 75 patients undergoing laparoscopic surgery at Taitung MacKay Memorial Hospital (August 2020–April 2023) were randomly assigned to general anesthesia group or general anesthesia combining transversus abdominis plane (TAP) block group.

Physiological signals, including electrocardiograms, were continuously recorded. Statistical analyses, including repeated measurement ANOVA and logistic regression, evaluated changes in HRV and its predictive value for postoperative pain.

Results and Discussion: Records showed significant hemodynamic changes during incision and insufflation, with increased BP and HR. TAP block influenced baseline HRV and its trends during surgery.

However, most HRV parameters and even the performance of the TAP block showed no correlation with postoperative pain scores, except for high-frequency (HF).

Conclusion(s): HRV analysis indicated sympathetic activation and parasympathetic suppression during noxious stimulation in laparoscopic surgery, with different HRV parameters trend in two groups.

HF before and after incision emerged as the only predictor of postoperative pain, suggesting a potential link between HF and pain thresholds under general anesthesia, as well as the important role of the parasympathetic nervous system in postoperative pain modulation.

The lack of significant correlations between HF after pneumoperitoneum inflation or TAP block and postoperative pain may be attributable to variability in perioperative analgesic dosing, the exclusion of somatic nerve blockade, and the heterogeneous effects of regional nerve block.

12AP01-6

Clavipectoral fascial plane block-Novel anesthesia techniques for clavicle surgery. Method of choice

I. Malkhasyan¹, A. Manukyan², E. Telyan¹ ¹Yerevan State Medical University, Anesthesiology and Intensive Care, Yerevan, Armenia, 2Heratsi University Hospital Complex, Anesthesiology and Intensive Care, Yerevan, Armenia

Background: Clavicle fracture is a common injury in adults and mostly requires surgical treatment for optimal recovery. To achieve the best results it is necessary to provide adequate intra and postoperative analgesia. Currently, various combinations of regional anesthesia are used, as well as sole techniques.

One of the novel techniques of regional anesthesia is the Clavipectoral plane block (CPB), which provides targeted anesthesia of supraclavicular nerve branches, with less systemic complications compared with interscalene and supraclavicular brachial plexus blocks. The CPB can be used as a sole technique, in combination with intravenous anesthesia or light sedation, due to sufficient analgesia.

Case Report: A 65-year-old male with grade 2 arterial hypertension, abdominal obesity and history of smoking had a closed, displaced clavicle fracture as a result of a fall. After premedication with 3 mg of Midazolam intravenously, the fracture line was visualized with linear ultrasound probe and solution of 0.5% 16 ml Bupivacaine with 4 mg Dexamethasone was injected 2 cm distally and proximally to the fracture line.

Sedation with Propofol 150 mg/hour was initiated after regional anesthesia. There was no response or sympathetic activation to the surgical stimulation. The patient's hemodynamics remained stable, the breathing was spontaneous.

Postoperative pain in first 12 hours was 0/10. 75 mg of Diclofenac was administered for postoperative analgesia after 12 h. The patient was discharged the day after the surgery.

Discussion: Several case reports have already been published to support the use of brachial plexus block (interscalene approach) or combinated blocks (interscalene with superficial cervical plexus) in clavicle surgeries.

However, these techniques can be time-consuming as two separate ultrasound-guided injections are needed to provide the surgical block. The CPB can avoid the possible adverse events, such as ipsilateral phrenic nerve palsy, vocal cord paralysis, vertebralartery injection, total spinal anesthesia, pneumothorax.

CPB can be the method of choice for clavicle surgeries, since it provides sufficient analgesia, doesn't cause motor block, can be used without general anesthesia, systemic complications are less common, and technically easy to use.

Dexamethasone vs. Dexmedetomidine as a perineural adjuvant to Erector Spinae Plane Block for idiopathic scoliosis surgery: a randomized, double-blinded clinical trial

M. Reysner¹, J. Huber², T. Reysner¹, P. Janusz³, G. Kowalski¹, T. Kotwicki³

¹Poznan University of Medical Sciences, Palliative Medicine, Poznan, Poland, ²Poznan University of Medical Sciences, Pathophysiology of Locomotor Organs, Poznan, Poland, ³Poznan University of Medical Sciences, Spine Disorders and Pediatric Orthopedics, Poznan, Poland

Background and Goal of Study: The Erector Spinae Plane Block (ESPB) is recognized for its adequate postoperative analgesia in scoliosis surgery.

This study evaluated and compared the analgesic efficacy of dexamethasone and dexmedetomidine as perineural adjuvants to ESPB in pediatric idiopathic scoliosis surgery.

Materials and Methods: Ninety pediatric patients (ages 10-18, ASA PS I-III) were randomized into three groups: Control (0.2% ropivacaine), DEX (0.2% ropivacaine + 0.1 mg/kg dexamethasone), and DEM (0.2% ropivacaine + 0.1 µg/kg dexmedetomidine). Primary outcome: time to first rescue opioid analgesia.

Secondary outcomes included total opioid consumption, pain scores, inflammatory markers (NLR, PLR), MEP changes, and adverse effects (p<0.05).

Results: The DEX and DEM groups had significantly prolonged times to first rescue analgesia (12.96 \pm 2.03 h and 11.65 \pm 2.95 h, respectively) compared to the control (5.15 \pm 1.69 h; p<0.0001). Total opioid consumption was lower in the DEX and DEM groups (p<0.0001).

Pain scores (NRS) were reduced at various postoperative time points in both groups, with no significant differences between DEX and DEM. No significant differences were found in NLR. PLR. or blood glucose levels (Table 1).

The DEM group had 11 cases of bradycardia and 5 of hypotension. No nerve injuries were reported. The DEX group showed improved MEP amplitudes (Table 2).

		Control	DEX	DEM	р	p DEX to Control	p DEM to Control	p DEX to DEM
Time to first rescue opioid analgesia (hours)		5.15 ±1.69	12.96 ±2.03	11.65 ±2.95	<0.0001	<0.0001	<0.0001	0.3975

Table 2. Changes in cumulative anesthesia, transcranial electrical stimulation, and motor-evoked potential parameters were recorded from the tibialis anterior muscle before and after the surgical correction procedures.

Conclusion: Dexamethasone and dexmedetomidine as ESPB adiuvants effectively prolonged analgesia and reduced opioid use in pediatric scoliosis surgery, with dexmedetomidine associated with more hemodynamic effects. These findings support optimizing analgesia and neuromonitoring strategies in pediatric spinal surgeries.

Efficacy of erector spinae plane block versus caudal block on postoperative analgesia in children undergoing surgery: a systemic review and meta-analysis

R. Kundal¹, V.K. Kundal^{2,1}, U. Parveen³ ¹All India Institute of Medical Sciences, Anaesthesia, Jammu, India, ²All India Institute of Medical Sciences, Pediatric Surgery, Jammu, India, 3All India Institute of Medical Sciences, Nursing, Jammu, India

Background and Goal of Study: Regional anesthesia is part of multi-modal analgesia in pediatric surgery for effective pain relief. Traditional techniques like the Caudal Block (CB) and, more recently, facial plane blocks like the Erector Spinae Plane Block (ESPB) have gained popularity.

This systematic review and meta-analysis compare CB and ESPB in pediatric lower abdominal and limb surgeries. It aims to clarify mixed outcomes from recent trials regarding the effectiveness of both techniques.

Materials and Methods: This review, registered with the International Prospective Register of Systematic Reviews (ID: CRD 42024533579), includes eight randomized controlled trials comparing postoperative analgesia between the erector spinae plane block and caudal epidural block in pediatric lower abdominal and limb surgeries.

The meta-analysis assessed the proportion of patients requiring rescue analgesia and postoperative pain intensity.

Results and Discussion: Among the 58 articles screened, 8 RCTs (575 patients) were finally included in the systematic review. Among them, a meta-analysis of four RCTs (217 patients) concluded a significant decline in the proportion of patients requiring rescue analgesia in the ESPB group compared to the CB group [OR = 0.55 (95% CI: 0.31, 0.96), p<0.05].

Also, analysis of six RCTs (360 patients) concluded a significant decline in pain intensity revealed by the fixed-effects model using standardized mean difference (SMD = -0.29, 95% CI: -0.51, -0.06: p < 0.05) and a significant difference was identified between ESBP and CB groups.

Conclusion(s): We conclude that ESPB provides better postoperative analgesia than CB in children undergoing lower abdominal and lower limb surgeries. ESPB reduces postoperative pain intensity scores and analgesic requirements compared to CB.

iPACK block with Adductor Canal Block vs. Lumbar Erector Spinae Plane Block (L-ESPB) in Total Knee Arthroplasty: a randomized, double-blinded, controlled trial

T. Reysner¹, K. Wieczorowska-Tobis¹, G. Kowalski¹, L. Łapaj², P. Daroszewski³, M. Reysner¹ ¹Poznan University of Medical Sciences, Palliative Care, Poznan, Poland, ²Poznan University of Medical Sciences, Orthopedics, Poznan, Poland, 3Poznan University of Medical Sciences, Organization and Management in Health Care, Poznan, Poland

Background and Goal of Study: Total Knee Arthroplasty (TKA) is associated with significant postoperative pain, often requiring substantial opioid use. This study compared the analgesic efficacy of a single-injection L2 erector spinae plane block (L2-ESPB) versus an ultrasound-guided iPACK block combined with an adductor canal block (ACB) in patients undergoing TKA under spinal anesthesia.

Material and Methods: Following IRB approval and informed consent, ninety patients (ages 65-89, ASA I-III) scheduled for TKA were randomized to receive iPACK+ACB (0.2% ropivacaine, 20 ml + 10 ml), L2-ESPB (0.2% ropivacaine, 20 ml on each side), or no block (control).

In the pre-anesthesia room, all patients received continuous monitoring, supplemental oxygen, and midazolam 7.5 mg p.o. as part of a multimodal analgesia protocol.

Spinal anesthesia (L3/4) was administered with 4 ml of 0.5% ropivacaine under mild sedation using propofol (5 mg/kg/h), with spontaneous ventilation maintained via an oxygen mask.

Ultrasound-guided blocks were performed by two experienced anesthesiologists, with no periarticular infiltration during surgery. The primary outcome was total opioid consumption within 48 hours postoperatively.

Secondary outcomes included pain scores, time to first rescue opioid analgesia, quadriceps strength, and inflammatory markers (NLR and PLR).

Results and Discussion: The iPACK+ACB group demonstrated significantly lower total opioid consumption (3.0±3.3 mg) compared to both the L2-ESPB (6.8±3.8 mg; p=0.0442) and control groups (18.2±4.0 mg; p<0.0001).

The time to first rescue opioid was longest in the iPACK+ACB group (12.0±1.9 h) versus the L2-ESPB group (9.2±1.9 h; p<0.0001) and control (4.3±1.1 h; p<0.0001). Both the iPACK+ACB and L2-ESPB groups exhibited lower pain scores and NLR and PLR levels across all time points compared to the control group.

The parametric distribution of numerical variables was evaluated using the Shapiro-Wilk normality test. The ANOVA or Kruskal-Wallis test with post hoc Tukey's or Dunn's test assessed group differences.

Categorical variables were compared with the Kruskal-Wallis test, and an analysis of contingency was compared with Fisher's exact test. A p-value <0.05 was considered statistically significant.

Conclusion(s): The iPACK+ACB block provided superior pain relief and reduced opioid consumption compared to L2-ESPB following TKA.

Both the iPACK+ACB and L2-ESPB reduced pain and extended the time to first opioid analgesia, though no differences in NLR or PLR levels were found between groups.

These findings suggest iPACK+ACB as a promising approach for enhanced analgesia in TKA.

12AP01-10

Erector Spinae Plane Block (ESPB) vs. Periarticular Nerve Group Block in total hip arthroplasty in elderly patients: a randomized, double-blinded, controlled trial

T. Reysner¹, G. Kowalski¹, M. Reysner¹, L. Łapaj², P. Daroszewski³, K. Wieczorowska-Tobis¹

¹Poznan University of Medical Sciences, Palliative Care, Poznan, Poland, ²Poznan University of Medical Sciences, Orthopedics, Poznan, Poland, ³Poznan University of Medical Sciences, Organization and Management in Health Care, Poznan, Poland

Background and Goal of Study: Total Hip Arthroplasty (THA) in elderly patients can result in significant postoperative pain. This study assessed and compared the analgesic efficacy of ultrasound-guided Erector Spinae Plane Block (ESPB) versus Pericapsular Nerve Group (PENG) block under spinal anesthesia in THA.

Materials and Methods: Following IRB approval and informed consent, ninety patients (aged 67–89, ASA II–III) scheduled for THA under spinal anesthesia were randomized into three groups: PENG block (n=30), ESPB (n=30), and Control (n=30). Each block was performed with 20 ml of 0.2% ropivacaine under ultrasound guidance.

The primary outcome was total opioid consumption within 48 hours.

Secondary outcomes included pain scores, time to first rescue opioids, quadriceps strength, and inflammatory markers (NLR and PLR).

The parametric distribution of numerical variables was evaluated using the Shapiro-Wilk normality test. Group differences were assessed with ANOVA or the Kruskal-Wallis test, followed by post hoc Tukey's or Dunn's tests. Categorical variables were compared using the Kruskal-Wallis test, and contingency analyses were performed with Fisher's exact test.

Results and Discussion: Both the PENG and ESPB groups had significantly lower total opioid consumption (PENG: 3.5 ± 4.0 mg; ESPB: 3.4 ± 3.8 mg) compared to the Control (16.07 ± 3.8 mg, p<0.0001). Time to first rescue opioid was extended in both PENG (12.3 ± 3.2 h) and ESPB (11.2 ± 2.9 h) groups compared to the Control (4.2 ± 1.1 h, p<0.0001).

Pain scores were consistently lower in the PENG and ESPB groups versus the Control. Quadriceps strength was reduced 6h postoperatively in the PENG group compared to ESPB. NLR and PLR were also lower in both block groups.

Conclusion(s): Both PENG and ESPB provide effective postoperative analgesia for elderly patients undergoing THA, reducing opioid consumption and enhancing recovery. These blocks offer valuable options for postoperative pain management in this population.

Success rate and effects of ipsilaterally-guided epidural analgesia for anterior cruciate ligament reconstruction: retrospective analysis of 308 consecutive patients

Y. Aoyama¹, S. Sakura², H. Ishimura³, Y. Takeda⁴, K. Sakai5, T. Nikai1

¹Shimane University Hospital, Anesthesiology, Izumo, Japan. ²Unnan Municipal Hospital, Anesthesiology. Unnan, Japan, 3Sakai Orthopedics Fukuoka Sports Clinic, Anesthesiology, Fukuoka, Japan, 4TSC, Takeda Sports & Beauty Clinic, Orthopedics, Fukuoka, Japan, ⁵Sakai Orthopedics Fukuoka Sports Clinic, Orthopedics, Fukuoka, Japan

Background and Goal of Study: Although epidural analgesia usually produces bilateral effects, asymmetric or unilateral blockade can occur depending on the location of the catheter tip in the epidural space. Thus, if we could deliberately place the catheter tip on one side, patients undergoing unilateral knee surgery may benefit from ipsilateral epidural analgesia without intense blockade in the non-operated limb. We started using ipsilaterally-guided epidural analgesia for major knee surgery under our current protocol in January 2021 in our institution.

In the present study, we retrospectively evaluated the rate of placing the catheter tip on the operated-side and effects on pain and motor function when ipsilaterally-guided epidural analgesia was conducted in patients undergoing anterior cruciate ligament (ACL) reconstruction surgery.

Materials and Methods: With IRB approval, we retrospectively analyzed data of consecutive patients undergoing ACL reconstruction surgery under combined spinal-epidural technique between January 2021 and December 2023 in a single institution. All epidural catheters were intentionally inserted toward the operated side, and catheter tip position was assessed by X-ray on postoperative day 1 as a care standard. Epidural analgesia was continued for 3 days.

The data included information on pain scores, analgesic requirements, motor blockade, dermatomes with sensory blockade, and complications over 4 postoperative days. We evaluated the success rate of catheter tip guidance to the operated side.

Additionally, we assessed the efficacy of epidural analgesia based on pain scores and distribution of sensory blockade and motor function.

Results and Discussion: After excluding patients who did not receive standard analgesic regimen, data from 297 patients were evaluated. Most catheters were inserted from the T11/12 or T12/ L1 intervertebral spaces.

The success rate of catheter tip guidance was 92.3%. Ipsilateraldominant sensory blockade on L1~S1 dermatomes was observed in more than 80% of the patients from the first day after surgery. Postoperative pain was well controlled and motor strength of both limbs was well preserved.

Conclusions: Ipsilaterally-guided epidural analgesia demonstrates a significant success rate and analgesic effect. This technique is feasible with motor-sparling and long-lasting analgesia and can benefit patients undergoing ACL reconstruction surgery.

12AP01-12

Combined anaesthesia for non-endocrine surgery in a patient with recurrent pheochromocytoma

C. Batista¹, R. Felgueiras¹, P. Cunha¹, J. Pinto¹, V. Almeida¹, A. Guedes¹ ¹Unidade Local de Saúde Viseu Dão-Lafões. E.P.E, Anaesthesiology, Viseu, Portugal

Background: Pheochromocytoma poses major intraoperative risks. Hypertensive crisis, arrhythmias, and myocardial ischemia can be triggered by anaesthetic induction, intubation, surgical stress and pain. Tumour resection is the primary treatment, though a 10% rate¹ of recurrence mandates follow-up. The need for non-endocrine surgery may arise and a specific approach is mandatory.

Case Report: A 80-year-old patient, ASA IV, was scheduled for surgical repair of a trochanteric fracture. His history was relevant for recurrent pheochromocytoma with three previous adrenal surgeries, under medical therapy with α and β -blockade (Phenoxybenzamine 10mg 1x/d, Carvedilol 6.25mg 1x/d). Comorbidities included 3 myocardial infarcts, atrial fibrillation and insulintreated diabetes.

The urgency of the procedure required adequate assessment and an optimal anaesthetic approach. A multidisciplinary team including endocrinology reviewed the patient's history, confirming stable dosage of ☐ and ☐-blockade for over 6 months and normal plasma metanephrine levels. BP and HR were consistent at approximately 110/70mmHg and 65bpm, respectively.

The anaesthetic plan combined general and regional anaesthesia. An arterial line was placed for continuous blood pressure monitoring before induction. US-guided Femoral and Lateral Femoral Cutaneous Nerve blocks were employed. Induction was performed with Etomidate, Fentanyl and Rocuronium, with an iGel no.5 supraglottic device for airway management and Sevoflurane for maintenance.

Analgesia was complemented with Paracetamol. Glycaemic control and positive 500-1000cc fluid balance were ensured. After surgery, the patient remained for 2 hours in the PACU, without incidents. He remained hemodynamically stable throughout the entire perioperative period.

Postoperative recovery was uneventful and he was discharged on day 4.

Discussion: Surgery in patients with Pheochromocytoma needs multidisciplinary approach. Efficient pain management is vital for haemodynamic stability. Peripheral nerve blocks provide excellent pain control extending to postoperative settings. The anaesthetic agents chosen supported minimal haemodynamic variability.

Learning Points: Non-endocrine surgery in pheochromocytoma patients mandates adequate preoperative medical therapy.

By minimizing intraoperative haemodynamic variability and planning for adequate pain control, the anaesthesiologist plays a major role improving postoperative outcomes.

Comparing linear and circular training models in ultrasound-guided regional anaesthesia education

A. Capdevila Feixas¹, R.J. Fabián Quillama¹, I. García¹, P. Aguilar², X. Sala-Blanch¹

¹Hospital Clínic Barcelona, Anaesthesiology, Resuscitation and Pain Treatment, Barcelona, Spain, ²Fundación Santa Fe de Bogotá, Anaesthesiology, Bogotá, Colombia

Background: The effective performance of ultrasound-guided regional anaesthesia requires trainees to develop advanced handeye coordination. While success improves with the number of blocks performed, the best instructional method for skill acquisition remains unclear.

This study aims to compare two training methods in a simulated environment that reflect clinical practices: a "linear" versus a "circular" approach.

Materials and Methods: This study compared two training methods for anaesthesiology residents learning four nerve blocks: femoral, sciatic-popliteal, interscalene, and axillary. Using a highfidelity anatomical model, the Linear Group (LG) practiced each block five consecutive times before moving to the next station, whereas the Circular Group (CG) rotated through all four blocks in sequence, repeating the cycle five times. Post-training evaluation focused on five axillary block attempts.

Each attempt was deemed successful if the resident met three of ten key criteria: avoiding vascular injection, accurately injecting into the target with real-time needle visualization, and completing the procedure within the time limit.

Results: The study was completed by 28 residents, with 14 assigned to each group. Among participants, 14.3% had no prior experience with ultrasound-guided punctures (7.14% in the LG and 21.4% in the CG), and 37.5% had performed fewer than 10 blocks. Final evaluations showed no statistically significant differences in success rates between groups (Table 1).

However, the CG demonstrated superior skill acquisition, achieving significantly higher scores on their final attempt (Table 2).

Conclusions: Our findings suggest that adopting a circular method could benefit residents during regional anaesthesia training. Although limited to a simulation environment, the circular approach may facilitate faster motor skill development due to constant technique variation, enhancing hand-eye coordination.

Attempt	1	2	3	4	5

Pericapsular nerve group block vs. fascia iliaca and femoral nerve blocks: optimizing pain control and motor function in frail elderly undergoing hip surgery

G. da Silva Goulart¹, A. Pozzer Gularte¹, C. Nogueira Reis Gurgel¹, E. Pascarella Redenschi^{1,2}, M. Mercedes do Carmo Gomes^{1,3,4},

E. Lo Bianco dos Santos^{1,5}

¹Hospital da Forca Aérea do Galeão, Anesthesiology, Rio de Janeiro. Brazil. ²Hospital Municipal Miguel Couto. Anesthesiology, Rio de Janeiro, Brazil, 3Universidade do Estado do Rio de Janeiro, Anesthesiology, Rio de Janeiro, Brazil, ⁴Instituto Estadual do Cérebro Paulo Niemeyer. Anesthesiology, Rio de Janeiro, Brazil, ⁵Hospital Central da Polícia Militar do Rio de Janeiro, Intensive Care Unit, Rio de Janeiro. Brazil

Background and Goal of Study: Effective regional anesthesia techniques are critical for frail elderly patients undergoing hip surgeries, as they reduce complications such as delirium, opioidrelated side effects, and delayed mobilization.

This study compares the pericapsular nerve group block, fascia iliaca compartment block, and femoral nerve block to identify the optimal approach for managing pain, preserving motor function, and improving clinical outcomes.

Materials and Methods: A systematic literature search was conducted in PubMed, Google Scholar, and Scopus, following PRIS-MA guidelines. Inclusion criteria were randomized controlled trials and observational studies published between 2018 and 2024, involving adult patients undergoing total hip arthroplasty or hip fracture surgeries.

Stage	Number of Articles
Articles Identified	546
Duplicates Removed	134
Screened	412
Excluded After Screening	375
Full-Text Articles Assessed	37
Excluded for Eligibility	27
Final Studies Included	10

Results and Discussion: The pericapsular nerve group block demonstrated the most effective pain relief, with lower visual analog scale scores compared to the fascia iliaca compartment block and femoral nerve block at 12 and 48 hours. It also resulted in the lowest opioid consumption and preserved motor function. with significantly reduced quadriceps weakness and earlier mobilization times compared to the other techniques.

These outcomes contribute to reducing postoperative complications like delirium and falls and shorter hospital stays, particularly in frail elderly patients.

Outcome	Pericapsular Nerve Group Block	Fascia Iliaca Compartment Block	Femoral Nerve Block
Pain score (Visual Analog Scale, 12 hours)	3.01 ± 1.08	3.91 ± 1.48	4.2 ± 1.1
Pain score (Visual Analog Scale, 48 hours)	2.1 ± 0.8	3.4 ± 1.2	4.0 ± 1.0
Opioid Consumption (mg)	54 ± 25.67	74.37 ± 18.87	80 ± 22
Quadriceps Weakness (6 hours)	25%	85%	90%
Time to mobilization (hours)	19.6 ± 9.6	26.5 ± 8.2	30 ± 10

Conclusion(s): The pericapsular nerve group block demonstrated superior pain management, opioid reduction, and motor function preservation compared to the fascia iliaca and femoral nerve blocks. Its benefits, particularly in reducing complications and facilitating early mobilization, make it the preferred regional anesthesia technique for frail elderly patients undergoing hip surgeries.

Erector Spinae Plane Block in Bariatric Surgery: A Meta-analysis of Randomized Controlled Trials with Trial Sequence Analysis

J. Sim1, W.J. Mak1, K. Tan1, C.H. Chan1 ¹Singapore General Hospital, Department of Anaesthesia and Perioperative Services, Singapore, Singapore

Background and Goal of Study: Post-operative pain after bariatric and metabolic surgeries may be significant and pain optimisation in obese patients is challenging. Excessive use of opioids in these patients exacerbate their obesity-related comorbidities including risk of airway obstruction from obstructive sleep apnoea and susceptibility to respiratory depression from opioid analgesia. Moreover, such surgeries are inherently associated with higher risk of post-operative nausea and vomitting (PONV), and opioids can exacerbate this. Erector spinae plane (ESP) block has been reported to improve pain and decrease opioid requirements for patients undergoing bariatric and metabolic surgeries.

This meta-analysis aims to evaluate the current evidence on the use of ESP block in bariatric surgeries, focusing on its effectiveness in the reduction in pain and opioid consumption. By consolidating existing research, we aim to provide a clearer understanding of the role of ESP block in this context and identify areas for future investigation.

Materials and Methods: MEDLINE, Embase, Scopus, and CEN-TRAL electronic databases were searched for all studies on ESP block in bariatric and metabolic surgeries from database inception through 9th July 2024. We have only included randomised controlled trials (RCTs) in this study. Two reviewers independently assessed, selected studies, collected data, assessed the risk of bias and quality of evidence.

The primary outcome for this review is opioid consumption in 24 to 48 hours post-operatively.

Secondary outcomes include intra-operative opioid consumption, incidence of PONV, and post-operative pain scores.

Results and Discussion: Six RCTs involving 462 patients were eligible. ESP block significantly reduced opioid consumption in the first 24 to 48 hours after surgery, with a mean oral morphine equivalent daily dose reduction of 28.45mg (95% CI -46.91 to -10.00, p = 0.003, I^2 = 94%).

Trial sequence analysis supported the statistical reliability of our data, favouring ESP block. Time to first request for analgesia was significantly prolonged with ESP block. Intra-operative opioid requirements, post-operative reported pain scores, and PONV rates were reduced in the ESP block group.

Conclusion(s): Bilateral ESP block appears to be a practical, safe and effective modality to improve peri-operative pain outcomes in bariatric surgeries. We propose future research to focus on comparing different block techniques with ESP for such patients.

12AP02-7

Prilocaine in subarachnoid anesthesia: which dosage for the best effectiveness and recovery of motor block?

A. Ragone¹, G. Montenero¹, G. Sfregola¹, M. Ciuffreda², C. Piangatelli2, D. Galante1

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, 2Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Prilocaine is a local anesthetic commonly used in subarachnoid anesthesia, particularly for lower abdominal and pelvic surgeries. Its favorable pharmacological profile, including a relatively low toxicity and rapid onset, makes it a useful alternative to other local anesthetics like bupivacaine or lidocaine.

This study aims to evaluate the advantages of prilocaine in subarachnoid anesthesia for lower abdominal surgeries and explore the effects of different dosing regimens.

Materials and Methods: A survey was conducted in 7 hospital centers where experienced anesthetists used three different doses of prilocaine and were asked to provide effectiveness evaluations. Patients (n. 60) received one of three doses of prilocaine: low dose (50 mg), medium dose (75 mg), or high dose (100 mg). Sensory and motor block characteristics, hemodynamic stability, and adverse effects were assessed. Pain control, duration of sensory and motor blockade, and recovery times were monitored over a 24-hour postoperative period.

Results and Discussion: The medium-dose group (75 mg) exhibited the most balanced outcomes, with rapid onset, effective sensory block, and satisfactory motor blockade without excessive prolongation. The low-dose group (50 mg) provided adequate analgesia but required higher supplementary doses during surgery. The high-dose group (100 mg) resulted in prolonged motor block and a higher incidence of hypotension and urinary retention.

No significant differences in postoperative pain scores or patient satisfaction were observed among groups. Adverse effects were minimal, with a low incidence of nausea and headache.

Conclusion(s): Prilocaine offers a safe and effective alternative for subarachnoid anesthesia in lower abdominal surgery. A medium-dose regimen (75 mg) provides optimal analgesia with minimal side effects and complications.

Future studies should further investigate its long-term effects and the use of prilocaine in specific patient populations.

Continuous adductor canal block improves pain control and quality of recovery in primary total knee arthroplasty surgery: a randomized double-blinded controlled trial

H. dos Santos Fernandes¹, Y. Gleicher¹, S. Peacock¹, C. Ma1, J. Wolfstadt2, N. Siddiqui1 ¹University of Toronto, Department of Anesthesiology and Pain Medicine, Toronto, Canada, ²University of Toronto, Division of Orthopaedic Surgery, Toronto, Canada

Background and Goal of Study: Adequate pain management is paramount for total knee arthroplasty (TKA). The duration of single shot adductor canal block (ACB) and IPACK (infiltration between the popliteal artery and capsule of the Knee) block is limited to no more than 24h. Conversely, the use of continuous ACB (CACB) may increase duration of analgesia. The purpose of this study is to evaluate the effectiveness of using CACB in patients undergoing primary TKA.

Materials and Methods: Randomized controlled trial planned to recruit 60 subjects undergoing unilateral primary TKA. All patients receive single shot ACB and IPACK block, spinal anesthesia with mepivacaine and fentanyl and postoperative CACB catheter insertion (ISAFE technique). Depending on the randomization, patients can have a 5ml/h infusion of normal saline (Control group) or ropivacaine 0.2% (Intervention group). Patients are assessed for QoR-15 scores, pain and opioid consumption for the first three postoperative days (POD).

Results and Discussion: Partial analysis of 49 enrolled subjects shows the Intervention group had a better performance (table 1). Groups were similar for age, body-mass index, sex, and laterality of surgery. Catheter related complications and side effects had similar low incidences in both groups.

	Control Group (n = 24)	Intervention Group (n = 25)	Р
POD 1 outcomes			
Pain score at rest, NVS 0 – 10	5 (0 - 8)	1 (0 - 6)	0.008℃
Pain score at movement, NVS 0 – 10	6.67 ± 2.26	4.33 ± 2.66	0.011a
Opioid consumption in last 24h, in mg of OME	19.5 (0 - 82)	5 (0 - 63)	0.004℃
QoR - 15, 0 - 150	109.38 ± 16.16	129.00 ± 12.20	0.0004a
POD 2 outcomes			
Pain score at rest, NVS 0 – 10	5 (0-8)	1 (0-5)	< 0.0001°
Pain score at movement, NVS 0 – 10	7.83 ± 1.88	4.42 ± 2.52	< 0.0001a
Opioid consumption in last 24h, in mg of OME	22.5 (0 - 82)	5 (0 – 35)	0.0007℃
QoR - 15, 0 - 150	109.58 ± 16.25	130.71 ± 10.49	< 0.0001a
POD 3 outcomes			
Pain score at rest, NVS 0 – 10	3.29 ± 2.20	1.88 ± 2.71	0.040a
Pain score at movement, NVS 0 – 10	7.13 ± 2.01	4.21 ± 2.73	0.0001a
Opioid consumption in last 24h, in mg of OME	10 (0 – 75)	5 (0 – 35)	0.015°
QoR - 15, 0 - 150	110.96 ± 17.59	130.58 ± 14.86	0.0005a

Table 1.

Data: mean ± standard deviation, median (minimum - maximum). OME: oral morphine equivalent. a: T-test; c: Mann-Whitney.

These findings suggest that CACB has additional benefit over single shot ACB.

Conclusion(s): CACB improves pain control and quality of recovery after primary TKA.

Anterior rerratus plane block in heart rate control in a patient with atrial fibrillation

F. Coelho¹, A. Ferreira¹, Â. Mendes¹, N. Lages¹, H. Machado¹

¹Centro Hospitalar Universitário de Santo António. Serviço de Anestesiologia, Porto, Portugal

Background: Atrial fibrillation (AF) with rapid ventricular response (RVR) is common in critically ill patients. This case illustrates how continuous superficial anterior serratus plane block provided effective analgesia for thoracic trauma, helping control heart rate (HR) in a patient with AF and contributing to clinical stabilization.

Case Report: A 52-year-old male with alcohol-related liver cirrhosis (Child-Pugh B) and non-anticoagulated AF was admitted after a fall, sustaining multiple left anterolateral rib fractures (2nd, 3rd, and 5th-11th ribs), left L1 and L3 transverse process fractures, and wedge compression fractures of D7, D11, D12, and L1 vertebrae.

Three days post-admission, he developed nosocomial pneumonia with severe respiratory failure requiring mechanical ventilation and ICU admission. By the 9th ICU day, with respiratory function improving, a weaning attempt from ventilation and sedoanalgesia failed, accompanied by the onset of AF with RVR, which was hemodynamically stable but refractory to medical therapy.

A continuous superficial anterior serratus plane block was performed with 20 mL of 0.375% ropivacaine, followed by a continuous infusion of 0.2% ropivacaine at 8 mL/h. This resulted in significant HR control improvement, enabling sedoanalgesia weaning and extubation on the 12th ICU day without complications.

The perineural catheter was removed after 11 days, transitioning the patient to conventional analgesia and HR control with bisoprolol 5 mg. ICU discharge occurred on the 16th day, with hospital discharge 10 days later.

Discussion: This case highlights uncontrolled pain as a potential AF with RVR trigger and the positive impact of regional anesthesia on pain control in thoracic trauma. The superficial anterior serratus plane block controlled pain and its associated sympathetic response, enabling hemodynamic stability, reduced opioid consumption, and safe sedation weaning.

This block may be an alternative to standard thoracic trauma analgesia techniques (e.g., epidural or paravertebral block), offering a safer, simpler approach with better hemodynamic stability and no anticoagulation adjustments.

Reference:

doi: 10.1016/j.ajem.2023.09.012; . doi:10.1001/jamasurg.2024.0969 **Learning Points:**

- 1. Regional anesthesia is a valuable ally for effective pain management.
- 2. Severe uncontrolled pain can have significant hemodynamic consequences.
- 3. Superficial anterior serratus plane block is a viable alternative for thoracic trauma analgesia.

12AP02-10

Real time ultrasound guided thoracic epidural placement in a patient with severe scoliosis for thoracotomy and laparotomy

H. dos Santos Fernandes¹, C. Ma¹, S. Peacock¹, N. Siddiqui¹, Y. Gleicher¹ ¹University of Toronto, Department of Anesthesiology and Pain Medicine, Toronto, Canada

Background: Thoracic epidural (TE) is the gold standard for postoperative analgesia in abdominal and thoracic surgery. Ultrasound (US) real time guidance for the insertion of TE has been demonstrated.

This novel report describes this technique in patient with spinal deformity.

Case Report: A 70 years old woman with severe scoliosis (Figure 1) and chronic pain presented for a open surgical resection of stomach and diaphragm.

Figure 1.

The patient was put in sitting position. Sagittal right paramedian scanning was performed on T9-T10 level. With one operator holding the US and the other performing needling, the Touhy needle was introduced in-plane, caudal-to-cranial and lateral to medial direction (Figure 2).

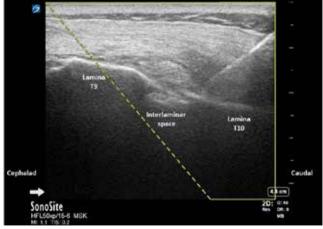

Figure 2.

When engaged to ligamentum flavum, the US was removed and a syringe was attached to the needle. Loss of resistance was found at 4cm from the skin. TE catheter was inserted. Epidural pressure waveform analysis was done (Figure 3).

Figure 3.

TE was kept for five days and provided good sensitive block. Discussion: Real time US guided TE has been described. However its use is limited by requirement for technical expertise. This report focuses on the novelty of using real time US guidance in placement of TE catheter in a patient with severe spinal deformity.

Reference:

Pakpirom J, Thatsanapornsathit K, Kovitwanawong N, et al. Real-time ultrasound-guided versus anatomic landmark-based thoracic epidural placement: a prospective, randomized, superiority trial. BMC Anesthesiol 2022;22(1):198.

Learning Points: Real time US guided TE placement is possible in those with spinal deformity.

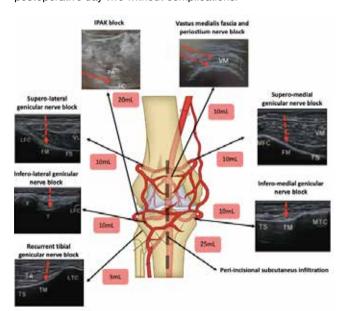

12AP03-1

Modified periarticular vasoconstrictor infiltration for total knee arthroplasty in a fast track program: eliminating tourniquet use

M. Roger Coscojuela¹, J.M. Mejia Kattah¹, T.M. Cuñat Lopez¹, N. Martin Marata¹, X. Sala Blanch¹, M. Tio Felip¹ ¹Hospital Clinic de Barcelona, Anaesthesia Department, Barcelona, Spain

Background: Total knee arthroplasty (TKA) poses challenges in controlling intra and post-operatory bleeding and managing pain. Tourniquets and tranexamic acid are standard for hemostasis, while nerve blocks address pain. In 2022, ultrasound-guided periarticular vasoconstrictor infiltration (PVI)1 emerged as an alternative to tourniquets and nerve blocks.

Case Report: We present two cases: an 83-year-old woman undergoing left TKA and a 71-year-old woman undergoing right TKA. both ASA 2. Spinal anesthesia with isobaric bupivacaine was followed by ultrasound-guided modified PVI (Figure 1), under strict aseptic conditions 15 to 30 minutes before incision, using 100 mL of ropivacaine 0,2% with 1:200,000 adrenaline, and intraoperative propofol sedation. Tourniquet was not used. Tranexamic acid, antibiotics, and 24mg of dexamethasone were administered per protocol. Intraoperative blood loss was under 200 mL in both cases. The first patient required a single tramadol dose for pain during the first 24 hours, while the second managed pain with non steroidal anti inflammatory drugs and paracetamol, without requiring opioids. Neither of the patients required blood transfusion. Both ambulated within six hours and were discharged on postoperative day two without complications.

e 1: Description of modified PVI. LFC: Lateral femoral condyle, FC: Femoral condyle, FM: Fe FS: Femoral shaft, VL: Vestus lateralis, LFC: Lateral femoral condyle, LTC: Lateral tibial condyle, MFC: Medial dyle, MTC: Medial tibial condyle, PA: Popliteal artery, T: Tibia, TA: Tibialis ante

Discussion: PVI combines adrenaline's vasoconstriction with ropivacaine's anesthetic effects, ensuring hemostasis and analgesia while preserving motor function for early mobilization². Literature favors tourniquet-free techniques for faster recovery and less ischemic complications. Unlike nerve blocks, PVI aligns with enhanced recovery protocols. Results are promising, but larger studies are needed to confirm its long-term benefits.

References:

1. J Clin Anesth. 2024;92.

2. Anaesthesia. 2023;78(2):188-196.

Learning Points: PVI represents a modern, safe, and effective alternative for TKA, aligning with enhanced recovery paradigms to improve patient outcomes and satisfaction.

12AP03-2

Continuous catheter block of deep peroneal nerve for acute neuropathic pain

R. Voloshchuk¹

¹Military Medical Clinical Center of Western Region, Anesthesiology and Intensive Care, Lviv, Ukraine

Background: Neuropathic pain is a common problem after traumatic amputations. Continuous nerve blocks have been proposed as a way to treat neuropathic pain [1].

While many reports focus on short-term catheterization of sciatic nerve, to our knowledge this is the first reported case of long-term continuous catheter block of a nerve at ankle level.

Case Report: A 50 year old male soldier presented on day 5 after blast injury with left femur fracture and traumatic amputation of 2nd and 3rd toes on the left foot. The patient's quality of life was mainly affected by severe phantom toe pain (8/10 by numeric rating scale) with allodynia and dysesthesia in the foot, causing sleep impairment. This pain did not respond to non-steroidal analgesics and gabapentin.

After trial deep peroneal nerve (DPN) block at ankle level, the patient reported immediate relief.

Next day, a perineural catheter was inserted with ultrasound guidance adjacent to the DPN at ankle level. The catheter was threaded 4 cm along the nerve in distal direction using the out-of-plane technique, and then tunneled intradermally.

With intermittent boluses of 10 mL 0.25% bupivacaine every 8-12 hours, the patient became pain free, and no other pain medication was required.

After 18 days, the pain in the foot and toes was gone, and the catheter was removed without any complications.

Discussion: Our case shows that neuropathic pain after toe amputation can be successfully treated with a perineural catheter placed adjacent to the deep peroneal nerve at ankle level. Selective catheterization of thin distal nerves potentially increases block density.

This may improve efficiency of early neuropathic pain reduction. Placement of a catheter adjacent to DPN at ankle level proved easy and straightforward. Importantly, after 18 days, the catheter did not dislodge, and was not infected.

Reference:

1. Ilfeld BM et al.; PAINfRE Investigators. Ambulatory continuous peripheral nerve blocks to treat postamputation phantom limb pain: a multicenter, randomized, quadruple-masked, placebo-controlled clinical trial. Pain. 2021 Mar 1;162(3):938-955. doi: 10.1097/j.pain.00000000000002087. PMID: 33021563; PMCID: PMC7920494.

Learning Points: Long-term continuous catheter block of deep peroneal nerve at ankle level is possible and feasible to treat neuropathic pain in selected cases.

12AP03-3

Postoperative analgesic efficacy of IPACK or genicular nerve block as an adjunct to femoral triangle block for arthroscopic anterior cruciate ligament reconstruction: a preliminary report

P. Leurcharusmee¹, S. Boonsri¹, A. Samerchua¹ Chiang Mai University, Anesthesiology, Chiang Mai, Thailand

Background and Goal of Study: Effective acute pain management following arthroscopic anterior cruciate ligament reconstruction (ACLR) promotes joint mobility and facilitates physiotherapy. A combination of femoral triangle block (FTB) and oral multimodal analgesia is commonly recommended for postoperative pain control and enhanced recovery. However, this regional anesthesia technique spares some parts of the knee joint, and some patients still experience postoperative pain.

This study aimed to compare the analgesic efficacy of the infiltration between the popliteal artery and the capsule of the knee (IPACK) and the genicular nerve block (GNB) when combined with FTR

A secondary aim was to evaluate the incidence of posterior knee pain following ACLR with these nerve blocks.

Materials and Methods: This was a single-center, patient- and assessor-blinded randomized controlled trial. Patients scheduled for ACLR were allocated to receive either IPACK or GNB before induction of general anesthesia.

Both FTB and the assigned additional block (IPACK or GNB) were performed using 0.25% bupivacaine and 1% lidocaine with adrenaline. The postoperative analgesic regimen consisted of regular paracetamol, NSAIDs, and tramadol/codeine.

Outcomes included intraoperative fentanyl use, postoperative morphine consumption at 12 and 24 hours, time to first morphine rescue, resting and dynamic pain scores (measured every 4 hours for 24 hours), and the number of patients reporting posterior knee pain.

Results and Discussion: Forty-three patients were recruited, with 22 patients allocated to the IPACK group and 21 to the GNB group. Intraoperative fentanyl use was similar between groups (p=0.281). Postoperative morphine consumption at 12 hours tended to be lower in the GNB group (p=0.093).

Additionally, the time to first postoperative morphine rescue was significantly longer in the GNB group (median [IQR]: 20 [13–34] hours vs. 12 [8–16] hours; p=0.048). Resting and dynamic postoperative pain scores within 24 hours were also significantly lower in the GNB group (p=0.027 and p=0.023, respectively). The incidence of posterior knee pain was approximately 30% in both groups.

Conclusion(s): This preliminary study suggests that GNB is superior to IPACK as an adjunct to FTB and multimodal oral analgesia in terms of postoperative pain management. However, around 1/3 of patients reported postoperative pain in the posterior knee. We suggest that this point requires further investigations.

12AP03-4

One epidural, two battles: navigating labor pain and sickle cell crisis

P. Gaspar¹, I.S.M. Carrapatoso¹, T. Estevens¹, C. Marques¹ ¹Hospital Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Labour heightens vaso-occlusive crisis (VOC) risk in pregnant women with sickle cell disease (SCD) due to stress. dehydration, and hypoxia. Systemic opioids, the standard pain management, can cause sedation and fetal risks. This case highlights managing labour pain and VOC with a single epidural catheter, offering effective relief while minimizing complications of systemic analgesia.

Case Report: A 25-year-old woman with SCD and recurrent VOC presented at 38+2 weeks destation in spontaneous labour with severe VOC pain in her right knee, unresponsive to IV analgesia. A lumbar epidural catheter provided dual-purpose analgesia, with an initial bolus of 20 mg ropivacaine 0.2% and 5 mcg sufentanil, effectively relieving contraction and VOC pain.

Patient-controlled epidural analgesia with ropivacaine 20mg 0,2% boluses ensured excellent pain control. She delivered vaginally without complications.

Postpartum, the catheter managed VOC pain with 14 mg ropivacaine 0.2% every 6 hours, transitioning to on-demand use as pain improved. The catheter was removed after stable pain control with IV analgesics. No adverse events occurred during labour or recovery.

Discussion: This case highlights the efficacy of epidural analgesia for simultaneous management of labour pain and VOC in women with SCD. Epidural analgesia reduces systemic opioid use and associated risks like sedation and maternal-fetal compromise while offering targeted pain relief. Postpartum catheter retention enabled continued VOC management, promoting recovery.

This dual-purpose approach improves comfort, reduces side effects, and optimizes outcomes in this high-risk group. While commonly used for labour pain, its role in VOC management is underreported, emphasizing the significance of this case.

Epidural analgesia is a safe, innovative strategy, enhancing maternal and neonatal outcomes through multidisciplinary care.

References:

- 1. Smith WR, Coyne P, Smith VS, et al. Pain in sickle cell disease: a multidimensional model. Am J Hematol. 2005;80(8):665-670. 2. Ballas SK. Sickle cell pain: a critical reappraisal. Blood.
- 2011;120(18):3647-3656.

Learning Points:

- 1. Labour significantly increases the risk of VOC in pregnant women with SCD.
- 2. Epidural analgesia offers a safe, effective, and dual-purpose solution for labour pain and VOC.
- 3. A multidisciplinary approach is essential in managing high-risk pregnancies, ensuring optimal maternal and neonatal outcomes.

12AP03-5

Intravenous 1 mg midazolam with subarachnoid block is recommended for clinical sedation without hemodynamic compromise - a randomized controlled trial

U. Fabeena Mangaladan¹, J. Punj¹, R.K. Pandey¹, V. Darlong¹, B. Garg²

¹All India Institute of Medical Sciences, Department of Anaesthesiology, Pain Medicine and Critical Care, Delhi, India, ²All India Institute of medical sciences, New Delhi, Orthopedics, New Delhi, India

Background and Goal of Study: Closed claim studies have highlighted cardiac arrest in healthy young male patients when subarachnoid block (SAB) was given with intravenous (IV) sedation. It was suggested to give lower or no IV sedative agents with SAB as SAB itself has inherent sedative effects due to decreased afferent stimulation of the reticular activating system.

The hypothesis of the present study was that inherent sedation of SAB would correspond to a numerical measure of Bi Spectral Index (BIS) less than 90 (BIS 60-90 sedation recommended in SAB) and that IV midazolam 1 mg, a common practice for intraoperative sedation during SAB, would not be required in these patients.

Primary objective was to compare BIS post SAB with or without IV midazolam.

Secondary objective was to determine hemodynamic stability.

Materials and Methods: 60 patients of age 20-60 years, ASA 1 or 2, undergoing lower limb surgeries were randomly allocated into two groups and given SAB with a 27-gauge spinal needle with 0.5% hyperbaric bupivacaine 2 mL (10 mg) and fentanyl 0.5 mL (25mcg);

Group A (n=30): SAB with 1ml IV saline, Group B (n=30): SAB with IV 1mg midazolam. BIS, heart rate, non-invasive blood pressure, oxygen saturation and respiratory rate were recorded every 15 minutes till 90 minutes.

Results and Discussion: In Group B, BIS was less than 90 but not less than 80 from 30 minutes to at least 90 minutes. In Group A, BIS was less than 90 from 45 minutes to 60 minutes and was more than 90 at all other time frames.

Mean BIS was significantly more in Group A compared to Group B (90.41 +/- 4.05 v/s 86.58 +/- 3.50 respectively) (P< 0.001). Hemodynamic parameters of heart rate, non-invasive blood pressure, oxygen saturation and respiratory rate were comparable between both groups (p value >0.05).

Group	Mean ± SD	"t' Statistics	P-value
Group A	90.41± 4.05	3.915	<0.001**
Group B	86.58± 3.50		

Table 1: Comparison of Mean BIS between Groups

Conclusion: SAB (0.5% bupivacaine 10 mg and 25 ug fentanyl in lower limb surgeries) does not produce numeric BIS <90 and thus may not result in patient sedation and comfort and thus IV midazolam 1 mg should be injected which produces numeric BIS < 90 from 30 minutes to at least 90 minutes without any hemodynamic compromise. Duration of effect of sedation of IV midazolam 1 mg beyond 90 minutes should be studied.

12AP03-6

Successful combined spinal-epidural anesthesia for caesarean section in a super-super obese patient with BMI > 70 kg/m² - a case report

V. Pustilnik¹, J. Bernardo², M. Brandstetter², J. Fellner¹, H. Simonis¹

¹Paracelsus Medical University of Salzburg, Department of Anesthesiology, Perioperative Medicine and Intensive Care Medicine, Salzburg, Austria, ²Paracelsus Medical University of Salzburg, Department of Gynecology and Obstetrics, Salzburg, Austria

Background: Obesity during pregnancy is increasingly common and associated with elevated perinatal risks. Super-super obesity (BMI ≥ 60 kg/m²) is rare, and anesthetic guidelines for such patients are limited. Taylor et al. recommend interdisciplinary assessment, early neuraxial techniques, and avoidance of emergency cesarean sections due to the high risks and complex management1.

We report a successful case of combined spinal-epidural anesthesia (CSE) in a super-super obese patient.

Case Report: A 25-year-old woman with a BMI of 72 kg/m² (225 kg, 176 cm) was admitted for her first childbirth. Her medical history included obstructive sleep apnea, bronchial asthma, and pregnancy-induced hypertension.

After multidisciplinary planning, an elective caesarian section was performed. CSE was conducted with ultrasound-guided midline and epidural depth assessment. Single-shot spinal anesthesia with 11 mg isobaric bupivacaine was placed at L2/3, followed by an epidural catheter at the same level. The patient was positioned in the ramp position and received nasal high-flow oxygen. Both mother and newborn were discharged in good health the following day.

Discussion: This case highlights the importance of multidisciplinary planning in managing super-super obese patients (1).

CSE with ultrasound guidance offers flexibility for extending the block via an epidural catheter, often necessary in prolonged sur-

Single-shot spinal anesthesia ensures reliable blockade and reduces the risk of excessive cephalad spread compared to epidural anesthesia. Isobaric bupivacaine minimizes the risk of failed spinal anesthesia in the ramp position, compared to hyperbaric agents2.

Moreover, CSE with ultrasound guidance may facilitate intrathecal space identification compared to standard single-shot spinal techniques1.

References:

- 1. Taylor CR et al. Obesity and obstetric anesthesia. Local Reg Anesth. 2019;12:111.
- 2. Demilie AE et al. Failed spinal anesthesia: incidence and factors. BMC Anesthesiol. 2024;24:129.

Learning Points:

- Multidisciplinary planning and avoiding emergency sections are vital for safely managing super-super obese patients.
- CSE is preferred in complex cases for its reliable single-shot spinal anesthesia and the flexibility to extend block duration with an epidural catheter.
- Ultrasound-guided CSE improves intrathecal space identification in super-super obese patients.

12AP03-7

Pericapsular Nerve Group (PENG) block for shoulder arthroscopy in day case surgery

M. Abreu Pires¹, A. Ferreira¹, C. Cavaleiro^{1,2}, H. Machado^{1,2} ¹Centro Hospitalar Universitário de Santo António. Unidade Local de Saúde de Santo António, Servico de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva Emergência e Urgência, Porto, Portugal, ²Instituto de Ciências Biomédicas Abel Salazar, Ensino Médico Pré-Graduado, Porto, Portugal

Background: Interscalene brachial plexus block is the goldstandard regional technique for shoulder surgery. Respiratory compromise poses an important consideration in day-case surgery. Pericapsular nerve group (PENG) block has been used for postoperative analgesia without pulmonary impact. The authors aim to perceive its analgesic effectiveness following shoulder arthroscopy surgery.

Case Report: Three patients were scheduled for shoulder arthroscopy and ligamentoplasty due to rotator cuff tear. Combined anesthesia (intravenous general anesthesia with a regional technique) was proposed. An ultrasound-guided (USG) shoulder PENG block (20mL 0,375% ropivacaine) was applied (Figure 1). Intraoperative multimodal analgesia was used: 50µg fentanyl and 2mg/kg intravenous lidocaine before induction; 2g magnesium sulfate, 20mg ketamine, and 1g paracetamol. Postoperative analgesia consisted of 1g paracetamol 8/8h, 60mg acemethacin, and SOS 100mg tramadol. All procedures were uneventful.

Table 1 presents patient's data, 24 hour's numerical rating scale score (NRSS) and pain control. No pulmonary complications or motor blocks were reported. Numbness and paresthesias were noted until 12 hours after surgery.

Patie	nt Age (years)	Gender	ASA- PS	Anesthesia duration (min)	Surgery duration (min)	NRSS 1 hour	NRSS 12 hours	NRSS 24 hours	Rescue analgesia in first 24 hours
1	49	Female	2	83	46	0	0	3	100 mg tramadol
2	67	Female	2	77	44	0	4	0	100 mg tramadol
3	61	Female	2	68	36	0	0	3	None

Table 1.

Figure 1. USG shoulder PENG block (blockade area marked in blue shade)

Discussion: Pain management after day-case shoulder surgery is crucial for patient rehabilitation. All patients were discharged 6 hours after surgery, with no respiratory complications noted, USG shoulder PENG block was able to provide adequate postoperative pain control.

References:

1. Küpeli İ, Kara MY. Anesthesia or analgesia? New block for shoulder surgery: pericapsular nerve group block. Braz J Anesthesiol 2022:72(5):669-672.

Learning Points: Shoulder PENG block may be a promising option for regional anesthesia in day-case surgery, with no pulmonary function compromise, as its combination with conventional multimodal approach seem to provide successful analgesia.

12AP03-9

Long term catheterization of sciatic nerve for management of acute pain in combat injuries: a case series

R. Voloshchuk¹, A. Halushko¹, Y. Skurativskyi¹ ¹Military Medical Clinical Center of Western Region. Anesthesiology and Intensive Care, Lviv, Ukraine

Background: Combat lower limb injuries cause severe acute pain from tissue and nerve damage, and require surgical debridements and painful negative pressure wound therapy over many weeks. We present a series of cases where sciatic perineural catheterizaition was routinely used for continuous pain relief over unusually long times.

Case Report: 45 male soldiers with severe nociceptive and/ or neuropathic pain from recent combat injuries to lower limbs were included. 51 sciatic perineural catheters were inserted under ultrasound guidance at upper, middle, or lower thigh levels. The catheters were threaded 5-10 cm inside the paraneurium, tunnelled intradermally and covered with transparent film dressing. All patients received 0.25% bupicavaine as infusion or regular boluses.

Subsequent perineural analgesia was patient-driven, i.e. every day patients were asked if they want to keep the catheter. Next day after catheter placement, 44 of 51 catheters were assessed by patients as effective in reducing pain and improving sleep (success rate 88%).

Of these 44 effective catheters, 17 (39%) were maintained till resolution of pain, 5 (11%) were removed unintentionally, and 5 (11%) were removed because of complications. 17 (39%) effective catheters were lost to follow-up (last follow-up date was recorded as catheter removal date). Median catheter in situ time was 14 days (range 3 to 57, total of 719 catheter-days).

Complications included 1 case of painful sciatic neuropathy (onset on day 9 after insertion of a second popliteal catheter, the patient was then lost to follow-up), 1 case of worsening of phantom limb pain under continuous sciatic nerve block, and 3 minor local infections (1 infection per 240 catheter-days), which resolved upon catheter removal and required no treatment.

Discussion: Our work shows that perineural sciatic catheters can be safely maintained for weeks. This is in contrast with most studies [1], where duration of perineural catheterization is usually limited to 7 or 10 days.

Prolonged sciatic nerve catheterization is a feasible way to control acute lower limb pain, which persists for a longer period of time, such as in combat injuries.

References:

1. Hagen Bomberg et al.; Prolonged Catheter Use and Infection in Regional Anesthesia: A Retrospective Registry Analysis. Anesthesiology 2018: 128:764-773

Learning Points: Perineural sciatic catheter can be effectively used for pain relief for much longer than 2 weeks with few complications.

12AP03-11

Identifying the barriers faced by anesthesia providers in performing nerve blocks for hip fracture surgeries

A. Naz1, J. Bruton1 Our Lady of Lourdes Hospital, Anesthesia, Drogheda, County Louth, Ireland

Background and Goal of Study: Nerve blocks, including fascia iliaca block (FIB), femoral nerve block (FNB), and pericapsular nerve group (PENG) block, are effective in managing pain for hip fracture surgeries. They reduce opioid use, minimize delirium, and shorten hospital stays. Despite their benefits, adoption remains low due to barriers like inadequate training, resource shortages, and time constraints.

This audit aimed to identify these barriers at Our Lady of Lourdes (OLOL) Hospital to improve care and procedural consistency.

Materials and Methods: A survey was conducted among 45 anesthesia providers, with a 71.1% response rate. Respondents included consultants, NCHDs, trainees, and SHOs. Data on demographics, training, confidence, and barriers to performing nerve blocks were collected via Google Forms between September 17 and October 2, 2024. Quantitative data were analyzed descriptively, and qualitative responses underwent thematic analysis.

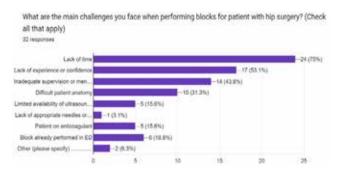

Figure. Main challenges when performing blocks for patient hip surgery.

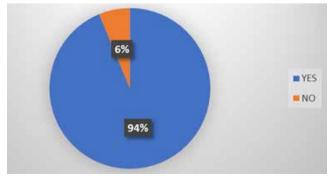

Figure. Interest in further training.

Results and Discussion: Most respondents (81.25%) had more than five years of experience, but formal training in nerve blocks was limited. Only 37.5% had training in FIB. 46.8% in FNB, and 9.4% in PENG. Confidence was highest for FIB (31.25% very confident) and lowest for PENG (6.25%).

Barriers included time constraints, lack of ultrasound machines, insufficient training, workflow inefficiencies, and limited mentorship. FIB was the most commonly performed block, but PENG was rarely utilized due to a lack of training and awareness.

Addressing these challenges through structured training, better resources, and mentorship can significantly improve nerve block adoption.

Conclusion(s): By targeting identified barriers, OLOL Hospital can enhance the use of nerve blocks, improving patient outcomes and adherence to best practices. Strategies include workshops, better resource allocation, mentorship, and optimized workflows.

12AP03-12

Safe and tailored: breast cancer surgery under regional anesthesia with low concentration ropivacaine for high-risk patient

J.N. Lim¹, J.B.L. Tey²

¹National Healthcare Group Education, Anaesthesiology, Intensive Care and Pain Medicine, Singapore, Singapore, ²Woodlands Health National Healthcare Group, Anaesthesiology, Singapore, Singapore

Background: Breast cancer surgery under regional anesthesia (RA) provides significant benefits including faster recovery and improved outcomes.

This case is noteworthy for using of low concentration(0.35%) ropivacaine in a frail patient, which is uncommon as higher concentrations(0.5%) are typically used to ensure effective anesthe-

Case report: A 72-year-old woman with significant dyspnea from likely C3 and C4 cervical myelopathy was diagnosed with left breast intraductal carcinoma, necessitating left mastectomy and possible axillary clearance. Decision made to proceed only under RA given her frailty. Ropivacaine 0.35% with adrenaline 1:200K,totaling 50mls(175mg) was prepared. Paravertebral block were performed at left T2 and T5 levels using 15mls each, left pectoral plane 2 block with 5mls given between pectoralis major and minor,10mls underneath pectoralis minor and left superficial cervical plexus block with 5mls(total 50mls).

Intraoperative sedation started due to patient's anxiety, but the block was effective with no additional LA required. She was discharged well next day.

Discussion: This case highlights the effectiveness of using 0.35% ropivacaine for mastectomy under RA. While literature suggests a minimum effective concentration(MEC) of around 0.257%, many studies reported at least 0.5% for paravertebral blocks in mastectomy.

This case aims to enhance understanding of safe anesthetic practices in high-risk populations, showing that lower concentrations can provide satisfactory anesthesia without compromising efficacy.

References:

1. Fang, G., et al. (2016). The minimum effective concentration(MEC90) of ropivacaine for ultrasound-guided supraclavicular brachial plexus block. Anaesthesia,71,700-705.

- 2. Pangthipampai, P.,et al. (2020). Ultrasound-guided multilevel thoracic paravertebral block and its efficacy for surgical anesthesia during primary breast cancer surgery. Journal of Pain Research.13.1713-1723.
- 3. Chhabra. A., et al. (2021). Paraverte bral anaesthesia with or without sedation versus general anaesthesia for women undergoing breast cancer surgery. Cochrane Database of Systematic Reviews,2(2),CD012968.

Learning points: This case emphasizes the feasibility of using 0.35% ropivacaine for RA in breast cancer surgeries, especially in high-risk patients.

It highlights the importance of tailoring anesthetic techniques to individual patient needs while ensuring safety and efficacy, contributing valuable insights into management strategy for vulnerable populations.

12AP04-1

Maxillary nerve block for transsphenoidal surgery: two case reports

R. Iwai¹, W. Kim¹, Y. Kamiya¹

Gifu University Graduate School of Medicine, Department of Anesthesiology and Pain Medicine, Gifu, Japan

Background: Transsphenoidal surgery (TSS) is commonly performed for pituitary tumours. Although this type of surgery is minimally invasive compared to craniotomy, some patients experience postoperative pain. The efficacy of maxillary nerve block (MNB) for endoscopic sinus surgery¹ has been reported in several cases, but there are few reports on TSS2.

We report two cases of MNB for TSS.

Case report: A 50-year-old man and a 36-year-old woman are scheduled for TSS for a pituitary tumour. They had no significant past medical history. After the induction of general anaesthesia, the patients underwent bilateral ultrasound-guided MNB with 2 mL each of 0.5% ropivacaine. No opioids were required except for a continuous intraoperative continuous infusion of remifentanil (up to 0.2 mcg/kg/min).

On awakening from general anaesthesia, the patients reported no pain during their hospital stay and did not require postoperative analgesia. No complications related to MNB were observed.

Discussion: The anatomical structures involved in the TSS procedure include the nasal cavity (nasal mucosa), sphenoid bone (sinus) and dura mater. Most of these are innervated by the branches of the maxillary nerve and postganglionic fibres from the pterygopalatine ganglion. General anaesthesia with MNB for TSS reduces perioperative opioid consumption and its side effects. It may also enable rapid emergence from anaesthesia and early neurological assessment.

Although There are several case reports of infraorbital nerve block for TSS on perioperative analgesia³, we did not find any case report of MNB. We performed ultrasound-guided MNB by injecting a local anaesthetic into the pterygopalatine fossa under the zygomatic arch. The pterygopalatine fossa is filled with fat and contains branches of the maxillary nerve, the pterygopalatine ganglion and the maxillary artery.

Local anaesthetic injected into the pterygopalatine fossa spreads easily and a small amount of local anaesthetic is sufficient to provide adequate analgesia. The procedure is considered safe as long as care is taken to avoid vascular puncture and excessive needle advancement.

- 3. Edward R. et al. Can J Anesth 2009: 56: 584-589.

Learning points: Ultrasound-guided MNB combined with general anaesthesia may provide good analgesic effects and reduce opioid consumption.

12AP04-2

Crystallization of mixtures of local anaesthetics with and without adjuvants in human cerebrospinal fluid - A semiguantitative in-vitro study

E. Gasteiger¹, O. Stundner¹, H. Hegen², A. Seisl¹, M. Hollmann³, L. Gasteiger¹ ¹Innsbruck Medical University, Department of Anesthesiology and Intensive Care, Innsbruck, Austria, ²Innsbruck Medical University, Department of Neurology, Innsbruck, Austria, ³Amsterdam UMC, Department of Anesthesiology, & Pain Medicine, Amsterdam, Netherlands

Background and Goal of Study: The use of mixtures of Local Anaesthetics (LA) with or without adjuvants is common practice in regional anaesthesia (RA), especially in obstetric patients. Most of these mixtures are not approved by governing bodies, and evidence for clinically relevant efficacy is low or absent. Recent studies reported significant crystal formation in some widely used LA-LA / LA-adjuvant mixtures1.

This follow-up study aims to assess the behaviour of LA-LA and LA-adjuvant mixtures in human cerebrospinal fluid (CSF) as a model for interstitial fluid.

Materials and Methods: The ethics committee approved this study. Fractionated additions of human CSF with commonly used combinations of LA+LA or LA+adjuvants (see Table 1) were produced. These mixtures were subsequently assessed for Grade of Crystallization (GoC) using a semiquantitative light-microscope scale (Grade 0 to 5), repeated up to 24 hours.

Additionally, pH of the LA-(adjuvant)-CSF mixtures was assessed at baseline (t₀) and after 24 hours (t_{24b}).

Results and Discussion: All mixtures showed GoC of Grade 4 or 5 in a time-dependent pattern (Table 1). Particularly ropivacaine + dexamethasone and ropivacaine + lidocaine + sodium bicarbonate developed high-level GoC early after admixture.

Combination*	pH t ₀	pH t _{24h}	GoC t ₀	GoC t ₁₅	GoC t ₃₀	GoC t ₆₀	GoC t ₁₂₀	GoC t ₁₈₀	GoC t ₂₄
Cerebrospinal fluid (CSF)	7,7								
Ropivacine 0,75% + Mepivacaine 2% (1 : 1)**	7,0	7,21	1	2	2	3	2	3	5
Ropivacine 0,75% + Chloroprocaine 2% (1 : 1)**	7,3	7,13	3	3	3	4	5	5	5
Ropivacine 0,75% + Dexamethasone (15 : 1)**	7,1	6,97	4	5	5	5	5	5	5
Ropivacaine 0,75% + Lidocaine 2% + NaBic 8.4% (5 : 5 : 0,5)**	7,3	7,55	3	4	4	4	5	5	5
Lidocaine 2% + Ropivacaine 0.75% (1 : 1)**	7,1	7,28	2	3	3	3	3	4	4
Lidocaine 2% + NaBic 8.4% (10 : 1)**	7,4	7,92	1	2	3	2	2	2	4

^{*} Mixing ratio for mixture: CSF was 1:1; ** mixing ratio in brackets is between first, second (and third) substance. GoC = Grade of crystallization (0: crystal size < 10 μ m; 1: one solid body >10 μ m; 2: 2–10 solid bodies >10 µm; 3: > 10 solid bodies >10 µm or one solid body >50 µm; 4: > 100 solid bodies >10 µm, or more than one solid body >50 μ m, or one solid body >100 μ m; 5: > 100 solid bodies >10 μ m and more than one solid body >50 μ m or more than one solid body >100 μ m)

Table 1.

Conclusion: Our results raise concern about the safety of using these mixtures in RA, as they may form persisting particulate bodies. Several reports indicate the risk of severe neurological injury when particulate substances are injected for RA2.

Their use should be critically weighed against their clinical benefit.

12AP04-3

Median effective local anaesthetic volume for ultrasound guided parasacral sciatic nerve blockade: a prospective dose finding study

T. Samra¹, J.P. George¹, K. Jain¹ ¹Postgraduate Institute of Medical Education and Research, Anaesthesia and Intensive Care, Chandigarh, India

Background and Goal of Study: The parasacral sciatic nerve block (PSNB) is an effective approach for lower limb surgeries, however, the median effective dose of Ropivacaine required for ultrasound guided PSNB is yet undetermined.

This study aims primarily to find the median effective volume of 0.5% ropivacaine for the PSNB for surgical anesthesia in 50% and 95% patients (ED₅₀, ED₉₅).

Materials and Methods: Study was conducted after ethiclearance (IEC-INT/2023/MD-961) and trial registry (CTRI/2023/05/053126) on 55 American Society of Anesthesiologists physical status I-III patients, from the ages of 18 to 80 years, undergoing below knee orthopedic surgeries under combined ultrasound-guided femoral and PSNB. In this study, we chose 20 ml of 0.5 % Ropivacaine as the starting dose.

Contingent on the success of the block, the volume of local anesthetic was escalated or de-escalated using Dixon's up-anddown method by 2 ml. Sensory and motor blockade was evaluated at 5 minute intervals for a period of 30 minutes by grading on a 4-point scale. A score of 3 for sensory blockade and 2 or more for motor blockade was accepted as successful surgical anesthesia. Data was analysed using isotonic regression with a pooled adjacent violators algorithm and a bootstrapping approach to estimate the $\mathrm{ED}_{\mathrm{50}}$ and $\mathrm{ED}_{\mathrm{95}}$ of 0.5% Ropivacaine with confidence intervals (CI).

Results and Discussion: The volume of local anesthetic administered for PSNB was found to be in the range of 12 - 20 ml. Centered isotonic regression with a bias-corrected Morris 95% CI derived by bootstrapping showed ED₅₀ of 16.5 (15.4-17.7) ml and ED₀₅ of 19.6 (95% CI 19.4-22.4) ml.

Conclusion(s): In patients undergoing below knee orthopedic surgeries, a 20-ml dose of 0.5% Ropivacaine will likely generate effective surgical anesthesia on PSNB guided by ultrasound in 95% of patients.

References:

1. Hemraj C, Kalaivani M, Binu H, Ramachandran R. Application of isotonic regression in estimating ED, and its 95% confidence interval by bootstrap method for a biased coin up-anddown sequential dose-finding design. Indian J Anaesth 2023;67(9):828-83

12AP04-4

Non-intubated video-assisted thoracic surgery (NI-VATS) for complicated pleural effusion under pararavertebral, serratus anterior plane and cervical vagus nerve block in a patient with multiple co-morbidities - a case report

S.N. Roque¹, R. Nogoy¹, K. Abenojar¹ ¹The Medical City, Anesthesia, Pasig City, Philippines

Background: NI-VATS with peripheral nerve blocks and sedation is a safer alternative to traditional VATS, especially for elderly or critically ill patients with severe co-morbidities. Unlike traditional VATS, it avoids deep sedation and muscle relaxation required for intubation, addressing issues like pain and delayed diaphragm recovery that can lead to atelectasis. Cough suppression via cervical vagus block ensures better visualization of the operative field.

Case report: A 58-year-old male with heart failure (EF 57%, previously 25%), stage 5 chronic kidney disease, and pulmonary tuberculosis presented with dyspnea from complicated pleural effusion despite chest tube thoracotomy. He was positioned in the left lateral decubitus position, and five nerve blocks were performed under ultrasound quidance.

Ropivacaine 0.5% was used for Paravertebral Right T5 and T7 (7 mL each) and for Cervical Vagus Nerve Block (2.5 mL). Serratus Anterior Plane Block was performed using Ropivacaine 0.25% (15 mL).

Sedation was maintained with low-dose Propofol TCI (1-2.5 mcg/ mL) to allow spontaneous ventilation. The procedure was successfully completed.

Discussion: Single-lung ventilation under general anesthesia increases risks of pneumonia, cardiac performance issues, and neuromuscular complications due to sedation and muscle relaxation. NI-VATS avoids these risks by maintaining spontaneous breathing, thereby making it a viable alternative for pleural effusion and treatment3. Paravertebral and serratus anterior plane blocks provide effective post-operative analgesia, enabling early incentive spirometry to prevent atelectasis.

Cervical vagus nerve block suppresses coughing, ensuring a stable operative field without the need for intubation or lung isolation. This approach is ideal for high-risk patients with multiple co-morbidities.

References:

- 2. Zhang, Y., et al. Serratus Anterior vs Paravertebral Nerve Block for VATS: A Randomized Trial. Videosurgery and Other Miniinvasive Techniques, 2021.
- 3. Karadayı Ş, et al. The Role of Awake VATS in Pleural Effusion Diagnosis and Treatment. Turk Toraks Derg, 2013.

Learning points: Combining paravertebral, serratus anterior plane, and cervical vagus nerve block techniques is a safe and effective strategy for NI-VATS in high-risk patients with multiple co-morbidities.

12AP04-5

Evaluating the impact of erector spinae plane nerve catheters for rib fractures - Should we be inserting more as standard practice?

E. Veglio-Taylor¹, M. Welstand-Patel¹, M. Beardmore¹ ¹Royal Cornwall Hospital, Anaesthetics, Truro, United Kingdom

Background and Goal of Study: Rib fractures caused by blunt trauma are associated with significant morbidity and mortality. Treatment is supportive care through multimodal analgesia, focussed on preventing pulmonary complications. Inserting erector spinae plane (ESP) catheters has significant benefits without the risks of sedation and respiratory depression caused by opiates. In our institution, these are sited on the basis of age, comorbidity, analgesic requirements and chest wall injury (CWI) score. This study evaluated the benefits of ESP catheters in chest wall injuries (CWI) in a UK trauma unit.

Methods: We conducted a retrospective single centre study of all 216 patients presenting with a CWI at a UK trauma unit in 2022. Data was collated from electronic patient records and the Trauma Audit Research Network database. Our data included CWI (STUMBL) scores, Rockwood frailty scores, total opiate consumption and length of hospital stay.

Results and Discussion: Patient demographics are summarised in Table 1.

	ESP	No ESP
Average Age	57.1	76.5
Rockwood Frailty Score	3.1	4.6
Chest Wall Injury Score	22.8	18.7
Length of Hospital Stay Isolated Chest Wall Injuries (Days)	8.4	12.9

Table 1.

Patients with ESP catheters were younger and less frail with higher CWI scores. However mortality risk is greatest in the older population with an average age of 80 compared to 72 in survivors, confirming that this group is most vulnerable to complications. To exclude the confounding effect of other injuries, we reviewed the 30 patients who had sustained an isolated CWI, 11 of whom received ESP analgesia. These patients spent an average 4.5 days fewer in hospital compared to those without. Patients with a CWI >30 had a significant reduction in daily morphine consumption, see Figure 2.

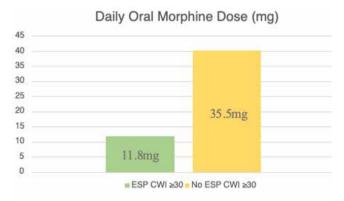

Figure 2. Graph showing daily oral morphine dose in patients with and without an ESP catheer in context of a CWI score >30.

Conclusion: The data demonstrates the significant benefits of ESP catheters for CWI patients, especially in reducing opiate consumption and length of hospital stay.

Future treatment pathways should lower the thresholds for catheter insertions in the older, frailer population given their higher risk of mortality.

12AP04-6

Perioperative analgesic management for sacral chordoma resection in two stages: a case report

V. Fernández¹, I. González Del Pozo¹

'Hospital Central de la Defensa Gómez Ulla,
Anesthesiology, Madrid, Spain

Background: Chordoma is one of the most common tumors of the spine, which benefits from extensive en bloc surgical resection. These types of surgeries, performed in two stages, are longlasting, highly complex, and that involve extensive and radical resection are exceptional and pose a significant challenge from an anesthetic perspective.

Opioids are considered the treatment of choice for both intraoperative and postoperative pain, with intrathecal morphine being one option to consider in this context⁽¹⁾.

Case report: The multidisciplinary approach for an en bloc resection of sacral chordoma in two surgical stages is described, where pain control both intraoperatively and postoperatively was based on the use of intrathecal morphine (400 and 350 micrograms, respectively) combined with multimodal analgesia under general anesthesia.

The patient had good pain control, with only one episode of nausea and vomiting after the first surgery and no episodes of respiratory depression.

Discussion: The administration of intrathecal morphine is a simple and quick procedure with a low complication rate. The "analgesic ceiling" beyond which the adverse effects outweigh the analgesic benefits has not been well established.

Although intrathecal morphine has been shown to reduce opioid requirements both intraoperatively and postoperatively, it is known to increase the risk of adverse effects such as nausea, vomiting, and respiratory depression, among others ⁽²⁾.

References:

- 1. Meylan N, Elia N, Lysakowski C, Tramèr MR. Benefit and risk of intrathecal morphine without local anaesthetic in patients undergoing major surgery: meta-analysis of randomized trials. *British Journal of Anaesthesia*. 2009;102(2):156–167.
- 2. Fléron MH, Weiskopf RB, Bertrand M, et al. A comparison of intrathecal opioid and intravenous analgesia for the incidence of cardiovascular, respiratory, and renal complications after abdominal aortic surgery. *Anesthesia and Analgesia*. 2003;97(1):2–12.

Learning points: In our experience, for highly complex surgeries that, due to their characteristics, result in significant postoperative pain, the optimal dose may be between 4.5-5 mcg/kg of intrathecal morphine, always including prophylactic treatment for postoperative nausea and vomiting.

12AP04-7

Comparative evaluation of deep versus superficial erector spinae plane blocks for post-operative analgesia in modified radical mastectomy

K.J. Bhinde¹, K.N. Saxena¹, L. Gupta¹, B. Wadhwa¹, S. Kerai¹ Maulana Azad Medical College and Associated Hospitals, Department of Anaesthesiology, New Delhi, India

Background and Goal of Study: The Erector Spinae Plane (ESP) Block is a promising technique for post-operative analgesia across various surgical procedures. Two distinct approaches have been described¹: the Superficial and Deep ESP Blocks.

This study aimed to compare the duration and quality of analgesia provided by these two techniques in female patients undergoing Modified Radical Mastectomy (MRM).

Materials and Methods: After approval from the IEC, we conducted a prospective, double-blinded, randomized comparative study. 44 ASA I and II female patients, aged 18-65 years, scheduled for MRM, were randomly assigned to either Group DES (Deep ESP block) or Group SES (Superficial ESP block). After administering general anesthesia, the block was performed as per the allocated group with 20 mL 0.25 % Bupivacaine and 6 mg Dexamethasone at T4 level. CONOX® (Fresenius Kabi) monitor was used to assess intra-operative analgesia and administer additional fentanyl boluses. Post-operatively, the time to the first request of rescue analgesia, NRS scores and total analgesic consumption over 24 hours were recorded. The Unpaired t-test, Mann-Whitney U Test (Continuous variables) and Chi square tests (Categorical variables) were used for statistical analysis.

Recorded Parameter	Group	Group	p-value
	DES	SES	(Statistical Test)
Percentage of patients requesting rescue analgesia within the study period of 24 hours post-operatively	18.2 %	63.6 %	0.002 (Chi Square Test)
Time to first request of rescue analgesic in hours (mean \pm SD)	9.875	10.429	0.721
	± 5.1377	± 4.3494	(Mann-Whitney U Test)
NRS scores at 12 hours post-operatively (mean ± SD)	0.55	1.86	0.010
	± 1.224	± 1.885	(Mann-Whitney U Test)
Analgesic consumption over 24 hours post-operatively in mg of diclofenac (mean \pm SD) (neither group had requirement of the second rescue analgesic tramadol)	17.05	51.14	0.004
	± 39.63	± 42.59	(Mann-Whitney U Test)

Table 1: Post-operative parameters recorded.

Results and Discussion: In the Deep ESP Block group, the cranio-caudal spread of the drug was likely to be more and hence covered multiple dermatomes. In the Superficial ESP block, the drug would need to cross an additional muscle layer in order to reach its site of action.2

Conclusion(s): Both the Deep and Superficial ESP Blocks had significant opioid-sparing effects. The Deep ESP Block provides superior and longer-lasting postoperative analgesia compared to the Superficial ESP Block in patients undergoing Modified Radical Mastectomy.

Possible local anesthetic systemic toxicity following ultrasound-guided bilateral paravertebral block with ropivacaine

C. Amarante Dias¹, A. Leite Moreita² ¹Unidade Local de Saúde da Região de Aveiro. Anestesiologia, Aveiro, Portugal, 2 Unidade Local de Saúde de São João, Anestesiologia, São João, Portugal

Background: Local Anesthetic Systemic Toxicity (LAST) is a rare but potentially life-threatening complication of local anesthetics. Its pathophysiology is primarily understood through animal models and case reports. This case reports a possible LAST following a bilateral ultrasound(US)-guided paravertebral block with ropivacaine.

Case Report: A 75-year-old male with a mandibular tumor causing limited mouth opening (~1cm) was admitted electively for computed tomography (CT)-guided percutaneous endoscopic gastrostomy placement. The anesthetic plan involved sedation followed by bilateral US-guided paravertebral block, level T8 with 135mg ropivacaine on each side, totalling 3mg/kg. Seconds after the second injection, the patient experienced a generalized tonicclonic seizure.

Emergency anesthesia team and internal emergency team were alerted, and the patient was repositioned, oxygenated, and given 10 mg of intravenous diazepam, terminating the seizure. Due to persistent bradypnea and postictal state, emergent nasotracheal intubation was performed.

Following the event the patient displayed return of motor function and intact pupillary reflexes. Hemodynamic stability and sinus rhythm were maintained throughout. The procedure was completed without further complications, and the patient was extubated about 2 hours after the event with no complications.

Discussion: The seizure was most likely due to Local Anesthetic Systemic Toxicity (LAST). Accidental local anesthetic injection into the neuraxis was unlikely given the US-guided technique and the absence of motor or sensory deficits shortly after the event. A new-onset epilepsy was ruled out by neurology and a brain CT excluded intracranial lesions. A transient low cardiac output event, such as vasovagal syncope, was not detected but cannot be excluded.

The rapid onset suggested a systemic reaction to ropivacaine, either from unnoticed intravascular injection or absorption after the first injection. Bilateral paravertebral blocks carry a recognized risk for LAST due to their proximity to major vascular structures.

Reference: Gitman M, Reg Anesth Pain Med. 2018

Learning Points: LAST is a rare but serious complication of local anesthetic use, especially in techniques involving proximity to blood vessels.

Early recognition and intervention, including airway management and seizure control, are crucial for patient safety.

Ultrasound guidance may reduce but does not eliminate the risk of LAS

12AP04-9 **Epidural catheter: how long is too long?**

J. M. Cabral¹, D. Fernandes², A.R. Teles¹, S. Fonseca¹ ¹ULS São João, Anesthesiology Department, Porto, Portugal, 2ULS São João, Intensive Care Department, Porto, Portugal

Background: Existing literature on infection rates associated with epidural catheters focuses on short-term use, and ranges from 0.8 to 4.9%. Prolonged use of epidural catheters lacks definition and remains controversial, owing to potentially increased infec-

This study aims to assess the incidence of epidural catheter-related infection when the catheter remains in situ beyond 10 days. Methods: A single-centre, retrospective cohort study was conducted, including all adult patients followed by the Acute Pain Unit from 2021 to 2022 who had an epidural catheter in place for a minimum duration of 10 days.

The primary composite outcome was the occurrence of any catheter-related infection, defined as skin and soft tissue infections or radiologically confirmed spinal space infections, requiring either medical or surgical intervention. Cases of self-limited local inflammatory signs were excluded.

Results: Among 2872 adult patients with continuous epidural analgesia, 347 met the inclusion criteria. Most were male (66.6%), with a median age of 64 years. The majority of epidural catheters (73.2%) were placed for a surgical procedure, most frequently at a thoracic level (51.9%). The duration of catheter use ranged from 10 to 92 days.

The overall incidence of catheter-related infection was 1.7% (95%) CI 0.7 - 3.9%). Three patients (0.9%) had skin or soft tissue infections managed with medical treatment, two (0.6%) had a spinal infection treated conservatively, and one (0.3%) developed an epidural abscess requiring surgical intervention. Catheters were removed at the first sign of infection in all six cases, which occurred after a mean duration of 42 days. Despite the infection, no cases of permanent functional impairment or mortality were reported.

Conclusion: In our study, 98% of epidural catheters in situ for more than 10 days remained infection-free, a rate similar to that previously described for short-term use.

However, in the absence of a clear definition of prolonged catheter use, the potential severe risks still warrant careful considera-

Periarticular infiltration analgesia vs. continues femoral nerve block for post operative pain managment in knee arthroplasty - a single center retrospective cohort study

R. Almaktoumi¹, F. Alhinai²

¹Oman Medical Speciality Board, Anesthesia, Alkhoud, Oman, ²Armed Forces Hospital, Anesthesia, Muscat,

Background and Goal of Study: Pain control in Total Knee Arthroplasty surgeries (TKA) is crucial for surgical outcomes and currently two widely used methods including Continuous Femoral Nerve Block (CFNB) catheter and Peri-articular Infiltration Analgesia (PAI) performed by surgeon.

The primary objective to evaluate the efficacy of PAI combined with single-shot adductor canal block compare with CFNB by assessing pain scores at rest and during movement at 24 and 48 hours following unilateral TKA surgeries performed under spinal anesthesia using low volume, low concentration of Local anesthetic with weak opioid (tramadol) as rescue analgesia in postoperative period.

The secondary objective to assess the safety profile of both analgesic methods by examining their adverse effects, and impact on length of hospital stay.

Materials and Methods: Retrospective Cohort Study done in Armed Forces Hospital for patients underwent elective unilateral TKA surgery under spinal anesthesia between January 1, 2020, and February 29, 2024.

Data including patients demographics, pain score at rest and during movement at 24&48 hours postoperative, medications side affects, frequency of using rescue analgesia(tramadol 50 mg po if VAS score >4), and length of hospital stay in days were all col-

Results and Discussion: A total of 179 patients were analyzed. 91 patients in CFNB group and 88 patients in PAI, there was no statistically significant difference between two groups comparing patient age, weight, gender, side of surgery, ASA physical state and pain scores at rest and during movement at 24 & 48 hours. PAI group shows increased tramadol requirement at 24 and 48 hours post-operation(50mg, 100 mg) respectively while CFNB consumed (0 mg,50 mg)respectively with p value < 0.01.

Our finding support that PAI group has shorter length of hospital admission with mean 5.27 days comparing to 6.26 days in CFNB with P-value < 0.001. Recorded side effects including nausea/ vomiting in 14 patients from PAI and 7 patients CFNB (P value 0.106) and constipation (7 PAI, 6 CFNB) with P-value of 0.78.

Conclusion(s): PIA demonstrates good efficacy in post-TKA pain control, early mobilization (not examined in our finding but evidence showed that CFNB associated with greater risk of quadriceps weakness), cost-effectiveness and ease of use.

Shorter hospital stay makes PIA suitable for Enhanced Recovery After Surgery(ERAS) protocols. It's recommended choice for postoperative analgesia in TKA surgeries.

12AP04-11

Advancements in regional anesthesia: the external oblique intercostal plane block as a game changer in upper abdominal surgery

J. Fernández Ruiz¹, M. Blesa-Ripollés¹, J. Llopis Lorente¹, S. Coeckelenbergh², O. Díaz-Cambronero³, M.P. Argente-Navarro⁴ ¹Hospital Universitario y Politécnico La Fe, Department of Anesthesiology, Valencia, Spain, ²Hôpitaux Universitaires Paris-Saclay, Department of Anesthesiology and Intensive Care, Orsav, France, ³Hospital Universitario v Politécnico La Fe, Head of Perioperative Medicine - Department of Anesthesiology, Valencia, Spain, 4Hospital Universitario y Politécnico La Fe, Head of Anaesthesiology and Resuscitation Department, Director of Anaesthesia, Resuscitation and Surgical Block, Valencia, Spain

Background and Goal of Study: The field of interfascial plane blocks has rapidly evolved, with the transversus abdominis plane (TAP) block serving as a fundamental technique that has sparked numerous derivative regional anesthetic approaches including subcostal TAP variations and the erector spinae block. Current evidence reveals limitations in existing fascial plane block techniques, particularly the subcostal TAP block.

Despite providing moderate analgesia for midabdominal incisions, this approach demonstrates insufficient analgesic potential for surgeries involving lateral abdominal wall such as hepatobiliary surgeries. Initially described by Hamilton et al., the external oblique intercostal plane block (EOIPB) represents an innovative regional anesthetic approach targeting upper lateral abdominal regions.

Clinical studies confirm its effectiveness delivering local anesthetics precisely to intercostal nerve branches across T6/7 to T10/11 segments, providing reliable pain management for lateral and anterior abdominal wall regions.

While 2024 PROSPECT guidelines recommend port-site infiltration or TAP block for laparoscopic cholecystectomy, emerging evidence highlights the EIOPB as a potentially superior regional technique.

The objective of this literature review is to evaluate the current evidence regarding EOIPB for upper abdominal surgeries.

Materials and Methods: We performed a search in the main databases with keywords "external oblique intercostal block" identifying 41 articles. After reading the abstracts 8 RCT were finally selected.

Results and Discussion:

See table, next page.

Conclusion(s): To our knowledge this is the first review published to date related to EOIPB for the perioperative pain management in upper abdominal wall surgeries.

Although existing literature suggests EOIPB may demonstrate potential superior analgesic efficacy, the current evidence remains limited, and further randomized studies are essential to conclusively establish its clinical effectiveness.

Name of first Author	Study Design	Intervention	Control	Anesthesia type/ intraop analgesia	Postop analgesia	Primary Outcome	Secondary outcomes	Differences between groups
Mo, K et al. (Oct. 2024).	RCT. TAP vs. EOIPB for laparoscopic cholecystectomy. N = 49	EOIPB group received UG-EOIPB combined with an RSB (rectus sheath block).	UG-TAP combined with an RS block.	Fentanyl (2 µg/kg), propofol (2–3 mg/kg), and rocuronium (0.1 mg/kg). Paracetamol (1 g) was administered intravenously 30 min before the end of surgery, followed by every 8 h.	1 g paracetamol iv every 8 hours and tramadol (15 mg iv bolus, 15 min locking) with a patient-controlled analgesia (PCA).	Postoperative 24-hour sufentanil consumption.	NRS scores in PACU and at 1, 6, 12, and 24 h postoperatively	The postoperative 24-hour suferitanil consumption in the EOI group was significantly lower than that in the TAP group ($P < 0.01$). Fewer patients in the EOI versus TAP group had a numerical rating score of >3.
Mehmet Selim, Ç et al. (Aug 2024).	RCT. EOIB group vs. oblique subcostal transversus abdominis plane block (Group OSTAP) for laparoscopic cholecystectomy.	For EOIB, 20 mL of bupivacaine, 25% was applied to the tissue plane between the external oblique and intercostal muscles and between the sixth and seventh ribs. N = 36	In the OSTAP block, 20 mL of bupivacaine .25% was applied to the fascia between the rectus abdominis and transversus abdominis muscles. N = 34	2 mg iv midazolam, 2 mg/ kg iv propofol, 6 mg/kg iv rocuronium, and 2 mcg/kg iv fentanyl. Anesthesia was maintained using sevoflurane at MAC 1 and remifentanil.	Perioperatively, 1 g paracetamol iv and 100 mg tramadol iv. As postoperative analgesics, 1 g paracetamol iv every 8 hours and tramadol (without basal infusion, 15 mg iv bolus, 15 min locking) with a patient-controlled an	Postoperative pain was assessed at 1st, 2nd, 4th, 6th, 8th, 12th, 18th, and 24th hours using VAS scores.	(1)Postoperative tramadol consumption was recorded as 0.4, 4-8, 8-16, 16-24 hours time intervals, and 24-hour total values. (2)Time to first analgesic requirement (imitudes), (3)Opioid-related postoperative nausea and vomiting.	There was no statistically significant difference between the groups in terms of postoperative VAS scores or transdol consumption at all time intervals ($P > .05$). The groups did not exhibit any statistically significant variance in terms of 24-hour transdol consumption ($P > .05$). Differences between the groups did not reach statistical significance in terms of time to first analgesic requirement ($P > .05$)
Kavakli, AS. et al. (May 2024).	RCT. EOI block group vs. control group for lapa- roscopic sleeve gastrectomy.	Ultrasound-guided bilateral EOI block with a total of 40 ml 0.25% bupivacaine after anesthesia induction (20 ml each side), N = 28	No intervention. N = 29	Midazolam 0.1 mg kg-1, propofol 2 mg kg-1, and rocuronium 0.6 mg kg-1, in addition to 100 μg of fentanyl. Anesthesia was maintained using sevoflurane at MAC 1 and remillentani. Tramadol 100 mg and paracetamol 1 gr // were also administered for postoperative analgesia.	Bolus of 2 mg IV morphine if the NRS score was greater than 4, and this was repeated every 10 min until the NRS score was below 5. Patients were connected to the intravenous PCA device on discharge from PACU. The PCA device consisted of 0.5 mg mi-1 morphine and was programmed to deliver a bolus dose of 1 mg morphine only on patient demand with a 8-min lockout time and 6 mg 1-1 limit.	IV morphine consumption in the first postoperative 24 h.	Rescue morphine dose in PACU (1); NRS scores in PACU and at 1, 6, 12, and 24 h postoperatively (2); rescue analgesia requirement (3); incidence of postoperative nausea and vomiting (4):	The total cumulative morphine dose in the first postoperative 24 h was lower in patients who received EOI block compared with the control group. Morphine was required by 15 EOI block group patients in the PACU compared to 26 patients in the control group (p=0.002). Postoperative NRS scores at rest were significantly lower in the EOI block group than in the control group at 1, 6, and 12 h (p=0.003, p=0.011, p=0.022, respectively). The postoperative NRS scores during movement were significantly lower in the EOI block group than in the control group until 12 h postoperatively and were then seen to be similar in both groups at 24 h. There were no significant differences between the two groups in respect of postoperative nausea and vomiting (p=0.360, p=0.529, respectively).
Doymus, O. et al (Dec 2023).	RCT. EOI vs. port-site infiltration (PSI) for laparoscopic bariatric surgery		5 ml of 0.25% bupivacaine (25 ml in total) was applied under the aponeurotic layer at each port entry site by the surgeon. N = 27	The same general anesthesis protocol was applied to all patients (not described in the article).	Paracetamol 1000 mg IV was given to each patient 30 min before the end of surgery and repeated every 6 h in the postoperative period. A patient-controlled analgesia device (PCA) was implanted iv in the PACU. The PCA device prepared with fentanyl was programmed with a concentration of 10 mcg/ mi, 15 min locked time, 25 mcg bolus, and no basal infusion and continued for 24 h.	VAS scores during resting at PACU, 1, 2, 4, 8, and 12 h postoperatively.	VAS score in active movement (1): 24-h postoperative fentanyl consumption (2); rescue analgesia (3).	The VAS scores were significantly higher during resting at PACU, 1, 2, 4, 8, and 12 h postoperatively in the PSI group than in the EOI group (p<0.05). The VAS scores were also significantly higher during active movement at PACU, 1, 2, 4, and 8 h postoperatively in the PSI group than in the EOI group (p<0.05). The 24-h postoperative fentanyl consumption was significantly higher in the PSI group (p<0.001). The number of patients requiring rescue analgesia was 14 in the EOI group and 26 in the PSI group (p=0.001).
Gangadhar, V. et al. (Jan 2024).	RCT. Right-sided EOIB + left sided RSB group VS. L1A group for laparoscopic cholecystectomy		LIA group underwent local infiltration at the political properties of the same solution (n=35)	General anesthesia was induced using fentany (2 gugkg), a titrated dose of propofu (2-3 mg/kg), and vecuronium (0.1 mg/kg). The airway was secured with an appropriately sized Proseal larryngeal mask airway. Paracetamol (1 g) was administered intravenously 30 min before the end of surgery, followed by every 8 h.	The time for rescue analgesia was defined as the time from block performance to the first dose of rescue analgesia. Rescue analgesia in the form of tramadol 1 mg/kg intravenously was administered on demand or if the VAS score was 4 or higher.	VAS at 1 h postoperatively.	The secondary outcomes included VAS scores for 24 h, time to first rescue nadipsis, cumulative 24-h analgesia requirement, and patient satisfaction.	that in the LIA group at 1 h, 2 h, 4 h, 8 h, and 12 h (all P < 0.001).
Turunc, E. et al. (Sep 2024).	RCT. Double blinded study. EOI block VS. M-TAPA (Modifed Thoracoabdo- minal Nerve Block Trough Perichondrial Approach) block for laperoscopic cholecystectomy	30 ml of 0.25% buplivaciane was injected into the plane between the external oblique-intercostal muscles between the 6th-7th ribs. The same process was repeated for the other side. N = 30	30 ml of 0.25% bupinecatine was injected into the midclavicular line, between the upper fascial of the transversus abdominsuscle and the lower fascial of the costochondral tissue, at the level of the 9th and 10th ribs. N = 28	Intravenous tramadol 100 mg and IV tenoxicam 20 mg were administered after induction, and IV morphine 0.05 mg/kg was added in the intraoperative period. Intravenous infusion of paracetamol (1 g), and ordansetron (8 mg) was administered 30 min before the end of the surgical procedure.	patients. PCA settings were adjusted: demand dose 20 µg/kg of morphine, lock-out time 8 min, and 4-h limit 80% of the total maximum achievable dose. In cases	Cumulative morphine consumption within the first postoperative 24 h.		In the postoperative 12th and 24th h, there was no statistically significant diference between the groups in terms of morphine consumption. Time to the first opioid demand from PCA, and number of patients using rescue analgesia and antiemetics were similar between the two groups (p>0.05). There were no significant differences between the groups in postoperative NRS resting/activity pain and PCNV scores at all measurement points. When considering the total CoR-15 scores of the groups, it was observed that the pre-operative, postoperative 1st day, and discharge scores were similar in both groups.
Suzuka, T. et al. (Jul 2024).	RCT. EOIB vs. Wound infiltration for laparoscopic gastrectomy	Following anesthesia induction, 20 mL of 0.25% levolupivacaine per side (total 40 mL). N = 15	The surgeon administered 40 mL of levobupivacaine (0.25%) to the peritoneum, fascia, and subcutaneous tissue via five port holes using a 23 gauge short needle before closure. N = 17	All participants underwent general anesthesia with 15-2 mg/kg propordi and 0.9 mg/kg rocuronium, fentanyl, and remilientanil for induction and were maintained with sevoflurane, remilientanil, and fentanyl, and return the proposition of the proposition of the proposition of the participant of the p	Patients received intravenous fentaryl patient-controlled analgesia with a fentaryl concentration of 0.5 µg/kg/mL, no basal flow, a bolus 1 mL on demand, and a 10-min lock-out interval.	Numeric rating scale (NRS) score 12 h after surgery.	NRS scores at 2 h postoperatively and on postoperative days (POD) 1 and 2 (1) postoperative days (POD) 1 and 2 (1) postoperative florations in quality of recovery (OGR-15 scores from preoperative baseline to POD 1.2, and 7 (3), and variations in World Health Organization Disability Assessment Scale 2 (D WHODAS 2.0) scores between baseline and 3 months post-surgery (4).	No differences in the NRS scores 12 h postoperatively at rest and during movement between the two groups: EOIB vs. WI. There were no significant differences in any of the secondary outcomes between the two groups, including postoperative fentanyl consumption and WHODAS 2.0 scores.

Recognizing and managing cerebrospinal fluid cutaneous fistulas: a case report

A.R. Mateus¹, F. Santos¹, A.C. Barros¹, L. Gonçalves¹, E. Valente¹

¹Local Health Unit of the Leiria Region, Anesthesiology Department, Leiria, Portugal

Background: Neuraxial techniques are considered the gold standard in obstetric anesthesia, for both labor analgesia and cesarean section.

Cerebrospinal fluid (CSF) cutaneous fistula is a rare complication of these procedures. As such, diagnosis may be delayed and specific management recommendations are lacking.

Case Report: A 35-year-old woman, ASA II, G2P1, at 39 weeks gestation, underwent a cesarean section due to failure of labor progression. A combined spinal-epidural was performed at first attempt, using an 18G Tuohy and 27G spinal needle. The surgical procedure was uneventful, and postoperative pain was managed with epidural morphine boluses.

On postoperative day 3, a few hours after the removal of the epidural catheter, a clear fluid drainage was noted through the puncture site. The patient was asymptomatic, with no signs of post-dural puncture headache or meningeal irritation. A quick glycemic test confirmed the presence of glucose, which suggested the diagnosis of a CSF cutaneous fistula.

After discussing the case with the Neurology and Neurosurgery Teams, the puncture site was sutured, and the patient was advised to maintain hydration and bed rest. No further leakage was observed

The patient was discharged on postpartum day 4, with no additional complications.

Discussion: When clear fluid is draining from the epidural site, it is important to differentiate between CSF, interstitial fluid and local anesthetic. Glucose tests provide a quick way of diagnosing CSF leakage and can guide management while awaiting definitive results from beta-2 transferrin or beta-trace protein testings.

Factors that may delay healing at the puncture site include immune compromise, multiple puncture attempts and the use of epidural steroids. Asymptomatic patients can often be effectively treated with minimally invasive measures such as suturing the epidural site, hydration and bed rest.

While some studies suggest using antibiotic prophylaxis to prevent meningitis, evidence is limited.

Reference:

Tsai A, Ahmed S, Wang J. Persistent cerebrospinal fluidcutaneous fistula after epidural analgesia: a case report and review of literature. Journal of Anesthesiology and Clinical Science, 2014

Learning Points: Anesthetic and obstetric teams should be mindful of this rare but possible complication associated with neuraxial techniques. This case highlights the effectiveness of conservative and minimally invasive approaches as reliable treatment options for CSF cutaneous fistula.

12AP05-2

Crystallization and pharmacological stability of local anesthetics in mixtures with dexamethasone for perineural administration

M. Dzhopua¹, V. Avetisian¹, B. Ezugbaya¹, W. Akuffo-Addo², V. Koryachkin³ ¹Ilyinsky Hospital, Department of Anesthesiology, Moscow, Russian Federation, 2Warsaw University of Medicine, Department of public health, Warsaw, Poland, 3St. Petersburg State Pediatric Medical University, Department of Anesthesiology, St. Petersburg, Russian Federation

Background and Goal of Study: Perineural administration of dexamethasone is unauthorized and may increase the risk of crystallization. However, it is often used as an adjuvant in regional anesthesia. In our study, we sought to investigate whether the severity of crystallization of different anesthetics remains the same when dexamethasone is added, what factors influence this process, and whether new compounds are formed during mixing.

Materials and Methods: The study evaluated the crystallization and pharmacological stability of the combination of local anesthetics with dexamethasone, using light microscopy, pH measurement and HPLC.

Results and Discussion: The crystallization process was more evident in the samples with 0.33% levobupivacaine, and the crystal sizes ranged from 37 to 108 µm, significantly exceeding the crystallization process in the samples with 0.33% ropivacaine (Fig.1). The study supported the hypothesis that there is a correlation between the crystallization process and hydrogen index (pH) level of the solution (Table 1). Calculations of the degree of separation according to the formula used Rs=2xa/(W-1+W-2) showed that the partition coefficients of dexamethasone with ropivacaine and levobupivacaine are 2.0 and 4.1 respectively, indicating complete separation of the drugs without chemical reaction since the partition coefficient >1.0.

Conclusion(s): Our study demonstrated that HPLC analysis did not reveal new compounds or structural changes from the medication source. Crystallization of local anesthetics with dexamethasone is pH-dependent: initial lower pH values lead to more evident crystallization.

Drugs and their mixtures	pH (22°C)	pH (37°C)
Dexamethasone p.	7,79	
Ropivacaine 0.33%	6,26	
Levobupivacaine 0.33%	5,59	
Ropivacaine 0.33%+dexamethasone 40% (20:2)	6,79	6,3
Levobupivacaine 0.33%+dexamethasone 40% (20:2)	6,70	6,4

The effectiveness of transverse abdominis plane block for postoperative pain management after category one emergency cesarean section with general anesthesia

N. Sakai1, K. Kira1, T. Michino1 ¹Daiyukai General Hospital, Dep. Anesthesiology, Ichinomiya, Japan

Background and Goal of Study: The PROSPECT recommends transverse abdominis plane block (TAPB) as a postoperative pain method after cesarean section (C-section) under spinal anesthesia with intraoperative paracetamol and non-steroidal anti-inflammatory drugs (NSAIDs) [1].

However, there is no evidence for pain management for category one emergency C-sections with general anesthesia, which are highly urgent situations for surgical delivery.

Our retrospective research examined the effectiveness of postoperative pain relief after ultra-urgent C-section with or without TAPB under a multimodal analgesia regimen.

Materials and Methods: We collected the medical records of the category one emergency C-sections under general anesthesia from April 2012 to October 2024. All patients received a patientcontrolled intravenous analgesia (IV-PCA) with fentanyl, a regular prescription of paracetamol and NSAIDs, in addition to a rescue analgesia under a multimodal analgesia regimen. Patients were divided into two groups: those with TAPB after surgery (TAP; n = 17) and those without (no TAP; n = 23).

Outcome measures of group comparison were postoperative pain scores, number of requests for and time to first use of postoperative supplemental analgesics, and time to completion of postoperative ambulation.

Results and Discussion: The postoperative NRS pain score at one hour after C-section was 2 [0-6] in TAP and 3 [0-7] in no TAP (p = 0.045); however, there was no difference in the other time points. The time to first use of supplemental analgesics was not different; otherwise, the achievement time for ambulation was significantly earlier in patients who received TAP (32 hours in no TAP v.s. 23 hours in TAP; p = 0.007).

The effectiveness of TAPB is limited only to somatic pain, and the systemic administration of opiate, paracetamol, or NSAIDs suppresses painful uterine contraction.

Conclusion: It is possible to achieve early postoperative pain relief and early ambulation by a multimodal analgesia regimen and performing a TAP block after a category one emergency C-section. Ultra-emergency cesarean section is a rare and time-sensitive procedure; therefore, it isn't easy to conduct prospective studies; however, evidence can be obtained by accumulating data.

Fascia iliaca plane block - an anesthetic alternative

P. Pinto¹, A.B. da Gama Cunha Soares¹, J. Ribeiro², A. Resende², L. Ormonde²

¹Instituto Português de Oncologia de Lisboa Francisco Gentil, Anesthesiology, Lisbon, Portugal, ²Unidade Local de Saúde de Santa Maria, Anesthesiology, Lisbon, **Portugal**

Background: Peripheral regional anesthesia oftentimes is a helpful alternative in high-risk patients, where general and neuraxial anesthesia can cause severe complications. Fascial plane blocks (FPB), like the fascia iliaca (FIPB), are a specific kind of peripheral block where the target of injection is the plane between fascial lavers in which certain nerves run.

Typically FPB are used as an analgesic technique, but they can also be successfully applied as an anesthetic strategy, avoiding general and neuraxial anesthesia. The FIPB can be performed above or below the inguinal ligament and consists in the injection of a large volume of local anesthetic in the iliac fascia that disperses and blocks the femoral and lateral femoral cutaneous nerves.

Case Report: This case depicts a 78-year old male who presented to the ER with sudden intense pain on his leg. He had a history of severe peripheral artery disease already subjected to multiple surgeries and was diagnosed with critical limb ischemia. He was also hemodynamically unstable and bradycardic (30 bpm) and his ECG showed a previously unknown 3rd degree AV block. He underwent emergency pacemaker implantation before going to the OR for a femoral thromboembolectomy, despite maintaining cardiogenic shock with need of aminergic support with noradrenaline and dobutamine.

We opted for an US-guided suprainguinal approach FIPB with 40mL of ropiyacaine 0.375%, verifying good dispersion. Total anesthesia of the surgical territory was achieved, without need for surgical local anesthesia.

A small infusion of propofol was maintained for patient comfort (BIS 80). The surgical procedure was performed successfully. and the patient maintained the same hemodynamic status.

Discussion: Our goal with this case report is to share the usefulness of FPB in solving anesthetic conundrums, where general and neuraxial anesthesia are contraindicated or could be related with severe complications.

In this case, the suprainguinal approach to the FIBP proves to be a successful alternative for procedures of the anterior thigh, such as the femoral thromboembolectomy.

Chin KJ, Versyck B, Elsharkawy H, et al. Anatomical basis of fascial plane blocks. Regional Anesthesia & Pain Medicine 2021;46:581-599.

https://acesse.dev/nysora-fipb

Learning Points: FPB are a useful anesthetic alternative in high risk patients for some surgical procedures; Suprainguinal fascia iliaca plane block is an option for femoral thromboembolectomy.

12AP05-5

Gastrostomy tube insertion under ultrasound-quided bilateral rectus sheath and external oblique intercostal plane blocks in a patient with glottic squamous cell carcinoma and superior vena cava syndrome - a case report

S.N. Roque¹, R. Nogoy¹ ¹The Medical City, Anesthesia, Pasig City, Philippines

Background: Larvngeal carcinoma can cause oral obstruction requiring gastrostomy tube placement. In addition to airway complications, co-morbidities like superior vena cava syndrome may lead to cardiovascular collapse during anesthetic management. A gastrostomy was successfully performed using ultrasound-guided peripheral nerve blocks.

Case Report: A 61-year-old male with laryngeal carcinoma, posttracheostomy and total laryngectomy, presented with poor oral intake and facial swelling. He was high-risk for general anesthesia and declined certain life-sustaining measures. The patient was placed in the supine position with a size 5 endotracheal tube inserted via the tracheostomy.

Bilateral rectus sheath blocks (RSB) and external oblique intercostal (EOI) blocks were administered under ultrasound guidance using an in-plane approach.

Incremental doses of 0.25% Bupivacaine (20 mL for RSB and 24 mL for EOI) were injected. Sedation was achieved with Sevoflurane at a MAC of 0.8-1, maintaining spontaneous ventilation. The procedure was successfully completed.

Discussion: The gastrostomy was necessary for nutritional support as part of palliative care. General and spinal anesthesia were avoided to minimize the risk of hemodynamic instability and cardiovascular collapse.

RSB provided somatic anesthesia to the anteromedial abdominal wall, effectively managing incisional pain, EOI blocks supplemented this by targeting retraction pain from the anterolateral abdomen (T7-T11 dermatomes).

These blocks reduced anesthetic requirements and postoperative pain medication needs, making them suitable alternatives in critically ill patients.

Ultrasound-guided nerve block from 1994 to 2024: a bibliometric and visualization perspective

X. Yu-fan¹, P. Liang²

¹Sichuan Uuniversity, West China School of Medicine, Chengdu, China, ²West China Hospital, Sichuan University, Day Surgery Center, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: Ultrasound-guided nerve block (UGNB) has witnessed three decades of development and significant advancements

This article is to review the evolution of UGNB, identify current research hotspots, and outline future developmental prospects for the global research community.

Materials and Methods: We selected original articles and reviews related to UGNB from the WoSCC database. Utilizing tools including VOSwiewer, CiteSpace, the "bibliometrix" package in R, and the online platform (https://bibliometric.com/), we conducted a comprehensive analysis and visualization of data encompassing general information, countries, organizations, authors, references, keywords and trend topics.

Results and Discussion: Our analysis included 3,271 papers published by 11,768 authors across 620 journals from 1994 to Oct 2024. UGNB-related research continues to be a hot topic, with a sustained interest expected in the foreseeable future.

North American and European countries, particularly the USA, lead in this field. The University of Toronto stands out among various organizations. ILFELD BM, MARIANO ER, and MARHOFER P are identified as the top three most influential authors. "REGION-AL ANESTHESIA AND PAIN MEDICINE," with the highest number of publications, citations, and H-index, emerges as the leading journal in the UGNB domain.

The papers by LOEB S (2013) in "EUR UROL" and FORERO M (2016) in "REGIONAL ANESTHESIA AND PAIN MEDICINE" are the most cited and co-cited works.

Continuous hotspots include modified radical mastectomy combined with UGNB, enhancing the quality of UGNB, erector spinae plane block, and the use of adjuvants.

Conclusion(s): UGNB remains a vibrant area of research. Organizations, journals, and authors from North America and Europe are at the forefront.

Future research directions are likely to focus on expanding applications to various surgical procedures, technological innovations, and strategies to improve the quality of anesthesia.

12AP05-7

Anaesthetic challenges in a case of Uremic Leontiais Ossea for left cephalic vein pseudo aneurysm rupture repair

B. Barkha¹, K. Suleiman¹, T. Kumar², S. Swalehin Bux³ ¹Bahrain Specialist Hospital, Anaesthesia, Manama, Bahrain. 2Bahrain Specialist Hospital, Nephrology. Manama, Bahrain, ³Bahrain Specialist Hospital, Cardiology, Manama, Bahrain

Background: A rare case of uremic leontiasis ossea with end stage renal disease (1) came for repair of pseudoaneurysm of left cephalic vein. This case is unusual because of difficult airway due to dysmorphic facial structure. We did this case under left infraclavicular block, (2) using peripheral nerve stimulator.

Case Report: 37yr old female patient with chronic kidney disease on hemodialysis, tertiary hyperparathyroidism with facial deformity, was taken up for surgery. Patient had AV fistula which now developed rupture of pseudo aneurysm of left cephalic vein.

Airway examination showed maxillary and mandibular hyperplasia with decreased mouth opening to less than 3cm, flattened nasal bridge and increased interdental spacing. Labs showed serum creatinine 2.1mg/dl and serum PTH 4310pg/ml.

After obtaining high risk consent, patient was given left infraclavicular block with PNS guidance, with 20 ml of 0.5 percent levobupivacaine at current threshold of 0.4 mA. Awake fibre optic cart with difficult airway and ENT surgeon for tracheostomy was kept standby. Case was done successfully without any periprocedural complications.

Discussion: Uremic leontiasis ossea is a rare condition that occurs with renal failure on hemodialysis with secondary hyperparathyroidism characterized by widening of nares, flattened nasal bridge, maxillary and mandibular hyperplasia.

We are reporting first time this condition done under regional anaesthesia, infraclavicular block for psedonaurysm rupture repair. Infra clavicular block is a phrenic nerve sparing block for surgeries for mid arm and forearm.

References:

1. Abhinava RJ. et al.Indian J Anaesthesia.2017Jul:61(7):581-586 2. G Yang, et al. Osteoporos Int. 2014 Mar;25(3):1115-21 Learning Points: The uremic leontiasis ossea is a rare difficult airway case. A phrenic nerve sparing block like infra clavicular block can be done for mid arm surgery.

12AP05-8

Comparison of analgesic efficacy of levobupivacaine with or without fentanyl in thoracolumbar inter-fascial plane block in adults undergoing elective lumbar spine surgery: a randomized control trial

H. Magadum¹, B. Singh², JA Aleem^{1,3} ¹All India Institute of Medical Sciences Raebareli, Department of Anesthesiology, Raebareli, India, ²All India Institute of Medical Sciences Gorakhpur, Department of Anesthesiology, Gorakhpur, India, ³All India Institute of Medical Sciences Raebareli, Department of Anesthesiology, Raebareli, India

Background: Posterior lumbar spine fusion surgeries are associated with significant postoperative pain, necessitating a multimodal approach to pain management. The thoracolumbar interfacial plane (TLIP) block is a relatively new regional anesthesia technique being investigated for its analgesic efficacy in lumbar spine surgeries.

Objective: This study aimed to compare the analgesic efficacy of levobupivacaine (LB) with and without fentanyl as an adjuvant in TLIP blocks for adults undergoing elective lumbar spine surgery. Secondary objectives included evaluating total tramadol consumption over 48 hours postoperatively (when Visual Analog Scale [VAS] > 4) and recording any associated side effects.

Methods: A prospective, randomized controlled trial was conducted at AIIMS Raebareli between August 2023 and November 2024. The trial was registered in the Clinical Trials Registry-India (CTRI REF 2024/05/085604) on 30/05/2024. A sample size of 45 participants per group was determined based on statistical calculations and prior research. Patients undergoing lumbar spine fixation surgery (up to two levels) were randomized into two groups:

- Group A: Received 20 mL of 0.25% LB + 1 mL normal saline (NS).
- Group B: Received 20 mL of 0.25% LB + 1 mL fentanyl.
- Both groups received bilateral TLIP blocks preoperatively.

Results: Group B demonstrated significantly lower postoperative VAS pain scores, both at rest and during movement, compared to Group A. The time to first rescue analgesia was significantly prolonged in Group B (442.7 \pm 126.47 minutes vs. 321.00 \pm 69.01 minutes, P < 0.001).

Additionally, Group B had significantly reduced cumulative tramadol consumption in the first 48 postoperative hours.

Conclusion: The addition of fentanyl as an adjuvant to levobupivacaine in TLIP blocks provides superior analgesia, with a longer pain-free duration, delayed requirement for rescue analgesia, and reduced total rescue analgesic consumption in patients undergoing elective lumbar spine surgeries.

Ultrasound-assisted neuraxial anesthesia: a safe approach in ankylosing spondylitis

A.R. Rocha¹, <u>A. Carneiro</u>¹, M. Marcelino¹, M. Sá¹, R. Graça¹, S. Caramelo¹ ¹Unidade Local de Saúde Trás-os-Montes e Alto Douro, Anesthesiology, Vila Real, Portugal

Background: Ankylosing spondylitis is a chronic inflammatory arthritis that primarily affects the axial skeleton and sacroiliac joints. In severe cases, this causes ossification of axial ligaments and vertebrae fusion, resulting in the formation of a classical "bamboo spine".

This presents a challenge for anesthesiologists due to the potential for a difficult airway, respiratory and cardiovascular complications, and a challenging neuraxial access.

Case Report: A 56-year-old male was proposed for an elective left total hip replacement surgery. The patient had ankylosing spondylitis, grade 1 obesity and hypertension. On physical examination, the airway was anticipated to be difficult due to the lack of cervical mobility. A spinal anesthesia by the conventional blind technique had previously been attempted without success.

Therefore, we decided to perform an ultrasound examination of the lumbar spine using a low-frequency (2-5 MHz) curved transducer. The spine was scanned from the sacrum level upwards in the transverse midline plane and parasagittal planes on both sides.

We were able to establish landmarks by visualizing the L3-4 and L4-5 intervertebral levels, the midline and measuring the depth of the posterior limit of the intrathecal space.

Dural puncture was successfully achieved using a 25-gauge Whitacre needle, and 11 mg of levobupivacaine and 0.002 mg of sufentanil (total volume of 2.6 mL) were administered intrathecally. The motor and sensory blocks were deemed adequate, and the surgery proceeded without complications.

Discussion: Ultrasound-assisted neuraxial anesthesia can be a useful tool when technical difficulty is anticipated, such as in patients with ankylosing spondylitis.

Comparing with the conventional method, this approach enhances clinical accuracy by anticipating the feasibility of a central neuraxial blockade and can improve patient safety. This enables

anesthesiologists to offer regional anesthesia as an alternative to general anesthesia for patients with abnormal spinal anatomy who would also benefit from a regional approach.

References:

1. BJA Education, 16 (7): 213–220 (2016) 2. Anaesthesia, 64: 540-548 (2009)

Learning Points:

- Ankylosing spondylitis presents a challenge since both airway management and neuraxial access may prove to be difficult.
- Neuraxial ultrasound can be a valuable tool in patients with ankylosing spondylitis as it enables the anesthetist to offer regional anesthesia as an alternative to general anesthesia.

12AP05-10

Urgent decision-making: to remove or maintain an epidural catheter in patient with acute pulmonary embolism (PE)

I. de Castro¹, <u>C. Dias</u>¹, D. Chaló¹, A.L. Afonso¹, N. Lareiro¹ ¹Unidade Local de Saúde da Região de Aveiro, Anesthesiology, Aveiro, Portugal

Background: According to the ESC guidelines, Pulmonary Embolism (PE) is one of the leading causes of cardiovascular death. Some risk factors for PE include knee arthroplasty, immobilization, hypertension and obesity.

Therefore, it is a comorbidity to consider in the postoperative period of major orthopedic surgery. Early prevention, diagnosis, and treatment are crucial.

Case Report: A 68-yo female patient, ASA II, with a history of hypertension and obesity underwent knee arthroplasty. On day 3 post-op, she was on prophylactic enoxaparin and receiving PCEA. Patient was found after a syncopal episode associated with desaturation and hypotension. After airway stabilization and oxygen administration, the patient regained consciousness with improved blood pressure.

Following stabilization, Troponin I, NT-proBNP, 12-lead EKG, transthoracic echocardiography, and pulmonary CT angiography were ordered and revealed bilateral PE with right ventricular dilation and mild dysfunction. In this context, a multidisciplinary team decided to remove the epidural catheter and initiate enoxaparin 1 mg/kg 1 hour after catheter removal, given the intermediate-highrisk PF.

Patient was transferred to the Intensive Care Unit (ICU) where she was monitored by the acute pain unit for new neurological changes and hemodynamic stability. Patient was discharged from the ICU 5 days after and from the hospital 15 days later, without sequelae of PE and without neurological deficits.

Discussion: The urgent initiation of anticoagulation in a patient with an epidural catheter is an infrequent situation for which there are no concrete management guidelines. In this case, it was decided to remove the epidural catheter before initiating anticoagulation to minimize the risks associated with an *in situ* catheter for an indeterminate period in a patient who would require anticoagulation for at least 3 months.

According to the ESAIC guidelines, anticoagulation should not be initiated in a patient with an *in situ* epidural catheter.

After a multidisciplinary discussion, the risk of epidural hematoma was assumed in a patient with intermediate-high-risk PE due to the potential life-threatening risk, while maintaining close monitoring.

Retrospective investigation of the anesthetic effectiveness of combined intersalene brachial plexus, superficial cervical plexus, and clavipectoral fascia plane blocks in anesthesia and analgesia management of clavicle fractures under ultrasound guidance

A. Yildirimer Kayhan¹, S. Telli¹, C. Balci² ¹Kutahya Health Sciences University, Anaesthesiology, Kutahya, Turkey, 2Istanbul Healty Science Un., Anaesthesiology, Istanbul, Turkey

Background and Goal of Study: Various regional anesthesia techniques are used for anesthesia and analgesia in clavicle surgery. In this study, the anesthetic effectiveness of combined Interscalene Brachial Plexus (IBP), Superficial Cervical Plexus (SCP), and Clavipectoral Fascia Plane Blocks (CPFPB) performed under ultrasound guidance for clavicular surgery was investigated retrospectively.

Additionally, this study aimed to determine whether there are significant differences in the amount of anesthetic used for peripheral blocks and the return times of pain sensation and motor block based on the type of peripheral block.

Materials and Methods: This study was planned to investigate the quality of anesthesia, analgesia, and motor block in patients undergoing combined IBP, SCP and CPFPB at kHSU through a retrospective review of records. The study group consisted of patients who underwent interscalene block, superficial cervical plane block, and clavipectoral fascia plane block together under ultrasound guidance.

The study included ASA I-III patients aged 18-80 years who were diagnosed with clavicle fractures by orthopedics and underwent clavicle surgery, receiving Interscalene Brachial Plexus, Superficial Cervical Plexus, and/or Clavipectoral Fascia Plane Blocks. The data of the included patients were planned to be compiled by retrospectively reviewing their anesthesia and pain monitoring

Results and Discussion: When the demographic data of both groups were analyzed, no statistically significant difference was found (p>0.05). When both groups were evaluated regarding intraoperative sedation needs, no statistically significant difference was identified. However, significant differences were found for VAS2, VAS4, and VAS24.

Conclusion(s): CFPB has additional advantages compared to combined plexus blocks. Its use in clavicle fracture surgeries for providing analgesia and anesthesia has started to be recommended, and the number of studies on this topic is increasing day

However, the lack of randomized controlled trials indicates a need for more research to propose CFPB over brachial and cervical plexus blocks.

Our study is one of the few that evaluates the anesthetic and analgesic efficacy of CFPB in combined blocks.

Pericapsular nerve group block in shoulder surgery: a case report

J. Gomes¹, F. Lemos¹, L. Pedro¹, A. Costa¹ ¹Unidade Local de Saúde de Santo António, Anesthesiology, Porto, Portugal

Background: As part of a multimodal pain management, regional anesthesia has its role well established in shoulder surgery, with the interscalene brachial plexus block being one of the main preferences among anesthesiologists. However, in patients with reduction of pulmonary reserve, the interscalene approach raises concerns about the diaphragmatic hemiparesis that may occur, leading to potential respiratory postoperative complications.

A pericapsular nerve group (PENG) approach has been described as a safe and effective option. 1

Case report: A 68-year-old male patient was admitted in the emergency department due to a fall from own height. He had a proximal left humerus fracture with surgical correction criteria, with no other injuries to report. A proposal for an open surgical reduction was made.

During the planning of the anesthetic approach, in the preoperative evaluation, the anesthetic team realized the patient suffered a severe restrictive ventilatory syndrome due to kyphoescoliosis, aggravated by a history of COPD owing to heavy smoking habits. On arrival to the OR, he was conscient and orientated, with no signs of respiratory difficulty, with peripheric O2 saturation of 90-

The patient was proposed to a combined anesthesia technique. In order to avoid potential respiratory postoperative complications due to diaphragmatic hemiparesis associated with regional techniques, a shoulder PENG approach was planned. The blockade was performed before anesthetic induction, ultrasound guided, with 100 mg of ropivacaine.

Surgery went uneventful. In the postoperative period, no pulmonary complications were reported and the patient had satisfactory analgesic control. He was discharged in the next day.

Discussion: Pain management strategies related to shoulder pain following surgery are crucial to early patient recovery. PENG block may be safely and effectively applied as a part of a multimodal analgesic regimen for shoulder surgery by blocking the articular branches of the glenohumeral joint.

Additional studies might be needed in order to better understand the technique and its benefits in comparison with other options.

Suprascapular and supraclavicular brachial plexus block as a successful anesthetic plan in a patient with neck radiation: a case report

M. Mugeiro¹, C. Martins¹, N. Carrilo-Alfonso¹, I. Portela¹, S. Gestosa¹, A. Lares¹

¹Unidade Local de Saúde do Algarve, Serviço de Anestesiologia, Faro, Portugal

Background: The management of patients with previous head and neck radiotherapy poses unique anesthetic challenges due to radiation-induced tissue fibrosis, resulting in limited mouth opening and restricted cervical mobility1.

This case is noteworthy as it illustrates the successful use of regional anesthesia (RA) in previously irradiated tissue of a patient with predicted difficult airway, avoiding the risks associated with general anesthesia. This unusual combination of conditions has no pair in the scientific literature, being the only case of this nature to be described.

Case report: A 75-year-old female, ASA III, with a complex medical history, including a prior base of tongue carcinoma treated with radical neck dissection and radiotherapy, was scheduled for open reduction and osteosynthesis of a proximal humerus fracture. Physical examination revealed severe neck fibrosis and limited mouth opening, suggesting a difficult airway. Given these findings, RA was chosen. A supraclavicular brachial plexus block was combined with a suprascapular nerve block, with dexmedetomidine for conscious sedation. The procedure was successful, and the patient was discharged on postoperative day two, requiring no opioids by day 15.

Discussion: This case underscores the effectiveness of a tailored RA approach for shoulder surgery in patients with radiation-induced tissue fibrosis. Literature supports the safety and efficacy of suprascapular and supraclavicular blocks for pain management, particularly in patients where traditional interscalene blocks may pose risks, such as phrenic nerve palsy or altered anatomy due to fibrosis^{2,3}.

This report aims to highlight RA as a viable alternative in similar high-risk cases.

References:

- 1. Nepon, H., et al. Radiation-Induced Tissue Damage: Clinical Consequences and Treatment. Semin Plast Surg, 2021.
- 2. Fredrickson, M. J., et al. Postoperative Analgesia for Shoulder Surgery. Anaesthesia, 2010.
- 3. Toubasi, A., et al. Continuous Suprascapular Catheter and Axillary Block for Analgesia in Shoulder Arthroplasty. Cureus, 2023.

Learning points:

- 1. RA, particularly suprascapular and supraclavicular blocks, can mitigate the risks of airway compromise in patients with head and neck radiation sequelae.
- 2. RA is safe and effective in patients with radiation-induced tissue fibrosis.
- 3. This case supports RA as an effective alternative to general anesthesia in complex patients, enhancing comfort and minimizing opioid reliance.

12AP06-3

Comparison of the efficacy of intrathecal morphine, ultrasound-guided erector spinae plane block with PCA fentanyl in the control of post-operative pain after modified radical mastectomy: a randomized controlled trial

R. Ralsun¹, R. Subramaniam¹, A. Chhabra¹, D. Bhoi¹, M. Kumar¹

¹All India Institute of Medical Sciences, New Delhi, Anaesthesiology, Pain Medicine and Critical Care, New Delhi. India

Background and Goal of Study: Breast cancer is the most common cancer in females and modified radical mastectomy (MRM) is the surgical procedure of choice. Regional analgesia techniques help in reducing acute postsurgical pain. We wanted to ascertain which regional technique viz. intrathecal morphine (ITM), ultrasound-guided erector spinae plane block (ESPB), as compared to conventional general anaesthesia (GA) control group was more effective in relieving pain after MRM.

Primary objective included:

- 1. PCA fentanyl consumption in 24-hour postoperative period. Secondary Objectives included:
- 1. Time to first analgesic requirement after end of surgery.
- 2. Assessment of post-operative pain using a 0-100mm Visual analogue scale (VAS) with patient at rest and on abduction of ipsilateral arm above the head
- 3. Incidence of adverse events (post-operative nausea, vomiting, respiratory depression, pruritus and urinary retention).
- 4. Patient satisfaction score

Materials: Type of study - Single blind randomized controlled trial. Place of study: Department of Anaesthesiology, Pain Medicine and Critical Care, All India Institute of Medical Sciences, New

Methods: 60 ASA grade I & II patients scheduled to undergo MRM under GA were randomly allocated to either ITM, ESPB or control group. Patients received conventional GA and postoperative PCA IV fentanyl.

Results and Discussion: The 24-hour post-operative fentanyl requirement was comparable between ITM and ESPB groups (p= 1.0000). Fentanyl consumption was significantly more in control group as compared to ESPB group (p= 0.0467). Time to first analgesia was longer in ESPB group with a mean duration of 2.605 (0-5.03) hours [median (range)]. Nausea was significantly more in ITM group (p=0.039).

Conclusion(s): ESP block was associated with significantly lower post-operative 24-hour PCA fentanyl consumption. ITM was accompanied by a high incidence of post-operative nausea.

12AP06-4

Retroclavicular approach of infraclavicular brachial plexus block for regional anaesthesia for upper limb surgeries: a systematic review and meta-analysis

H. Garg¹, D. Jain¹, J. Bulbul¹, S.Y. Hussain¹, S. Kumar¹ ¹All India Institute of Medical Sciences, Anaesthesiology, Pain Medicine and Critical Care, Delhi, India

Background and Goal of Study: Retroclavicular block (RCB) is an alternative approach of infraclavicular block (ICB) of the brachial plexus for upper limb (UL) surgeries. The objective of the analysis was to assess the feasibility, efficacy and safety outcomes in adult patients undergoing UL surgeries under the RCB versus other brachial plexus blocks (BPBs).

Materials and Methods: Search was carried out from MEDLINE. EMBASE, SCOPUS and manually from inception to November 1, 2023. Randomized controlled trials comparing RCB to other BPBs were included. Studies including administration of block via landmark or nerve stimulator guidance, paediatric population or under general anesthesia were excluded. The quality of evidence was assessed using Cochrane Revman risk of bias (ROB) tool.

The primary outcomes were adequate surgical anesthesia from the block alone and the block performance time (BPT).

Secondary outcomes were block onset time - sensory and motor, number of attempts, duration of block and any complications. Results and Discussion: Nine trials (n=742, RCB=360, Others=382) were included. Block success rate was similar in all the blocks (Risk ratio (RR) 1.02; 95% confidence interval (CI) 0.98, 1.07; p=0.23, moderate quality of evidence (QOE)).

No significant difference was seen in needling time (Standardised mean difference (SMD) -0.26; 95% CI -0.89, 0.36; p=0.41), BPT (needling and imaging time) (SMD = -0.36; 95%CI -1.23, 0.51, p=0.41), pain during procedure (SMD =-0.39; 95%CI -0.94, 0.15, p=0.16) and complications (RR 0.56: 95% CI 0.23, 1.40, p=0.22). The needle visibility was significantly better in RCB (M.D. 1.14: 95%CI 0.80, 1.49, p<0.00001). The QOE for all these outcomes was low. In the RCB approach, the needle insertion point being posterior to the clavicle, allows an almost perpendicular alignment of the ultrasound beam and needle shaft leading to an enhanced needle visibility. This was consistent in our results.

However, this did not equate to better needling time with RCB. Moreover, needling time was defined differently in all studies which could have led to inconclusive results and high heterogeneity in the pooled analysis. Limitations of the analysis are smaller number of studies and heterogeneity in the block drug and volume used.

Conclusion: The retroclavicular approach of ICB, though showing better needle visibility, was not found to be superior or inferior to other BPBs in terms of needling time, BPT, success rate or complications.

12AP06-5

Successful supraclavicular block for diabetic patient with traumatic injury in the emergency department

I. de Castro¹, B. Silva¹, N. Lareiro¹ ¹Unidade Local de Saúde da Região de Aveiro, Anesthesiology, Aveiro, Portugal

Background: Patients presenting to the emergency department (ED) often experience significant pain. Regional anesthesia (RA) is increasingly used in these settings, providing effective and safe pain control, especially in patients with multiple comorbidities.

Case report: A 51-yo male ASA III, presented to the ED with a penetrating trauma to the right forearm caused by a wooden board. Patient had a history of poorly controlled type 1 diabetes mellitus. In ED the patient was monitored with ECG, pulse oximetry, and non-invasive blood pressure.

He was conscious, maintaining a patent airway with spontaneous breathing and hemodynamically stable. He reported severe pain but had no sensory or motor deficits. Considering the patient had a 5h fasting period, a RA strategy was chosen for urgent wound cleaning, foreign body removal and debridement. 20 minutes after admission, a ultrasound-guided supraclavicular brachial plexus block was performed administering 20 ml of 2% mepivacaine after negative aspiration and without sensory complaints.

The block provided effective anesthesia within 5 minutes, allowing for the procedure without any sedation. Patient was admitted for inpatient care, prescribed intravenous analgesia and referred to the acute pain unit. 12h post-procedure, patient reported 0/10 pain on NRS at rest and with movement, with no new sensory or motor deficits.

Discussion: This case highlights the efficacy and safety of RA in managing pain for complex procedures in high-risk patients in ED.

In a patient with a risk of a full stomach, RA proved to be an effective and safe strategy, not only provided sensory anesthesia for the procedure but also effective analgesia in the initial hours. **Reference:**

12AP06-6

The wolf in sheep's clothing: a case report about unmasking atypical symptoms in a common complication

M. Mugeiro¹, <u>C. Martins</u>¹, N. Carrilo-Alfonso¹, I. Portela¹, S. Gestosa¹, A. Lares¹ ¹Unidade Local de Saúde do Algarve, Serviço de Anestesiologia, Faro, Portugal

Background: Obstetric patients have increased risk of PDHD due to their sex, young age and widespread use of neuroaxial blocks, even with fine-gauge spinal needles.¹ Although PDPH sometimes presents with atypical symptoms, other differential diagnoses should be considered, as they may reveal neurological emergencies

Case report: A 29-year-old woman at 40 weeks of gestation underwent an urgent c-section due non-reassuring fetal status, under spinal anesthesia, using a 25G Quincke needle, with Sufentanil, Bupivacaine and Morphine with no immediate complications. After thirty hours, the patient developed a sudden, severe holocranial headache (9/10), improved by orthostatism and worsened with head elevation, neck stiffness, nausea, vomiting and photophobia, with no neurological deficits or fever.

Given the diagnostic hypotheses of aneurysm rupture or sinus venous thrombosis, a non-contrast computed tomography scan was performed and was unremarkable. Conservative treatment with hydration and analgesics was started. The next day there was no relief of symptoms, so a sphenopalatine block was performed, with temporary improvement.

The headache recurred after 24 hours but it worsened with orthostatism, which pointed to PDPH. A magnetic resonance imaging revealed cerebrospinal fluid leakage at the L2-L3 level. Symptoms completely resolved after an epidural blood patch.

Discussion: We report a case of PDPH management, following c-section spinal anaesthesia with a 25G Quincke needle. The paradigm of our case is an atypical headache, which initially worsened in the supine position and was relieved by head elevation associated with meningeal signs. After a multidisciplinary approach, the final diagnosis of PDPH was reached. The present case rein-

forces that complications resulting from the neuraxial approach do not always present themselves in a typical manner, and that the approach must be multidisciplinary.

1. Dinesh A, et al. A case of post dural puncture headache following labour epidural analgesia, managed by sphenopalatine ganglion block. *International Journal of Reproduction, Contraception, Obstetrics and Gynecology.* 2022;11(12):3421

Learning points:

- 1. PDPH can occur after atraumatic spinal anaesthesia with a fine-gauge. needle, highlighting the need for vigilance and early recognition in obstetric patients.
- Although PDPH may present with atypical symptoms, other differential diagnoses must be considered, such as neurological emergencies.

Ultrasound guided epidural blood patch in an obstetric patient with previously difficult neuraxial approach

J. Caldeira¹, <u>D. Henriques</u>¹, P. Silva¹, E. Semedo¹, J. Carvalhas¹, L. Ferreira¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Post-dural puncture headache (PDPH) is a complication of accidental puncture of the dura mater during epidural technique or intentional puncture during subarachnoid block. For PDPH refractory to conservative treatment, injecting autologous blood into the epidural space (epidural blood patch, EBP) is often effective!

Neuraxial ultrasound can aid EBP by allowing visualization of spinal anatomy and determining the epidural space depth, contributing to procedural success¹.

Case Report: We report a case of a 31-year-old obese woman, BMI of 31, who underwent ultrasound-guided EBP for persistent PDPH 4 days after elective caesarean section.

For elective caesarean delivery, four combined spinal-epidural attempts were unsuccessful, although no evidence of dural puncture was noted. The team opted to perform a spinal block using a 25G Quincke needle, reaching the L4-L5 intrathecal space at 11cm depth. The procedure was uneventful and both the patient and the newborn were asymptomatic on discharge (postoperative day 3)

On the fourth post-caesarean day, she developed PDPH unresponsive to conservative treatment. Neurological examination was normal and MRI was inconclusive, leading to a PDPH diagnosis with recommendation for an EBP. Lumbar ultrasound allowed identification of anatomical landmarks, including vertebral level, and located the epidural space at 10 cm depth, in accordance with MRI findings.

This space was identified by loss of resistance through a 12 cm Tuohy needle, and 15 mL of fresh autologous blood were injected. The procedure was uneventful. Eight hours later, the headache subsided, and the patient was able to stand and ambulate without neurological deficits or lumbar pain. After thorough explanation of warning symptoms, the patient was discharged home.

Discussion: This case highlights the value of ultrasound in neuraxial approaches, particularly in EBP after a previous difficult technique in obese patients.

Reference:

1. Uppal V, et al. Postdural puncture headache guidelines. *Reg Anesth Pain Med.* 2024:49:471–501.

Learning points: Ultrasound enhances vertebral structure identification and accurately estimates the depth of the epidural space, optimizing the efficacy and safety of neuraxial procedures.

This case highlights the role of neuraxial ultrasound in the anaesthesiologist's daily practice, revealing its potential impact on first attempt technique success rate, incidence of complications, patient satisfaction, and cost effectiveness.

Postoperative dyspnea after arthroscopic rotator cuff repair: an unexpected complication of surgical irrigation

A. Sakate¹, H. Yoshinuma¹, K. Ueda¹

¹Kameda Medical Center, Department of Anesthesiology, Chiba, Japan

Background: Among the known complications of brachial plexus block via the interscalene approach, including vascular puncture, Horner's syndrome, and total spinal anesthesia, pneumothorax and phrenic nerve paralysis are well-recognized causes of post-operative respiratory distress. However, when a patient develops respiratory difficulty, it is important to consider not only these factors but also complications associated with the surgical procedure itself. We report a case that highlights this issue.

Case report: A 68-year-old male, ASA-PS I, (height 170 cm, weight 59 kg), right-sided arthroscopic rotator cuff repair surgery. Prior to general anesthesia, an interscalene block was performed using ultrasound and nerve stimulation guidance without any complications. The surgery lasted 3 hours 24minutes, with minimal blood loss and a total of 58.8 L of irrigation fluid used. Following extubation in the operating room, the patient was alert with stable respiratory function. However, one hour postoperatively in the ward, he developed dyspnea. Chest X-ray revealed reduced transparency across the entire right pleural cavity, and chest CT demonstrated pleural effusion with bilateral subcutaneous tissue infiltration. As the patient's oxygen saturation remained at 99% with 2 L of supplemental oxygen, he was managed conservatively in the general ward. Clinical and radiological improvement was observed the following day, and the patient was discharged on the 8th postoperative day.

Discussion: Upon the patient's onset of dyspnea, initial differential diagnoses included phrenic nerve paralysis or pneumothorax secondary to the interscalene block. Imaging studies, however, revealed pleural effusion and soft tissue edema, likely resulting from surgical irrigation fluid accumulation. The postoperative complications appear to be associated with the prolonged surgical duration and the substantial volume of irrigation, which is consistent with findings reported in previous literature.

References:

Matsumoto Y, et al. Orthop Surg Traumatol. 2022;71(3):382-385.
 Abutalib RA, et al. Am J Case Rep. 2020;21:e926357.

Learning points: When a patient presents with postoperative dyspnea, it is crucial to consider not only anesthesia-related complications but also potential issues arising from the surgical procedure itself. Furthermore, comprehensive imaging studies are invaluable in establishing an accurate differential diagnosis.

12AP06-10

Analgesic efficacy of cervical retro-laminar block in patients undergoing posterior cervical spine surgery: a randomized controlled trial

J. Hu¹, J. Hu¹, C. Gong², J. Yang¹

¹West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China, ²West China Fourth HospitaDepartment of Urology, Department of Urology, Chengdu, China

Background and Goal of Study: Posterior cervical spine surgery (PCSS) often requires extensive dissection of paravertebral muscles, and the surgical process also has certain damage to muscle attachment points, facet joint capsules, and other areas, which can cause significant pain in a short and a considerable time after surgery, seriously affecting the postoperative rehabilitation of patients.

This study explored the efficacy and safety of cervical retrolaminar block on postoperative pain after posterior cervical spine surgery.

Materials and Methods: 84 patients with the American Society of Anesthesiology functional status scores of I-III were included and assigned to two groups, and 60 patients were included in the final analysis. All included patients were randomly assigned to the CRL or LIA groups. Patients in the CRL group received cervical retrolaminar block 30 minutes before surgery, while patients in the LIA group received LIA before the wound was sutured.

The primary outcome was cumulative morphine consumption within the first 24 hours after surgery.

The secondary outcomes were postoperative pain scores on a Numeric Rating Scale (NRS), cumulative morphine consumption within the first 72 hours after surgery, intraoperative opioid consumption (sufentanil and remifentanil), and postoperative complications

Results and Discussion: Patients in the CRL group consumed significantly less morphine than the LIA group within the first 24 hours and the first 72 hours after surgery. The CRL group had significantly lower pain scores at rest in the PACU and 3, 6, 12, and 24 hours after surgery. The two groups did not differ significantly in the incidence of postoperative complications.

Conclusion(s): Cervical retro-laminar block postoperative could improve pain relief, and reduce opioid use in patients undergoing posterior cervical spine surgery.

12AP06-11

Sedation during surgical treatment of combat-related limb injury under regional anesthesia: patient preference and cortisol response

M. Frank¹, I. Kuchyn¹, K. Bielka¹, Y. Klys², I. Shukurlu¹, N. Semenko¹

¹Bogomolets National Medical University, Surgery, anesthesiology and intensive care of postgraduate education, Kyiv, Ukraine, 2Bogomolets National Medical University, Department of modern technologies of medical diagnostics and treatment, Kyiv, Ukraine

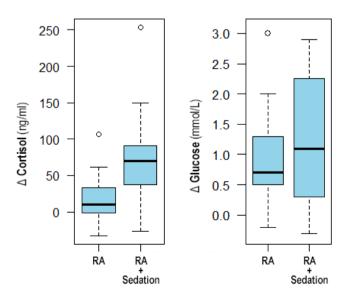

Background and Goal of Study: Wounded soldiers may refuse optional intravenous sedation due to previous negative experience or fear of adverse effects. Insufficient consciousness inhibition during stress-inducing medical procedures may negatively impact this patient population, delaying or limiting their physical and mental recovery.

This study aimed to determine whether initial patient preference is sufficient to predict unacceptable stress response to the intervention conducted under fully adequate regional anesthesia.

Parameter		Group R (n = 16)	Group RS (n = 16)	p-value	
	Before	97.5 ± 37.1 (74-127)	95.6 ± 47.2 (58-115)	0.897	
Cortisol (ng/mL)	After	115.9 ± 35.0 (87-136)	172.6 ± 79.4 (137-178)	0.002	
	Difference	77.0 ± 64.0 ((-1)-29)	18.41 ± 33.7 (40-90)	0.0006	
	Before	4.20 ± 0.85 (3.7-4.7)	4.44 ± 0.83 (3.9-5.0)	0.273	
Glucose (mmol/L)	After	5.13 ± 1.03 (4.5-5.5)	5.64 ± 0.97 (4.9-6.1)	0.117	
	Difference	0.93 ± 0.76 (0.5-1.3)	1.2 ± 1.13 (0.3-2.0)	0.705	

Table 1. Measured serum concentrations of cortisol and glucose and the difference between the measurements before and after the surgical procedure. Shapiro-Wilk test was used to establish normality, followed by Mann-Whitney U test due to predominantly non-parametric distribution.

Presented as mean ± standard deviation (25-75% interval).

Materials and Methods: Patients with blast and gunshot limb injuries that were scheduled for minor surgical interventions (secondary wound debridement, wound closure, VAC bandage placement or removal, removal of external fixation devices) that could be adequately anesthetized through up to two nerve blocks were consulted by an anesthesiologist on a day before the procedure.

Patient's preference on whether supplementary intravenous sedation should be conducted was used to distribute him into regional only (R) or regional plus sedation (RS) group. Blood samples were obtained before and after the procedure.

Results and Discussion: Out of the 52 initially included patients, 32 met the final criteria, 12 were excluded due to unplanned use of opioids.

Conclusions: When choosing anesthetic approach for minor surgical procedures during treatment of combat injuries of the limbs. patient preference appears to be unreliable as a sole measure for the need for sedation to minimize cortisol stress response when adequate analgesia is provided via regional methods. No significant difference in serum glucose concentration changes was observed.

Maxillary and mandibular nerve block: Two-in-one – A cadaveric study with preliminary results

G. Molins Ballabriga¹, J. Tomas-Aliberas², N. Felipe-Espada², C. Ramirez³, A. Valls-Ontañon⁴ ¹Universitat Internacional de Catalunya, Anaesthesia / Maxillofacial Surgery / Dentistry, Sant Cugat del Vallès (Barcelona), Spain, ²Universitat Internacional de Catalunya, Dentistry, Sant Cugat del Vallès (Barcelona), Spain, 3Universitat Internacional de Catalunya, Anaesthesia, Sant Cugat del Vallès (Barcelona), Spain, ⁴Universitat Internacional de Catalunya, Maxillofacial Surgery / Dentistry, Sant Cugat del Vallès (Barcelona), Spain

Background and Goal of Study: The volume of local anaesthetic injected into the pterygopalatine fossa for maxillary nerve block is controversial. The typical volume of the pterygopalatine fossa in adults has been reported as close as 1mL in dry skulls. However, 2-5 ml are clinically injected. After filling the pterygopalatine fossa during maxillary nerve block, where the remaining local anaesthesia diffuses has not been formally investigated.

The objective of this study was to identify the degree of local anaesthesia disseminated to the nerve branches of the mandibular nerve when performing the maxillary nerve block.

Materials and Methods: Maxillary nerve dye injection and dissection were performed bilaterally in the pterygopalatine fossa of four lightly embalmed cadaveric specimens (4 specimens, 8 injections). Infiltration of 2ml or 5ml of contrast into the pterygopalatine fossa was performed using a suprazygomatic approach and ultrasound-guidance through an infrazygomatic window.

Results and Discussion: The pterygopalatine fossa, pterygopalatine ganglion, infraorbital nerve, palatine nerves, and mandibular nerve branches (auriculotemporal nerve, inferior alveolar nerve, lingual nerve) were dyed consistently in both groups.

Images:

Conclusion(s): This cadaveric study shows that a single block applying 2 or 5mL of local anaesthetic in the pterygopalatine fossa can spread to the second and third branches of the trigeminal nerve, and could provide anaesthesia/analgesia for surgeries involving the lower two thirds of the face.

Postoperative analgesic effectiveness of PENG block and lumbar erector spinae plane block in total hip arthroplasty: A prospective randomized study

B.B. Özkurt¹, B. Bilgili¹ ¹Marmara University, Anesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Total hip arthroplasty is one of the orthopedic surgeries with moderate to severe postoperative pain. While choosing peripheral nerve block in multimodal analgesia, targeting only sensory block contributes to reduced postoperative opioid consumption, early mobilization and shortens the length of hospital stay. We hypothesized that combined application of Pericapsular Nerve Group (PENG) block and Lumbar Erector Spinae Plane Block (L-ESPB) changes postoperative opioid consumption compared to their application alone.

Materials and Methods: In this single-center study conducted from January 2023 to July 2024, 66 patients with ASA I-III undergoing total hip arthroplasty surgery were randomized into three groups: L-ESPB, PENG, or L-ESPB and PENG combined. After spinal anesthesia, 20 ml of 0.25% bupivacaine was applied to the operated side in the PENG group, 40 ml of 0.25% bupivacaine was applied in the L-ESPB group and in the PENG+L-ESPB group, local anesthetic was applied in the same volume, but not exceeding a maximum of 2,5 mg/kg.

Postoperative analgesia was provided with patient-controlled intravenous morphine, and tramadol as rescue analgesia for NRS pain scores above 4. The primary outcome was 24-hour total opioid consumption, with secondary outcomes including opioid consumption at 6 and 48 hours, pain scores, rescue analgesia requirements, and time to discharge from hospital.

Results and Discussion: NRS scores were similar between the groups and NRS <4 was recorded at all measurement times (p>0.05). Total 24-hour morphine consumption (mg) was 17.32±12.99 in the L-ESPB group, 14.32±9.66 in the PENG group, and 13.77±8.61 in the L-ESPB+PENG group and was comparable among the groups (p=0.8). Morphine consumption was similar between the groups at all time intervals (p>0.05). Morphine consumption at 24-36 hours was significantly higher in the L-ESPB group than at 0-2 hours (p=0.005, Bonferroni corrected) and 6-12 hours (p=0.007, Bonferroni corrected) Rescue analgesic requirement was similar between the groups at all time intervals.

Conclusion(s): PENG and L-ESPB blocks provided effective postoperative analgesia in patients undergoing hip surgery. The combination of PENG and L-ESBP blocks was not superior to the application of either block individually.

12AP07-2

The single-injection femoral triangle block (FTB) for total knee arthroplasty (TKA) towards safety and better postoperative functionality

A. Djurdjevic Svraka1, D. Svraka1, B. Pejakovic1, M. Stojkovic1, L. Skrbo Garcia1 ¹General Hospital Gradiska, Dep. of anaesthesia, resuscitation and intensive care, Gradiska, Bosnia and Herzegovina

Background and Goal of Study: The femoral triangle block (FTB) is an important technique in regional anaesthesia, mainly utilised to manage postoperative pain for patients undergoing total knee arthroplasty (TKA). This report outlines the significance, methodology, comparisons, and outcomes associated with the FTB in the context of knee prosthesis surgery.

The study aims to compare the effectiveness of spinal anaesthesia alone versus spinal anaesthesia enhanced with ultrasoundguided FTB in improving perioperative pain relief and functional recovery in patients undergoing TKA.

Materials and Methods: We conducted a prospective observational study in which patients were randomised based on informed consent to receive a regional anaesthesia block after spinal anaesthesia for TKA. 117 patients scheduled for TKA were divided into two groups: one group received spinal anaesthesia alone (SA group; n=41), and the other group received spinal anaesthesia in conjunction with an FTB (SARB group; n=76).

In the SARB group, the femoral nerve block was administered postoperatively under ultrasound guidance with 15 millilitres of 0.25% bupivacaine. The spinal anaesthesia was ordinated with 2,8 millilitres of 5% levobupivacaine.

We included patients with ASA I-III but excluded those with opioid addiction, rheumatoid arthritis, and allergies to local anaesthetic

Results and Discussion: The two groups showed a significant correlation regarding the onset of pain postoperatively, VAS 5 or more (p = 0.03), and the total amount of analgesics required in the first 36 postoperative hours (p = 0.05). PONV, intraoperative and postoperative hemodynamic stability did not exhibit significant differences between the groups.

However, postoperative hypotension was linked to reduced functional recovery, as evidenced by physical treatment on the day of surgery (p < 0.01) and functional mobility test level (p = 0.02). Additionally, the time to the onset of pain, measured on the VAS scale (rating of 5 or higher), was associated with the functional mobility test (p = 0.02) and the length of hospitalisation (p = 0.05).

Conclusion(s): The administration of a single-injection femoral triangle block (FTB) after spinal anaesthesia for total knee arthroplasty (TKA) is a crucial intervention that prioritises patient safety and significantly boosts postoperative functionality. It facilitates a smoother recovery process and improved mobility for patients.

12AP07-3

Successful low-dose continuous spinal anesthesia for retrograde intrarenal surgery in a patient with hereditary muscular dystrophy: A case report

A. De Oliveira¹, C. Cunha da Silva¹, A.S. Coutinho¹, S. Santos Rodrigues¹

¹Hospital Senhora da Oliveira Guimarães - Unidade Local de Saude do Alto Ave, Serviço de Anestesiologia. Guimarães, Portugal

Background: Endoscopic procedures for renal stones are increasingly popular due to their minimally invasive nature. Spinal anesthesia (SA) offers comparable outcomes to general anesthesia (GA), with added benefits for patients with significant comorbidities.1,2

We present a case of a woman with severe respiratory impairment successfully undergoing RIRS with low-dose continuous spinal anaesthesia (CSA), achieving excellent tolerance and no complications.

Case report: A 66-yr-old woman, ASA 4, with hereditary muscular dystrophy (heterozygous TTN gene mutation), causing severe restrictive respiratory syndrome requiring 24-hour/day non-invasive ventilation, daily cough-assist, and moderate dysphagia.

Comorbidities includes hypertension, dyslipidemia and renal lithiasis, and she was scheduled for RIRS. CSA was proposed after discussing risks and benefits, and informed consent was obtained. In the operating room, standard ASA monitoring was established, and 1mg of intravenous (IV) midazolam and 50mcg of IV fentanyl were administered.

A subarachnoid catheter was placed via a paramedian approach, delivering 2mg of 0.5% isobaric bupivacaine and 2mcg of sufentanyl, with an additional 1mg of bupivacaine given at surgery onset. Paracetamol and dexamethasone were also administered. The 93-minute procedure in lithotomy position was completed with adequate intraoperative conditions. The patient had an uneventful recovery, being discharged after 2 days.

Discussion: This case highlights the successful use of CSA in a high-risk patient undergoing RIRS. CSA avoided the risks of GA, such as respiratory decompensation and hemodynamic instability, as mentioned in other published case reports.1,2

The approach ensured effective surgical conditions, excellent postoperative tolerance, and a smooth recovery.

1. Yoldas M, Yoldas K. Spinal versus general anesthesia in retrograde intrarenal surgery. Arch Ital Urol Androl. 2022 Jun 29;94(2):195-198. doi: 10.4081/aiua.2022.2.195. PMID: 35775347 2. Namba, Y., Yamakage, M., & Tanaka, Y. (2016). Satisfactory spinal anesthesia with a total of 1.5 mg of bupivacaine for transurethral resection of bladder tumor in an elderly patient. JA Clinical Reports, 2(1),10-12. https://doi.org/10.1186/s40981-016-0030-0

Learning points: Low-dose CSA enables precise anesthetic titration, ensuring optimal surgical conditions while effectively minimizing the risk of hemodynamic instability and respiratory compromise, particularly in high-risk patients.

12AP07-4 Halloween costume: The ASA I patient in disguise

D. Bastos Martins¹, D. Henriques¹, D. Rodrigues¹, M. Martins¹, M. Miranda¹ ¹CUF Tejo Hospital, Anesthesiology, Lisboa, Portugal

Hemophilia A is a rare, X-linked disorder characterized by a deficiency in coagulation factor VIII. Diagnosis often hinges on a thorough personal or family history of bleeding, as clinical suspicion typically precedes laboratory findings, making a detailed history the first line of diagnostic investigation.

Standard tests, including prothrombin time (PT) and activated partial thromboplastin time (aPTT), frequently remain within normal limits; in fact, aPTT abnormalities may only emerge when factor VIII activity drops below 15%. In those cases neuraxial anesthesia is contraindicated due to a hematoma risk of approximately 1 in 315, while peripheral nerve blocks may be cautiously considered, contingent on ultrasound guidance and appropriate factor VIII supplementation.

Here, we present a case that challenges conventional preoperative assumptions. A 16-year-old ASA I patient, evaluated for elective knee surgery to excise an osteoarticular cyst, displayed entirely normal laboratory results during the anesthesiology consultation.

Combined anesthesia (general anesthesia with epidural block) was administered without intraoperative incidentes. The epidural catheter was removed after 48 hours due to urinary retention and patient discomfort.

Unexpectedly, the postoperative course was complicated by escalating hemorrhage in the operated limb, prompting a focused anamnesis, which uncovered a previously unreported family history of hemophilia only 72 hours after the initial procedure.

Further assessment, including lumbosacral imaging, excluded any epidural technique complications, while laboratory testing subsequently revealed a factor VIII activity level of 28%, with aPTT still within normal range.

This case emphasizes the limitations of standard preoperative screenings in determining the appropriateness of regional anesthesia techniques, even in patients without known comorbidities. Although the anesthetic management yielded a favorable outcome, this case underlines the need for a potentially more rigorous preoperative assessment for latent bleeding disorders, especially when postoperative complications arise that initially appear isolated to the surgical field.

Such findings may prompt a re-evaluation of preoperative protocols to enhance patient safety.

12AP07-5

The effect of Body Mass Index on postoperative acute pain in lumbar disc herniation surgery

D. Çolak¹, M. Zengin², M.S. Kotanoğlu², A. Atasoy, A. Sezgi¹, J. Ergil² ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Çankaya, Turkey, ²University of Health Sciences, Ankara Etlik City Hospital, Anesthesiology and Reanimation, Cankaya, Turkey

Background and Goal of Study: Obesity has become a global public health issue. Elevated BMI complicates the application of nerve blocks and adversely affects postoperative pain levels.

This study aimed to investigate the relationship between body mass index (BMI) and postoperative pain levels in patients undergoing lumbar disc herniation (LDH) surgery, anesthesia, and analgesia.

Materials and Methods: Our study was conducted prospectively and observationally on patients in ASA I-II-III risk groups who underwent LDH surgery in the neurosurgery clinic of our hospital (https://clinicaltrials.gov/NCT06257953). Patients were classified into three groups based on their BMI levels: Group 1 (BMI: 18-24.9 kg/m²), Group 2 (BMI: 25-29.9 kg/m²), and Group 3 (BMI: 30-40 kg/m²). Erector spinae plane (ESP) block was performed under ultrasound guidance at the lumbar transverse process level, with 15 mL of 0.25% bupivacaine administered bilaterally.

Between the three groups, the following parameters were compared: patient age, BMI, gender, any complications observed during the procedure or postoperative follow-up, duration of anesthesia, duration of surgery, postoperative pain scores (Visual Analog Scale, VAS), and postoperative additional analgesic consumption. Results and Discussion: A total of 75 patients were included in our study between January 14, 2024, and April 19, 2024. In Group 3, remifentanil consumption, block application duration, the number of failed attempts, and additional analgesia requirements were significantly higher compared to Group 1.

Patients in Group 3 had significantly higher VAS-rest and VAScough scores at 1, 2, 6, 12, and 24 hours compared to those in Group 1. Similarly, VAS-rest and VAS-cough scores at 1, 6, 12, and 24 hours were significantly higher in Group 3 than in Group 2. Additionally, patients in Group 2 exhibited significantly higher VAS-rest and VAS-cough scores at 1, 2, 6, and 12 hours compared to Group 1. Additional analgesia was required in 35 patients (36.7%), and this need was significantly higher in obese patients (72%).

Conclusion(s): In patients undergoing LDH surgery, an increase in BMI was associated with higher pain scores, greater additional analgesic requirements, increased remifentanil consumption, a higher number of failed attempts, and prolonged block application times. Consequently, obese patients should be evaluated more carefully for postoperative pain management.

12AP07-6

Long term popliteal sciatic nerve block catheter for combat trauma management: a case report

A. Halushko¹, R. Voloshchuk¹, A. Medvid¹ ¹Military Medical Clinical Center of Western Region, Anesthesiology and Intensive Care, Lviv, Ukraine

Background: Combat lower limb injuries cause severe pain from fractures and tissue damage and require multiple surgical debridements. Popliteal sciatic nerve catheter can be used for intraoperative and postoperative pain relief.

We present a case where such a catheter was maintained for 57 days without complications, which is much longer than described in literature.

Case Report: A physically healthy 28-year-old with severe nociceptive pain (numerical pain score of 8) due to externally fixated tibial fracture and infected fasciotomy wounds after a recent blast injury. The pain was not responsive to NSAID's.

After obtaining the patient's consent, a 20G perineural catheter was placed inside the sciatic nerve paraneurium under ultrasound guidance via the popliteal approach.

The catheter was threaded 14 cm to the skin level, tunneled intradermally and fixed with a sticker. After a trial bolus of 20 ml of 1% lidocaine, effective analgesia was obtained, with numerical pain score reduced to 0.

Subsequently, an elastomeric pump with 0.25% bupivacaine was attached to the catheter at a rate of 10 ml/h. Over the next 45 days, the patient underwent 9 surgical procedures using combined inhalational non-opioid anesthesia with a LMA and perineural anesthesia with 20 ml of 0.5% bupivacaine.

Also, 20 ml of 0.25% bupivacaine was administered before each dressing change, which provided sufficient analgesia. A month later, due to a slight increase in pain, the patient received additional 10 ml of 0.25% bupivacaine every morning using patientcontrolled analgesia.

During the entire time the catheter was in place, the pump was replaced five times, the patch was replaced twice and the maximum pain on the numerical pain scale was 4 points.

Two weeks after wound closure, on the 57th day of catheter in place, the patient was pain-free, and the catheter was removed. There were no signs of inflammation at the puncture site.

Discussion: Our case demonstrates that long-term placement of continuous popliteal nerve block catheter provides sufficient pain relief for the entire cycle of combat wound healing and minimizes the use of opioids during anesthesia.

Learning points: Perineural sciatic catheter can function successfully for 57 days without complications.

12AP07-7

Use of saphenous block and sciatic block in guillotine amputation of the lower limb

J.C. Callejas-Rodelas¹, A. Martín-Arrabal¹, M. Díaz-Rueda¹, I. Moh-Martínez¹, M.A.C. Roussel¹, M. Olvera-García1

¹University Hospital Clínico San Cecilio, Department of Anesthesiology, Resuscitation and Pain Therapy, Granada, Spain

Background: Peripheral nerve blocks (PNBs) are a widely accessible anesthetic technique used in various surgeries. This case report presents the use of sciatic-popliteal and saphenous blocks in a vascular surgery.

Case Report: A 65-year-old woman with Type 2 Diabetes, Hypertension, bronchial asthma, and corticosteroid-dependent bronchiectasis (which caused baseline dyspnea with minimal exertion and poor tolerance to lying down) presented with right lower limb pain and wet gangrene, requiring urgent guillotine amputation. She had a history of femoropopliteal bypass.

Her baseline oxygen saturation was 88%, and lab results showed elevated inflammatory markers (C-reactive protein 253 mg/dL, procalcitonin 5.1 mg/dL), worsening renal function (creatinine 1.5 mg/dL, GFR 59 ml/min), and coagulopathy (INR 1.8).

Given her clinical condition, general or neuroaxial anesthesia were not suitable. Therefore, a sciatic-popliteal block and saphenous block were performed under ultrasound guidance. The blocks were successful, with proper anesthetic distribution and no complications.

The patient reported no pain (VAS 0/10) in the intraoperative period as well as in Post-Anesthesia Care Unit (PACU) and was discharged to the ward four hours later.

Discussion: Coagulopathy prevented neuroaxial anesthesia, and the patient's respiratory issues made general anesthesia challenging.

The peripheral nerve blocks allowed safe completion of the procedure. Ultrasound guidance was essential in ensuring proper block placement and avoiding complications like vascular puncture.

Learning Points: Peripheral nerve blocks offer an alternative to general or neuroaxial anesthesia in high-risk patients. However, they are operator-dependent, so a backup anesthetic plan should always be prepared.

12AP07-8 Continuous ESP block for Kommerell diverticulum resection: a case report

V. Artilheiro¹, <u>J. Labisa</u>², F. Rodrigues¹ ¹Hospital Santa Cruz, ULSLO, Anesthesiology, Lisboa, Portugal, ²Hospital Garcia de Orta, ULSAS, Anesthesiology, Almada, Portugal

Background: Kommerell diverticulum (KD) is a developmental anomaly of the aortic arch characterized by a diverticulum at the proximal descending aorta. While usually asymptomatic, it can be associated with tracheoesophageal compression. Given the worldwide implementation of ERAS pathways and the recognition of regional techniques as part of multimodal analgesic strategies. we report a case of KD resection performed under combined general anesthesia with a continuous Erector Spinae Plane block (ESPB).

Case Report: A 63 year old woman, ASA II, diagnosed with KD following complaints of dysphagia and persistent cough, was scheduled for surgical removal via left thoracotomy. Following induction of general anesthesia and vascular catheterization, an ESPB was performed at T5 level with 20mL of Ropivacaine 0.375%, followed by ultrasound-guided perineural catheter placement. Additional intraoperative analgesia was obtained with fentanyl boluses (total of 400mcg over 4h). The procedure was uneventful and the patient was transferred to the ICU under mechanical ventilation and IV sedation. In addition to conventional post-operative analgesia, a 48h perineural infusion of 0.2% ropivacaine at 7mL/h was initiated at the end of the procedure. The patient was extubated within the first 4 hours following surgery with adequate pain control, and discharged from ICU after 48h.

Discussion: Multimodal opioid-sparing analgesic strategies are an essential component of ERAS pathways, allowing a safe and early extubation, less postoperative pulmonary complications and better clinical outcomes. Despite its established role in thoracic surgery, regional techniques such as thoracic epidural or paravertebral blocks have a limited use in cardiac surgery, given the systemic heparinization associated with these procedures (1). In this setting, ESPB has emerged as a safe and effective alternative. This case reports the successful use of continuous ESPB for postoperative pain management, enabling an early extubation and rapid recovery following KD resection.

Reference:

1. Nair, A., et al. (2023). Erector spinae plane block for postoperative analgesia in cardiac surgeries- A systematic review and meta-analysis. Annals of cardiac anaesthesia, 26(3), 247-259.

Learning points: Continuous ESPB should be considered as an effective alternative to neuraxial techniques for cardiac surgery, as part of a multimodal opioid-sparing analgesic strategy.

12AP07-9

Awake breast surgery: a regional strategy for a patient with pulmonary hypertension

N. Mascarenhas¹, <u>J. Labisa</u>¹, D. Sampaio¹ ¹Hospital Garcia de Orta, ULSAS, Anesthesiology, Almada, Portugal

Background: Most women diagnosed with breast cancer will undergo surgery as part of their treatment. When advanced and severe cardiorespiratory pathology is present, rendering them unsuitable for general anesthesia (GA), an alternative approach involving a combination of regional techniques becomes imperative, particularly in time-sensitive breast and axillary surgeries.

Case Report: We report the case of a 69-year-old woman, ASA IV, with severe untreated pulmonary hypertension (PSAP 81 mmHg) and compromised functional capacity (2 MET), diagnosed with invasive breast cancer and scheduled for mastectomy with sentinel lymph node biopsy. Physical examination additionally revealed multiple difficult airway predictors and basal SpO2 88%.

The patient was deemed unfit for GA and the procedure was performed under regional anesthesia and moderate sedation. Thoracic paravertebral blocks (TPVB) were performed at T3 and T5 levels, with 15+13 mL of Levobupivacaíne 0.4% with adrenaline, followed by catheter placement at T5 level; additionally, Interpectoral Plane (IPPB) and Pectoserratus plane blocks (PSPB) were performed, with 20+10 mL of Levobupivacaíne 0.25%.

The patient was sedated with continuous dexmedetomidine and bolus ketamine without complications. Paracetamol 1000 mg, ketorolac 30 mg, and dexamethasone 8 mg were given as multimodal analgesia. The postoperative period was uneventful and for postoperative analgesia, intermittent perineural boluses with 10 mL of ropivacaine 0.2% were prescribed.

Discussion: TPVB is a well-established option for adequate surgical anesthesia for breast surgery. Given the complex innervation of the breast and axillary region, an association of multiple techniques is required, and the optimal combination is still up for debate.

This case reports the successful use of TPVB with PSPB and IPPB for anesthesia and pain management for mastectomy with sentinel lymph node biopsy.

References:

1. Schnabel, A., et al. (2010). Efficacy and safety of paravertebral blocks in breast surgery: a meta-analysis of randomized controlled trials. British Journal of Anaesthesia, 105(6), 842-852. 2. Hamilton, D. L., & Pawa, A. (2022). Anaesthesia for awake breast surgery. BJA education, 22(12), 452-455.

Learning Points: Two-level TPVB in association with PSPB and IPPB provides adequate surgical anesthesia for breast and axillary surgery and should be considered as an alternative to GA in selected cases.

12AP07-10

Brugada syndrome: epidural analgesia with ropivacaine as a safe option

C. C. Duarte¹, S. Lourenço¹, J. Pacheco² ¹Unidade Local de Saúde Santa Maria, Anesthesiology, Lisboa, Portugal, ²Hospital Beatriz Ângelo, Anesthesiolgy, Loures, Portugal

Background: Brugada syndrome is an autosomal dominant disorder characterized by abnormal myocardial transmembrane sodium conduction, which predisposes to ventricular tachyarrhythmias and sudden cardiac death in the absence of structural heart disease. Many factors during anesthetic management could precipitate malignant dysrhythmia.

We present a case of epidural management with ropivacaine of a Brugada Syndrome patient.

Case Report: We present the case of a 63-year-old male with an ASA II physical status and a past medical history of Brugada Syndrome diagnosed through routine ECG and genetic analysis. He was diagnosed with a splenic flexure tumor and a right inguinal hernia, for which laparoscopic extended right hemicolectomy and Lichtenstein hernioplasty were proposed.

First, defibrillator pads were placed and isoprenaline infusion was prepared. A 5-lead ECG, invasive blood pressure, capnography, pulse oximetry, and bispectral index (BIS) were used for monitoring. We administered 200 µg of intrathecal morphine and induced balanced general anesthesia with propofol, maintained with sevo-

Due to surgical difficulties, the procedure was converted to an open surgery, and at the end, a thoracic epidural catheter was inserted at the T9-T10 level for postoperative analgesia.

During the 72-hour postoperative period, PIEB with 0.1% ropivacaine (6 mL/h, PCA 4 mL, lockout interval 30 minutes) were administered under continuous ECG monitoring in an intermediate care unit. Hemodynamic stability and pain control were maintained, and no rhythm alterations were observed.

Discussion: During anesthesia, several drugs can interact with cardiac ion channels, potentially triggering malignant arrhythmias and, therefore, should be avoided in patients with Brugada Syn-

Of particular concern is the administration of local anesthetics due to their sodium channel-blocking properties, with adverse effects related to the plasma concentration achieved due to systemic absorption. To date, there is limited evidence regarding the safety of using epidural ropivacaine in these patients.

Our case report highlights the successful use of epidural ropivacaine 0.1% for postoperative analgesia. We emphasize the importance of monitoring these patients closely during the anesthetic procedure.

Learning points:

Epidural analgesia with ropivacaine is a suitable option for these

Antiarrhythmic drugs and a defibrillator must be ready to use.

12AP07-11

Two days with single shot block? It's possible

P. Santos Segueira¹, G. Araújo¹, R. Margues da Silva¹ ¹Unidade Local de Saúde Gaia Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: Peripheral nerve blocks (PNB) are common in anaesthesia, with a low incidence of nerve injury.1 In cases of prolonged sensory and motor block, a multidisciplinary approach is essential

Case Report: A 35-year-old male with obesity and hypertension underwent outpatient arthroscopic meniscectomy. Neurological exam was normal. With ASA monitoring, 1 mg midazolam and 50 μg fentanyl were given IV. Ultrasound-guided PNB of the saphenous nerve in the adductor canal and popliteal sciatic nerve (10 + 15 mL of 0.375% ropivacaine) were performed, with no blood aspiration, increased pressure or reported symptoms.

There were no complications, except for technical difficulties due to low image quality. General anaesthesia followed, and 4 mg dexamethasone administered IV. A tourniquet was applied at 280 mmHg (systolic blood pressure of 132 mmHg) on the right thigh for 23 minutes, with surgery lasting 33 minutes.

He was monitored in recovery and discharged 6 hours later, with expected motor and sensory block in the right leg. At 24-hour follow-up, he reported persistent motor block of the right lower limb, moving only his toes, with sensory block and paresthesia in L4 and L5 dermatomes. Deficits were confirmed in the emergency department. Orthopedic evaluation ruled out nerve compression, and ultrasound excluded deep vein thrombosis. It was assumed that the deficits were related to the PNB, after assessment by the acute pain unit.

At 40 hours post-surgery, he had 3/5 strength in the quadriceps and mild sensory reduction in L4-L5 dermatomes below the knee. By 52 hours, all deficits had resolved, and he was discharged.

Discussion: In cases of prolonged nerve block, ruling out other causes of deficits is crucial. Literature shows that 0.5% ropivacaine for sciatic nerve blocks yields sensory block lasting up to 11.2 hours and motor block up to 9.3 hours.2

With 0.375% ropivacaine a shorter duration was expected.

The longer effect may have resulted from low image quality affecting adequate anesthetic deposition, with possible subepineural administration.3

References:

- 1. BJA Education. Volume 18, Issue 12, 384-390.
- 2. Turk J Anaesth Reani. 2018;46(1):15-20.
- 3. Korean J Pain. 2021;34(1):132-136.

Learning points: Optimal conditions are essential for PNB safety. Even with relatively low concentration ropivacaine, prolonged blocks may occur, requiring a multidisciplinary approach and close monitoring. Subepineural administration may explain extended block duration.

High-transhumeral amputation under regional anesthesia in a fragile patient: a case report

İ. Topcu¹, A. Sezgi¹, M. Zengin², A. Atasoy, M.S. Kotanoğlu², J. Ergil² ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Çankaya, Turkey, ²University of Health Sciences, Ankara Etlik City Hospital, Anesthesiology and Reanimation, Cankaya, Turkey

Background: Peripheral nerve blocks (PNB) have advantages over general anesthesia, including preventing respiratory complications in the risky patient group, accelerating mobilization, shortening the hospital stay, and reducing postoperative opioid use. In this report, we presented our fragile patient who underwent high-transhumeral amputation surgery under regional anesthesia.

Case Report: A 85-year-old female patient who has a history of coronary and peripheral artery disease, asthma, and hypertension was evaluated in the ASA-4 risk group. Transhumeral amputation was planned for the patient with necrosis spreading from the distal part of the right hand to the right arm.

The patient was planned to undergo PNB to avoid respiratory and hemodynamic complications, provide effective postoperative analgesia, and shorten the duration of postoperative intensive care

The patient, for whom consent was obtained from herself and her relatives for the procedure, was monitored. A 30 ml solution consisting of 15 ml of 0.5% Bupivacaine, 7.5 ml of 2% Lidocaine, and 7.5 ml of physiological serum was prepared. After sterilization, a 50 mm PNB needle was advanced into the interscalene space using the in-plane technique under ultrasound guidance. 15 ml of local anesthetic (LA) solution was applied to the brachial plexus in the interscalene space.

Then, the brachial plexus trunks were visualized around the subclavian artery for a supraclavicular block. 15 mL of LA solution was administered using a similar technique. After 30 minutes, the operation began after a pinprick test.

The patient underwent a high-transhumoral amputation without any problems. The patient was transferred to the surgical intensive care unit for close follow-up in the postoperative period, with her general condition and hemodynamic parameters being compatible with those before the operation.

After 24 hours of CYB hospitalization and 2 days of ward followup, the patient was discharged with recovery.

Discussion: Complications that may occur due to general anesthesia can be prevented with awake surgery, especially in risky patients.

In addition, anesthesia and surgery times may be shorter, and the discharge time may be faster. In high-risk and geriatric patients, peripheral nerve blockade may be preferred to general anesthesia unless there is an absolute contraindication.

12AP08-2 PECS blocks that reached brachial plexus: is it possible?

J. Magalhães Pereira¹, H. Petiz Lousã¹, J. Novo¹, T. Barbosa¹ ¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Regional anaesthetic techniques, usually combined with general anaesthesia, have become common in perioperative management of the patient for breast cancer surgery. The use of pectoral nerve blocks (PECS) I and II, provide an excellent postoperative analgesia, an opioid sparing, and reduction in postoperative nausea and vomiting.1

Case Report: We present a case of a female patient, 58 yearsold, ASA II. Proposed for surgery to remove breast expanders with placement of implants. With a personal history of breast cancer. A combined anesthetic technique was performed, total intravenous anesthesia with PECS I and II block, ultrasound-guided, bilateral, with ropivacaine 3 mg/mL, 150 mg (50 ml) in total, uneventful.

The surgery was uneventful, extubated without complications, paracetamol and ketorolac were administered for postoperative analgesia, sparing opioids use, and transferred to the Post-Anesthetic Care Unit (PACU). In PACU, the patient denied any pain but complained of lack of strength in her left upper limb. Upon evaluation, she presented complete motor and sensory blockade in the territory of the median and musculocutaneous nerve, unable to elevate the left upper limb against gravity.

After a complete neurological examination with no other changes, it was explained to the patient that it was a rare complication of local anesthetic migration and that she would be kept under observation until complete resolution.

This distribution of the local anesthetic, from the plane of the pectoral nerve and serrated to the plane of the brachial plexus, may have occurred due to the alteration of normal anatomy due to the dissection of tissues and muscles in the previous surgery.

She was discharged to the infirmary, with continuous monitoring, having complete resolution of the blockade after 10pm, without any residual deficit.

Discussion: This case highlights the importance of knowing this type of complications that although rare, may become more common with the increase in regional anesthesia techniques in postmastectomy or lumpectomy breast reconstructive surgery.

Reference:

A. Sherwin, D.J. Buggy, Anaesthesia for breast surgery, BJA Education, 18(11): 342e348 (2018)

Learning points: A high degree of clinical suspicion is necessary, exclusion of other differential diagnoses such as stroke or nerve injury due to perioperative compression and poor positioning, close surveillance in the postoperative period and reassurance of the patient are essential.

12AP08-3

Comparison between Supra-inguinal Fascia Iliaca Block, intrathecal morphine and their combination in postoperative pain trajectory after total hip arthroplasty: preliminary results of a double-blind randomized clinical trial

A. Desmecht¹, F. Beck¹, N. Piette¹, V. Bonhomme¹, M. Carella¹

¹Liege University Hospital, Department of Anaesthesia and Intensive Care Medicine, Liege, Belgium

Background and Goal of Study: Posterolateral-approached total hip arthroplasty (PLTHA) can be characterized by moderate to severe early postoperative pain with potential impairment of functional recovery. Low-dose intrathecal morphine (ITM) or suprainguinal fascia iliaca (SFIB) blocks have been recommended to provide adequate analgesia.¹

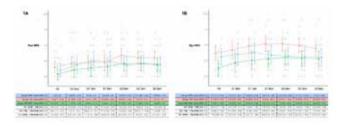

Our aim was to compare these techniques and their association regarding pain trajectory during the first 48 hours following PL-THA.

Materials and Methods: Thirty-eight consenting patients scheduled for PLTHA with spinal anesthesia were prospectively and randomly allocated into three groups. Patients received either SFIB [40mL ropivacaine 0.375% (SFIB and ITM-SFIB groups) or saline (ITM group)], and 1 mL of intrathecal morphine 0.01% (ITM and ITM-SFIB groups) or saline (SFIB group).

A blinded observer noted the evolution of rest and dynamic pain on 11-points numeric rating scale (Rest NRS and Dyn NRS) 8 hours after surgery (H8) and at 8am, 1pm and 6pm at postoperative day-1 (D1) and day-2 (D2). Differences between groups and time-groups interactions were analyzed using generalized linear mixed model tests.

Results and Discussion: No significant effect of group (P=0.31) nor time-group interaction (P=0.65) was observed for rest NRS. A significant effect of group was observed for dynamic pain (P=0.02), without group-time interaction (P=0.55).

Post hoc comparisons revealed that the ITM-SFIB group had better pain trajectory than the ITM group, over all observed time-points (Figure).

Conclusion(s): In PLTHA, no difference was observed between the SFIB and the ITM regarding postoperative pain trajectory at rest and movement during the first 48 hours. The association of SFIB with ITM is superior to ITM alone, but not to SFIB alone, regarding dynamic pain during the first 2 days. These results need to be confirmed once the planned sample size (114) will have been recruited.

12AP08-4

Comparison of the analgesic efficacy of Erector Spinae Plane Block and superficial parasternal block in open cardiac surgery: a pilot study

A.Y.-T. Chang¹, C.-H. Shen¹, T.-W. Liang²
¹Taichung Veterans General Hospital, Anesthesiology
Department, Taichung, Taiwan, ²Show Chwan Memorial
Hospital, Anesthesiology Department, Changhua, Taiwan

Background and Goal of Study: Postoperative pain management is crucial for recovery. While regional analgesia methods are effective, direct comparisons between techniques are limited. This study evaluates the efficacy of erector spinae plane (ESP) and superficial parasternal blocks in postoperative opioid consumption and dynamic pain control.

Materials and Methods: This pilot study, part of a randomized controlled trial (NCT06322810) at Taichung Veterans General Hospital, included 36 patients undergoing first-time open-heart surgery via sternotomy. Patients were randomly assigned to receive either an ESP or a superficial parasternal block. Both blocks involved the administration of 20 mL of 0.5% Ropivacaine bilaterally preoperatively and 0.16% Ropivacaine boluses every 4 hours postoperatively. All patients received IV acetaminophen 1 g every 6 hours, with IV tramadol as rescue analgesia. The primary outcome was 48-hour oral morphine equivalent (OME), and secondary outcomes included static and dynamic pain scores measured using the Numeric Rating Scale (NRS, 0–10) at 12, 24, 36, and 48 hours.

Results: The median age of patients was 59 years, with a median EuroSCORE of 2.52. Of the 36 patients analyzed (18 ESP, 18 parasternal), demographic characteristics were comparable between groups. There were no significant differences in post-operative ventilator-dependent duration or length of hospital stay. Postoperative 48-hour OME was also similar (ESP: 17.5 mg [9–30] vs. Parasternal: 25 mg [15–41], p = 0.125). Resting pain scores showed no significant differences.

However, dynamic pain scores were significantly lower in the ESP group at all time points:

- 12 hours: ESP 0 (0-3) vs. Parasternal 3 (2-5), p = 0.035
- 24 hours: ESP 0 (0-3) vs. Parasternal 5 (2-5), p = 0.004
- 36 hours: ESP 2 (0-4) vs. Parasternal 4 (2-6), p = 0.010
- 48 hours: ESP 2 (0–3) vs. Parasternal 3 (2–5), p = 0.035 (Fig. 1).

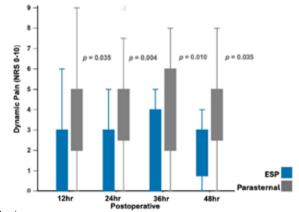

Fig. 1.

Conclusion: Both blocks provided similar resting pain control, opioid-sparing effects, ventilator duration, and hospital stay, but the ESP Block demonstrated superior dynamic pain control post-operatively.

12AP08-5

Ultrassound-guided Infrazygomatic Pterigopalatine Fossa Block (IZPFB) for tonsillectomy surgery in adults

A.S. Vaz¹, A. Amaral¹, <u>A.C. Salgueirinho da Silva Ferreira</u>² ¹Unidade Local de Castelo Branco, Anestehsiology, Castelo Branco, Portugal, ²Centro Hospitalar de São João, Anesthesiology, Porto, Portugal

Background: Tonsillectomy is a very common surgical procedure, but frequently associated with moderate to severe postoperative pain.

An optimal analgesia promotes comfort, reduces anxiety and allows an early oral intake and hydration¹.

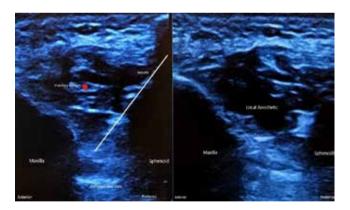

With a median recovery time of 10 days, the first 3-5 days after surgery are the most painful. A multimodal analgesia should be performed, avoiding adverse effects, particularly those related to opioids.²

Regional analgesia techniques, like infrazygomatic pterygopalatine fossa block (IZPFB) are great alternatives and should be included as part of multimodal analgesia.

Case Report: A 26 and 41 year-old women, ASA I and II, respectively; and a 45 year-old man, ASA II, were admitted for tonsillectomy due to recurrent tonsillitis.

For all patients, general anesthesia was performed followed by bilateral ultrasound-guided IZPFB with Ropivacaine0.2% 20mg and dexamethasone 8mg. Paracetamol and ketorolac were also administered.

In the Post Anesthetic Care Unit (PACU), only one of the patients mentioned little discomfort, mostly associated to swallow movement. Patients reported little to zero pain during hospital stay with paracetamol and ketorolac.

Discussion: Ropivacaine and dexamethasone injected in the pterygopalatine fossa bathes the maxillary nerve promoting a long lasting analgesic effect.

The infrazygomatic approach using landmarks present some risks like puncture of the maxillary artery, submucosal abcess or intraorbital injection.

An ultrasoung guided technique allows identification of the internal maxillary artery, needle tip and spread of local anesthetic.

Reference:

1. Qian, L., Li, X., Chen, H. & Chi, X. (2020). Recent advances in post-tonsillectomy analgesia. Digestive Medicine Research; Vol 3 (September 2020): Digestive Medicine Research; Opioidfree anesthesia. Beloeil H. Best Pract Res Clin Anaesthesiol. 2019;33:353–360. doi: 10.1016/j.bpa.2019.09.002. [DOI] [PubMed] [Google Scholar]

Learning points: Regional analgesic techniques, whenever possible, should be applied in order to promote better comfort, as well as avoid possible adverse effects related to opioids.

12AP08-6

Effectiveness of Combined Serratus Anterior Plane Block in managing acute pain after breast-conserving surgery: a case series

E. Soyaslan¹, <u>U.C. Ozagar</u>¹, H.A. Sarıbudak¹, L.F. Eser Çelik¹, E. Güngördü¹, E. Arik¹ ¹Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Serratus anterior plane block (SAPB) is a frequently preferred in breast surgeries due to its prolonged duration of action, wide block coverage, and low risk of severe complications related to procedure. Local anesthetics (LA) can be administered beneath serratus anterior muscle,onto the overlying fascia,or in a combined. Third to sixth intercostal nerves, as well as the long thoracic and thoracodorsal nerves, are blocked. In this report, we aim to present analgesic effects of combined SAPB (CSAPB) administered for perioperative analgesia in three patients undergoing breast-conserving surgery (BCS).

Case Report: After monitoring with ASA standards, they were intubated following induction. In supine position, patients underwent ultrasound-quided CSAPB on operative side with a singleneedle insertion. First, deep SAPB (15 mL of 0.25% bupivacaine) was administered, followed by superficial SAPB (15 mL of 0.25% bupivacaine). Intraoperative remifentanil dose was titrated between 0.05-0.25 mcg/kg/min, considering 20% change in baseline mean arterial pressure or heart rate. For postoperative multimodal analgesia, patients were given 50 mg IV dexketoprofen and 100 mg IV tramadol. Demographic data, intraoperative vital signs, remifentanil usage, postoperative pain levels (visual analog scale: VAS), and additional analgesic requirements were recorded. All patients were female with an average age of 57.6 years and average body mass index (BMI) of 27.3 kg/m2. They were all ASA II. Average surgery duration was 118 minutes, average remifentanil use was 283 mcg, and the average postoperative VAS scores were recorded as follows: 1st hour: 1.66,2nd hour: 1.33,8th hour: 124th hour-1

No block-related complications developed in any patient. Postoperative vital signs were stable, and no additional analgesic was required.

Case	Age (Year)	Gender	BMI (kg/m²)	ASA	Surgery duration (min)	Remifentanyl dosage (mcg)
1	46	Woman	26	II	120	250
2	62	Woman	29	II	116	400
3	65	Woman	27	Ш	118	200

Discussion: Severe postoperative pain is common after chest wall surgeries, potentially leading to complications like atelectasis. Effective pain management reduces these risks. CSAPB was effective in alleviating acute pain post-BCS and is safe,easily performed technique under ultrasound guidance.

Learning points: Postoperative Analgesia, Combined Serratus Anterior Plane Block

12AP08-7

Combined spinal anaesthesia with hypobaric bupivacaine and erector spinae plane block (ESPB) for microwave ablation of a T9 osteoid osteoma in the prone position in a patient with opioid use disorder

M. Eizaguirre Cotado¹, A. Abad Motos¹, A. Larrea Aseguinolaza¹, O. Zubimendi Redondo¹, M. Chueca Bolaño¹, L. Roteta Nazabal¹, RI-TEAM ¹Hospital Universitario Donostia, Anesthesiology and Critical Care, San Sebastian, Spain

Background: Osteoid osteomas are benign tumors that involve the long bones and spine. Microwave ablation (MWA) under CTguidance is gradually being established as a treatment option for osteoid osteoma, delivering high-energy electromagnetic waves reaching temperatures up to 150° C, leading to coagulative necrosis. This procedure must be performed under general or regional anaesthesia.

Case Report: 43 year old man with an osteoid osteoma in the T9 left transverse process, scheduled for MWA in the prone position. BMI 15.8 kg/m², smoker, ocasional alcohol drinker, history of illegal drug abuse, taking prescription opioids for pain (tramadol and codein), paracetamol and diazepam. Before entering the Interventional Radiology room and after administering 2mg i.v. midazolam we performed an ultrasound guided left erector spinal plane block (ESPB) at T9, with 20 mL 0,25% L-bupivacaine. Afterwards, just before standing in the prone position, an hypobaric spinal anaesthesia was administered, with 6mg 0.5% L-bupivacaine and 10 mcg fentanyl diluted in sterile distilled water to a total of 4 mL. Propofol TCI at 2 mcg/ml was started after positioning the patient, and the ablation was performed uneventfully, with the patient mantaining spontaneous breathing comfortably in the prone

Discussion: Patients with opioid use disorder are more likely to have inadequate postoperative relief from acute pain, and perioperartive multimodal opioid-sparing techniques are recommended. In addition, general anaesthesia in the Interventional Radiology room can be challenging due to the limited room for the equipment. We performed a hypobaric spinal anaesthesia with 6mg of 0.15% L-bupivacaine, with the purpose of blocking only dorsal sensory roots in the prone position. In addition, the ESPB would bring additional intraoperative sensory block and provide postoperative analgesia.

References:

Paliwal N, et al. Spinal Anaesthesia Using Hypobaric Drugs: A Review of Current Evidence. Cureus 2024;16(3):e56069. Cazzato RL, et al. Percutaneous microwave ablation of bone tumors: a systematic review. Eur Radiol 2021;31(5):3530-3541.

Learning points: The sum of a hypobaric spinal anaesthesia and a thoracic ESPB is a good choice in patients undergoing percutaneous painful procedures in the low thoracic spine, avoiding general anesthesia and maintain spontaneous breathing, and providing adequate intra and postoperative analgesia as part of a multimodal opioid-sparing regime.

12AP08-8

Is spinal anesthesia always to blame? A tale of two cases

R. Şerefoğlu¹, B.B. Kurt², S. Islamoğlu³, G.H. Alay¹, A. Tas Tuna4

¹Başakşehir Çam and Sakura City Hospital, Department of Critical Care Medicine, Istanbul, Turkey, ²Basaksehir Cam and Sakura City Hospital, Department of Anesthesiology and Reanimation, Istanbul, Turkey, 3Silivri State Hospital, Department of Anesthesiology and Reanimation. Istanbul, Turkey, ⁴Sakarya University Faculty of Medicine, Department of Anesthesiology and Reanimation, Sakarya, Turkey

Background: Spinal anesthesia is a widely used technique due to its safety and faster recovery. However, rare neurological complications can be severe¹. But not all postoperative complications can be attributed to the procedure2.

This report presents two cases where symptoms initially seemed related to spinal anesthesia but were ultimately linked to other conditions, emphasizing the importance of thorough evaluation and prompt diagnosis.

Case 1: A 28-year-old male, classified as ASA 1, underwent spinal anesthesia for anal fissure surgery. Eight days later, he presented with persistent headaches. Examination findings inconsistent with a typical post-spinal headache prompted cranial imaging. Diffusion MRI showed restricted diffusion, while lumbar puncture revealed elevated cerebrospinal fluid (CSF) protein levels. PCR analysis of the CSF confirmed Mycobacterium tuberculosis. Spinal MRI subsequently identified Pott disease. Anti-tuberculous therapy and neurosurgical stabilization were initiated, leading to significant improvement.

Case 2: A 42-year-old male, classified as ASA 2, underwent spinal anesthesia for anal abscess drainage. Two days later, he presented with new-onset right thigh pain and difficulty mobilising. Neurological examination revealed radicular pain in the L1-L3 region. A possible nerve root compression or pelvic pathology was suspected. Lumbar MRI showed no abnormalities, but pelvic MRI identified an obturator abscess extending to the anal region. Interventional radiology successfully drained the abscess, and the patient showed significant improvement upon discharge.

Discussion: Spinal anesthesia carries risks such as headaches and neurological complications, but these complications can obscure serious underlying conditions. Both cases highlight the importance of accurate assessment, detailed history-taking, and timely imaging in differentiating procedure-related complications from unrelated pathologies.

References:

1. Parnass SM, Schmidt KJ. Adverse effects of spinal and epidural anaesthesia. Drug Saf. 1990 May-Jun;5(3):179-94. 2. Hewson DW, Bedforth NM, Hardman JG. Spinal cord injury arising in anaesthesia practice. Anaesthesia. 2018 Jan;73 Suppl 1:43-50

Learning points:

- Not all postoperative symptoms stem from spinal anesthesia.
- Thorough evaluation, including imaging and history-taking, is essential for accurate diagnosis.
- Multidisciplinary collaboration ensures optimal outcomes for complex cases.

12AP08-9 Intrathecal hydromorphone for postoperative pain management in gastrectomy

L. Ding1, Q. Li1

West China Hospital of Sichuan University, Chengdu, Sichuan Province, China, Department of Anaesthesiology, Chengdu, China

Background: Current guidelines recommend regional anesthesia as a fundamental component of multimodal analgesia for gastrectomy. Single-dose intrathecal hydromorphone or transversus abdominis plane (TAP) block has emerged as alternative options. However, the optimal dose of intrathecal hydromorphone in gastrectomy remain unclear.

This study aims to determine the effective dose 95% (ED95) of intrathecal hydromorphone, as well as to compare its analgesic efficacy with the TAP block following gastrectomy.

Methods: A double-blind sequential allocation trial using up-down design determined the ED95 dose of intrathecal hydromorphone in 51 patients aged ≥18 years undergoing elective gastrectomy (ASA I-III). The starting dose was 50 µg, and responses were assessed using the numeric rating scale (NRS).

A subsequent randomized controlled trial (RCT) enrolled 96 patients meeting the same criteria, randomized to receive either intrathecal hydromorphone (ED95 dose, ITHM group) or TAP block (15 mL of 0.2% ropivacaine per point).

The primary outcome was the area under the curve (AUC) of NRS scores at active within 24 hours post-surgery.

Secondary outcomes included AUCs at various time points at rest or active, analgesic use, adverse events, and recovery outcomes.

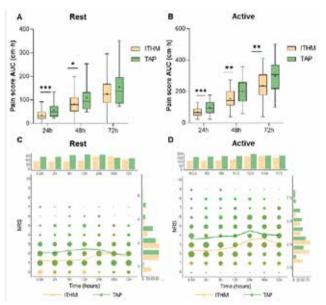

Figure 1: Pain scores AUC and numerical rating scores (NRS) over time for intrathecal hydromorphone versus TAP block.

Results and Discussion: The ED95 dose for gastrectomy was 131.67 μg (95% CI: 113.19–150 μg). In the RCT, 89 patients completed the final modified intention-to-treat analysis. The ITHM group showed a 30% reduction in 24-hour pain score AUCs at active compared to the TAP group (65.0 cm·h vs. 93.0 cm·h, P = 0.001, Figure 1).

Postoperative hydromorphone consumption was significantly lower in the ITHM group at 24 hours (4.2 mg vs. 5.2 mg, P = 0.008)

and 48 hours (8.4 mg vs. 10.0 mg, P = 0.027). No significant differences were observed in recovery outcomes or adverse events between two groups.

Conclusion(s): At the ED95 dose (150 µg), it delivers effective postoperative analgesia for gastrectomy, significantly enhancing pain control and reducing opioid consumption without increasing adverse events.

12AP08-10

ESP block in mastectomy: experience and prospects of use in breast cancer

N. Batyrbekova, Master of medicine¹, M. Zhumabaev, PhD², E. Umbetzhanov, chef of department¹, NROC Study Group ¹National Research Oncology Center, Anesthesiology, Astana, Kazakhstan, ²Astana medical university, Anesthesiology, Astana, Kazakhstan

Background and Goal of Study: General anesthesia is widely used for radical mastectomy but cannot fully block central nervous system pain signals. High anesthetic doses may lead to PONV, respiratory depression, and poor outcomes. Mastectomy is highly traumatic, necessitating effective pain management. To evaluate if ESP block enhances postoperative pain control, reduces analgesic use, and accelerates recovery in breast cancer

Materials and Methods: Forty adult women undergoing mastectomy were included. Exclusion criteria: severe chest injuries, drug allergies, and refusal to participate. Patients were randomized into two groups: standard general anesthesia (control) vs. anesthesia + ESP block (MCA+ESP). Pain was assessed using the Visual Analogue Scale (VAS), with Promedol administered if VAS exceeded 4. The ESP block (30 ml 0.75% Ropivacaine) was quided by ultrasound at Th5–Th6.

Results and Discussion: ESP block significantly reduced VAS scores and opioid consumption. Pain relief was sustained postoperatively, improving mobility and rehabilitation markers at 12 and 24 hours (e.g., sitting up, deep breathing, raising arms). This technique showed superior postoperative outcomes, minimized risks, and enhanced recovery compared to the control group.

Conclusion: ESP block is effective in mastectomy anesthesia protocols, reducing pain and opioid reliance while accelerating recovery. Ultrasound guidance ensures precision and safety, enhancing patient outcomes and guality of life.

Comparison of respiratory effects of interscalene and superior trunk blocks as sole anesthetic techniques for shoulder arthroscopy: a randomized controlled trial

B.M. Büyükgebiz Yesil¹, G. Emmez¹, D.B. Günaydın¹, U. Kanatlı², K. Oğuzülgen³, İ. Güngör¹ ¹Gazi University, Anesthesiology and Reanimation, Ankara, Turkey, ²Gazi University, Orthopaedics and Traumatology, Ankara, Turkey, ³Gazi University, Pulmonary Medicine, Ankara, Turkey

Background and Goal of Study: Interscalene brachial plexus block (ISB) is the "gold standard" for shoulder surgery but involves a high risk of hemidiaphragmatic paralysis (HDP) due to phrenic nerve involvement¹.

Superior trunk block (STB) has emerged as a potential alternative brachial plexus block for analgesia that minimizes respiratory impairment².

We aimed to compare the respiratory effects of ultrasound (USG) guidedISB and STB for shoulder arthroscopy.

Materials and Methods: After approval of the ethics committee, 118 patients scheduled for elective shoulder arthroplasty were enrolled in this prospective observer-blinded study. Patients were randomly assigned to two groups to perform USG-guided either ISB or STB using 25 mL of 0.5% bupivacaine.

Respiratory outcomes were assessed pre- and post-block 30th minute, including diaphragm excursion (DE) and spirometry values (FEV1: Forced Expiratory Volume in 1 second, FVC: Forced Vital Capacity, and FEV1/FVC). HDP was graded based on DE reduction. Secondary outcomes included analgesic efficacy, patient satisfaction, and complications. Surgical anesthesia was successful without general anesthesia support.

Results and Discussion: The demographic data was comparable between the groups. The DE reduction was significantly higher in the ISB group compared to the STB group both in normal and deep breathing (63.67% vs. 24.18% and 63.84% vs. 23.67%; p <0.001).

The incidence of HDP was higher in the ISB group (96.6% vs. 37.3%; p <0.001). FEV1, FVC, and FEV1/FVC reductions were more significant in the ISB group (33.40%, 30.17%, and 4.27%) compared to the STB (20.04%, 19.99%, and 0.28%; p <0.001). No patients required rescue analgesia.

Despite the pulmonary function differences, time to first analgesic request and patient satisfaction were similar between groups. The STB demonstrated a superior safety profile with fewer respiratory and neurological complications in patients undergoing shoulder arthroscopy.

Conclusion(s): The USG-guided STB provides an effective and safer alternative to ISB for shoulder arthroscopy to achieve surgical anesthesia. STB preserves respiratory function and reduces HDP incidence, making it a safer option for patients at risk of respiratory complications, such as those with chronic obstructive pulmonary disease, asthma, or obesity.

12AP08-12

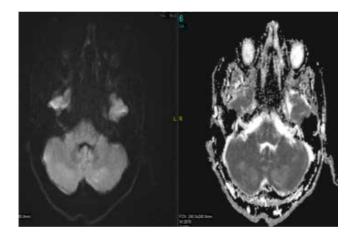

From post-dural puncture headache to posterior reversible encephalopathy syndrome: a case report

F.C. Yerebakan¹, N.S. Bayburt¹, B.N. Evliya Felek¹, H. Duzla¹, Ç. Yıldırım Güçlü¹ ¹Ankara University, Faculty of Medicine, Deparment of Anesthesiology and Reanimation, Ankara, Turkey

Background: Post-dural puncture headache (PDPH) occurs after dural puncture during spinal anesthesia, within 24-48 hours. The headache is fronto-occipital and worsens with upright posture. Rare complications include subdural hematoma, cerebral venous sinus thrombosis, Reversible Cerebral Vasoconstriction Syndrome (RCVS), and Posterior Reversible Encephalopathy Syndrome (PRES) (1).

This report discusses a PDPH patient later diagnosed with PRES. **Case Report:** A 19-year-old male with no significant medical history underwent pilonidal sinus surgery with spinal anesthesia. Six hours postoperatively, he developed nausea, vomiting, and a headache, diagnosed as PDPH. Conservative treatment was initiated.

On the second postoperative day, he developed blurred vision and seizure-like symptoms. Brain CT revealed extra-axial dense areas. Diffusion MRI showed vasogenic edema in both cerebral hemispheres and occipital regions, raising suspicion for PRES.

Spinal MRI showed no CSF leakage, and MR Venography without thrombosis. MR Angiography showed no major arterial occlusion. Antiepileptic treatment was started. Imaging showed no progression, symptoms improved, and he was discharged on day 6. A follow-up MRI showed regression, confirming the PRES diagnosis.

Discussion: PDPH is typically treated conservatively, but neurological symptoms like those seen in PRES can indicate serious complications.

PRES is a rare syndrome characterized by headache, visual disturbances, and seizures, often associated with blood-brain barrier dysfunction, cerebral edema and disrupted cerebral autoregulation.

MRI shows symmetrical vasogenic edema in the parieto-occipital regions and subcortical white matter (2).

Posterior Reversible Encephalopathy Syndrome and Reversible Cerebral Vasoconstriction Syndrome: Clinical and Radiological Considerations, Front Neurol, 2020 Feb. 14:11:34.

Learning Points: Understand the importance of evaluating neurological symptoms in PDPH patients to early diagnose and manage serious complications like PRES.

12AP09-1

Use of three-dimensional spine reconstruction to guide perivertebral thoracic epidural insertion - a prospective observational pilot study

R. Shaylor¹, V. Verenkin¹, V. Rabkin¹, C. Weiniger¹, B. Cohen^{1,2}

¹Tel Aviv Medical Center, Division of Anesthesiology, Intansive Care and Pain Medicine, Tel Aviv, Israel, ²University of Texas, Outcomes Research Consortium, Huston, United States

Background and Goal of Study: Thoracic epidural (TEA) inserted via palpation techniques has a failure rate of 3-11%. Use of CT to pre-plan surgical procedures has become increasingly popular.

We hypothesized that by employing similar principles and technology we could create a 3D model, plan the optimal insertion site and angle for TFA.

Materials and Methods: Using a 3D model of a patient's CT scan, the TEA insertion site was planned by marking a tract from the epidural space to the skin avoiding bony structures. The skin insertion site of the tract was measured as the lateral and caudal distance to the nearest spinous process. This was then marked on the patient and the anesthesiologist was given the angle of the epidural tract.

The primary outcome was successful loss of resistance)LOR) allowing insertion of the epidural catheter. Secondary outcomes were epidural success, defined as a TEA in use on POD 1; the number of epidural insertions; the number of needle re-angulations: needle insertion time.

Results and Discussion: 15 patients underwent TEA with 3D planning. Successful loss of resistance allowing insertion of the epidural catheter, was achieved for all patients. 14/15(93%) epidurals were successful. In one patient the procedure was abandoned due to blood aspirated from the epidural catheter.

LOR was achieved on the 1st attempt in 13/15 (86%), the maximum number of epidural insertions was two (0[0-0]). 8/15 (53%) of patients required zero needle re-angulations, the maximum number of re-angulations was three, O[0-1]. Median time from needle insertion to loss of resistance was 56(37-66.5)[29-119] seconds

This study represents the first utilization of pre-procedure 3D modeling to plan patient-specific optimal TEA insertion sites. Loss of resistance allowing insertion of an epidural catheter was achieved in 100% of patients and 93% of patients had an effective epidural.

Additionally, the number of patients who had an epidural on the first attempt was higher than the departmental average for TEA 86% vs 46%, the number of needle re-angulations was also much less than data for neuraxial anesthesia previously published by our department

Conclusion(s): In this proof of concept study we have shown that it is possible to successfully pre-plan the epidural insertion site and angle from a 3D model of CT images. This represents a critical step in the development of CT guided navigation for TEA and potentially other invasive anesthesia procedures.

12AP09-2

Peng block as part of multimodal analgesia for pain management in hip arthroplasty

A. Arregui Rodriguez¹, A. Lara¹, N. Echeverria¹, A. Abad¹, C. Yarnoz¹, C. Garicano¹

¹Donostia University Hospital, Anesthesia and Critical Care, San Sebastian, Spain

Background and Goal of Study: Total hip arthroplasty is one of the most common and frequent orthopedic procedure. Effective pain management after total hip arthroplasty is essential for early rehabilitation, patient satisfaction, and functional recovery.

Materials and Methods: We conducted a retrospective analysis with the aim of evaluating the analgesic quality of a multimodal analgesia program in patients who underwent total hip arthroplasty over a period of 6 months. A total of 30 patients were included, all of whom received intradural anesthesia combined with a PENG block. The following data was evaluated during the first 48 postoperative hours: ENA scale, analgesic medication used, milligrams of dexamethasone administered, opioid consumption, side effects, recovery time from the anesthetic block, time to the onset of sitting and ambulation, and length of hospital stay.

Results and Discussion:

- 76.6% received a complete multimodal analgesic treatment, which consisted of the administration of an analgesic (paracetamol), a NSAID (dexketoprofen or ibuprofen), and intraoperative dexamethasone, along with the performance of a PENG block (levobupivacaine 0.25%, 20 ml).
- 60% of the patients received a dose of dexamethasone ≥ 10 mg. The average dose used was 13.4 mg.
- In 90% of cases, the PENG block was performed before the surgery.
- The average morphine consumption per patient during the first 48 hours was 1.5 mg IV. In patients with complete treatment who received a dose of dexamethasone ≥ 10 mg, the average morphine consumption was 2.31 mg.

	In PACU	24h	48h	
Mild pain	82,6%	47,8%	100%	
Moderate-to-severe pain	17,4%	51,2%		
Patients with INCOMPLETE	multimodal analge	esic treatment (23.3%)		
	In PACU	24 h	48 h	
Mild pain	71,4%	57,1%	71,4%	
Moderate-to-severe pain	28.6%	42,9%	28,6%	

Conclusion(s): We observed that the PENG block is a safe and effective block. However, further studies are still needed to determine the optimal timing and dosage for its administration.

Stellate ganglion block: the future treatment for electrical cardiac storms - case report

M.J. Nascimento¹, R. Góis¹, E. Semedo¹ ¹Unidade Local de Saúde de Coimbra, Anestesiologia, Coimbra, Portugal

Background: Electrical cardiac storms, characterized by rapid recurrence of episodes of ventricular tachycardia (VT) or ventricular fibrillation (VF), are life-threatening medical emergencies difficult to treat. Current pharmacological treatment (amiodarone, beta-blockers) have limitations regarding their effectiveness[1,2]. Increasingly evidence suggests that ultrassound guided stellate ganglion block (SGB) (cervical sympathetic chain) with a local anesthetic (Moore technique) may be a treatment option, and without limitations regarding the patient's anticoagulation status[1]. We present a case of a patient with electrical storm treated with stellate ganglion block.

Case Report: A 69-year-old male patient with a past medical history of atrial fibrillation (on dabigatran anticoagulation), heart insufficiency (EF 49%), alcohol and tobacco consumption, type II diabetes mellitus and benign prostatic hyperplasia (BPH), was admitted for revascularization angioplasty after an inferolateral STEMI.

On the 4th day of hospitalization, developed septic and cardiogenic shock, electrical storm with multiple episodes of VT and cardiac arrest with ROSC after 40 minutes of advanced life sup-

On the 7th day of hospitalization, was proposed a ultrasoundguided left-sided SGB. With a 30 mm needle, lidocaine 2% 5 mL and bupivacaine 0.25% 5 mL, were administered without compli-

Confirmation of the block was achieved by immediately observing miosis, hyperemia, and increased skin temperature on the blocked side. Three VT episodes were recorded within 24 hours after the SGB, hemodynamic stability was achieved and no further dysrhythmic episodes were observed subsequently.

Discussion: SGB is an effective, minimally invasive and with low risk of complications technique for recurrent VT/VF. Currently, it's not included in the guidelines, with the potential to be part of the treatment for refractory VT/VF[1,2].

Learning Points: SGB could be a promising treatment for electrical cardiac storms.

12AP09-5

Comparative evaluation of analgesic efficacy of the ultrasound guided erector spinae plane(ESP) block versus transversus abdominis plane(TAP) block in children undergoing unilateral abdominal surgeries: a prospective randomised controlled trial

HDL.A. Poumai¹, R.K. Pandey¹, G. Prasad¹, V Darlong¹, J. Punj¹, R. Ramachandran¹

¹All India Institute of Medical Sciences, Anaesthesiology. Pain Medicine and Critical Care, New Delhi, India

Background and Goal of Study: Pain in children, especially infants are frequently underestimated with the assumption that the immature nervous system protects against acute pain experience. However, recent studies reveal that physiological instability. altered neurodevelopment, and decreased pain threshold are a sequelae of pain exposure in early development.

Currently, multimodal analgesia with caudal block is the primary management for paediatric acute post-operative pain.

Regional anaesthesia techniques such as Transversus abdominis plane (TAP) block and Erector spinae plane (ESP) block have been shown to provide excellent analgesia and decrease the use of peri-operative opioid requirements. TAP block provides analgesia for somatic and parietal pain, sparing visceral nerves, while ESP block provides somatic and visceral analgesia.

Therefore, this study aims to evaluate the analgesic efficacy of ultrasound-guided ESP block as compared to TAP block in the first 24 hours in children undergoing unilateral abdominal surgeries.

Materials and Methods: Seventy patients between 6 months-12 years of age, ASA physical status I and II were included in the study. Patients randomised into Group E (n= 35 patients) and Group T (n= 35 patients) received ultrasound-guided unilateral ESP block and unilateral TAP block respectively using 0.5ml/kg of 0.25% Ropivacaine plus Clonidine1µ/kg after general anaes-

Primary objective was to compare the duration of analgesia (time to first rescue analgesia requirement) of ultrasound-guided ESP Vs TAP block in children undergoing unilateral abdominal surger-

The secondary objectives were the trend of intraoperative hemodynamic parameters, total fentanyl consumption in the first 24 hours, FLACC scores at 0, 2hrs, 4hrs, 6hrs, 12hrs and 24 hours in children up to 7 years and VAS scores at the same point of times in children more than 7 years, duration of putting block (needling time), parental satisfaction and incidence of any side effects.

Results and Discussion: The median (IQR) time to first rescue analgesia requirement was 30 min (30min-120min) in Group E and 30 min (30min -75min) in Group T (p = 0.725) which was comparable in both the groups. The total fentanyl consumption was comparable in both groups.

Conclusion(s): The ESP and TAP Block are both equally effective modalities for perioperative pain management in paediatric patients undergoing unilateral abdominal surgeries.

The role of rectus sheath block in high-risk patients undergoing peritoneal dialysis catheter placement: a case report

C. Perdigão¹, L. Neuparth Vieira¹, A.C. Teixeira¹, F. Rodrigues¹

¹Hospital Central do Funchal, Anaesthesiology, Funchal, Portugal

Background: Perioperative care for patients undergoing peritoneal dialysis catheter (PDC) placement surgery is challenging due to associated serious comorbidities.

This case report demonstrates that regional anesthesia may offer a safe and effective option for those with complex cardiovascular and renal conditions.

Case Report: A 71-year-old male, ASA IV, 76 kg, with sarcoidosis, hypertension, atrial fibrillation, pulmonary hypertension (pulmonary artery systolic pressure 63mmHg) with right heart failure, end-stage chronic kidney disease secondary to refractory cardiorenal syndrome, and chronic obstructive pulmonary disease, underwent PDC placement surgery.

Anesthesia management consisted of left rectus sheath block (RSB) with a total of 20 mL of 0.5% ropivacaine (100 mg) administered as a single shot. Additional 10mL of 2% lidocaine was administered in the lateral zone of the incision by the surgeon. This was supplemented with sedation using midazolam 1mg and ketamine 20mg. Intraoperative and postoperative periods were uneventful

Discussion: Previous literature supports the challenges of anesthesia in patients undergoing PDC placement, emphasizing tailored strategies to minimize cardiovascular stress and optimize renal outcomes. The RSB provided effective analgesia, however, due to its limited coverage, there was the need for additional local infiltration. Sedation with ketamine was preferred due to its minimal hemodynamic impact, which is crucial in patients with significant cardiovascular compromise.

This case underscores the viability of regional anesthesia in high-risk patients undergoing PDC placement. Combining other regional techniques, namely the TAP Block, may enhance patient comfort and further improve safety in complex cases.

References:

Haro, E.S; et al; Bilateral rectus sheath block as the sole anesthetic technique for urgent incarcerated umbilical hernia repair. Rev. Chil. Anest. 2023

Li, J, et al; US-guided unilateral TAP combined with RSB vs. subarachnoid anesthesia in patients undergoing peritoneal dialysis catheter surgery; J of Pain Research, 2020

Learning Points: Regional anesthesia with sedation, is a safe and effective option for high-risk patients undergoing PDC placement.

Personalized anesthesia strategies, emphasizing hemodynamic stability and effective analgesia, are crucial for managing patients with complex comorbidities.

12AP09-7 Lost in epidural space: a tipless tale

R. Santa Barbara¹, M. Laires¹, D. Martins¹, I. Flor de Lima¹, M. Miranda¹

¹Hospital Cuf Tejo, Serviço de Anestesiologia, Lisboa, **Portugal**

Background: Epidural anesthesia is a widely used neuroaxial technique, known for its analgesic effectiveness and safety profile. Among the rare complications associated with the epidural technique, catheter entrapment and knotting stands out, with an occurrence rate of 0.0015%, while catheter breakage occurs in approximately 0.002% of cases.

Case Report: 76-year-old male, ASA status II, was scheduled for left knee arthroplasty. A combined epidural-spinal anesthesia was performed, proceeding without complications. At the end of the surgery, an attempt to administer a test dose via the epidural catheter was unsuccessful due to high pressure during administration.

The catheter was then removed, although requiring much more resistance than usual, ending up broken, with the tip left inside. Neurosurgery team was consulted, and it was decided to maintain monitoring.

Subsequently, an ultrasound continuous femoral nerve block was performed for postoperative analgesia. The patient remained stable in the postoperative period, with controlled pain and without referring other symptoms.

Discussion: According to the literature, the main causes of epidural catheter entrapment and breakage include: catheter defect, knot formation, multiple insertion attempts, and excessive catheter length in epidural space.

When the catheter becomes trapped in the epidural space, it is recommended to wait 15 to 30 minutes to allow tissue relaxation. The patient should be placed in the same position during insertion.

Before attempting removal again, an injection of saline should be tried. An unsuccessful saline test bolus indicates a knot at the catheter tip. In this case, the insertion technique was achieved on the first attempt. However, during the catheter extraction, the patient's positioning was not optimized, which could have facilitated catheter removal and prevented breakage.

On the other hand, the failure of the saline injection suggests the presence of a knot. In the presence of epidural catheter breakage, most studies show that imaging exams are unable to locate the retained catheter.

In the absence of symptoms, only monitoring is recommended, as it is an inert and sterile material, and surgical exploration may be more harmful than beneficial. However, follow-up should be maintained for months or even years.

The effect of four-point Transversus Abdominis Plane block on diaphragm thickness in patients undergoing laparoscopic cholecystectomy: a randomized controlled trial

N. Akinci Ekinci¹, Y. Tire², M.A. Yazar², E. Karaarslan¹, Y. Mutluay², B. Kozanhan²

¹Konya City Hospital, Anesthesiology and Reanimation, Konya, Turkey, ²University of Health Sciences, Konya City Hospital, Anesthesiology and Reanimation, Konya, Turkey

Background and Goal of Study: After laparoscopic cholecystectomy, postoperative respiratory dysfunction is often associated with impaired diaphragm movement due to pain. The four-point Transversus Abdominis Plane (TAP) block, targeting upper abdominal pain, may positively affect diaphragm thickness by reducing postoperative pain.

This study aims to evaluate the effect of the four-point TAP block on diaphragm thickness.

Materials and Methods: The study included patients aged 18-65 years with an ASA I-II undergone for laparoscopic cholecystectomy. Following randomization, Group B received a four-point TAP block postoperatively, while Group C did not receive any interventional treatment.

In Group B, 10 ml of 0.25% Bupivacaine was administered under ultrasound guidance to the upper abdomen (T6-T9) and the bilateral typical TAP regions (T10-T12).

The primary outcome measure was diaphragm thickness (DT), assessed via ultrasonography preoperatively and at 5 and 30 minutes post-extubation.

Secondary outcome measures included Visual Analog Scale (VAS) scores and Quality of Recovery-15 (QoR-15) scores.

Results and Discussion: A total of 86 patients were enrolled in the study (Group B=43, Group C=43). At 5 minutes post-extubation. DT in both the inspiratory and expiratory phases showed no statistically significant differences between the groups (p=0.523 and p=0.057, respectively).

At 30 minutes post-extubation, expiratory DT was also not significantly different between the groups (p=0.394). However, at the same time point, inspiratory DT was significantly higher in Group B (4.60±0.62 mm) compared to Group C (4.34±0.40 mm, p=0.025).

VAS scores at 5 and 30 minutes, as well as at 2, 8, and 24 hours postoperatively, were significantly lower in Group B compared to Group C (p<0.05).

Additionally, QoR-15 scores were significantly higher in Group B (131.39±4.91) than in Group C (114.51±11.36, p<0.001), indicating better recovery quality in Group B.

Conclusion(s): Our study demonstrates that the four-point TAP block preserves diaphragm thickness and improves pain management in the postoperative period.

These findings suggest that the TAP block is effective in pain control through its impact on the diaphragm. However, further studies with larger sample sizes are needed to confirm and expand upon these findings.

12AP09-10

Minimal dose, maximum safety: continuous spinal and peripheral nerve blocks for femur surgery in a high-risk patient

I. Mendes Leitão¹, C. Jantarada¹, L. Godinho¹, J. Magalhães Fernandes¹, S. dos Santos Rodrigues¹ ¹Unidade Local de Saúde do Alto Ave, Anesthesiology, Guimarães, Portugal

Background: Continuous spinal anesthesia (CSA) allows precise titration of local anesthetics, ensuring optimal surgical conditions with minimal sympathetic blockade. Peripheral nerve blocks (PNBs) reduce the need for intrathecal anesthetics and opioids. enhancing safety for elderly patients with complex comorbidities, such as cardiac, respiratory, and renal dysfunction.

Although spinal anesthesia has been contraindicated in severe aortic stenosis (AS), CSA offers greater hemodynamic stability compared to single-shot spinals, making it a viable option for these patients.1,2

Case Report: An 86yo woman, ASA IV, was admitted for delayed emergency femur fracture repair. Her history included severe AS (aortic valve area 0,88 cm²), ischemic coronary artery disease, hypertension, atrial fibrillation (on anticoagulation), bifascicular block (with a pacemaker), asthma, pulmonary hypertension (pulmonary artery systolic pressure 65mmHg), and chronic kidney disease. Surgery was delayed due to intestinal ischemia caused by hypoperfusion and anemia requiring transfusion.

In the operating room, ASA standard monitoring was supplemented with invasive blood pressure monitoring. Premedication included 50mcg fentanyl and 1mg midazolam. Ultrasound-guided femoral and lateral femoral cutaneous nerve blocks were performed with 75mg ropivacaine (20mL 0,375%).

An intrathecal catheter was placed at L2-L3 and 2,5mg of hyperbaric bupivacaine were administered. 2 hours into surgery, perineal discomfort due to limb traction prompted an additional 1mg intrathecal bupivacaine, 20mcg IV fentanyl and 1g paracetamol.

The patient remained hemodynamically stable throughout and after surgery, requiring no vasopressor support, and was discharged 4 days later without complications, including no postdural puncture headache.

Discussion: Timely hip fracture repair is essential for improving outcomes, and this case underscores the value of combining CSA with PNBs to provide a tailored approach for frail patients with multiple comorbidities, thereby minimizing the risk of hemodynamic instability.

Urgent fournier's gangrene surgical debridement managed with continuous spinal block

B. Soares¹, <u>P. Pinto¹</u>, J. Ribeiro², M. Ferreira² ¹Instituto Português de Oncologia de Lisboa Francisco Gentil, Anestesiologia, Lisboa, Portugal, ²ULS de Santa Maria, Anestesiologia, Lisboa, Portugal

Background: Fournier's gangrene consists of a polymicrobial infection of the soft tissues of the perineum, which may cause significant systemic involvement, resulting in high mortality in the perioperative period. The anesthetic approach is particularly challenging in this patients, considering the various comorbidities they present but also the multiorgan dysfunction that often develops in this context.

Case Report: We present a 75 year old man proposed for urgent surgical debridement of Fournier's gangrene. The patient had ischemic heart disease with previous angioplasty, poorly controlled diabetes mellitus with end organ damage, namely diabetic nephropathy undergoing scheduled hemodialysis and peripheral artery disease with bilateral infragenicular amputation.

After hemodynamic stabilization and monitoring, we opted for a continuous spinal block, where intermittent boluses of 2.5 mg Bupivacaine were administered. After this time a bolus of 2.5mcg of Sufentanil was administered to improve the quality of the sensory block.

An intravenous bolus of ketamine (10mg) was used to complement the anesthetic approach. The patient remained hemodynamically stable during the procedure, with vasopressor support (noradrenaline) infusion (maximum 0,32 mcg/kg/min).

Discussion: The preoperative evaluation of a patient with Fournier's gangrene is complex and there are several factors to take into consideration, namely the patient's physical state, comorbidities, degree of multiorgan dysfunction and extent of the lesion. The literature is scarce regarding anesthetic approaches in this context but does not seem to demonstrate superiority of any anesthetic technique. Given this patient's frailty, we considered that a continuous spinal anesthesia would be the anesthetic technique with the least hemodynamic impact, allowing titrated administration of local anesthetic.

Reference:

Boran ÖF, et al. Are there factors in the disease of peroneal necrotizing fasciitis which should be used when choosing the anesthetic technique?: Descriptive analysis of a cohort from two centers. Ulus Travma Acil Cerrahi Derg. 2022 Jan;28(1):48-56. doi: 10.14744/tjtes.2020.15088.

Learning points:

- Patients with Fournier's gangrene often present multiple comorbidities and multiorgan dysfunction, which contributes to the complexity of the anesthetic-surgical approach;
- Continuous spinal anesthesia is an effective anesthetic strategy for surgical debridement of Fournier's gangrene.

12AP10-1

Innovative analgesia for major abdominal surgeries: the role of ESP blocks

C.S. Silva¹, Â.Z. Oliveira¹, M. Silva¹, C. Antunes¹, S.S. Rodrigues¹ ¹Unidade Local de Saúde do Alto Ave, Anesthesiology, Guimarães, Portugal

Background: Hepatopancreatobiliary (HPB) surgeries are associated with a significant risk of complications, often exacerbated by inadequate postoperative pain control. While epidural analgesia remains a widely used and effective technique, continuous erector spinae plane (ESP) blocks have emerged as a promising alternative, with fewer side effects.

We present a series of three cases demonstrating the effectiveness of ESP blocks in managing pain for major HPB procedures.

Case Report: The first case involved a 51-year-old obese male (ASA III) with a history of acute myocardial infarction four months prior, still on dual antiplatelet therapy, scheduled for an open cephalic duodenopancreatectomy.

The second case was a 32-year-old female (ASA I) diagnosed with a tumor of the pancreatic tail, planned for laparoscopic corpus-caudal pancreatectomy.

The third case featured a 77-year-old male (ASA III) with hypertension, dyslipidemia, atrial fibrillation, and obstructive sleep apnea syndrome managed with C-PAP, diagnosed with cholangio-carcinoma, and scheduled for open cholecystectomy with partial resection of the common hepatic duct.

After discussing risks and obtaining informed consent, patients were positioned seated, and bilateral ESP blocks were performed at the T6–T7 level. A catheter was placed on the right side for continuous analgesia. General anaesthesia was subsequently induced. Surgeries lasted 3 to 4 hours without complications. During the procedures, 120 mg of 0.2% ropivacaine was administered in three boluses.

Postoperatively, additional ropivacaine boluses ensured effective pain control. No opioid rescues were necessary in the post-operative period

Discussion: These cases illustrate the feasibility and efficacy of ESP blocks in providing perioperative analgesia for abdominal surgeries, even in patients with complex medical conditions.

2. Cai Q, Liu Q, Huang LS, Yang ZX, Gao ML, Jing R, Liu Z, Pan LH. Effects of erector spinae plane block on postoperative pain and side-effects in adult patients underwent surgery: A systematic review and meta-analysis of randomized controlled trials. Int J Surg. 2020.

Learning Points: Continuous ESP block may offer a simpler and potentially safer alternative to epidural block for perioperative analgesia in major HBP surgeries.

Elderly heart, delicate hands: peripheral regional anesthesia in severe aortic stenosis, a case report

S. Freitas¹, S. Vieira¹, S. Carneiro¹, E. Soares¹, L. Ribeiro¹ ¹Unidade Local de Saúde de Braga, Department of Anesthesiology, Braga, Portugal

Background: Severe aortic stenosis (AS) is a critical condition that significantly increases perioperative risks, especially in elderly patients1.

This case underscores the importance of individualized perioperative strategies and the role of regional anaesthesia in optimizing outcomes for high-risk elderly patients.

Case Report: A 90-year-old woman, ASA IV, with a right femoral neck fracture was scheduled for a short intramedullary nailing fixation. Her medical history included hypertension and severe aortic valve disease, with a maximum transvalvular gradient of 90 mmHg. During the pre-anesthetic visit, the patient presented with new-onset atrial fibrillation which was successfully managed with digoxin and bisoprolol.

Intraoperatively, standard ASA monitoring was used and peripheral regional anesthesia was chosen to mitigate the risks associated with neuraxial and general anesthesia.

An ultrasound-guided supra-inguinal fascia iliaca block (SIFIB) was performed with 15 ml of ropivacaine (7.5 mg/mL) and 10 ml of lidocaine (10 mg/mL) for effective hip anesthesia. Multimodal analgesia was administered. She was hemodynamically stable throughout the surgical procedure.

Postoperatively, the patient was transferred to the Post-Anesthesia Care Unit for further monitoring. She did not require rescue analgesia, indicating effective pain control.

Discussion: Intramedullary nailing fixation for femoral neck fractures provides significant benefits, including reduced bedrest duration and enhanced functional recovery. The SIFIB, typically used for perioperative analgesia, can serve as the primary anesthetic approach for this surgical procedure, offering effective sensory blockade with minimal sympathetic impact².

This case highlights the challenges of managing elderly patients with severe comorbidities for urgent orthopedic surgery. The chosen anesthetic approach ensured both hemodynamic stability and optimal anesthesia and analgesia throughout the procedure.

- 2. Genc C, Tulgar S. "Ultrasound-Guided Suprainguinal Fascia Iliaca Block in Anesthesia for Lower Extremity Surgeries: A Retrospective Cohort Study." Cureus, 2023.

Learning points: Regional anesthesia, such as SIFIB, ensures effective anesthesia and pain control while reducing hemodynamic instability, making it an optimal choice for managing high-risk elderly patients.

12AP10-3

Bilateral proximal humeral shaft fractures - phrenic nerve-sparing regional anaesthesia

P. Branco¹, M. Guarda¹, D. Levier¹, T. Seixas¹, N. Santos¹ ¹Hospital Prof. Dr. Fernando Fonseca, Anaesthesiology, Amadora, Portugal

Background: The interscalene brachial plexus block (ISB) is considered the gold standard regional anaesthesia approach for shoulder surgery. However, it encompasses potential side effects such as hemidiaphragmatic paralysis due to phrenic nerve block1, hence bilateral ISBs are not typically performed as they might lead to complete diaphragmatic paralysis.

Case Report: We report a clinical case of a blunt trauma patient with bilateral proximal humeral shaft fractures and a left pulmonary contusion, who was scheduled for bilateral osteosynthesis. The anaesthetic plan included ultrasound-guided regional anaesthesia and sedation with propofol.

Firstly, a left ISB was performed with 10mL of 0.5% ropivacaine. After successful osteosynthesis, a right infraclavicular brachial plexus block (ICB) was performed with 20mL 0.5% ropivacaine, associated with a posterior approach suprascapular nerve block (SCNB) with 5mL ropivacaine 0.75%.

A superficial cervical plexus block (SCPB) was also performed with 5mL ropivacaine 0.75% in order to cover the supraclavicular nerves. Supplemental oxygen was provided and the patient did not report any complaints. The procedure was performed uneventfully.

Discussion: Pulmonary contusion is fairly common in the setting of blunt trauma and might progress to atelectasis or acute respiratory distress syndrome².

The association of the ICB with the SCNB has been described as a strategy to minimize hemidiaphragmatic paralysis whilst providing adequate surgical anaesthesia for shoulder surgery³.

The addition of the SCPB provides cutaneous anaesthesia of the shoulder cape. In this clinical case, left pulmonary function was already compromised, hence the advantages of avoiding general anaesthesia and right phrenic nerve block as respiratory failure could be induced.

- 2. Rendeki, S., & Molnár, T. F. (2019). Pulmonary contusion. Journal of Thoracic Disease, 11(S2), S141-S151. https://doi. org/10.21037/jtd.2018.11.53
- 3. Tran, D. Q., Elgueta, M. F., Aliste, J., & Finlayson, R. J. (2016). Diaphragm-Sparing Nerve blocks for shoulder surgery. Regional Anesthesia & Pain Medicine, 42(1), 32-38.

Learning points: The combination of different phrenic nervesparring blocks provides adequate surgical anaesthesia for shoulder surgery in patients with preexisting lung complications.

Locoregional anesthesia, an alternative in elderly patients? A case report

M. Almeida Santos¹, <u>C. Pereira Pinto</u>¹, I. Rodrigues¹, L. Ormonde¹

¹ULS Santa Maria, Anesthesiology Department, Lisboa, Portugal

Background: Perioperative anesthetic and analgesic management in elderly patients is a significant challenge. Regional anesthesia has gained prominence as an effective alternative to general anesthesia and intravenous analgesia, particularly in situations of high fragility1,2.

Case Report: A 71-year-old male with past medical history of hypertension, heart failure, and acute myocardial infarction with cardiopulmonary arrest was initially admitted for urgent surgical debridement of slough and leg burn under general anesthesia. During the initial surgery, severe hemodynamic instability was identified requiring hemodynamic support with vasopressors and recovery in the ICU. Given the need for multiple future interventions, the need for a strategy change and careful anesthetic planning became evident.

For new surgical debridement, revision of pedicled flap and vacuum dressing a preoperative evaluation, reported intense pain, not controlled with intravenous analgesia, indicating as well the need for a distinct analgesic strategy.

Thus, a regional anesthesia technique with peripheral nerve blocks was chosen, after discussion with the patient and surgical team. A Sciatic-popliteal and lateral femoral cutaneous block were performed and a sciatic-popliteal perineural catheter was placed for postoperative analgesia.

As an adjunct, light sedation with dexmedetomidine was used. The perineural catheter was subsequently used to optimize analgesia and perform further surgical procedures, with no further episodes of hemodynamic instability.

Discussion: Literature shows that regional anesthesia is effective in the perioperative period, offering benefits of promoting faster, less painful recovery and reducing opioid consumption3.

This report shows the importance of regional anesthesia in the elderly, demonstrating its advantages in perioperative hemodynamic control and postoperative pain control.

Learning points: Highlighting the importance of personalized anesthetic strategies, as well as the importance of multidisciplinary collaboration in clinical decision-making.

12AP10-5

Comparison of postoperative pain incidence in patients undergoing oncological mastectomy: general anesthesia vs general anesthesia associated with regional block

<u>G. Balieiro Moriggi Pimenta</u>¹, P. Romero Domingues¹, G. Giroldo Badessa¹, C. Haddad Silveira¹, A. Lino Alfano¹, B. Gonçalves Miron¹

¹Centro Universitário São Camilo, Anestesiologia, São Paulo, Brazil

Background and Goal of Study: Oncological mastectomy is one of the most common surgical interventions in the treatment of breast cancer. General anesthesia is the most commonly used technique, and its association with regional blockade has been gaining attention as a promising anesthetic alternative.

The aim of this study was to evaluate the incidence of postoperative pain in the immediate postoperative period in patients undergoing mastectomy with general anesthesia or general anesthesia combined with regional blockade during the study period.

Materials and Methods: This study was conducted in an observational, cross-sectional and retrospective manner between January 2023 and December 2023, at a public hospital unit for oncological patients located in São Paulo, Brazil. Inclusion criteria were patients undergoing oncological mastectomy during the period. Exclusion criteria included patients who underwent autologous breast reconstruction and surgeries from other specialties.

Interpectoral and pectoro serratus regional blocks were performed at the end of the surgical procedure, under ultrasonographic guidance, and the patients were evaluated for the presence of pain in the post-anesthesia recovery unit (PACU).

Results and Discussion: A total of 304 mastectomies were performed during the study period. Only intravenous or balanced general anesthesia was performed in 255 (83.88%) patients, followed by general anesthesia combined with epidural in 37 (12.17%) patients and general anesthesia combined with peripheral blockade in 12 (3,94%) patients.

The regional blocks performed were the interpectoral block and the pectoro serratus block. When evaluating the presence of pain in the PACU, only the patients who received general anesthesia reported pain, with n=47 (15,46%) of total.

Conclusions: This comparative study suggests that the combination of general anesthesia with regional blockade provides superior analgesia compared to isolated general anesthesia in patients undergoing oncological mastectomy when evaluated from the perspective of postoperative pain reduction and, consequently, reduced need for opioid analgesics in the PACU.

However, the study has statistical limitations due to the lower number of patients who received regional anesthesia in comparison, and it does not assess pain and opioid consumption after discharge from the PACU, highlighting the need for more studies in this area to conclude the advantages of one technique over the other.

Pericapsular Nerve Group block versus Fascia Iliaca compartment block for hip surgery: an updated systematic review and meta analysis of 24 randomized controlled trials

L.F.S. Ribeiro¹, L.R. De Freitas², E. Maia³, M. Gaya da Costa4

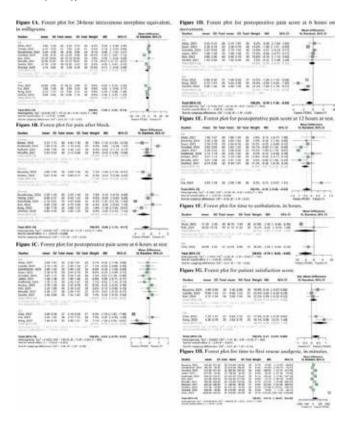

¹Federal University of São João del-Rei, Medicine, Divinópolis, Brazil, ²Federal University of Juiz de Fora, Medicine, Juiz de Fora, Brazil, 3Federal University of Minas Gerais, Medicine, Belo Horizonte, Brazil, 4University Medical Center Groningen, Anaesthesiology, Groningen, Netherlands

Background and Goal of Study: Fascia Iliaca (FI) block is a widely used regional technique for hip surgeries. Pericapsular Nerve Group (PENG) block has emerged as an alternative, offering potential improved analgesia and recovery.

This meta-analysis compares PENG versus FI block for patients undergoing hip surgery.

Materials and Methods: We searched PubMed, Embase, and Cochrane until November 2024 for randomized controlled trials (RCTs) comparing PENG and FI blocks.

Our primary outcome was 24-hour postoperative opioid consumption. Secondary outcomes included pain scores after the block, 6- and 12-hours postoperative pain, on movement and at rest, respectively, time to ambulation, patient satisfaction scores, and time to first rescue analgesic. R software, version 4.4.0, was used for mean difference (MD), and standardized mean difference (SMD), in a random-effect model.

Results and Discussion: 24 RCTs. comprising 1.521 patients. were included. PENG block significantly reduced 24-hour postoperative intravenous opioid consumption (MD -2.58 milligrams morphine equivalents [95% CI -4.42; -0.74]; p=0.006, I²= 99%), pain after block (MD -0.66 points [95% CI -1.15; -0.17]; p=0.008, I²= 94%), 6 hours pain on movement (MD -0.70 points [95% CI -1.36: -0.031: p=0.04. I²= 85%), 12 hours pain at rest (MD -0.35) points [95% CI -0.68; -0.02]; p=0.038, I²= 79%), and time to ambulation (MD -4.79 hours [95% CI -8.63; -0.95]; p=0.014, I²= 76%), compared to FI block. Additionally, PENG block statistically increased patient satisfaction score (SMD 0.31 [95% CI 0.01; 0.60]; p=0.041, I²= 46%). No statistical differences were observed 6 hours pain at rest and time to first rescue analgesic.

Conclusion(s): PENG block was associated with significantly lower opioid consumption, 6 hours pain score on movement, 12 hours pain score at rest, and time to ambulation compared to FI block. A statistically higher patient satisfaction score was also noted. No differences were found in time to first rescue analgesic or 6 hours pain at rest.

12AP10-8

When general anesthesia is not an option: belt and brace approach with regional anesthesia for awake radical mastectomy

C. Pereira Pinto¹, L. Umanets¹, J. Valente Jorge¹, L. Ormonde¹

¹ULS Santa Maria, Anesthesiology Department, Lisboa, **Portugal**

Background: Breast cancer is the most prevalent malignancy among women, with an increasing number of older patients presenting for surgical intervention due to longer life expectancy and associated comorbidities.1

Traditionally, modified radical mastectomy is performed under general anesthesia, but peripheral nerve block techniques offer a less invasive alternative that may benefit high-risk patients. 1,2

Case Report: We report an 85-year-old woman, diagnosed with advanced invasive carcinoma of the right breast. The patient presented with multiple comorbidities, including pulmonary hypertension, respiratory failure, heart failure, and others.

Given her high anesthetic risk, a comprehensive regional anesthesia plan was implemented, utilizing a belt and brace technique to block all sensory innervation to the right breast. This included a paravertebral block at three levels, supplemented by intercostal, pectoralis major, supraclavicular nerve blocks, and a pectointerfascial block. To enhance safety, a high thoracic epidural catheter was placed. Due to technical difficulties performing a paravertebral approach in one of the levels an erector spinae plane block was performed as a rescue in T3-T4. This tailored anesthetic strategy resulted in a safe and painless surgical experience.

Discussion: This case illustrates the possibility of a different approach for a common breast surgery. Radical mastectomy with lymph node dissection is usually done under general anaesthesia but in this case we demonstrated that regional techniques are feasible and safe in this type of surgery. In order to perform a locoregional approach in this type of surgery it is mandatory to understand the nerve supply to the breast and the axila. It is essential to suit the anesthetic technique to the patient.

References:

1. Garreffa, E., Cantagalli, F., et al. (2020), Pectoral nerves blocks (PECS) and sedation: A way to avoid general anesthesia in breast surgery - A single institution early experience. Breast J, 26: 303-305;

2. Matsumoto M, Flores EM, Kimachi PP, et al. Benefts in radical mastectomy protocol: a randomized trial evaluating the use of regionalanesthesia. Sci Rep. 2018:8:7815.

Learning points: This case underscores the importance of customizing anesthetic techniques to patient-specific factors, particularly in the geriatric population with significant comorbidities. It highlights the necessity of flexibility in anesthetic planning to ensure optimal care in complex surgical cases.

12AP10-9

Continuous median and radial nerve blocks for hand burn management: a case report

B. Cozart¹, A. Van Erp¹, J. Lee², L. Haines², J. Santorelli², J. Finneran IV1

¹University of California San Diego, Anesthesiology, La Jolla, United States, ²University of California San Diego, Surgery, La Jolla, United States

Background: Burn pain is notoriously difficult to manage. While opioids remain the mainstay, they carry risks such as hyperalgesia, dependence, and systemic side effects. Continuous peripheral nerve blocks (cPNBs) provide targeted, prolonged analgesia with fewer systemic effects and facilitate bedside wound care. We report a case using median and radial cPNBs for hand burn management.

Figure 1: The patient had burn wounds confined primarily to the median and radial nerve distributions

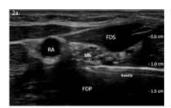

Figure 2a and 2b: Block needle advanced adjacent to the median nerve (2a) and radial nerve (2b).

Figure 3: Median and radial perineural catheters secured

Case Report: A 40-year-old male presented with 4% TBSA burns (face, neck, hands) after falling into a campfire. Severe pain from left hand burns precluded bedside debridement despite opioids. Regional anesthesia was consulted, and ultrasound-guided median and radial cPNBs were placed with 0.2% ropivacaine infusions (1 mL/hour continuous; 2 mL bolus, 30-minute lockout).

Pain improved from 10/10 to 3/10 at rest and 4/10 during wound care. The nerve blocks enabled daily debridements and facilitated active participation in physical and occupational therapy. Catheters were removed after Suprathel dressing placement, and the patient was discharged with oral analgesics. No complications were noted.

Discussion: This case highlights cPNBs' utility in burn pain management by providing targeted analgesia without systemic opioid side effects. Ultrasound-guided placement ensured precise blockade, reducing pain while preserving motor function. This enabled physical therapy, essential for preventing contractures and promoting recovery. Additionally, cPNBs allowed bedside wound care without general anesthesia, streamlining treatment. Regional anesthesia is a valuable tool in burn management, supporting both recovery and pain control.

References:

Holtman JR. Jellish WS. J Burn Care Res. 2012;33(6):692-701. Ilfeld BM. Anesth Analg. 2016;123(3):652-675.

Finneran IV JJ, Ilfeld BM. Curr Opin Anesthesiol. 2023;36(5):525-532.

Town CJ et al. Clin J Pain. 2019;35(4):368-74. Perkins L et al. Reg Anesth Pain Med. 2024; In Press.

Learning points:

- · cPNBs provide site-specific analgesia with reduced systemic effects, facilitating non-operative burn care.
- · Median and radial nerve blocks effectively manage hand burn pain while preserving motor function.
- · Regional anesthesia expertise is vital for the successful implementation of cPNBs in burn management.

12AP10-10

A safe anesthetic alternative for intertrochanteric fractures in high risk patients: a case series

R. De Oliveira¹, G. Freitas Pinto¹, R. Laranja Pontes¹, A. Martins¹

¹Unidade Local de Saúde Gaia Espinho, Anesthesiology, Vila Nova de Gaia, Portugal

Background: Intertrochanteric fractures (ITF) are common femoral fractures. Regional anesthesia (RA) is the preferred technique at our institution, however, certain comorbidities/drugs preclude a neuraxial approach (NA). We report two cases managed solely with peripheral nerve blockade (PNB).

Case Report: Case1: A 68-year-old female with a severely depressed ejection fraction and a drug-eluting stent on clopidogrel was proposed for urgent percutaneous ITF repair. Due to comorbidities, RA was considered most adequate, however, clopidogrel precluded a NA.

Ultrasound-guided suprainguinal fascia iliaca (US-SIFI) block was performed with 40mL 0.5% ropivacaine. Block quality was assessed and the patient was positioned for surgery.

Proximal surgical incision point revealed block insufficiency, which resolved with local anesthetic infiltration. The remainder of surgery was successful.

Case 2: A 50-year-old female with hydrocephalus was proposed for urgent ITF repair. Concerns about complications with NA motivated PNB. US-SIFI block (40mL 0.5% ropivacaine) was complemented with an iliohypogastric/ilioinguinal nerve block (10mL 0.5% ropivacaine), providing block sufficiency for the entire procedure.

Discussion: Anesthetic management of ITF is challenging as patients are often high risk. Certain comorbidities and the presence of anticoagulants may preclude NA. Although waiting for the elimination of these drugs can allow for the safe application of a neuraxial technique, treatment delay and its impact on mortality is well known. Hip innervation is complex, rendering PBN challenging. The SIFI block is attractive as it is capable of blocking the femoral, lateral femoral cutaneous (LFCN) and obturator nerves.

However, surgical incision is performed in a transition of dermatomes and the LFCN block can be insufficient as this territory may have subcostal/iliohypogastric nerve contributions, which may explain block insufficiency in case 1 and complete surgical anesthesia in case 2. To our knowledge, this is the first case that describes the combination of these two blocks for ITF repair.

References: BJA Educ. 2024 Jun;24(6):191-202.

Learning points: Balancing the need for timely surgical intervention with safe anesthetic practices remains a critical consideration in managing ITF patients. SIFI block complemented with ilioinguinal/iliohypogastric nerve block may be a safe management option, avoiding risks posed by neuraxial and general anesthesia.

Analgesic efficacy of ultrasound-guided rectus sheath block in children undergoing midline abdominal hernia repair: A systematic review and meta-analysis

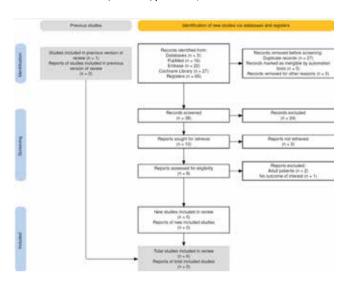

A. Samuel¹, L. Tebar², L. Rodrigues³, M. Pitombo³ ¹Rio de Janeiro State University, Ambulatory Surgery Unit, Rio de Janeiro, Brazil, ²União das Faculdades dos Grandes Lagos, Medical Sciences Faculty, São José do Rio Preto, Brazil, ³Rio de Janeiro State University, Medical Sciences Faculty, Rio de Janeiro, Brazil

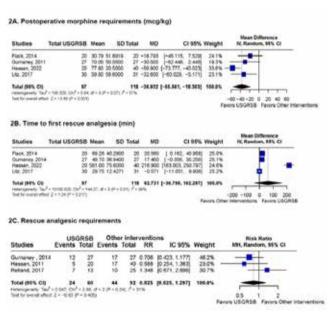

Background and Goal of Study: This systematic review and meta-analysis evaluated the analgesic efficacy of ultrasound-guided rectus abdominis sheath block (USGRSB) compared to other anesthetic methods in children undergoing midline abdominal hernia repair.

Materials and Methods: PubMed, Embase, and Cochrane databases were systematically searched. Randomized controlled trials (RCTs) reporting USGRSB for abdominal midline hernia repair were included. Primary outcomes were postoperative morphine equivalent consumption, time to first analgesia, and postoperative rescue analgesic requirements. Effect sizes were summarized as weighted mean differences (MD) for continuous outcomes and risk ratios (RR) for binary outcomes, with 95% confidence intervals (CI). Heterogeneity was assessed by the I² statistic. R was used for statistical analyses.

Results and Discussion: Of 65 studies, 6 RCTs were included, involving 305 patients (USGRSB n=137; control n=168). Main anesthetic techniques compared were wound infiltration, caudal epidural block, and intraoperative rectus sheath block by the surgeon. Patients had a mean age of 6.5 years, 48.5% were female,

and the weight was 24.4kg. USGRSB significantly reduced post-operative morphine equivalent consumption (MD=-36.93mcg/kg; 95% CI -55.56 to -18.30; I^2 =57%; p<0.001) and was associated with longer time to first rescue analgesia (MD=62.73min; 95% CI -36.80 to 162.26min; I^2 =98%; p=0.217). However, no significant difference was found in rescue analgesic requirements (RR=0.82; 95% CI 0.52 to 1.13; I^2 =31%; p=0.405).

Conclusion(s): In this meta-analysis, USGRSB was associated with significantly lower postoperative morphine equivalent consumption and time to tracheal extubation compared with other anesthetic techniques. Overall, these findings support the efficacy and safety of USGRSB for use in midline abdominal hernia repair in children.

Description of the effectiveness of BRILMA block in breast surgery

S. Moreno Jurico¹, B. Tena¹, M. Magaldi¹. M. Vendrell Jordá¹, M.P. de Santos¹, I. León Carsí¹ ¹Hospital Clínic Barcelona, Anaesthesiology, Barcelona, Spain

Background: Advances in ultrasound and regional anaesthesia have led to important changes in breast surgery. Blocking the cutaneous branches of intercostal nerves in the mid-axillary line (BRILMA block) is an option that allows us to block the main innervation of the breast, including the areola-nipple complex, and even achieve analgesia of the axillary compartment (1).

Primary objective: to evaluate pain in patients undergoing breast surgery with or without BRILMA block according to the VAS score.

Secondary objective: to observe the effectiveness of the BRIL-MA block in breast surgery, studied with VAS score and opioids consume.

Materials and Methods: This is a single-center retrospective observational study. 212 patients who underwent breast surgery in 2023 in our center were analysed. We record the patients' characteristics and the surgery and the anaesthetic management from the pre-anaesthetic and operating room reports.

Acute pain during the first 48 hours was assessed by reviewing the nursing pain record according to the VAS score. T1:2h, T2:8h, T3:16h, T4:24h, T5:32h, T6:40h, T7:48h. Moreover we analyse the opioid consume in the postoperative period.

Results and Discussion: Of all the patients analysed, 25,7% underwent mastectomy and 74,3% underwent non-mastectomy breast surgery. BRILMA block was performed in 73,71% of these patients. In the group without BRILMA block, the averages VAS ptp score were: T1:1.51, T2:1.13, T3:0.32, T4:0.57, T5:0.11, T6:0.5, T7:0.36. In the group with BRILMA block, the averages VAS ptp score were: T1:1.66, T2:0.95, T3:0.51, T4:0.36, T5:0.83, T6:0.45, T7:0.50.

However, the comparison between the two groups was not statistically significant (p>0,05). In the subgroup of mastectomized patients, average postoperative methadone consumption was 3,08mg in no-BRILMA group and 2,5mg in BRILMA group, but comparing these results they were no statistically significant neither (p>0,05).

Conclusion: We found evidence that the group with BRILMA block has a lower VAS score and lower opioid use than the group without BRILMA block, although the results were not statistically significant.

Transverse abdominis plane (TAP) block in extreme lateral interbody fusion (XLIF) surgery: a randomized feasibility trial

J. Geudens¹, K. Nijs¹, B. Keunen¹, H. Jalil¹, B. Stessel¹, J. Vandenbrande¹

¹Jessa Hospital, Department of Anaesthesiology and Pain Medicine, Hasselt, Belgium

Background and Goal of Study: Minimally invasive surgical techniques, such as eXtreme Lateral Interbody Fusion (XLIF), play a key role in enabling Enhanced recovery after surgery (ERAS) programs. Equally important are multimodal anaesthetic strategies with the potential to reduce the need for long-acting opioids. Regional anaesthesia, as part of the multimodal analgesia regimen, is especially important in this context. This study aims to investigate the impact of the Transversus Abdominis Plane (TAP) block on outcomes after XLIF surgery.

Materials and Methods: In this prospective, double blinded, monocentric, randomized controlled trial, the feasibility of a TAP block in elective XLIF surgery was evaluated in the Jessa Hospital, Hasselt, Belgium. Patients were randomized on a 1:1:1 ratio in to three groups: lateral TAP block, posterior TAP block and no block. The TAP intervention groups received an ultrasound-guided TAP block (lateral or posterior) in supine position with 40ml of bupivacaine 0.25%. The control group did not receive any locoregional technique. The received general anaesthesia was standardized. To asses feasibility outcome included TAP visualization and adverse events.

Results and Discussion: In total 30 patients were included in this pilot trial. TAP visualization was evaluated acceptable, good or very good (Table 1).

No significant intergroup differences were present. No block-related adverse events were registered (Table 2).

	Acceptable	Good	Very good	Poor	Very poor
Lateral TAP block	4 (40%)	1 (10%)	5 (50%)	0 (0%)	0 (0%)
Posterior TAP block	3 (30%)	5 (50%)	2 (20%)	0 (0%)	0 (0%)

Data are presented as frequencies (%).

Table 1: Identification rate of the correct TAP block by ultrasound as assessed by a five-point-scale (very good - good - acceptable - poor - very poor).

	Lateral TAP block	Posterior TAP block	p-value
Dizziness	0 (0%)	2 (20%)	0.47
Vomiting	0 (0%)	1 (10%)	0.31
Sweating	0 (0%)	1 (10%)	0.31

Data are presented as frequencies (%), A p-value of <0.05 is considered statistically significant.

Table 2: Side effects.

Conclusion(s): The results of this prospective, randomized pilot trial support the feasibility of a TAP block in patients undergoing XLIF surgery. Visualization of the TAP was adequate and no block-related adverse events occurred. Future research is needed to evaluate the effect of a TAP block on pain and recovery outcomes in patients undergoing XLIF surgery.

Anesthetic management for open scapular fixation surgery in prone position in a polytraumatized patient with associated clavicle and multiple rib fractures: Double-lumen tube for one-lung ventilation to prevent recurring pneumothorax combined with erector spinae plane and brachial plexus blocks

A. Arias López¹, G. Savone¹, V. González Sotelo¹, M.C. Velasco León², I. Romero Bhathal², I. Lavado Flores¹ ¹Hospital de Asepevo, Anesthesiology and Pain. Barcelona, Spain, ²Parc de Salut Hospital del Mar, Anesthesiology, Pain and Intensive Care, Barcelona, Spain

Background: Few literature reports regard the anesthetic management of scapular surgery and none in patients with previous pneumothorax despite the fact that it represents a challenge for the high risk of pulmonary and haemodynamic complications.

Case Report: 48 y.o. male, thoracic trauma after vehicle collision with the following right-side fractures: clavicle, 2nd to 6th ribs (displaced), scapula and brachial plexus avulsion (C5, C6 roots). Initially admitted to ICU due to hemopneumothorax requiring thoracic drainage, intubation and RBC transfusion; stable after the procedure, drainage withdrawn on D7. Scheduled for scapular surgery in prone position on day 14.

Regional anesthesia was performed first: ESP block at T3 level and interescalene block1 (both US-guided, ropivacaine 0,5%). Afterwards, induction and tracheal intubation with a 39Fr left-DLT. OLV was settled to check its plausibility, being well tolerated; and followed with two-lung ventilation during surgery. No respiratory complications arised. No further opioid requirements after intubation. Extubation was achieved in the operating room. In the first 24 hours, main VAS for pain was 0.

Discussion: The management of scapula fractures with previous pneumothorax in prone position requires careful consideration for the risk of recurrence due to manipulation above the underlying rib fractures. The placement of a double-lumen tube was decided for setting the patient in one-lung ventilation in case of signs of pneumothorax while the patient is in prone with an open surgery field, isolating the lung and avoiding a potential tension pneumothorax. Regional anesthesia techniques permitted an almost opioid-free procedure with no pulmonary complications in the postoperative course, allowing a safe weaning and extubation in the OR.

Reference:

1. Vinsard et al. Regional anesthesia for scapulothoracic fixation surgery: Anatomic review and case series. Clin Anat. 2023.

Learning points: Double-lumen tube for not-thoracic surgery to prevent severe pulmonary complications using OLV. Combined anesthesia (thoracic ESP and interescalene blocks) proves effective, allowing an opioid-free approach for open scapular surgery.

12AP11-3

Anaesthetic management of an achondroplastic patient undergoing humeral fixation: Challenges and insights

J. Chaves¹, R. Linhares¹, L. Fontes¹, V. Bianchi¹ ¹Hospital Municipal Miguel Couto, Anesthesiology and Pain Medicine. Rio de Janeiro. Brazil

Background: Achondroplasia, the most common skeletal dysplasia, affects 1 in 20,000-30,000 live births and presents unique challenges in anaesthetic management.

Case Report: A 44-year-old male, 130 cm tall and weighing 85 kg (BMI > 47), presented with a right supracondylar humeral fracture requiring ORIF with plate and screws. The patient had typical features of achondroplasia: short limbs, scoliosis, thoracic deformity, midface hypoplasia, and macroglossia, along with morbid obesity. He denied comorbidities or respiratory symptoms but reported discomfort in the supine position. Airway assessment revealed Mallampati grade III, limited cervical mobility, and normal mouth opening. Preoperative ECG and lab results were unremarkable. The plan involved a right brachial plexus block with sedation. Standard monitoring was applied, and a 20G IV cannula was placed under ultrasound guidance due to a thick adipose layer. A supraclavicular approach to the brachial plexus was chosen. Despite anatomical challenges, the block was performed using 20 ml of 0.5% ropivacaine and 1% lidocaine, achieving effective motor and sensory blockade.

During the procedure, the orthopaedic team requested a prone position, necessitating general anaesthesia. Preoxygenation was followed by induction with fentanyl, lidocaine, propofol, and suxamethonium. Intubation was performed with videolaryngoscopy, a bougie, and a size 7.5 endotracheal tube. Anaesthesia was maintained with sevoflurane and rocuronium. The 3-hour surgery proceeded uneventfully, with careful positioning and monitoring. The patient was extubated awake, recovering with an Aldrete 8.

Discussion: Patients with achondroplasia present challenges, including difficult airway management due to midface hypoplasia. macroglossia, and atlantoaxial instability. Macrocephaly and short limbs complicate positioning for regional blocks and surgery. Spinal abnormalities may hinder neuraxial anaesthesia, but regional blocks remain beneficial when carefully planned.

References:

- 1. Kim J, et al. Anesthetic Considerations in Patients With Achondroplasia. Cureus, 2021.
- 2. Oliveira CRD, et al. Anaesthesia and Uncommon Coexisting Diseases; Achondroplasia. Brazilian Society of Anaesthesiology, 2017.

Learning points: Regional anaesthesia is not contraindicated in achondroplasia and offers significant benefits. However, unique anatomical characteristics require meticulous planning and adaptation to ensure safe and effective anaesthetic management.

12AP11-5

Intermittent bolus vs. continuous infusion after paravertebral block for thoracic surgeries: a systematic review and meta-analysis

E. Maia Pereira¹, L. Rezende De Freitas², L.F.S. Ribeiro³, R. Theodoro¹, M. Gaya da Costa⁴ ¹Federal University of Minas Gerais, Medicine, Belo Horizonte, Brazil, ²Federal University of Juiz de Fora, Medicine, Juiz de Fora, Brazil, 3Federal University of São João del-Rei, Medicine, Divinópolis, Brazil, 4University Medical Center Groningen, Anaesthesiology, Groningen, Netherlands

Background and Goal of Study: Thoracic surgeries are associated with moderate to severe postoperative pain, which may lead to complications such as atelectasis or respiratory insufficiency. The paravertebral block (PVB) is an effective strategy for analgesia and can be performed with a postoperative infusion of local anaesthetics through a catheter. Nonetheless, there is still no consensus on which infusion method is superior: intermittent bolus or continuous infusion.

Therefore, we sought to compare both methods in terms of 24hour pain scores (visual analogue and numeric rating scales) and the need for rescue analgesia.

Materials and Methods: We systematically searched MEDLINE, Embase, and Cochrane for randomised controlled trials (RCTs) involving adult patients (>18 years old) undergoing thoracic surgery and comparing intermittent bolus vs. continuous infusion for postoperative analgesia with paravertebral catheters.

Standardised mean difference (SMD) and risk ratio with 95% confidence interval (CI) were computed under a random effects model. Statistical analyses were performed with Review Manager 5.4.

Results and Discussion: Eight RCTs (n=386) were included in the final analysis. Video-assisted thoracoscopic surgery and thoracotomy were performed in six and two studies, respectively. Five studies performed PVB under ultrasound guidance.

One study used bupivacaine (0.25 - 0.375%), three studies used levobupivacaine (0.2 - 0.5%), and four studies used ropivacaine (0.2 - 0.75%)

There were no differences between both methods in 24-hour pain scores at rest (SMD -0.02, 95% CI -0.45 to 0.42, p=0.93, Figure A) and at movement (SMD 0.33, 95% CI -0.21 to 0.87, p=0.24, Figure B). Similarly, there was no difference in the need for rescue analgesics (RR 1.07, 95% CI 0.65 to 1.75, p=0.80, Figure C).

Conclusion(s): Intermittent bolus delivery and a continuous infusion for PVB in thoracic surgeries appear to be equally effective for postoperative analgesia. Nonetheless, the differences in volume and concentrations of local anaesthetic, frequency of bolus delivery, use of ultrasound, and minimally invasive vs. open surgery impaired a more granular assessment of the findings.

12AP11-6

Motor-sparing knee blocks vs adductor canal plus LIA for total knee replacements

P. Campanini¹, J. John², U. Barabash³ ¹Robert Jones Agnes Hunt Orthopaedic Hospital, Anaethesia, Oswestry, United Kingdom, ²RJAH, Anaesthesia, Oswestry, United Kingdom, 3RJAH. anaesthesia, Oswestry, United Kingdom

Background and Goals: Patients undergoing knee replacements (TKR) experience severe postoperative pain. Our institution has an established enhanced recovery programme with early mobilisation and daycase rate close to 50%. A short acting spinal anaesthetic, adductor canal block and large volume local infiltration (LIA) is the standard approach. Motor sparing nerve blocks of four geniculate nerves, nerves to rectus femors, vastus lateralis, intermedius and medialis, saphenous, popliteal plexus, and the anterior and lateral femoral cutaneous nerves have been used as an alternative to LIA. A maximum dose of 2-2.5 mg/kg bupivacaine was used in both techniques. We aimed to compare the analgesic quality between the two techniques.

Materials and Methods: Patients were classed into 2 groups.

Group 1 was a standard group of 30 consecutive patients undergoing primary TKR by one surgeon with the following criteria. Successful spinal anaesthesia, surgical LIA, adductor canal block, paracetamol and NSAID given, not on strong opioids preoperatively.

Group 2 was selected from a consecutive series receiving motor sparing blocks without LIA using same inclusion criteria. We retrospectively compared the post-operative opiate requirements between patients having either method.

All opiates doses were converted to intravenous morphine equivalents. Demographic data like age, sex, ASA status were collected. T test on MS excel was used to analyse the data.

Results and Discussion Demographic data showed similarity between both groups. 80% of LIA group required opiates in the first 6 hours versus 37% of the block group.

Average opioid requirement at 6hrs was 8.7mg in the LIA group Vs 3.2mg in the block group(p= 0.002). At 24hrs or discharge 87% of LIA group required opiates Vs 67% in the block group. Average opiate doses at this point were 18.4mg in LIA group Vs 10.7mg in the block group.(p=0.049). 33% of block group were opioid free at 24hrs compared to only 13% in the LIA group. Average length of stay for both groups was one day.

Conclusions: We demonstrated a significant difference in opioid requirements at 6 and 24 hrs when comparing motor sparing nerve blocks against LIA plus adductor canal block. 6 hrs post op is an ideal time to measure quality of analgesia as spinal has worn off and opioid requirements are a good measure of quality of analgesia.

Addressing frailty and risk: Continuous spinal block in emergency abdominal surgery

C.S. Silva¹, Â.Z. Oliveira¹, C. Antunes¹, S.S. Rodrigues¹, J. Magalhães¹

¹Unidade Local de Saúde do Alto Ave, Anesthesiology, Guimarães, Portugal

Background: Continuous spinal block (CSB) is an underused regional technique for abdominal surgery, allowing prolonged anaesthesia with precise titration of local anaesthetic, minimal hemodynamic and respiratory impact¹.

This case report highlights the use of CSB in emergent abdominal surgery in a frail and unstable patient.

Case Report: A 94-year-old male patient, ASA status IV, fully dependent (Barthel index 15), presented to the emergency department with abdominal pain and vomiting. The patient was hypotensive, with low peripheral oxygen saturations (92%), lactate 4.9 mmol/L and C-reactive protein level 132 mg/L. CT scan revealed an incarcerated right inguinal hernia with high suspicious of bowel ischemia and pneumonia.

After exposing the anaesthetic risks to the patient's family, informed consent was obtained. Under ASA standard monitoring, a paramedian CSB was performed at the L4-L5 interspace in right lateral position, using an 18G Tuohy needle. After confirming freeflow of cerebrospinal fluid, 3 cm of an epidural catheter was inserted and an initial 2.5 mg of hyperbaric bupivacaine plus 0.002 mg of sufentanil was administered. The patient was repositioned supine.

When a T8 sensitive level block was achieved, surgery proceed with a right inguinal incision. After 40 minutes, an additional 2.5 mg of bupivacaine was administered, to maintain patient comfort and allow bowel inspection. 10 mg of ephedrine was administered after each bolus of local anaesthetic. Analgesia was supplemented with paracetamol and wound infiltration with 15mL of ropivacaine 0,75%.

At the end of the procedure, the catheter was removed and the patient transferred to the post-anaesthesia care unit, remaining comfortable and stable. No post-dural puncture headache was reported.

Discussion: This case underpins CSB as a valuable technique to approach critical and frail patients with significant comorbidities, maintaining hemodynamic stability, safety and patient comfort².

1. Hay, R., & Gupta, A. (2022). Continuous spinal anaesthesia. *BJA Education*, 22(8), 295-297. 2. Spannella, F. et al. (2020). Thoracic continuous spinal anaesthesia for high-risk comorbid older patients undergoing major abdominal surgery: one-year experience of an Italian geriatric hospital. Minerva Anestesiology, 86(3), 261–269.

Learning points: CSB minimizes side effects and provides clinical efficacy, offering a tailored solution for patients unsuited for general, single-shot spinal, or epidural anaesthesia.

12AP11-9

Comparison of the anesthetic effects of dexmedetomidine and dexamethasone as adjuvants added to infraclavicular brachial plexus block under ultrasound guidance in upper extremity surgery

E. Bal Köylü¹, Z. Tuncel¹¹University of Health Sciences, anesthesiology and reanimation, Istanbul, Turkey

Background and Goal of Study: This study aimed to investigate the effects of dexmedetomidine and dexamethasone as adjuvants during ultrasound-guided infraclavicular block in patients undergoing upper extremity surgery.

Materials and Methods: This prospective observational study included 44 patients undergoing upper extremity surgery. The patients were divided into two groups: Group A (Dexmedetomidine, n=22) and Group B (Dexamethasone, n=22).

The duration of hospital stay, sensory and motor block onset times, total block duration, time to first postoperative analgesic requirement, total postoperative analgesic consumption within 24 hours, adverse events, hemodynamic parameters, Ramsay Sedation Scale (RSS) scores, and Visual Analog Scale (VAS) scores were recorded.

Results and Discussion: There was no significant difference in demographic data between the groups. The duration of hospitalization was significantly shorter in Group A (p<0.001). The sensory and motor block onset times were significantly shorter in Group A (p<0.001). However, the sensory and motor block durations were also significantly shorter in Group A (p=0.003 and p=0.023, respectively). Cumulative time analgesia (CTA) was significantly lower in Group A at T3 (p=0.009) and T4 (p=0.021) measurements. RSS scores were significantly higher in Group A at T1 (p=0.019) and at T2, T3, and T4 (p=0.009). The first postoperative analgesic requirement occurred earlier in Group A (p<0.001). Analgesics were required in all patients (100%) in Group A, while only 5 patients (22.7%) in Group B required analgesics (p<0.001). VAS pain scores were significantly higher in Group A at T3 (p=0.015) and T4 (p<0.001).No cases of nausea, vomiting, hypotension, or nerve damage were observed in either group. Bradycardia was reported in 5 patients (22.7%) in Group A and 1 patient (4.5%) in Group B. Conclusion: In the dexmedetomidine group, the need for postop-

Conclusion: In the dexmedetomidine group, the need for postoperative analgesia occurred earlier, and the total amount of analgesic consumption was higher due to the shorter block initiation and total block duration.

On the other hand, the sedation observed in the dexmedetomidine group could be considered an advantage, potentially enhancing intraoperative comfort. No significant adverse events requiring intervention were observed with either adjuvant.

Further comprehensive studies are necessary to establish optimal adjuvant selection and dose standardization strategies for peripheral nerve blocks or alternative regional block techniques.

The role of the quadratus lumborum block in multimodal pain management following inguinal hernia surgery

N. Stefanović¹, E. Đukić¹, B. Tošković¹, N. Nikolić¹, J. Martinoski1, A. Aleksić1 ¹Clinical Hospital Centre Bežanijska kosa, Anaesthesiology, Belgrade, Serbia

Background and Goal of Study: The use of ultrasound in anesthesiology has enabled truncal blocks as part of multimodal analgesia. Studies show that ultrasound-guided quadratus lumborum block (QLB) reduces pain for over 24 hours and lowers opioid use when combined with Paracetamol, NSAIDs, and other analgesics. This study assesses the efficacy of QLB following inguinal hernia repair.

Materials and Methods: This study enrolled 40 patients undergoing unilateral inguinal hernia repair. The eligibility criteria were ASA physical status I, II, or III and no chronic pain conditions. In 20 patients, the block was performed before surgery, and non-opioid analgesics were regularly prescribed in the first 24 hours postsurgery (QLB group).

In the control group (20 patients), only non-opioid analgesics were prescribed without nerve block. The block was performed preoperatively using an ultrasound-guided single-shot technique, in-plane.

The outcomes assessed included postoperative pain at 1h, 6h, 12h, 24h, motion pain at 12h and 24h, and opioid consumption. We also evaluated intraoperative fentanyl consumption.

Results and Discussion: Postoperative pain scores were evaluated at 1h, 6h, 12h, and 24 hours after surgery, as well as motion pain at 12h and 24h. Pain scores in the QLB group were significantly lower than in the control group. In the QLB group, there was no need for opioid analgesics, while in the control group, 7 patients (35%) received opioid analgesics.

Opioid consumption during general anesthesia was significantly lower in the QLB group compared to the control group. The fentanyl dose in the QLB group (3.06 mcg/kg ±0.91) was significantly lower than in the control group (4.18 mcg/kg ±1.00).

Conclusion(s): Our results indicate that the guadratus lumborum block, as part of multimodal analgesia, provides adequate postoperative analgesia for adult patients undergoing inguinal hernia repair surgery.

12AP11-11

Adductor canal block versus femoral nerve block in total knee arthroplasty: Network meta-analysis

L. Berikashvili^{1,2}, M. Yadgarov¹, A. Kuzovlev³, A. Smirnova^{1,4}, K. Kadantseva^{1,5}, V. Likhvantsev^{1,6} ¹Federal Scientific and Clinical Center of Intensive Care Medicine and Rehabilitology, Department of clinical trials and intelligent IT, Moscow, Russian Federation, 2Moscow Regional Research Clinical Institute n.a. Vladimirsky, Department of intensive care, Moscow, Russian Federation, 3Federal Scientific and Clinical Center of Intensive Care Medicine and Rehabilitology, Laboratory of clinical pathophysiology of critical states, Moscow, Russian Federation, 4Oncological Center No. 1 of the S. S. Yudin City Clinical Hospital of the Moscow Department of Health. Department of anesthesiology and intensive care, Moscow, Russian Federation, 5A, Loginov Moscow Clinical Scientific Center, Department of anesthesiology and intensive care, Moscow, Russian Federation, 61.M. Sechenov First Moscow State Medical University of the Russian Ministry of Health, Department of anesthesiology and intensive care, Moscow, Russian Federation

Background and Goal of Study: Postoperative rehabilitation is crucial for preventing complications, with regional anesthesia (RA) playing a key role, especially in orthopedic surgery. Total knee arthroplasty (TKA) traditionally used continuous femoral nerve block (CFNB) as the gold standard for pain management, but recent PROSPECT Society guidelines now recommend the single-shot adductor canal block (SACB). Its advantage lies in the absence of motor block, though evidence on its analgesic effectiveness is limited. This study aims to compare adductor canal and femoral nerve blocks in elective primary TKA.

Materials and Methods: A systematic review and network meta-analysis were conducted in accordance with PRISMA-NMA guidelines. Studies published between 2013 and June 2023 were identified through Medline, PubMed, Google Scholar, and Cochrane CENTRAL. The search included randomized and non-randomized studies comparing adductor canal blocks and femoral nerve blocks in TKA. Data extraction was performed by three independent reviewers, with opioid consumption converted to oral morphine equivalents. A frequentist random-effects network meta-analysis was conducted using CINeMA and STATA 17. Risk of bias was evaluated using the RoB2 and ROBINS-I tools, while the certainty of evidence was assessed through the GRADE methodology integrated within the CINeMA framework.

Results and Discussion: Thirty-six studies with 3,308 patients were included. CFNB provided superior pain relief compared to SACB at both 24 and 48 hours (MD 0.55-0.71), though SACB was associated with higher opioid use (MD 7.35). SACB, however, led to faster functional recovery at 24 hours (MD -22.11), but this benefit was no longer seen at 48 hours. Continuous adductor canal block (CACB) emerged as the most effective, offering better functional recovery and shorter hospital stays compared to CFNB, despite slightly higher opioid consumption. The certainty of evidence varied from low to moderate.

Conclusion(s): The analysis suggests that changing the gold standard to SACB for pain management after total knee arthroplasty may be premature. While SACB improves mobility, it provides insufficient analgesia compared to CFNB. CACB stands out, offering both effective pain relief and a shorter hospital stay. Further research is warranted.

12AP11-12

Placement of an epidural catheter near the drain in cardiac surgery patients during MIDCAB surgery

A. Yakimchuk¹, A. Dzyadzko², P. Volk³, Y. Kastiakhin⁴, N. Miadzvetskaya5

¹Aliaksei Yakimchuk, Anestesiology and Rasustitation #4, Minsk, Belarus, ²Aliaksander, Dzyadzko, Minsk, Belarus, ³State Healthcare Institution "Molodecheno Regional Center for Emergency Medical Care". Molodetsenskava Emergency Medical Care Center, Visiting Team Doctor, Molodetseno Emergency Medical Care Center, Molodecheno, Belarus, 4 Yauheni Kostiakhin, Anestesiology and Rasustitation #4, Minsk, Belarus, 5State Institution Minsk Scientific and Practical Center for Surgery. Transplantation and Hematology, Anesthesiology and Resuscitation #4, Minsk, Belarus

Background and Goal of Study: In minimally invasive cardiac and thoracic surgery, there is still a problem of postoperative pain relief. The best method of pain relief for these patients is the introduction of anesthetic into the drainage.

However, this affects depressurization and infectious complications. An epidural catheter inserted near the pleural drainage can relieve these problems.

Materials and Methods: 45 Patients undergoing MIDCAB and thoracoscopic surgery using catheter placed near the pleural drain and, as a comparison group, 45 patients who underwent paravertebral anesthesia were studied. The pain level was assessed using a visual analogue scale.

The general principle of pain relief was as follows. For paravertebral anesthesia, 20 ml of 0.25% ropivacaine solution was used three times a day. When installing an epidural catheter near the pleural drainage, 20 ml of 0.25% ropivacaine solution was also used three times a day.

During rehabilitation, 35 of the 45 patients in the paravertebral anesthesia group received morphine or trimeperidine. In the group of patients with a catheter near the chest drain, none received an opioid.

Results and Discussion: In the paravertebral anesthesia group, the level of the visual analogue scale postoperatively was from 3 to 5 in 35 patients out of 45. In the group with the installation of an epidural catheter next to the pleural drainage, the visual analogue scale did not rise above 2 points in all 45 patients.

Conclusion(s): Inserting a catheter next to the pleural drainage is the most comfortable and simple method of pain relief after MIDCAB and thoracoscopic operations and eliminates possible problems with drainage depressurization and infectious complications.

12AP12-3

Accidental intrathecal morphine overdose - do not forget it

S. Cabete¹, M. Carvalho¹

¹Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Servico de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal

Background: Epidural catheters are routinely used, and anaesthesiologists must identify an off-site catheter and manage its complications.

Case report: An 81-year-old woman with arterial hypertension and class I obesity was transferred to the post-anaesthesia recovery unit (PACU) after total knee arthroplasty under spinal anaesthesia as part of a combined spinal-epidural technique that required multiple attempts.

After (<5 minutes) a negative epidural test dose, 2 mg of morphine were administered. Minutes later, the patient reported motor blockade of the lower limbs. Clear fluid was freely aspirated from the catheter, which was removed.

The patient remained under overnight surveillance.

In the morning (14 hours after the accidental administration), the patient had altered consciousness and was hypoventilating without improving after naloxone boluses. Arterial blood gas values were: pH 7.1, paO, 67.1mmHg, paCO, 88.2mmHg, HCO, 28mmol/L, lactate 5.6 mmol/L. Bilevel-positive air pressure ventilation and a continuous naloxone infusion were initiated.

The patient improved after 2.5 hours of noninvasive ventilation and 10 hours of naloxone infusion (0.24-0.04mg.h-1).

Twenty-eight hours after the accidental intrathecal administration the acidemia had resolved.

The patient remained stable over the next 12 hours and was transferred to the ward.

Discussion: The catheter could be intrathecal due to unrecognised initial misplacement or later migration. Factors that could have contributed to failed timely detection were neglected aspiration, the catheter partially in the intrathecal space, inadequate testing for motor blockade, insufficient waiting time after the test dose and delayed patient report.

After recognition of intrathecal morphine overdose, the side effects were treated as they developed. However, a naloxone infusion started before the patient becomes symptomatic and closely after morphine injection can control side effects without the need for ventilatory support1.

References:

1. Cannesson, M, Nargues, N, Bryssine, B, Debon, R, Boselli, E, & Chas sard,D(2002)Intrathecalmorphineoverdoseduringcombinedspin al-epiduralblockforCaesareandelivery.BJA89(6)925-927

Learning points: Test dose in combination with aspiration should always be used to check the correct placement of an epidural catheter.

After an intrathecal morphine overdose, patients should be managed in a specialised unit with the possibility of early initiation of naloxone infusion and, if necessary, ventilatory support.

Regional Anaesthesia

12AP12-4

Stellate ganglion blockade for the treatment of refractory atrial fibrillation

A.F. Freitas Silva¹, D. Levier¹, R. Carvalho¹
¹Hospital Professor Doutor Fernando Fonseca,
Anesthesiology, Amadora, Portugal

Background: Stellate ganglion blockade (SGB) has been described as an effective adjunct treatment for refractory ventricular tachyarrhythmias.¹

However, there is no evidence of its use in the management of refractory atrial fibrillation (AF).

Case Report: AA 60-year-old male with unknown medical history, presented to the emergency department with a thyroid storm, causing rapid AF and decompensated dilated cardiomyopathy, resulting in cardiogenic shock.

The initial approach was made by the cardiology team: tracheal intubation, sedation, vasopressors and treatment of thyroid storm. Due to unstable tachyarrhythmia, patient underwent 1 trial of single electrical cardioversion followed by 3 trials of dual synchronized electrical cardioversion without reverting to neither sinus rhythm nor rate control. Considering the clinical circumstances and the high risk of pharmacological cardioversion, the anesthesiology team was called for SGB.

Initially, the team performed an ultrasound-guided unilateral left SGB with 10mL ropivacaine 0,2%, that went uneventfully.

After 10 minutes, there was no rate nor rhythm control, and an US-guided right-sided SGB with 10mL ropivacaine 0,2% was perfored for bilateral blockade, as the patient had already been intubated.

After 15 minutes, there was a small decrease in the heart rate (170 bpm to 150bpm), although the patient remained in rapid atrial fibrillation, there was no increase in the vasopressors needs after the technique. Patient had, however, an unfavorable evolution and died 18 days post-admission.

Discussion: SGB has been suggested to suppress sympathetic activity and downregulation of beta1-adrenergic receptors. The vagal stimulation and nitric oxide release may contribute to its effects on atrial tachyarrhythmias.

Although this technique had no efficacy in this patient, the SGB was a viable option as the atrial fibrillation was probably highly sympathetic-dependent due to the thyroid storm.

References:

Learning points: There is need for further investigation, if, in selected cases, SGB can be usefull in the management of refractory AF with rapid ventricular response.

12AP12-6

Efficacy and safety of PENG block for shoulder surgery: a case series

J.J. Tortajada Soler¹, P. Cuesta-Montero², J.Á. Ródenas-Rubio², J.L. Jover-Pinillos¹, J.P. García-Belmonte¹ ¹Hospital Verge dels Lliris, Anestesiología y Reanimación, Alcoy, Spain, ²Complejo Hospitalario Universitario de Albacete, Anestesiología y Reanimación, Albacete, Spain

Background: Multimodal analgesic treatment is a fundamental component of perioperative care for patients undergoing shoulder surgery. Pericapsular Nerve Group (PENG) block for shoulder surgery is an innovative regional anesthesia technique specifically designed to provide targeted analgesia to the glenohumeral joint.

This technique involves placing the linear ultrasound transducer between coracoid process and humeral head, identifying humeral head, subscapular muscle, and deltoid muscle. Using an in-plane approach, local anesthetic is injected between deltoid and subscapular muscles.

Case Report: Report of four cases of adult patients undergoing shoulder surgery (shoulder arthroplasty / arthroscopy). The anesthetic strategy was shoulder PENG block under ultrasound guidance, followed by general anesthesia.

The efficacy of the block was assessed using the visual numeric scale (VNS) of pain during the stay in the post-anesthesia care unit (PACU) and the first 12 postoperative hours.

The safety of the block was assessed by evaluating the motor block of the upper extremity and the occurrence of associated nerve, vascular or respiratory complications.

Discussion: Shoulder PENG block associated with acetaminophen, NSAIDs and tramadol provided optimal postoperative pain control (VNS < 3) during the stay in PACU and first 12 postoperative hours in four patients (90%). One patient required a rescue dose of morphine. No patients evaluated presented motor block of upper extremity or associated nerve, vascular or respiratory complications.

According to anatomical studies, local anesthetic spreads through glenohumeral capsule surrounding humeral head, with potential extension toward axillary region. However, further clinical studies are necessary to determine its efficacy, anesthetic volume, and surgical applicability

References:

- 1. Altinpulluk, E. Y., et al. (2020). Pericapsular nerve group block for postoperative shoulder pain: A cadaveric radiological evaluation. *Journal of Clinical Anesthesia*, 67, 110058.
- 2. Küpeli, İ., et al. (2022). Anesthesia or analgesia? New block for shoulder surgery: Pericapsular nerve group block. *Brazilian Journal of Anesthesiology*, 72(5), 669-672.

Learning points: Compared to the interscalene block, shoulder PENG block avoids motor block and pulmonary complications, making it an optimal alternative for patients at risk of respiratory complications, such as severe respiratory diseases, obesity or contralateral recurrent paralysis.

12AP12-7

Analgesia for 'positioning pain' in hip fracture patients receiving spinal anaesthesia

J. Camilleri¹, A. Grech¹

¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care & Pain Management, Msida, Malta

Background and Goal of Study: Positioning pain refers to patient discomfort experienced during positioning for a procedure. Hip fracture patients receiving spinal anaesthesia were identified as a target for quality improvement in this regard in our institution. PubMed and EMBASE were searched up to March 2024.

Two observations were made – higher level evidence was sparse and regional analgesia strategies at odds with intravenous techniques. Local expert opinion was sought to culturally contextualise this in our setting.

Materials and Methods: A 7-item questionnaire was synthesised de novo according to best practice guidance1 and examined for face validity before circulation within a tertiary acute general and teaching hospital. No piloting was conducted in view of anticipated small sample size and low response rate.

Results and Discussion: The questionnaire was extended to 130 anaesthesiologists of mixed grade, with 25 responses obtained. 96% (n=24) indicated either fentanyl, ketamine or both as viable analgesia; midazolam (48%, n=12) or propofol (48%, n=12) were predominantly suggested for sedation.

Regional analgesia was deemed unnecessary by 36% (n=9); the remainder indicated a preference for fascia iliaca compartment block (32%, n=8), femoral nerve block (28%, n=7) or either of these (4%, n=1) with implementation limited however by time pressure (48%) more than technical ability (44%).

No respondent indicated pericapsular nerve group (PENG) blocks despite these being suggested as superior in this context². Greater clinician experience was correlated via Spearman statistical analysis with less frequent nerve block consideration (rs = -0.46, p = 0.02).

Conclusion(s): Intravenous analgosedation is predominant but its approach heterogeneous, while regional analgesia and its challenges merit exploration.

Local expert opinion requires amalgamation with existing evidence-based medicine, but promoting regional strategies may require stakeholder analysis, discussion of patient workflow, and provider education initiatives.

Horner's syndrome following infraclavicular brachial plexus block: a rare postoperative complication

L. Umanets¹, R. Campos¹, S. Domingues¹, L. Ormonde¹ ¹ULS Santa Maria - Hospital de Santa Maria, Anesthesiology, Lisboa, Portugal

Background: We present a rare complication of brachial plexus block during postoperative analgesia: Horner's syndrome. This condition developed after an infraclavicular brachial plexus analgesic block was performed for surgical treatment of a human

This case is noteworthy due to the unusual presentation of Horner's syndrome, its successful management, and its implications for safe regional anesthesia practices.

Case Report: A 50-year-old male, with no significant medical history, underwent left hand debridement of infected soft tissues and bone. The procedure was conducted under balanced general anesthesia with placement of a left infraclavicular brachial plexus perineural catether for continuous postoperative analgesia. Pacient Control Regional Analgesia (PCRA) protocol was instituted with ropivacaine 0.2% (5.2 mL/h basal rate, 5 mL bolus, 240 min lockout).

On the second postoperative day, by the time of Acute Pain Unit observation, the patient presented with paresthesia, ptosis and miosis, leading to a suspicion of Horner's syndrome. The infusion was stopped, and analgesia was managed with manual boluses of ropivacaine 0.1%. Symptoms resolved.

Discussion: Horner's syndrome is a rare complication of infraclavicular blocks, primarily due to the unintentional spread of local anesthetic to the stellate ganglion or sympathetic chain.

While the literature primarily associates Horner's syndrome with brachial plexus interscalene and supraclavicular blocks, reports of this condition following infractavicular blocks are rare (1)(2). Early recognition and management of these complications are crucial to avoid patient anxiety and ensure recovery.

The complete resolution of symptoms in this case underscores the importance of monitoring patients and also the reversible nature of Horner's syndrome when promptly addressed.

Reference:

1. Jandard C, Gentili ME, Girard F, et al. Infraclavicular block with lateral approach and nerve stimulation: extent of anesthesia and adverse effects. Regional Anesthesia and Pain Medicine. 2002;27(1):37-42. 2) Kilka HG, Geiger P, Mehrkens HH. Infraclavicular vertical brachial plexus blockade. A new technique of regional anaesthesia. Anaesthesist. 1995;44(5):339-344.

Learning points: Horner's syndrome can occur as a rare complication of infraclavicular brachial plexus blocks due to unintended local anesthetic spread.

Vigilant monitoring and prompt management are essential to address regional anesthesia complications.

12AP12-9

Double epidural catheter anesthesia in a super-obese patient – a case report

I. Carrapatoso¹, P. Branco¹, N. Santos¹, T. Estevens¹, M. Guarda¹. C. Carmona¹ ¹Hospital Prof. Dr. Fernando Fonseca, E.P.E., Anesthesiology, Amadora, Portugal

Background: The anesthetic management of obese critical patients is often challenging. Patients with BMI above 50 are classified as super obese by World Health Organization (WHO). Airway management and respiratory function are common anesthetic concerns, hence neuraxial anesthesia has invaluable benefits to minimize perioperative complications.1

Case Report: We report the successful management of a super obese woman (BMI 64) with extensive necrotizing fasciitis and respiratory distress. A 54-year-old woman (160 Kg, 158 cm) reported to the emergency department a week after falling with right-sided impact on her trunk. She had hypertension and sleep apnea with nocturnal CPAP therapy.

Truncal skin inflammation and increased respiratory rate were evident, with hypoxemia on room air. CT scan showed an extensive subcutaneous hematoma extending from her axilla to the inguinal crease.

CPAP was instituted in ICU and 2 epidural catheters were inserted (T5-T6 and L2-L3) for analgesia. 10 ml of 0,5% Ropivacaine were used in each catheter to cover the extension of the hematoma. Surgical debridement with large truncal incisions was successfully accomplished. The patient reported no complains during the procedure, with respiratory and hemodynamic stability.

Discussion: There are no clinical reports on the use of two epidural catheters for extensive truncal anesthesia of super obese patients. Epidural catheter placement is often difficult due to positioning and increased distance from the skin to the epidural space.1

While infection is a relative contraindication for neuraxial anesthesia, there is a low incidence of infection (0.007%-0.6%) of the central nervous system after neuraxial punctures in patients at risk or with bacteremia2.

The use of two epidural catheters can extend anesthetic coverage, avoiding general anesthesia.3

- 3. Guay, J. et al. Neuraxial anesthesia for the prevention of postoperative mortality and major morbidity: an overview of Cochrane systematic reviews. Anesthesia & Analgesia 2014, vol 119, nº3, 716-725.

Learning points:

Epidural anesthesia for surgical super obese patients is an invaluable alternative when trying to avoid major airway management and respiratory complications.

12AP12-10

The effect of pectointercostal fascia plane block applied in addition to serratus anterior plane block on postoperative analgesia in breast reduction surgery

E. Biricik¹, A.I. Bozkurt², F. Karacaer², D. Tunay² ¹Çukurova University Faculty of Medicine, Anesthesiology and Reanimation, Adana, Turkey, ²Cukurova University, anesthesiology and reanimation, Adana, Turkey

Background and Goal of Study: We aimed to investigate the effect of applying another plane block, Pectointercostal fascia plane block (PIFB), in addition to Serratus anterior plane block (SAPB) before bilateral breast reduction surgery on postoperative morphine consumption and pain scores (rest + movement).

	Group I (n=30)	Group II (n=30)	P values

VAS (Movement) 15.min 2th hours 6th hours 12th hours 24th hours	4.4±1.5 3.6±1.0 3.3±1.4 2.8±1.2 2.1±1.3	5.8±2.1 5.2±1.9 4.9±1.8 4.6±1.6 3.7±1.6	0.003 0.00 0.001 0.00 0.00

	Group I (n-50)	Group II (n-30)	Pvalues
Nauva	9	8	0.783
Nansca (vomiting	141	6	
Stay in PACU time (min)	38.8±25.6	32.7±8.1	0.806
Morphine consumption in			
24th hours(mg)	3.7±2.2	7.9±2.3	0.00
Median	4.0	8.0	
Min.max	0.0-8.0	3.0-12.0	
Morphine demand for PCA in			
24th hours	4.5±2.7	10.4±3.7	0.00
Median	[4.0	10.0	
Min Max	0.0-10.0	4.0-20.0	
Rescue analgesic requirement			
(+).	20 (66.7%)	28 (93.3%)	0.01
(6)	10 (33.3%)	2 (6.7%)	

Materials and Methods: 64 patients aged 18 years and older, ASA I-II, were included in the study and divided into two groups. General anesthesia was induced with 2 mg/kg propofol, 0.6 mg/ kg rocuronium and 2 µg/kg fentanyl in all patients and maintained with sevoflurane 1-2%, 40/6002/air, remifentanil infusion.

After intubation, patients in Group I received PIFB (bilateral 15 ml 0.25% bupivacaine) in addition to SAPB (bilateral 20 ml 0.25% bupivacaine). Patients in Group II received only SAPB (bilateral 20 ml 0.25% bupivacaine).

All patients received postoperative patient-controlled analgesia with IV morphine (1mg bolus, 10 min lockout, 4-hour limit of 10 mg). Intraoperative hemodynamic data, sevoflurane and remifentanil consumption, surgery duration, extubation duration, and duration of stay in the postanesthetic care unit (PACU) were recorded. Morphine consumption in the first 24 hours postoperatively, number of morphine rdemands, visual pain scores (VAS) at rest and movement, additional analgesic requirement, sensory blockade monitoring, and complications were recorded.

Results and Discussion: The groups were similar in terms of demographic data, duration of surgery, extubation time, duration of stay in PACU. Postoperative 24-hour morphine consumption was 3.7±2.2mg in patients in Group I and 7.9±2.3mg in patients in Group II (p<0.05). When we look at the number of postoperative morphine demands, it was 4.5±2.7 in Group I and 10.4±3.7 in Group II (p<0.05). VAS scores at both rest and movement in the first 24 hours postoperatively were higher in Group II than in Group I (p<0.05). There was no difference between the groups in terms of additional analgesic requests (p>0.05). No complications were observed.(Table1,figure1)

Conclusion(s):It was concluded that addition of PIFB to SAPB applied preoperatively in breast reduction surgery reduced morphine consumption and pain scores in the first 24 hours postoperatively compared to SAPB alone without causing any complications.

12AP12-11

Anaesthesia mumps after epidural anaesthesia for caesarean section in a patient with long QT syndrome: A rare case report

E. Papachatzopoulou¹, K. Fillipa², E. Liazou², D. Liazou².

Anaesthesiology, Thessaloniki, Greece

E. Pozidou², D. Iordanidou²
¹Agios Pavlos General Hospital, Anaesthesiology,
Thessaloniki, Greece, ²Hippokrateion General Hospital,

Background: Anaesthesia mumps (AM) is a rare transient post-operative sialadenitis encountered most commonly after general anaesthesia. Long QT syndrome (LQTS) is defined as QTc \geq 480ms or QTc \geq 460ms in symptomatic individuals.

We report the case of a woman with LQTS, who received epidural anaesthesia (EPD) for caesarean section and developed AM.

Case Report: A primiparous 42-yo woman was referred to our hospital at 39 weeks of gestation for elective caesarean section. She had a past history of anorexia nervosa with a hospital admission due to hypokalaemia (K^+ 1.9).

Preoperative lab results and ECG revealed a K^+ value of 3,1 and a long QTc of 460ms. Cardiology consult was requested and the K^+ was corrected to 3,7. The preoperative evaluation was otherwise normal. EPD was selected as the most haemodynamically stable technique. The catheter was placed at the L3-L4 level under sterile conditions.

Intraoperatively, lidocaine 2% 2ml, ropivacaine 0,75% 9ml and fentanyl 50mcg were given EPD. After delivery, intravenous cefoxitin 2gr, midazolam 1mg and carbetocin 100mcg were given, as well as morphine 2mg EPD for postoperative analgesia, without adverse reactions.

The patient remained haemodynamically stable; vital signs \pm 25% from the baseline. Within 10 minutes after exiting the operating room, she complained of a painless bilateral parotid swelling, that was hard on palpation with no signs of crepitus. She received hydrocortisone 200mg and ENT consult was requested. Ultrasound of the structures supported the clinical diagnosis of AM and watchful waiting was proposed. The swelling resolved spontaneously on the 4^{th} postoperative day with no complications.

Discussion: The proposed pathophysiological mechanisms of AM include the use of muscle relaxants and vasopressors, as well as surgical position, intratracheal manipulation and preoperative dehydration. AM following EPD is extremely rare, with only 3 other cases reported to our knowledge¹.

In this case the use of the aforementioned drugs was avoided, due to concerns of exacerbating the LQTS, leaving increased viscosity of the saliva due to dehydration as the only probable explanation of the phenomenon.

Learning points: Pathophysiological mechanism of AM.

AM is a benign phenomenon that can be encountered even after

12AP12-12

Thoracic epidural anesthesia is considered to be the gold standard for regional anesthesia in thoracic surgery. But is this method always effective?

A. Perkonos¹, <u>O. Hanol</u>¹, T. Storcheva¹

¹National Cancer Institute, Anesthesiology and Intensive Care, Kyiv, Ukraine

Background and Goal of Study: The effectiveness of thoracic epidural anesthesia (TEA) for pain management of thoracic surgery has been proved and now it is among the recommendations. However, the method is technically difficult, has limitations in use and when used is not always effective. The National Cancer Institute is a leading national centre for surgical treatment of lung, mediastinal and chest wall tumors in Ukraine. More than 500 surgeries are performed annually.

The aim of this study was to assess the proportion of operations covered by regional methods, including TEA, and to determine the problems anesthesiologists faced when using TEA in thoracic surgery.

Materials and Methods: We analyzed the use or the attempts of use of TEA in 429 thoracic surgeries over a 10-month period. We calculated the percentage of successful catheter placement attempts, the percentage of effective TEA (the criterion for effectiveness was the need for morphine of less than 10 mg/day in the postoperative period), the dependence of the success and effectiveness of attempts on the experience of the anesthesiologist performing the manipulation. We estimated the percentage of complications of TEA.

Results and Discussion: Out of 429 thoracic surgeries, 297 (69.2%) were covered by regional (TEA, TPVB, ESP) methods of analgesia, including 52.2% covered with TEA. 204 TEA attempts were performed during 10-month period , 43 (21%) attempts failed.

The effectiveness of TEA was insufficient in some patients (17.4%) who underwent it. The proportion of successful TEA correlated with the experience of the anesthesiologist performing the manipulation (Table).

The incidence of complications of TEA was not significant (6.4%) and the complications themselves (vascular puncture, subarachnoid space puncture, hypotension, bradycardia, nausea) were not life-threatening.

Experience of the anesthesiologist	Attempts	Failed attempts	Attempts resulted in successful catheter placement	Ineffective TEA
Anesthesiologists with the experience > 10 years	86	8 9.3%	78	15 19.2%
Anesthesiologists with the experience 5-10 years	40	7 17.5%	33	5 15.2%
Residents	78	28 35.9%	50	8 16 %

Table. Correlation between the success and the effectiveness of attempts and the experience of the anesthesiologist performing the manipulation

Conclusion(s): TEA is a technically challenging method of regional anesthesia, the use of which does not always lead to success. The effectiveness of TEA in thoracic surgery also depends significantly on the experience of the anesthesiologist.

12AP13-1

Application of bilateral recto-intercostal fascial plane block as rescue analgesia after laparoscopic cholecystectomy: a case report

M. Taşkır Turan¹, D. Hökelek, D. Güzelkaya¹, H.A. Sarıbudak¹, E. Güngördü¹, J. Ergil¹ ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Çankaya, Turkey

Background: For postoperative pain control in laparoscopic cholecystectomies, various fascial plane blocks such as the Transversus Abdominis Plane Block (TAPB), Erector Spinae Plane Block (ESPB), Modified Pericostal Approach to Thoracoabdominal Nerve(M-TAPA) Block, and External Oblique Intercostal Block(EOIB) are performed in combination with intravenous (IV) analgesics.

Recently, Tulgar et al. described a new interfascial plane block technique called the "Recto-Intercostal Fascial Plane Block" (RIFPB). RIFPB is performed between the rectus abdominis muscle and the sixth and seventh costal cartilages just inferior lateral to the xiphoid. RIFPB targets the anterior and lateral cutaneous branches of the T6-T9 thoracoabdominal nerves.

This case report, consisting of two cases, aims to share the analgesic effects of RIFPB when applied as rescue analgesia in patients whose pain could not be controlled with IV analgesics following laparoscopic cholecystectomy.

Case Report: Informed consent was obtained, and standard ASA monitoring was performed for laparoscopic cholecystectomy surgery on a 51-year-old female patient with ASA II due to smoking and a 49-year-old female patient with ASA II due to hypertension. Anesthesia induction was performed with 1 mcg/kg fentanyl IV 1 mg/kg lidocaine IV and 2 mg/kg propofol IV.

Maintenance anesthesia included sevoflurane inhalation and remifentanil infusion. For postoperative analgesia,100 mg tramadol hydrochloride IV and 50 mg dexketoprofen tromethamin IV were administered.

Additionally,3 mg granisetron IV was given for postoperative nausea and vomiting. Following extubation, both patients reported severe pain during follow-up in the recovery room at the 5th and 15th minutes (visual analog scale [VAS] scores of 9 and 8, respectively). Bilateral RIFPB Block under ultrasound guidance was planned as rescue analgesia.

After sterilization, 20 ml of local anesthetic solution (10 ml 0.5% bupivacaine + 10 ml normal saline) was administered bilaterally using a peripheral block needle (80 mm, Vygon) under ultrasound guidance. Ten minutes after the block, the patients' VAS scores decreased to 5. At 20 minutes. VAS scores were recorded as 3. Both patients, with stable vital signs, were transferred to the ward.

Discussion: We believe that the newly defined RIFPB can be considered a viable option for postoperative analgesia management in patients undergoing laparoscopic cholecystectomy, as it effectively blocks peripheral nerves between T6 and T9.

Background and Goal of Study: Spinal anesthesia in obese parturients poses significant challenges due to difficulty in identifying anatomical landmarks and achieving optimal positioning. Ultrasound-guided spinal anesthesia has emerged as a potential alternative to traditional landmark-based techniques, offering improved visualization and accuracy.

This study aimed to compare the efficacy, safety, and patient satisfaction of ultrasound-guided spinal anesthesia with conventional techniques in obese parturients undergoing cesarean

Materials and Methods: A prospective, comparative study was conducted over one year, including 120 obese parturients scheduled for cesarean sections. Participants were divided into two groups: Group A (n=60), receiving ultrasound-guided spinal anesthesia, and Group B (n=60), using conventional landmark-based

The primary outcomes included the number of puncture attempts, success rates of anesthesia, post-anesthetic complications, and maternal satisfaction. Postoperative pain was evaluated using the Visual Analog Scale (VAS), and results were statistically compared between the two groups.

Results and Discussion: The gestational age was similar between groups (37.7 \pm 2.53 weeks in Group A vs. 39.5 \pm 2.14 weeks in Group B, p=0.07). Ultrasound guidance significantly reduced the number of puncture attempts, with 100% of patients in Group A requiring 1-2 attempts, compared to only 66.6% in Group B, where more than five attempts were often needed.

The failure rate was also lower in Group A (6 cases) than in Group B (15 cases). Post-dural puncture headache (PDPH) incidence and severity were similar across groups. Sensory block levels (T6 or higher), block onset times, and durations were comparable between groups.

Postoperative pain scores were equivalent at rest and during mobilization, but maternal satisfaction was significantly higher in Group A, with 53 patients reporting being "very satisfied" versus 41 in Group B.

Most studies support ultrasound's role in improving anesthetic outcomes by enhancing visibility of anatomical structures . This results in fewer attempts, reduced procedure time, and higher patient satisfaction.

Conclusion(s): Ultrasound-guided spinal anesthesia offers significant advantages for obese parturients undergoing cesarean sections, including fewer puncture attempts, higher success rates, and improved maternal satisfaction.

12AP13-3

Case report: Horner's syndrome following interscalene block in a 24-year-old female undergoing shoulder arthroscopy

H. Ribera¹, J. Ariño Larrañaga², I. Hernandez Zubelzu³, G. Etxebarria Larreina³, M. Ibarguren Zubikarai³ ¹Alto Deba Hospital, Anaesthesiology, Arrasate, Spain, ²Donostia university Hospital, Anaesthesiology, Donostia, Spain, ³Donostia University Hospital, Anaesthesiology, Donostia, Spain

Background: Horner's syndrome (HS) is a rare neurological condition resulting from disruption of sympathetic nerve pathways to the eye, characterized by ptosis, miosis, anhidrosis, and enophthalmos. It can occur after an interscalene brachial plexus block (ISB), a complication due to local anesthetic affecting sympathetic fibers near the brachial plexus. This case describes a young female who developed HS following an ISB for shoulder arthroscopy, highlighting the importance of recognizing this complication in elective surgeries.

Case Report: A 24-year-old female with no significant medical history was scheduled for elective arthroscopic shoulder surgery due to recurrent dislocations. Preoperative examination and lab tests were normal. The anesthesia plan included a single-shot interscalene block with 15 mL of 0.25% levobupivacaine. The block was performed without incident, and the patient was positioned for surgery.

Approximately 20 minutes post-block, the patient developed ptosis, miosis, and mild anhidrosis on the right side of her face. Surgery proceeded without complication under general anesthesia, and the patient remained hemodynamically stable. In the recovery unit, Horner's syndrome persisted for about 24 hours. Neurological exams, including brain and cervical spine MRI, were normal. The patient was discharged, and by the second postoperative day, the symptoms had resolved fully.

Discussion: HS following ISB, while rare, is well-documented. Sympathetic nerve fibers near the brachial plexus can be affected by local anesthetics, causing the characteristic signs of HS. Although transient and self-limited in most cases, early recognition is important to avoid misdiagnosis of more serious conditions like brainstem lesions or carotid artery dissection. In this case, imaging excluded other causes, confirming the block as the likely source.

Previous reports suggest that HS may occur with higher volumes of anesthetic or suboptimal needle placement. However, in this case, the condition resolved without intervention, reinforcing its typically benign nature.

Learning Points:

- Horner's syndrome is a rare but important complication of ISB caused by inadvertent sympathetic nerve blockade.
- The condition is usually transient and resolves without treatment.
- Early recognition is crucial to differentiate HS from other neurological conditions.
- Proper technique and volume control during ISB can help minimize the risk of sympathetic nerve involvement.

12AP13-5

Comparison between epidural analgesia and intrathecal opioid analgesia for pain management in open nephrectomy: a prospective randomized controlled pilot study

P. Bajto¹, M. Mirčeta¹, S. Došenović¹, I. Šarić¹, I. Dželalija¹, L. Šarić¹

¹University Hospital of Split, Department of Anesthesiology and Intensive care medicine, Split, Croatia

Background and Goal of Study: Open nephrectomy is associated with significant postoperative pain, which can impair patient recovery.

In this study, we compared two different approaches to pain management regarding acute pain during the first 24 hours.

Materials and Methods: Patients undergoing open nephrectomy were randomized to one of the two groups: epidural analgesia (Control) or intrathecal opioid (Intervention) group.

The intervention group received 300 mcg of morphine intrathecally before the general anesthesia, while the control group received a continuous infusion of levobupivacaine during the postoperative period.

The main outcome was the difference in pain on the numeric rating scale (NRS score) 24 hours after the procedure. NRS was recorded postoperatively at rest and during movement.

Secondary outcomes were the incidence of adverse effects, systemic analgesics consumption, and hospital LoS.

Demographic data were analyzed using descriptive statistics. As appropriate, group comparisons were compared using the Mann-Whitney U-test or Chi-squared tests.

Results and Discussion: Sixteen patients were randomized in this pilot study: 9 in the intervention group and 7 in the control group There was no statistically significant difference in NRS score after 24 h between the two groups at rest as well as during movement.

There was also no difference in secondary outcomes. Results are shown in Table 1.

Outcomes	Intervention	Control	P value
NRS score at 24 h			
At rest	3 (2-5)	3 (1.5-4.5)	0.748
At movement	5 (4-5)	5 (4-6)	0.616
Total amount of rescue analgesia during 24 h			
Metamizole, g	2.5 (2.5-5)	2.5 (2.5-5)	0.476
Tramadol, mg	0	0	
Total amount of rescue analgesia during 72 h			
Metamizole, g	7.5 (5-7.5)	7.5 (6.25-8.75)	1
Tramadol, mg	0	0	

Table 1. Comparison of outcomes. Results are presented as medians (IQR)

Modern multimodal approaches for perioperative care often include epidural analgesia. However, various adverse effects need to be taken into consideration. Intrathecally administered opioids can produce a specific analgesic effect with fewer motor, sensory, or autonomic side effects when used in the appropriate dosage. Conclusion: Intrathecal analgesia with morphine provides the same level of postoperative analgesia as epidural analgesia with-

12AP13-6

Rebound pain occurrence in patients undergoing forefoot bone surgery under popliteal sciatic nerve block or distal sensory ankle block

out an increased incidence of adverse effects.

M. Heroufosse¹, N. Touil¹, A. Pavlopoulou¹, E. Henry¹, B. Manczak¹, P. Lavand'homme¹ ¹Cliniques Universitaires Saint-Luc, Anesthesiology, Woluwe-Saint-Lambert, Belgium

Background and Goal of Study: Rebound pain (RP) when peripheral nerve block (PNB) wears off affects nearly 50% of patients (1). The underlying mechanisms of RP remain poorly understood but induced inflammation at surgical site might play a role (1-2). Forefoot surgery can be performed under either ankle block (AB, sensory block) or popliteal sciatic nerve block (PSNB, mixed motor/sensory block). This study compares RP incidence between PSNB and AB and questions the role of local inflammation (3).

Materials and Methods: Patients were randomized to receive either ultrasound-guided PSNB or AB with 0.5% ropivacaine followed by standardized general anesthesia. RP was defined as severe pain (NRS > 7; NRS 0-10) within 12 to 24 hours after PNB resolution. Repeated measures of foot temperature and oxygen perfusion near the surgical site (INVOS) were used as indirect assessment of local inflammation. Chi-squared tests and a mixed linear model will be used for statistical analysis.

Results and Discussion: 54 were analyzed. No difference in RP occurrence was observed between PSNB 36% (9/25) and AB 31% (9/29) groups and (p=0.92). Temperature elevation and IN-VOS values did not differ according to the type of block. Only temperature elevation was significantly associated with time (p=0.01) and RP occurrence (p=0.04), (Table 1).

Conclusion(s): According to these preliminary results, RP in forefoot surgery does not depend on the type of PNB but is correlated with foot local temperature increase (i.e., with the degree of local inflammation induced by surgery and facilitated by the PNB (3)).

Dependent Variable	Explanatory Factor	F Value	DDL (Denominator)	p-Value
	4 time points	4.26	35.61	0 .01*
Temperature	Occurrence of RP (yes/no)	4.54	39.38	0 .04*
	Type of PNB (PSNB vs AB)	0.32	40.34	0.56
	4 time points	2.59	35.68	0.07
INVOS Values	Occurrence of RP (yes/no)	1.79	40.70	0.19
	Type of PNB (PSNBys AB)	0.58	41 95	0.45

Table 1: Results of Mixed Linear Analysis

F Value: statistic calculated to assess the significance of each explanatory variable

DDL: degrees of freedom for the denominator of the F statistic

p-Value: statistical significance of the F value for each explanatory factor *statistically significant results (p-value < 0.05)

4 time(t) points: t1=Pre-block time/t2=Post-block time/t3=Time in the recovery room/ t4=Day 1 time

Walant technique for clavicle surgery, regarding

M.R. Pretel Lara¹, A. Martín Arrabal¹, M. Diaz Rueda¹, D. Diaz Perez¹, J.C. Callejas Rodelas¹, I. Moh Martínez¹ ¹San Cecilio University Hospital, Anesthesiology, Granada, Spain

Background: The WALANT (Wide awake local anesthesia no tourniquet) locoregional anesthesia technique has been developed to avoid the use of ischemia in various surgical procedures (1), thereby obtaining the advantages of avoiding its use.

We present the case of a healthy 37-year-old patient who suffered trauma while riding a bicycle, thus sustaining a fracture of the middle third of the clavicle (the most frequent location of this fracture).

Case Report: Using ultrasound, we infiltrated the superficial cervical plexus with 0.75% ropivacaine in 5 ml to anesthetize the area that the surgeons were going to work on, which in the vast majority of cases depends on the supraclavicular nerve. Next, we used a 100 ml solution of 0.2% ropivacaine to which 1 mg of adrenaline was added. This infiltration was performed at different levels (distributing the 100 ml to the different points shown below):

- · At the perifracture level.
- Subcutaneous plane at the level of the surgical incision.
- · At the level of the entire anterior cortex of the clavicle, including the proximal and distal third.

After using the 100 ml of the solution, an ultrasound scan was performed, both in the longitudinal and axial plane, thus verifying that the bone was bathed in the anesthetic solution.

Discussion: We waited 5-10 minutes and checked that the patient was able to mobilize the ipsilateral upper limb without pain. The surgery was carried out without the patient showing any pain and with little bleeding seen in the surgical field aspirator (2). This technique was accompanied by sedation for the patient's comfort.

References:

1. Niempoog S, Tanariyakul Y, Jaroenporn W. Wide-awake local anesthesia for clavicle fracture fixation: A case report. Int J Surg Case Rep. 2021 Feb;79:112-115. doi: 10.1016/j.ijscr.2021.01.005. 2. Kafiabadi MJ, Sabaghzadeh A, Biglari F, Sadighi M,

Ebrahimpour A. Effects of fixation of clavicle fracture using wide-awake local anesthesia no tourniquet (WALANT) technique on intra-operative bleeding volume, surgical duration, and postoperatively visual analog scale (VAS); A case series study. Injury. 2023 Feb;54(2):557-560. doi: 10.1016/j.injury.2022.11.063.

Learning Points: In conclusion, this is a novel technique that is currently performed in few centers, since it involves a learning curve for the anesthesiologist as well as a certain consensus and familiarity with the surgeons. But there is no doubt that this is the future of regional anesthesia in many procedures.

12AP13-8

Suprainguinal Fascia Iliaca Nerve Block as the anesthetic option of a Child Pugh C patient for a percutaneous fixation of hip fracture - a case report

F. Machado¹, R. Lima¹, P. Frias¹, J. Borges¹, C. Soares¹,

¹Hospital do Divino Espírito Santo de Ponta Delgada, E.P.E., Anesthesiology, Ponta Delgada, Portugal

Background: Managing anesthesia in Child Pugh C (CPC) patients is challenging due to coagulopathy, hyperdynamic circulation, and increased perioperative risks.

This case highlights the use of a suprainguinal fascia iliaca nerve block (SFINB) as an alternative to general anesthesia (GA) or neuraxial anesthesia (NA) in a high-risk patient undergoing hip fracture (HF) fixation.

Case Report: A 57-year-old female, ASA IV, with ethanol-related cirrhosis and CPC, presented with an unstable pertrochanteric fracture. Preoperatively, hematological optimization included transfusion of red blood cells (RBC), fresh frozen plasma (FFP), platelets, albumin, and placement of a subclavian central venous catheter.

Intraoperatively, after standard monitoring, an invasive arterial line was placed, followed by ultrasound-guided SFINB with 40mL of 0.5% ropivacaine.

Adequate sensory block was confirmed 15 minutes later, and remifentanil was initiated (max dose 0.05 ug/kg/min). The patient remained responsive, cooperative, and hemodynamically (HD) stable despite 800mL estimated blood loss.

Over 2 hours, she received 2 units of RBC, 2 of FFP, 1 of platelets, and 1g of tranexamic acid. The patient was transferred to a high-dependency unit for 2 days of HD monitoring before being discharged to the ward.

Discussion: CPC patients face higher perioperative morbidity and mortality due to coagulopathy and other complications. NA is often contraindicated, while GA poses HD challenges1.

SFINB offers a safe alternative by targeting the nerves beneath the iliacus muscle's fascia, avoiding the systemic complications. Though its use as primary anesthesia for hip surgery in cirrhotic patients is rare, it is gaining support in the literature as a viable option when traditional anesthetic approaches are not ideal2.

This case emphasizes the importance of tailored, multidisciplinary perioperative care.

Learning Points: Individualized, multidisciplinary planning is essential in managing complex cases like HF in CPC patients. SFINB is a reliable anesthetic alternative for high-risk patients with severe liver disease, minimizing complications associated with GA and NA.

Anterior Quadratum Lumborum Block analgesia for total hip arthroplasty: a case report

M. Pereira¹, P. Camões¹, M.J. Nascimento² ¹Unidade Local de Saúde de Coimbra, Anesthesiology Department, Coimbra, Portugal, 2 Unidade Local de Saúde de Coimbra, Anesthesiology department, Coimbra, **Portugal**

Background: The quadratum lumborum block (QLB) is one of several techniques that revolutionized modern regional anesthesia. First described in 2007, QLB is now used for analgesia in abdominal surgeries and also some orthopedic procedures.¹

We are presenting a case of the use of anterior QLB analgesia in postoperative pain control for total hip arthroplasty.

Case Report: A 76-year-old patient was admitted for total right hip arthroplasty. He had many comorbidities, history of postoperative pain and a difficult airway.

Intraoperatively, a single-shot ultrasound-guided anterior QLB was performed using a curved probe and a 100mm Tuohy needle, and a total of 20mL of 0.5% ropivacaine was administered. Subsequently, spinal anesthesia was conducted.

Postoperative pain control was effective, as well as early ambulation and prophylaxis for deep vein thrombosis and infection. No additional opioid analgesics were required. The surgery and anesthesia were uneventful.

Discussion: Total hip arthroplasty is a common procedure and often causes significant postoperative pain. The advanced age and comorbidities of typical patients amplify anesthetic challenges. In light of the current evidence, QLB appears to be a viable analgesic option for hip surgery, especially the anterior approach, as it facilitates the continuous spread of local anesthetics to the lumbar plexus, providing a consistent analgesic block.1

It offers the advantages typical of regional anesthesia, including enhanced pain control, reduced opioid consumption and lower pain scores.2

Additionally, evidence seems to indicate minimal motor weakness compared to placebo, facilitating faster recovery and earlier discharge, as demonstrated in this case.3

Learning points: Anterior QLB seems to offer effective postoperative pain control and a fast recovery in total hip arthroplasty, minimizing opioid use and complications.

Regional Anaesthesia 199

12AP13-11

Comparison of postoperative analgesic effects of intrathecal morphine and modified thoracoabdominal nerve block with perichondrial approach in patients undergoing major abdominal surgery: a prospective randomized study

A.D. Kayır¹, B. Bilgili¹, E. Guclu Ozturk¹ ¹Marmara University, Anesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Aim was to compare the efficacy of intrathecal morphine(ITM) and the modified thoracoabdominal nerve block with a perichondrial approach (M-TAPA) for postoperative pain management in patients undergoing major open abdominal surgery.

The primary outcome was the total opioid consumption within the first 24 hours postoperatively (measured in morphine milligram equivalents, MME).

Secondary outcomes included resting and mobilization Numeric Rating Scale (NRS) scores and the incidence of postoperative side effects.

Materials and Methods: In this prospective, randomized, singleblind study, 50 patients with an American Society of Anesthesiologists (ASA) physical status classification of I-III were randomly assigned to one of two groups: ITM (25 patients) or M-TAPA (25

Preoperatively, the ITM group received 200 mcg of intrathecal morphine, while the M-TAPA group underwent bilateral nerve blocks with 20 mL of 0.25% bupivacaine per side.

Postoperative pain management included patient-controlled analgesia (PCA) with 1 mg/mL intravenous(IV) morphine, IV paracetamol (4x1 g), and rescue analgesia with tramadol (1.5 mg/kglV) for NRS>3. Opioid consumption (MME), NRS scores, side effects, and rescue analgesic use were recorded at 2, 6, 12, 24, 36, and 48 hours postoperatively.

Results and Discussion: Total 24-hour opioid consumption(MME) was significantly lower in the ITM group compared to the M-TAPA group (9.72 \pm 6.32 mg vs. 14.96 \pm 8.51 mg, p=0.025,95% CI:-9.51,-0.97). During the first 6 hours and the 36-48-hour interval, opioid consumption were comparable among the groups.

However, in the 6-12, 12-24, and 24-36-hour intervals, opioid consumptions were significantly lower in the ITM group (1.44 \pm $2.71 \text{ mg}, 2.20 \pm 2.59 \text{ mg}, \text{ and } 2.48 \pm 1.64 \text{ mg}, \text{ respectively, p<0.001},$ p<0.001, p=0.007; 95% Cl:-3.13,-0.23; 95% Cl:-5.34,-1.06; 95% CI:-3.06,-0.55).

Resting and mobilization NRS scores were both consistently <4 across all time points in both groups. The mean duration of the M-TAPA sensory block was 7.68 ± 2.98 hours.

Postoperative pruritus occurred in one patient in the ITM group. The incidence of nausea and vomiting was similar between the two groups.

Conclusion(s): Opioid consumption was significantly lower in the ITM group compared to the M-TAPA group, likely due to differences in the duration of analgesic effects between the two techniques. Future studies should explore the efficacy of extendedduration M-TAPA techniques in comparison to ITM.

12AP13-12

A tailored anaesthetic approach: continuous subarachnoid block for an 87-year-old with hip fracture

C.S. Silva¹, Â.Z. Oliveira¹, C. Marques¹, C. Antunes¹, S.S. Rodrigues¹

¹Unidade Local de Saúde do Alto Ave. Anesthesiology. Guimarães, Portugal

Background: General and neuraxial anaesthesia are often associated with significant hemodynamic instability¹, particularly in frail, high-risk patients. Continuous subarachnoid block (CSB) enables precise titration of local anaesthetics, achieving an optimal level of sensory blockade while minimizing cardiovascular perturbations2.

This case report describes the successful use of CSB in a frail patient undergoing surgical repair of a hip fracture.

Case Report: An 87-year-old female, ASA III, presented for hip fracture repair. Frail with a BMI of 15.8 (38 kg), her medical history included hypothyroidism and recurrent deep vein thrombosis managed with dabigatran.

Following anticoagulation suspension and confirmation of normal coagulation parameters, informed consent was obtained. Standard ASA monitoring was instituted. A CSB was performed with the patient positioned in the right lateral decubitus using an 18G Tuohy needle inserted at the L3-L4 interspace via a median approach.

Once cerebrospinal fluid flow was confirmed, a catheter was introduced, and the patient was repositioned supine. An initial 2.5 mg dose of isobaric bupivacaine 0.5%, followed by a saline bolus, achieved a T8 sensory block.

An additional 1 mg of bupivacaine was administered to address mild positional discomfort before surgery, which lasted 45 minutes. Standard multimodal analgesia (ketorolac, paracetamol) and prophylactic ondansetron were provided. The patient remained hemodynamically stable throughout, with no requirement for vasoactive medications.

The catheter was removed at the end of the procedure, and the patient was transferred to the post-anaesthesia care unit. Postoperatively, no complications, including post-dural puncture headache, were reported.

Discussion: This case highlights the safety and efficacy of CSB in frail elderly patients requiring orthopedic surgery. CSB facilitates titrated neuraxial anaesthesia with reduced local anaesthetic doses, mitigating hemodynamic instability. It is a valuable anaesthetic option for high-risk populations.

References:

1. Koole, C., et al. (2024). Haemodynamic effects of continuous spinal anaesthesia. British Journal of Anaesthesia, 132(5), 1160-1162

2. Hay, R., & Gupta, A. (2022). Continuous spinal anaesthesia. BJA Education, 22(8), 295-297.

Learning points: CSB delivers titrated anaesthesia effectively with minimal cardiovascular impact. It is a safe, reliable option for high-risk, frail patients undergoing orthopedic procedures.

12AP14-1

Facilitating weaning in an ICU patient with necrotizing fasciitis using bilateral infraclavicular catheters: a case report

G. Traore¹, B. Dönmez¹, H. De Cuyper¹, H.-N. Truong¹ ¹UZ Brussel, Anaesthesiology and Perioperative Medicine, Jette, Belgium

Background: Pain management in ICU patients is challenging. While opioids are commonly used, their side effects make them suboptimal in critically ill patients. Regional analgesia techniques provide an alternative, reducing opioid and sedative requirements while improving patient comfort.

This case report demonstrates how regional analgesia can address pain management challenges and facilitate weaning.

Case Report: We describe a 78-year-old man referred to our hospital for necrotizing fasciitis in both forearms. He underwent urgent escharotomy and debridement and was admitted to the ICU postoperatively. Severe pain during wound care persisted despite a multimodal analgesic regimen, including continuous morphine and esketamine infusions.

Additional opioid and propofol boluses were required for each wound care session. Bilateral infraclavicular nerve blocks with perineural catheters for continuous local anesthetic infusion were performed. This intervention effectively managed the patient's pain, allowing for discontinuation of opioids and facilitating extubation within 48 hours.

Discussion: This case highlights the challenges of managing severe pain in critically ill patients and underscores the potential of regional anesthesia as an alternative to systemic opioids and sedatives. To our knowledge, this is the first reported case of using bilateral infraclavicular catheters in an ICU patient to facilitate weaning.

Infraclavicular blocks provide effective pain relief for the arm, elbow, and hand without risking phrenic nerve blockade. They also allow for catheter placement to enable continuous or bolus administration.

Despite their benefits, regional blocks in ICU patients can pose challenges due to complex pathologies and treatments. Sedated ICU patients are at increased risk for local anesthetic systemic toxicity (LAST) due to continuous local anesthetic administration and the lack of specific warning signs.

References:

Don't unnecessarily touch the patient: case report

M. Burmuzoska¹, S. Trenchevska², A. Dimitrovski¹, S. Tudjarova Gjorgova³, A. Gavrilovska Brzanov¹, A. Petrusheva¹

¹University Clinic of Anesthesiology, Anesthesiology, Reanimation and Intensive Care, Skopje, North Macedonia, The Republic of, ²Clinic Hospital Dr. Trifun Panovski-Bitola, Anesthesiology, reanimation and intensive care, Bitola. North Macedonia. The Republic of, 3University Clinic for Plastic and Reconstructive Surgery-Skopje, Plastic surgery, Skopje, North Macedonia, The Republic of

Background: Epidermolysis bullosa is a rare disease with skin and mucosal bullae formation due to minor mechanical trauma as its hallmark. These blisters heal with scars and strictures which can possibly lead to difficult airway management and esophageal strictures with inability for nutritional intake leading to anemia and malabsorption1.

Case Report: A 36 years old female patient was admitted for left forearm amputation due to aggressive cutaneous cancer. Her medical history revealed a rare disease Epidermolysis bullosa. Preoperatively she suffered from severe iron deficiency anemia with hemoglobin level 49 g/L, which was corrected prior surgery to 87 g/L.

Due to her condition, precautionary measures for avoiding new bullae formation were taken. A decision for regional anesthesia with ultrasound guided infraclavicular block with lidocaine 100 mg and bupivacaine 60 mg was made. She was sedated with 2 mg midazolam, 50 mg ketamine and low dose propofol and 50 mcg fentanyl prior to performing the block.

Due to persistent anemia she received one more package of erythrocytes concentrate and 1g TXA. She recovered well after surgery.

Discussion: Regional anesthesia is favoured because of the potential difficult airway management, increased risk of aspiration and limited mouth opening, but avoiding puncture near open wounds is important because of increased infection risk1.

Another challenge is placing the various monitoring devices without further damage by them. Wrap-around pulse oximeter secured with coban, avoiding tourniquet and adhesive electrodes are mandatory.

J Anaesthesiol Clin Pharmacol. 2013 Jul;29(3):390-3. doi:10.4103/0970-9185.117112. 2. Mittal BM, Goodnough CL et al. Anesthetic Management of Adults With Epidermolysis Bullosa. Anesth Analg. 2022 Jan 1;134(1):90-101. doi:10.1213/ANE.0000000000005706.

Learning points: Multidisciplinary team approach is needed for planning and optimizing the patient with this disease before any surgery. Preparation of the operating room and modified care by every staff member is needed for proper treatment².

12AP14-3

The importance of ergonomics: a case report

R.J. Tavares Portela E Silva¹, C. Guimarães¹, M.L. Coutinho¹, A. Postiga¹, J. Li¹, C. Retroz¹ ¹ULS de Coimbra, Anesthesiology, Coimbra, Portugal

Backgroud: Ergonomics in relation to anaesthesia is the scientific study of the interaction between anaesthetists and their workspace environment in order to promote safety, performance and well-being.1

Everyday, anesthesiologists are presented with challenging cases, high risk patients and surgeries, difficult procedures and techniques. We must strive to optimize ergonomic factors at every step of the way, so that we can improve outcomes for both our patients and ourselves.

Case report: A 75 years old woman presented for total knee arthroplasty revision. She was obese and had multiple cardiovascular comorbidities. She had a history of two previous knee interventions under general anesthesia, and mentioned that in both surgeries the anesthesiologists tried to perform neuraxial techniques unsuccessfully.

Given the comorbidities, consent to perform spinal anesthesia was still obtained, with the possibility of conversion to general anesthesia. All the conditions for the technique were optimized: the procedure was explained to the patient, the positioning perfected and she was lightly sedated; the OR was calm and quiet with sufficient lighting; the sterile field was spacious allowing for landmark identification; all the equipment was ready to use and an experienced assistant was present; the operator was comfortably sitting and a successful spinal was performed, in the first try, by an anesthesiology resident through a midline approach to the L4-L5 space.

The patient was positioned for surgery and the team was prepared to start. Unfortunately, the block level was insufficient. Another spinal was attempted by the same resident. At that point the same extent in optimization was not obtained, in the positioning of the patient and the operator, and in the environment or equipment. After multiple tries (>5), with different approaches, the technique was unsuccessful.

Then, the senior anesthesiologist experienced the same difficulties but after multiple attempts (>5) completed the technique and the surgery was performed under regional anesthesia without complications.

Discussion: Since the first attempt at spinal anesthesia was easily achieved, the team chose to repeat the technique and complement the local anesthetic dose. As the conditions were not optimized, the technique revealed much more demanding.

Reference:

1. Anaesthesia vol. 76,12 (2021): 1635-1647

Learning points: During a procedure, optimization of every attempt is crucial for a successful result.

12AP14-4

A randomised controlled study on bilateral ultrasound guided erector spinae block for postoperative analgesia in lumbar spine fusion surgery

R. J Babu^{1,2}, D. Vinod³

¹Fortis Hospital, Department of anaesthesia, Mumbai, India, ²Manipal Hospitals, Department of Anaesthesia, BangaloreIndia, India, 3Aster CMI Hospital, Department of Anaesthesia, Bangalore, India

Background and Goal of Study: ESPB is one of the newer interfascial techniques and we conducted a prospective randomised controlled trial to study the efficacy of USG ESPB in lumbar spine surgeries by assessing the NRS score and total quantity of opioids consumed.

Materials and Methods: A prospective RCT was conducted on 40 patients and were enrolled in two groups;

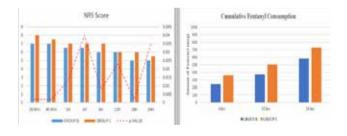

Group B: patients received bilateral USG ESPB using 0.2% Ropivacaine -20ml and I.V PCA fentanyl;

Group C patients received only I.V PCA fentanyl as post operative analgesia. We had monitored haemodynamic parameters, total opioid consumption, NRS scores and post operative side effects like PONV and sedation were recorded up to 24 hours postoperatively. Continuous data of the two groups were compared using student t-test and NRS score using Mann Whitney U test. Chi square was used to compare categorical data.

Results and Discussion: Fentanyl consumption in group B versus group C at 6hours (112 \pm 78 vs 292 \pm 77 mcg, p<0.001), 12 hours $(151 \pm 103 \text{ vs } 478 \pm 151 \text{ mcg}, p<0.001)$ and 24 hours $(219 \pm 158 \text{ vs})$ 745 ± 291 mcg, p<0.001) were statistically significant.

The incidence of nausea was higher in group C (66.6%) compared to group B (23.8%).

Around 95.2% of patients in group B were satisfied with the guality of postoperative pain relief when compared to 33.3% of patients in group C.

PARAMETERS	GROUP B / BLOCK (N=20)	GROUP C / CONTROL (N=20)	P VALUE
NRS	5-7	5-8	<0.05*
FENTANYL -6HRS	244+-58	363+-56	<0.001*
12HRS	373+-76	504+-80	<0.001*
24HRS	582+-91	728+-92	<0.001*
NAUSEA	6(30%)	13(65%)	0.026*
VOMITING	4(20%)	7(35%)	0.289 (NOT SIGNIFICANT)
SEDATION -SCORE 1	19(95%)	11(55%)	0.000*
SCORE 2	1(5%)	9(45%)	0.003*
PATIENT SATISFACTION	16(80%)	8(40%)	0.009*

Conclusion(s): In our study, the NRS, post operative opioid consumption, PONV, and sedation scores were significantly lower in patients with ESPB. Hence, ESPB could be used as a part of multimodal analgesia in lumbar spine fusion surgeries.

Reference:

Singh S, Choudhary NK, Lalin D, Verma VK. Bilateral ultrasound-guided erector spinae plane block for postoperative analgesia in lumbar spine surgery: a randomized control trial. Journal of neurosurgical anesthesiology. 2020 Oct 1;32(4):330-4.

12AP14-5

The association between epidural analgesia and intrapartum maternal temperature trajectories

<u>V. Michael</u>^{1,2}, S. Gerry³, I. Henderson⁴, M. Chester-Jones³, P. Watkinson^{1,2,5}

¹Oxford University Hospitals, NHS Trust, Oxford, United Kingdom, ²Kadoorie Centre for Critical Care Research and Education, Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, United Kingdom, ³Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Botnar Research Centre, University of Oxford, Oxford, United Kingdom, ⁴National Perinatal Epidemiology Unit, Nuffield Department of Population Health, University of Oxford, Oxford, United Kingdom, ⁵NIHR Biomedical Research Centre, Oxford University Hospitals NHS Foundation Trust, Oxford, United Kingdom

Background and Goal of Study: Epidural analgesia is associated with intrapartum maternal fever (temperature ≥38.0°C), which may independently be associated with adverse neonatal outcomes. The aim of this study was to establish the incidence of fever in a healthy cohort, and to compare temperature trajectories by epidural provision.

Materials and Methods: The Pregnancy Pattern Physiology Prediction (4P) study was a multi-centre, longitudinal, observational cohort study conducted in the UK. It recruited women who met the criteria for a normal, healthy pregnancy as defined by the American Society of Anaesthetists Grade 1 (ASA-1). We extracted intrapartum temperature from the partograph and plotted the trajectories for epidural and non-epidural groups as smoothed contiles.

Results and Discussion: In this study of 1,054 women recruited in early pregnancy, 596 women contributed at least one intrapartum temperature. Women who used epidural analgesia (n = 220) were more likely to be nulliparous (69.1% vs 45.7%), to have an intrapartum caesarean birth (19.1% vs 6.6%), and have a longer labour (12.1 \pm 5.7 hours vs 7.6 \pm 4.7 hours) than those who did not use epidural analgesia (n = 376). There were similar rates of fever in the epidural (1.8% (4/220)) and non-epidural (1.1% (4/376)) cohorts (odds ratio 1.7, 95% confidence interval 0.3 – 9.3). The median temperature trajectories across the intrapartum period were also similar for both cohorts (Figure 1). The change in the temperature trajectory of the epidural cohort post epidural provision in a mixed-effects model was minor (0.06°C/hour). The conclusions did not change when investigating the effects of confounding or mediating factors such as parity or length of labour.

Conclusion(s): In this observational study of healthy women, fever rates were low and there was little association of epidurals with maternal fever or temperature trajectories. The low fever incidence in this study may be attributable to the observational nature of the study and ASA-1 restriction. We conclude that maternal fever should not be dismissed as being epidural induced in clinical practice.

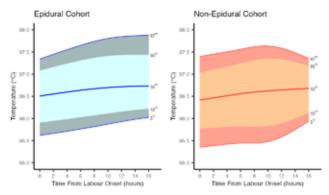

Figure 1. Intrapartum temperature trajectory with respect to labour onset.

12AP14-6

Comparison the impact of the method of anaesthesia on intraoperative nociceptive response throughout spine surgeries: prospective randomised control trial

M. Barsa^{1,2}

¹Danylo Halytsky Lviv National Medical University, Anesthesiology and Intensive Care, Lviv, Ukraine, ²Yuri Semenyuk Rivne Regional Clinical Hospital, Anaesthesiology and Intensive Care, Rivne, Ukraine

Background and Goal of Study: Surgical intervention triggers nociception, whereas the main aim of anaesthesia is to suppress nociceptive signal processing. The impact of different methods of anaesthesia on the nociception response and its correlation with postoperative outcomes remain unclear. Regional anaesthesia affects transduction, transmission, and modulation by interrupting the conduction of pain impulses by local anaesthetics.

Moreover, nerve blocks influence perception by reducing sensitization and tolerance to pain by reducing opioid consumption (OC). Owing to this mechanism, an essential balance between nociception and antinociception is sustained, and violation of this balance can lead to postoperative complications.

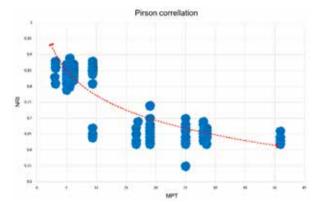

Aim: To compare the impact of general anaesthesia (GA) with erector spinae plane block (ESPB) versus GA without ESPB on intraoperative nociceptive response index (NRI), OC, postoperative pain intensity (PPI), and hyperalgesia in patients undergoing spine surgery.

Materials and Methods: This prospective, randomized-controlled study was conduct in clinical hospital with affiliate university department, from December 2021 and November 2022. 151 patients who underwent spine surgery with the posterior approach were randomly assigned to either the GA control group (CG) or GA with ESPB study group (SG). Outcomes: NRI, OC, PPI and hyperalgesia. ClinicalTrials.gov: NCT04697498

Results and Discussion: Average NRI throughout surgery differed between groups: $SG - 0.66\pm0.28$; $CG - 0.86\pm0.19$. Amount of fentanyl and morphine was lower in SG (1.84±0.75µg kg-1; 5.62±5.00mg) compared to CG (3.64±1.2µg kg-1; 28.97±9.75mg) correspondingly.

PPI at rest and during movement was higher in the CG after surgery than in the SG at all stages of observation. mechanical pain threshold (MPT) did not differ before surgery: $SG - 21.05\pm6.64$; $CG - 21.55\pm6.06$.

After surgery, MPT was lower in the CG - 5.60±1.93 than in the SG - 23.26±6.8. The NRI had the strongest negative correlation with hyperalgesia in comparison with the other data.

Conclusion(s): ESPB, as a component of GA, decreases NRI, OC, and PPI and, as a result, does not trigger hyperalgesia after spine surgery.

12AP14-7

Combined lumbar erector spinae plane and femoral nerve block in open femoral artery pseudoaneurysm repair surgery, a case report

L.M. Bottazzo^{1,2}, G. Cosenza¹, G. Sepolvere². M.B. Passavanti¹, M.C. Pace¹, F. Coppolino¹ ¹University of Campania "L. Vanvitelli", Department of Woman, Child, General and Specialistic Surgery, Napoli, Italy, ²San Michele Hospital, Department of Anesthesia and Cardiac Surgery Intensive Care Unit, Maddaloni, Italy

Background: Open vascular surgery in the pelvis and lower body typically requires neuraxial anesthesia. This case report describes the use of a lumbar erector spinae plane (ESP) block as an alternative when neuraxial anesthesia is contraindicated.

Case Report: A 78-year-old patient with COPD and atrial fibrillation on Warfarin underwent endograft placement for an abdominal aortic aneurysm. During the procedure, a tear in the left femoral artery led to a pseudoaneurysm, necessitating surgical repair a few days later. The repair involved a 15 cm incision across the inguinal ligament, but the patient's comorbidities and INR > 2.5 made both neuraxial and general anesthesia unfeasible.

A lumbar ESP block was performed at L1-L2 transverse processes with 20 mL of 0.5% levobupivacaine, alongside a femoral nerve block with 10 mL of 0.5% lidocaine and 1% mepivacaine, plus light sedation with 5 mg of midazolam (RASS -1). Spontaneous breathing and hemodynamic stability were maintained, and the 30-minute procedure was completed without complications.

Discussion: First time, the ESP block has been used for postoperative pain management in thoracic1, abdominal, and orthopedic surgeries. No literature, however, documents its application as a primary anesthetic in vascular surgery.

Given the variable sensory block associated with the ESP block2, a femoral nerve block was added to ensure analgesia of the thigh's surgical area.

Regarding anticoagulation, the ESP block's distance from major neural and vascular structures minimizes the risk of significant hematomas, despite theoretical concerns of compression in the erector spinae muscles.

2. Sørenstua M, Zantalis N, Raeder J, Vamnes JS, Leonardsen AL. Spread of local anesthetics after erector spinae plane block: an MRI study in healthy volunteers. Reg Anesth Pain Med. 2023 Feb;48(2):74-79. doi: 10.1136/rapm-2022-104012. Epub 2022 Nov 9. PMID: 36351741

Learning Points: Based on our experience, lumbar ESP combined with femoral nerve block appears to be a safe and effective anesthetic alternative for emergency patients on anticoagulant therapy for surgeries in the inguinal and suprainguinal areas.

12AP14-8

The role of the thoracolumbar interfascial plane (TLIP) block in managing intraoperative opioid requirements for lumbar spinal surgery

N. Aghasaryan^{1,2}, A. Varosyan^{1,2}, H. Mangoyan^{1,3}, Y. Varosyan4, D. Anjelova4

¹Yerevan State Medical University, Anaesthesiology and Intensive Care, Yerevan, Armenia, 2Erebuni Medical Centre, Anaesthesiology, Yerevan, Armenia, ³Erebuni Medical Centre. Intensive Care. Yerevan. Armenia. 4 Vardanants Centre for Innovative Medicine. Anaesthesiology, Yerevan, Armenia

Background and Goal of Study: Lumbar spinal surgery frequently leads to significant pain, requiring substantial opioid doses for effective intraoperative pain management. Unfortunately, these high doses can lead to considerable adverse effects. The thoracolumbar interfascial plane (TLIP) block, a relatively new regional anesthesia technique, offers promising potential as part of multimodal analgesia to reduce opioid use.

Although not yet widely implemented, the TLIP block is gaining attention alongside other fascial plane blocks, such as the erector spinae plane (ESP) block, for their potential to enhance pain

This study evaluates the effect of the TLIP block on intraoperative opioid consumption in adults undergoing lumbar spinal surgery.

Materials and Methods: This prospective, randomized, casecontrol study included 98 adult patients scheduled for elective lumbar spinal surgery in a tertiary care academic hospital.

After ethics committee approval and patients' informed consent, patients were randomly assigned to two groups. The TLIP group (n=51) received general anesthesia (GA) with bilateral ultrasoundguided TLIP block following anesthesia induction, while the control group (n=53) received GA alone. Fentanyl was the only opioid administered intraoperatively in both groups.

Fentanyl consumption between groups was compared using independent samples t-tests, with significance set at p<0.05. Statistical analysis was conducted using IBM SPSS for Windows, version 29.

Results and Discussion: The TLIP group demonstrated significantly lower intraoperative fentanyl consumption compared to the control group: 229.4 \pm 64.2 mcg vs. 283.02 \pm 101.4 mcg (mean values and standard deviations respectively), p=0.0018. All control group patients required supplemental fentanyl doses,

whereas only 5 patients in the TLIP group needed additional fentanyl. These results indicate the TLIP block's efficacy in reducing opioid requirements.

Conclusion(s): The TLIP block significantly reduces intraoperative opioid requirements in lumbar spinal surgery, underlining its value as a promising analgesic strategy. Further studies should investigate its broader benefits, including effects on intraoperative blood loss, postoperative pain relief, and opioid-related complications. Comparative studies examining the TLIP block alongside other fascial blocks, such as the ESP block, will help refine clinical practice and optimize pain management strategies.

12AP14-9

Postoperative motor weakness related to lumbar erector spinae plane block: case reports

A.M. Lambert¹², A. Defresne^{1,2,3}, J. Montupil^{1,2,3}
¹University of Liège, Department of Anaesthesia and Intensive Care Medicine, Liège, Belgium, ²Citadelle Hospital, University Department of Anaesthesia and Intensive Care Medicine, Liege, Belgium, ³Liege University, Anaesthesia and Perioperative Neuroscience Laboratory, GIGA-Consciousness Thematic Unit, GIGA-Research, Liege, Belgium

Background: Lumbar erector spinae plane block (ESPB) is considered a safe, effective opioid-sparing technique for postoperative pain management after spinal fusion surgery. This report describes two cases of postoperative lower limb weakness following lumbar ESPB for L5-S1 arthrodesis.

Case Report: Following general anaesthesia (GA), in a 56-yo ASA I patient, a ESPB (20ml of 0.3% ropivacaine per side) was performed under ultrasound guidance in the prone position. An in-plane cephalocaudal approach (80 mm needle) was used to reach the transverse process of L5. Postoperatively, the patient experienced right foot dorsiflexor paresis prompting a magnetic resonance imaging (MRI) and electromyography, which showed no surgical complications. Recovery was complete within 31 hours (hrs). Second patient, 46-yo ASA II, received an ESPB (20 ml of 0.35% ropivacaine per side). Postoperatively, the patient experienced complete left lower limb paralysis. An MRI also ruled out complications. Motor recovery was complete within 24 hrs. In both cases, the transient lower limb paralysis was attributed to ESPB.

Discussion: Few case reports describe transient lower limb motor weakness or paralysis following lumbar ESPB. Selvi (1) observed motor weakness after an out-of-plane ESPB (25ml of bupivacaine 0.3% + lidocaine 0.1%) for cesarean section under GA resolving within 16 hrs. Another case with in-plane ESPB (40 ml bupivacaine 0.25% + lidocaine 0.5%) resulted in T10–S4 motor block, recovering in 14 hrs. (2). Similarly, two patients receiving out-of-plane ESPB (20ml bupivacaine 0.25%) before lumbar surgery experienced a sensory-motor blocks lasting 1.5 hrs (3). Possible explanations include local anaesthetic spread to the ventral ramus, posterior epidural space, or lumbar plexus.

- 1. Selvi O et al. Ultrasound guided erector spinae plane block as a cause of unintended motor block. Rev Esp Anestesiol Reanim. 2018;65(10):589-592.
- 2. Karaca Ö. Unexpected motor block after ultrasound-guided lumbar erector Spinae plane block. Agri. 2023;35(2):112-114.

3. Guna Pratheep K et al. Transient paraplegia in lumbar spine surgery-a potential complication following erector spinae plane block. Eur Spine J. 2022;31(12):3719-3723

Learning points: Lumbar ESPB can be complicated by transient lower limb paralysis. This seems to be rare as few cases have been reported. The mechanism is still not clear. Anesthesiologists and surgeons should be aware of this possible complication.

12AP14-10

Transversus Abdominis Plane (TAP) block in patients undergoing colorectal surgery

K. Boiko¹, <u>O. Khomenko</u>²¹, A. Borysenko¹
¹O. O. Shalimov National Scientific Center of Surgery and Transplantology, National Academy of Medical Sciences of Ukraine, Anaesthesiology and Intensive Care, Kyiv, Ukraine, ²Bogomolets National Medical University, Surgery, Anaesthesiology and IC IPE, Kyiv, Ukraine

Background and Goal of Study: Epidural anesthesia (EA) is considered the gold standard for analgesia during colorectal surgery. However, a number of complications and contraindications require the search for other methods anesthesia[1]. An alternative to EA can be the use of Transversus Abdominis Plane (TAP) block [2]. The aim of the study is to evaluate and compare the effects of EA and TAP block on analgesia, hemodynamics, and recovery of patients undergoing colorectal surgery.

Materials and Methods: Patients undergoing colorectal surgeries were evaluated. Group A received EA at the T11-T12 level, followed by intraoperative administration of 0.25% bupivacaine 6 ml/hour. Group B received a lateral TAP block under ultrasound guidance with the administration of 20 ml of 0.25% bupivacaine on each side. Intra- and postoperative hemodynamic parameters, pain levels using the VAS at 0, 6, 24 hours after surgery, frequency of adverse reactions were recorded.

Results and Discussion: In the study 21 patients were included. Group A-15, Group B- 6 patients. In Group A, intraoperatively lower systolic blood pressure values (89.8±10.56 vs. 95.83±8.05), heart rates at 1, 6 and 12 hours postoperatively (68.8±7.89, 66.47±5.1, and 66.9±5.3 vs. 74.3±11, 74.17±6.89, and 80±9 respectively) were observed, along with a higher frequency of norepinephrine use (26.7% vs. 16.7%). Pain scores on the VAS were lower at 1 hour in Group B (1.83±0.56 vs. 1.93±1), but higher at 6 and 12 hours (3.17±1.17 vs. 1.73±1.35 and 2.3±1.67 vs. 4.5±0.8). In Group A, 13% of patients exhibited unilateral motor block, while 33% of Group B required postoperative narcotic analgesics. The incidence of nausea was 20% in Group A and 33% in Group B. Group B reported greater postoperative comfort and faster mobilization.

Conclusion(s): TAPB may serve as an alternative to epidural anesthesia during colorectal surgical procedures as it results in less complications, helps maintain stable hemodynamics, and provides effective early postoperative analgesia. This enhances patient safety in the operating room, improves treatment outcomes.

Regional Anaesthesia 205

12AP14-11

Optimizing Anesthesia for High-Risk Patients: Scalp Block for Frontal Lobe Epithelioma **Excision**

F. Sifaki¹, Y. Zevgaridou¹, A. Pappas², E. Koraki¹ ¹Papageorgiou General Hospital of Thessaloniki, Anesthesiology, Thessaloniki, Greece, ²Papageorgiou General Hospital of Thessaloniki, Plastic Surgery, Thessaloniki, Greece

Background: Patients with multiple comorbidities often present challenges in their anesthesia management and regional anesthesia (RA) provides a viable alternative to general anesthesia (GA).

This case demonstrates the utility of a scalp block in providing both surgical anesthesia and effective analgesia for the wide excision of a frontal lobe epithelioma in a high-risk patient.

Case Report: An 85-year-old Caucasian male (BMI: 23.5 kg/m², METS = 4) presented for wide excision of a frontal lobe epithelioma. His medical history included arterial hypertension, atrial fibrillation, benign prostatic hyperplasia, rheumatic polymyalgia, and fatty liver disease. His medications included furosemide, pantoprazole, prednisone, hydroxychloroquine, apixaban, and amiloride. The patient was a heavy smoker and exhibited plectrodactyly. Baseline laboratory tests were within the normal range. Cardiac echocardiography revealed mitral, aortic and tricuspid regurgitation. He was categorized as ASA III, whilst he exhibited bronchial secretions, increasing the risk of respiratory complications under GA. To mitigate these risks, a RA plan was recruited. A landmark guided scalp block targeting the supraorbital, supratrochlear, zygomaticotemporal, auriculotemporal, lesser and greater occipital nerves bilaterally was performed using 1 mL of 0.5% ropivacaine and 1 mL of 1% lidocaine at each injection point. Surgical anesthesia was achieved and the 60-minute procedure was completed with the patient awake, breathing spontaneously and with no additional analgesia. Postoperatively, the patient bypassed the postanesthesia care unit (PACU) and was transferred directly to the plastic surgery ward, where the analgesic regimen consisted of paracetamol every 8 hours. Discharge followed three days later with an uneventful recovery.

Discussion: This case highlights the efficacy of RA both as the sole anesthetic plan, as well as the cornerstone of a multimodal analgesia plan, particularly in patients with multiple comorbidities. RA aligns with ERAS protocols by promoting improved postoperative outcomes, reducing PACU admission and shortening hospital stays. This case underscores how individualized anesthetic planning can optimize outcomes, particularly in frail patients with significant systemic diseases.

Learning points: RA is useful in patients with multiple comorbidities. Scalp block is an effective anesthesia and analgesia strategy for head surgery. RA enhances quality of recovery.

12AP14-12

Unusual presentation and management of local anesthetic systemic toxicity (LAST) in a high-risk patient with multiple comorbidities

A. Khrapov^{1,2}, H. Smith¹, S. Kransingh³ ¹Te Whatu Ora South Canterbury, Timaru Hospital, Anaesthetic, Timaru, New Zealand, 2Timaru Hospital, Anaesthetic, Timaru, New Zealand, 3Te Whatu Ora South Canterbury, Timaru, New Zealand

A 64-year-old lady presented with alcohol intoxication, fall at home, right displaced rib fractures (7th-10th), hemopneumothorax, severe chest pain, confusion and multiple comorbidities: COPD, emphysema, pneumonia, heavy smoking, epilepsy, low body weight (43 kgs) and albumin, deranged liver function, alcoholism, frailty,

The initial analgesic management: Panadol, NSAIDs, IV morphine with limited efficacy.

She received right ESP block, PNB catheter at T8 level. Bolus of 30 mL of 0.2%ropivacaine followed by an infusion at 2-7mL/h by pump. The VAS pain score dropped from 8 to 0 after 30 minutes after bolus and sustained for 20 hours. Patient deteriorated 20-24 hours post PNB catheter insertion with confusion, fluctuating drowsiness, hypoventilation, desaturation.

There were subtle neurological but no overt cardiovascular signs of LAST. Regional anesthesia stopped; high-flow oxygen and In-

therapy initiated: 75 mL bolus followed by 12.5 mL/min over 10 minutes. There was an

improvement in mentation. 18 hours later, the ESP block restarted via the same PNB catheter with 0.1% ropivacaine at 2-7 mL/h, effective analgesia and no recurrence of LAST symptoms.

Patient underwent rib plating with subsequent improvement. Challenges in dosing and diagnosing LAST (1) were patient's comorbidities:

hypoalbuminemia - resulting in a higher fraction of free local anaesthetic, liver dysfunction - with

decreased metabolism of the LA, anticonvulsants. The use of opioids may have masked some of the LAST(2,3) signs .The presentation was also atypical, with no cardiovascular features and the only neurological symptom was the altered mentation and no prodromal symptoms: perioral paresthesia, metallic taste, tinnitus.

Evidence-Based References:

- 1. Neal, J. M., et al. (2018). "ASRA Practice Advisory on Local Anesthetic Systemic Toxicity."Regional Anesthesia and Pain Medicine, 43(2), 113-123.
- 2. Litz, R. J., et al. (2014). "Successful resuscitation of a patient with ropivacaine-induced asystole

after axillary plexus block using lipid infusion." Anesthesia & Analgesia, 108(5), 1578-1580.

3. Picard, J., & Meek, T. (2010). "Lipid emulsion to treat overdose of local anaesthetic "Anaesthesia, 65(2), 115-120.

Learning Points are the awareness of atypical presentations in patients with altered

pharmacokinetics. Lipid emulsion therapy can reverse life-threatening LAST, even when initiated

late. Lower concentration ropivacaine may be safely reintroduced post-LAST with monitoring.

Ambulatory Anaesthesia

Endoscopic retrograde cholangiopancreatography as a "treatment and discharge' day care procedure under general anaesthesia: a retrospective analysis in a tertiary care cancer centre in Oman

P. Raghavan Ravi¹, D.I.S. Al Qarshoubi¹, J. Pulikkodan² ¹University Medical City/SQCCCRC. Anaesthesiology. Muscat, Oman, 2University Medical City/SQCCCRC. Interventional Gasteroenterology, Muscat, Oman

Background and Goal of Study: Multiple studies have demonstrated that GA (General Anaesthesia) with endotracheal tubes reduces sedation-related adverse effects (SRAEs). We set up the concept of a "treatment and discharge" daycare facility for the GA ERCP. We did this study to evaluate the efficiency and safety of this system.

Materials and Methods: We did a descriptive analysis of retrospectively collected data of all the patients undergoing GA ERCP in our centre from the period from March 2022 to March 2024. Data was collected from the hospital information system/ Electronic medical records. Individual patient medical reports apart from the anesthesia records and endoscopy procedure notes were reviewed

Results and Discussion: 473 patients in the endoscopy suit underwent 1131 episodes of ERCP. The commonest indication for ERCP was CBD stones, followed by pancreatic malignancy. Hypertension was the commonest comorbidity. 63 % of the patients underwent stent placement, removal, or exchange and it was the most common procedure performed. Spyglass ERCP was done on 112 patients.142 (32.06 %) patients underwent sphincterotomy. In 28 patients the procedure was abandoned. The majority of the patient's ERCP was done in the prone position. In 51 it was done in a lateral position and in 23 patients in the supine position. 88 % of the episodes were done as elective. Most of the patients were either sent back to the referral hospitals or to home. 46 patients were admitted to the ward for various reasons, of which 22 patients developed post-procedure pancreatitis . The mean average time to do the ERCP in our study was 66±22.46 minutes. Most of the patients were under GA with ETTO. 36 out of 42, who were done under moderate to deep sedation were converted to GA. The average PACU time was 109±34.22 mins 139 patients developed nausea/vomiting of various grades. 63 patients had 116 episodes of hypotension amounting to 148 minutes. 36 of them required inotropic/vasopressor support, while 28 episodes of hypoxia amounting to 72 minutes.

Conclusion(s): The establishment of the local network for endoscopy procedures at daycare is safe and feasible from the anesthesia and endoscopic point of view whether elective or in an emergency. This first such ERCP network in Oman demonstrates that mild alterations in certain institutional practices can lead to optimized utilization of endoscopic facilities and patient satisfaction.

13AP01-2

Acute neurogenic pulmonary edema following electroconvulsive therapy: a case report

S. Ramos¹

¹CUF Hospital Lisbon, Ansthesiology, Lisboa, Portugal

Background: Neurogenic pulmonary edema (NPE) is a rare, lifethreatening complication linked to acute central nervous system (CNS) insults such as seizures. This report examines a case of NPE following electroconvulsive therapy (ECT) for refractory bipolar disorder, emphasizing the importance of timely diagnosis and management.

Case Report: A 52-year-old woman with bipolar disorder underwent elective ECT after failing pharmacologic therapy. Induction was performed with etomidate and succinvlcholine, followed by bilateral ECT. Post-seizure, the patient experienced severe hypoxemia (SpO2 of 60%), hemoptysis, and respiratory distress despite 100% oxygen supplementation. Bedside imaging revealed bilateral pulmonary opacifications consistent with edema. Immediate treatment included oxygen therapy, diuretics, and corticosteroids. The patient demonstrated gradual improvement, achieving full recovery within three days.

Discussion: The hyperadrenergic state induced by ECT likely triggered NPE, marked by elevated pulmonary capillary pressures and fluid leakage. Unlike negative pressure pulmonary edema, NPE arises from CNS-mediated sympathetic overactivation without airway obstruction. This case aligns with prior reports highlighting autonomic dysregulation during ECT. Vigilant post-ECT monitoring is critical for early detection and intervention, improving outcomes in such rare complications.

Learning Points:

NPE is a rare but severe complication of ECT requiring prompt recognition and intervention.

Pre-ECT evaluations and intra/post-procedure monitoring are vital for patient safety.

Multidisciplinary coordination optimizes management of ECTinduced complications.

Is inhalational better than intravenous sedation in the MRI suite? Eleven months of Audit in a Private University Hospital

N. Brogly¹, E. Alsina¹, A. Sancho de Avila¹, J. Puertas¹, E. Matute¹

¹Hospital Universitario Sanitas La Zarzuela, Servicio de Anestesia, Madrid, Spain

Background: Sedation (SED) is indicated for Magnetic Resonance Imaging (MRI) in case of claustrophobia, pain or anxiety. The ideal SED should ensure immobility, avoid complications (awareness and desaturation), and allow an early discharge from hospital. We audited 11 months of SED for MRIs in a Private University Hospital.

Material and Methods: Data on MRIs performed between January and November of 2024 were retrieved concerning the SED technique (inhalational, Intravenous or mixed intravenous and inhalational), age and ASA status, number of MRI sequences, complications, SED side effects (headache or PONV) and time elapsed between the end of procedure and discharge from the hospital. We analysed risk factors for complications and delayed discharge (>30 minutes) from Hospital. p<0,05 was considered statistically significant.

Results: 198 patients (age: 56 [0,6; 82] yrs; ASA: 2 [1;4]), were scheduled for 1 [1;5] MRI sequences. 125 (63,1%) received inhalational SED versus 65 (32,8%) intravenous SED, and 8 (4,0%) mixed techniques.

Complications were observed in 52 (26,3%) cases: MRI sequence was interrupted or repeated in 42 (21,2%) cases and 27 (13,6%) patients presented a desaturation. An older age (p=0,65), greater number of sequences (p=0,47) or ASA status (p=0,29) were not associated with more complications.

SED technique had a significant influence on complications (p<0.001); the use of propofol (OR: 6.29 [3.15: 12.55], p<0.001) and midazolam (OR: 3,15 [1,51; 6,57], p<0,001) were associated with an increased risk, while sevoflurane (OR: 0,18 [0,09; 0,36]; p<0,001) decreased this risk.

A late discharge from hospital was observed in 50 (25,3%) patients: an age < 12 years (OR: 0,2 [0,04; 0,90]; p= 0,02), an exclusive use sevoflurane (OR: 3,26 [1,6; 6,63]; p=0,01), the use of propofol (OR: 0,48 [0,23; 0,99]; p=0.04) or midazolam (OR: [0,28; 0,84], p=0,01), and SED side effects (OR: 5,86 [1,64; 20,97]; p=0,003) were identified as associated factors, but not the number of MRI sequences (OR: 1,96 [0,98; 3,93]; p=0.06) or the occurrence of complications (OR: 0,85 [0,41; 1,79], p=0,72).

Discussion and Conclusions: Although sedation using inhalational techniques for MRI seems a safer procedure, it increases the time of recovery and might affect time before discharge of the patient from hospital.

REZUM technique for benign prostatic hyperplasia: what is the best anesthetic treatment?

G. Sfregola¹, G. Montenero¹, A. Ragone¹, M. Ciuffreda², C. Piangatelli2, D. Galante1

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, 2Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Benign prostatic hyperplasia (BPH) is a prevalent condition among older men, leading to bothersome lower urinary tract symptoms (LUTS). The REZUM procedure, a minimally invasive treatment utilizing steam to ablate prostatic tissue, is an effective option for managing BPH. The choice of anesthesia or sedation for the REZUM technique is crucial for patient comfort and procedural success, yet the optimal approach remains uncertain.

Materials and Methods: A survey was conducted in 5 hospital centers where experienced anesthetists performed anesthesia to 115 male patients undergoing the REZUM procedure for BPH between 2022 and 2023. Three different anesthesia methods were compared: local anesthesia with conscious sedation (Group A), spinal anesthesia (Group B), and general anesthesia (Group C). Patient outcomes, including pain scores (measured on a visual analog scale, VAS), procedure duration, post-operative recovery time, and complications, were assessed.

Results and Discussion: Group A, using local anesthesia with sedation, demonstrated the shortest procedure time (mean 15 minutes) and a significantly lower incidence of post-procedural complications compared to Groups B and C. Pain scores were slightly higher in Group A (mean VAS 3) compared to spinal (mean VAS 2) and general anesthesia (mean VAS 1), but patients reported guicker recovery and fewer post-operative urinary retention issues. General anesthesia was associated with the longest recovery time, while spinal anesthesia showed higher complication rates (e.g., transient urinary retention) than local anesthesia.

Conclusion(s): Local anesthesia with conscious sedation appears to be the most efficient and safe anesthetic option for RE-ZUM in BPH patients, offering shorter recovery times and fewer complications. Further studies with larger sample sizes and longterm follow-up are warranted to validate these findings.

Gastroscopy in pediatric patients: which anesthesia or sedation protocol?

G. Montenero¹, G. Sfregola¹, A. Ragone¹, C. Di Terlizzi¹, M. Ciuffreda², D. Galante¹ ¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, 2Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Gastroscopy is a commonly performed procedure in pediatric patients for diagnostic and therapeutic purposes. Ensuring patient comfort while minimizing complications is essential. The choice of anesthesia or sedation for gastroscopy in children remains a key factor influencing procedural success, safety, and patient experience. This study evaluates the efficacy and safety of different sedation protocols in 75 pediatric patients undergoing gastroscopy.

Materials and Methods: A survey was conducted in 9 hospital centers on 75 pediatric patients (ages 4-12 years) who underwent gastroscopy between 2023 and 2024. Three sedation regimens were assessed: intravenous (IV) midazolam and fentanyl (Group A), IV propofol (Group B), and inhalational sevoflurane (Group C). Primary outcomes included sedation efficacy (measured by the Ramsay Sedation Scale), complication rates (e.g., respiratory or cardiovascular issues), and recovery times. Secondary outcomes involved parental satisfaction and post-procedural discomfort.

Results and Discussion: Group B (IV propofol) showed the most rapid onset of sedation and shortest recovery times (mean 10 minutes). Complication rates were lowest in Group B, with only mild hypoxia observed in four patients, resolved without intervention. Group A (midazolam and fentanyl) had moderate sedation efficacy and longer recovery times, while Group C (sevoflurane) demonstrated similar sedation levels but higher incidences of transient respiratory issues (4/8 patients). Parental satisfaction was highest in Group B due to reduced anxiety and shorter postprocedural recovery.

Conclusion(s): IV propofol offers superior sedation quality with fewer complications and faster recovery in pediatric gastroscopy. It represents the optimal choice for minimizing adverse events and enhancing patient and family satisfaction. Further studies with larger cohorts are needed to corroborate these findings.

Outpatient surgery in a patient with chronic inflammatory demyelinating polyneuropathy (CIDP): a case report

M. Coimbra¹, S. Fernandes¹, J. Cortesão¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Chronic Inflammatory Demyelinating Polyneuropathy (CIDP) is a rare autoimmune disorder causing motor and sensory deficits. Perioperative management is challenging due to altered responses to neuromuscular blockers, heightened pain sensitivity, and respiratory issues. Outpatient surgery in CIDP patients is rarely reported, making this case clinically relevant.

Case Report: A 62-year-old male with lumbar radiculopathy due to L4-L5 spondylolisthesis and a herniated disc underwent transforaminal lumbar interbody fusion in an outpatient setting. History included diabetes mellitus, hypertension and CIDP, managed with azathioprine, prednisolone, and plasma exchange every three weeks, with the last session one week prior to surgery. Neurological exam revealed strength preserved in all limbs except for grade 4 in left-hand finger abduction, generalized areflexia, and muscle atrophy. Preoperative assessment (ASA III) included normal blood tests, chest X-ray, and ECG.

Anesthesia was conducted with total intravenous anesthesia using propofol and remifentanil, avoiding neuromuscular blockers. After intubation, the patient was positioned prone. Surgery was uneventful. Multimodal analgesia was used, and the patient was transferred to the PACU. Maximum pain score was 4 (Numeric Rating Scale), reduced to 0 at discharge, with no postoperative opioids required. He was discharged in under 24 hours after clinical and neurological stability. At one-week follow-up, he reported symptom improvement, pain control without medication, and no neurological deficits or exacerbations. He remains under neuroloay follow-up.

Discussion: This case demonstrates the feasibility of outpatient surgery with one overnight stay in CIDP patients with stable disease. Patients with CIDP often exhibit heightened pain sensitivity due to neuropathic mechanisms, making multimodal analgesia essential for effective pain control. Avoiding neuromuscular blockers minimized neuromuscular dysfunction risks, while careful airway management and prone positioning enabled safe surgery. Despite elevated baseline risks, including pulmonary complications, the patient experienced rapid recovery and no adverse events.

References: Takekawa D, et al. JA Clinical Reports. 2019;5(1):19 Learning Points: Outpatient surgery in stable CIDP patients is feasible with thorough planning, tailored anesthesia to minimize risks, close neurology collaboration, and follow-up to ensure recovery and monitor outcomes.

Analysis of predictors for airway intervention during sedation in magnetic resonance image; a retrospective study

B.-S. Koo¹, Y.-H. Chung¹, M. Lee¹, S.-H. Cho¹, W.S. Chae¹, J. Jung¹

Soonchunhyang University Bucheon Hospital, Anesthesiology and Pain Medicine, Bucheon-si, Korea, Republic of

Background and Goal of Study: Magnetic resonance imaging (MRI) examinations require patients to remain motionless, often necessitating sedation for those who are claustrophobic or uncooperative. The head coil, essential for enhancing imaging quality, enforces a neutral head position and restricts neck extension, which increases the risk of airway obstruction during sedation. The STOP-Bang questionnaire, originally developed to screen for obstructive sleep apnea (OSA), has been used to predict difficult mask ventilation and intubation in perioperative settings. This study aims to identify predictors for airway intervention, including nasal/oral airway or supraglottic airway insertions.

Materials and Methods: This retrospective study analyzed patients aged 18 years or older who underwent sedation for MRI examinations. Demographic variables, such as age, body mass index (BMI), and neck circumference, American Society of Anesthesiologists (ASA) physical status, and responses to the STOP-Bang questionnaire were extracted from medical records. Binary logistic regression was performed to identify predictors of airway intervention.

Results and Discussion: Between November 2021 and April 2024, 153 eligible patients were analyzed. Of these, 66 were classified as low risk for OSA, 44 as intermediate risk, and 43 as high risk. Airway intervention was required in 102 patients (66.7%). Univariate analysis revealed that BMI, ASA physical status, snoring, risk score, and neck circumference as significant factors for airway intervention. Multivariate analysis further confirmed that higher BMI (p = 0.028, Odds ratio (OR) = 1.152 [1.015-1.308]), ASA class 3 compared to class 2 (p=0.003, OR = 4.717 [1.715-12.987]), and high risk compared to low risk (p = 0.005, OR = 6.730 [1.771-25.581]) or intermediate risk (p < 0.001, OR = 11.236 [3.125-40]) were significant predictors.

These findings align with prior studies on airway obstruction during general anesthesia or conscious sedation. Considering that two-thirds of patients requiring head coils needed airway intervention, particular attention is warranted for high-risk patients.

Conclusion(s): BMI, ASA physical status, and STOP-Bang risk score were significant predictors of airway intervention during sedation for MRI examinations. Recognizing these risk factors can enhance patient safety by enabling proactive preparation and timely intervention to prevent sedation-related airway obstruction during MRI examinations.

13AP01-8

Remimazolam with peripheral nerve blocks as sole sedative agent for ASA 4 joint arthroplasty revision patients

V. Gulia1

¹George Eliot Hospital, Anaesthesia and Intensive Care, Nuneaton, United States

Background: ASA 4 patients undergoing Emergency surgery. Reduction of dislocation / washout post hip/knee Arthroplasty. Pt not fit for General Anaesthesia due to the need to avoid respiratory depression due to severe COPD/OSA/ Dementia. Pt on anticoagulants and not fit for central Neuraxial blockade.

Anticipated Surgery duration <1 hour. Remimazolam is a benzodiazepine sedative available for procedural sedation in adults in the UK which has rapid onset and rapid offset with minimal respiratory depression is small doses.

Case report: 5 ASA 4 Patients for post knee joint replacement infection washout / hip dislocation reduction. Use of Remimazolam 2. 5 mg i.v as initial bolus on induction with 2.5 mg increments along with Ultra sound guided Fascia illiaca block with 30 ml 0.25 Levobupivacaine. The Modified Observer's Assessment of Alertness and Sedation (MOAA scale) was used to observe patients in recovery. The score was between 2 to 3 for all patients and they were awake in recovery. No adverse effects like hypotension or respiratory depression were observed.

Discussion: Remimazolam is a novel ultrashort acting sedative Benzodiazipine (BZD) with esterase hydrolysis (rather than the usual cytokines) and doesn't cause respiratory depression. Its 'inactive' metabolite (300 x less active than parent compound). Its use in ASA 4 cases with multiple co-morbidity in small doses is safe and gives sedation and hypnosis with amnesia.

J Bronchology Interv Pulmonol. 2022 Jan 1;29(1):54-61. doi: 10.1097/

Learning points:

• No remimazolam treatment-emergent adverse events occurred during the evaluation

Remimazolam used was 5 mg

- Mean time to onset of sedation was 3 min and Mean recovery time after end of procedure was 5.0 min
- No flumazenil / Naloxone intervention was required

LBR.0000000000000784. PMID: 34238838.

Comparative evaluation of remimazolam, midazolam, and propofol for sedation in IBD patients undergoing colonoscopy: Discharge readiness, satisfaction, and safety outcomes

C. Ferrari¹, C. Bezzio², G. Franchellucci², C. Hassan², A. Repici², R. Monzani¹

¹Humanitas Research Hospital, Anesthesia and Intensive Care, Rozzano, Italy, ²Humanitas Research Hospital, Gastroenterology Department, Rozzano, Italy

Background and Goal of Study: : Endoscopy plays a crucial role in managing inflammatory bowel disease (IBD). IBD patients often experience heightened pain and discomfort during these procedures compared to the general population. Remimazolam has been recently introduced as a novel benzodiazepine for sedation in procedural endoscopy.

This study aims to compare effectiveness, satisfaction and safety of Remimazolam (R) vs Midazolam (M) or Propofol (P) in IBD patients undergoing colonoscopy.

Materials and Methods: Observational single-center study including consecutive IBD patients undergoing colonoscopy for therapy response monitoring between May and July 2024. Patients divided into three groups based on the type of sedation administered: R group, M group and P group. The primary endpoint was discharge readiness, evaluated using the PADSS (Post Anesthesia Discharge Scoring System) score at 10 and 20 minutes post-procedure (eligibility for discharge if PADSS ≥ 9). Secondary endpoints included: patient satisfaction according to a four levels scale, pain assessed using numeric rating scale (NRS) and the rate of terminal ileum intubation. Sedation-related adverse events were recorded to assess safety.

Results and Discussion: 195 patients enrolled: 95 received R, 52 M, and 51 P. The three groups were comparable in terms of age. IBD duration, BMI, history of abdominal surgery, ongoing use of antipsychotic or opioid therapy, Fentanyl dosage during the procedure, ASA score, presence of perianal disease, and clinical or endoscopic remission. About PADSS at 10 minutes: 14 out of 52 patients (26.9%) in the M group were eligible for discharge, compared to 23 out of 51 in the P group (45.1%) and 65 out of 95 patients (68.42%) in the R group (p < 0.001 R vs M; p 0.006 R vs P). No significant differences in discharge readiness were observed between the three groups at 20 minutes. No differences in terms of patient satisfaction were assessed between the groups. No serious adverse events were reported in any group, and there were no significant differences in mild adverse events among the groups. Terminal ileum intubation was successfully achieved in all patients across all groups.

Conclusion(s): Remimazolam was associated with a significantly higher discharge readiness rate at 10 minutes post-procedure with a safety profile and patient satisfaction comparable to both Midazolam and Propofol.

13AP02-2

Establishment and validation of a prediction model for hypoxemia in middle-aged and elderly outpatient patients undergoing painless gastroscopy diagnosis and treatment: a retrospective cohort study

C. Ou¹, M. ZHANG¹, L. Zheng¹, Z. Wang¹, B. Yi², Y. Zhang¹ ¹Second Affiliated Hospital of Zunyi Medical University, Department of Anesthesiology, Zunyi, China, ²First Affiliated Hospital of Army Medical University, Department of Anesthesiology, Chongging, China

Background and Goal of Study: Hypoxemia is a very common complication associated in painless gastroscopy diagnosis and treatment services. The number of cases of hypoxemia among middle-aged and elderly patients is increasing. However, tools for predicting hypoxemia in middle-aged and elderly patients are lacking. Machine learning can efficiently perform complex nonlinear data processing, risk prediction, disease diagnosis, and other functions.

In this study, we investigated the risk factors for hypoxemia in middle-aged and elderly outpatients undergoing painless gastroscopy based on machine learning and constructed a risk prediction model

Materials and Methods: In this retrospective study, we included the data on 1,348 outpatients undergoing painless gastroscopy. Five machine learning algorithm models were selected. The 26 characteristic variables selected by BorutaShap were incorporated into five machine learning algorithms. The best models were selected based on the area under the receiver operating characteristic curve. Model feature importance was explained and analyzed using Shapley Additive Explanations.

Results and Discussion: In the final cohort of 984 patients, 11% of patients (108/984) experienced hypoxemia during the painless gastroscopy procedure. The AUROCs of the five models were as follows: Logistic Regression (AUROC = 0.893, 95Cl: 0.881-0.899), SVM (AUROC = 0.855, 95Cl: 0.812-0.884), Random Forest (AUROC = 0.914, 95Cl: 0.889-0.924), XGB (AUROC = 0.902, 95Cl: 0.865-0.919), and LightGBM (AUROC = 0.891, 95Cl: 0.847-0.917). Regarding the explanation of the importance of SHAP features, preoperative variables (baseline SpO2, body mass index, and micrognathia) and intraoperative variables (operating time of gastroscopy, induction dose of etomidate and propofol mixture, append anesthetic, cough, and repeated pharyngeal irritation) significantly contributed to the model.

Conclusion(s): We identified eight potential risk factors related to the occurrence of hypoxemia in middle-aged and elderly patients undergoing painless gastroscopy, based on machine learning feature engineering. Among the five machine learning algorithms, RF exhibited the best predictive performance in the internal test set and had a certain degree of generalization ability in the external validation set. This model was more likely to enhance the accuracy of hypoxemia prediction in middle-aged and elderly patients undergoing painless gastroscopy.

Is dexmedetomidine safe for sedation of a patient with myotonic dystrophy type 1 in an outpatient basis? A case report

R. Góis¹, <u>M. Silva</u>¹, M.J. Nascimento¹, C. Infante¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Type 1 myotonic dystrophy (DM1) is a rare muscular dystrophy with multisystemic manifestations that increase susceptibility to some anesthetic drugs.¹ Dexmedetomidine, a highly selective alpha-2 adrenergic agonist, offers sedative, anxiolytic and analgesic properties with a low risk of respiratory depression. Its short duration of action supports outpatient use. However, its cardiovascular adverse effects are still a major concern. As a sympatholytic agent, it can induce significant bradycardia and hypotension, particularly in susceptible patients and during or after the initial bolus.¹

Case Report: A 52-year-old man with DM1 and cognitive impairment was scheduled for outpatient correction of severe ptosis. He had significantly impaired respiratory function, a first-degree atrioventricular block, and a complete left bundle branch block on his electrocardiogram. The surgery was performed under local anesthesia and dexmedetomidine infusion (4 mcg/mL). The initial bolus was set at an intermediate dose (0.7 mcg/kg/h) to minimize cardiac instability and then adjusted to 0.3-0.5 mcg/kg/h guided by bispectral index and hemodynamic effects. The patient maintained spontaneous ventilation and hemodynamic stability throughout the 1-hour procedure. There were no postoperative complications, and he was discharged 4.5 hours later.

Discussion: Patients with DM1 may exhibit sympathetic dysfunction, vagal predominance,² and a tendency for cardiac arrhythmias.³ This patient had cardiac conduction anomalies previously associated with asystole after dexmedetomidine infusion.¹ While his systolic blood pressure decreased by 16% from baseline, no episodes of bradycardia occurred. Only one similar case has been reported, involving a patient with a pacemaker³, which provided additional safety against bradycardia. This is the first case stating the use of dexmedetomidine in a DM1 patient undergoing ambulatory surgery.

- 3. Liu AY, Dower A, Nair S. Dexmedetomidine infusion for sedation in a patient with myotonic dystrophy. Anaesth Rep. 2020 Oct 16;8(2):135-137.

Learning points: Dexmedetomidine could be a promising drug for use in this patient population.

13AP02-4

Perioperative factors associated with prolonged time to ambulation for robotic prostatectomy in an Ambulatory Surgery Center (ASC)

M. Bennett¹, M. Assel², E. Vertosick², J. Serafin¹, S. Carlesson³, <u>A. Afonso¹</u>, JRSC ERAS Team ¹Memorial Sloan Kettering Cancer Center, Anesthesiology & Critical Care, New York, United States, ²Memorial Sloan Kettering Cancer Center, Epidemiology and Biostatistics, New York, United States, ³Memorial Sloan Kettering Cancer Center, Surgery, New York, United States

Background and Goal of Study: Enhanced Recovery After Surgery is a standardized perioperative protocol that reduces physical and metabolic stressors during surgery. Radical proctectomies performed with enhanced recovery protocol are associated with better post-operative outcomes including earlier time to ambulation.

The objective of this study was to identify factors associated with delayed ambulation among patients undergoing radical prostatectomy in an ambulatory surgery setting (23 hr stay).

Materials and Methods: Patients who underwent robotic-assisted prostatectomy at Memorial Sloan Kettering Cancer Center's Josie Robertson Surgery Center between January 11, 2016, and December 27, 2022, were eligible for inclusion. Predictors of interest were identified from literature review and included age, American Society of Anesthesia physical status (1/2 vs 3/4), operative time, amount of intravenous fluids, estimated blood loss, intraoperative morphine equivalents, use of a block and post-operative nausea and vomiting score via Apfel scoring criteria, and real-time locating system (RTLS) to measure ambulation.

Results and Discussion: The final cohort consisted of 3677 patients undergoing prostatectomy. Median time to ambulation was 5.1 hours (IQR 4.2, 6.3). 141 (3.8%) patients had an Apfel post-operative nausea score of 3. When assessing covariates, we found that only Apfel score was significantly associated with delayed ambulation; having a score of 3 was associated with more than double the odds of next-day ambulation vs those with scores \leq 2 (OR 2.15, 95% CI 1.25, 3.60, p=0.006).

Conclusion(s): Our study showed an association between preoperative Apfel and delayed ambulation indicating that PONV control is important even among men undergoing radical prostatectomy. Postoperative nausea and vomiting (PONV) is a significant factor associated with delayed ambulation after robotic-assisted prostatectomy. Strategies to minimize PONV, such as prophylactic antiemetic therapy, may help improve postoperative recovery and reduce the incidence of delayed ambulation.

Efficacy of THRIVE and target controlled infusions for sedation in SpyGlass cholangioscopy - a retrospective case series analysis

N. Joachim¹, S. Rioniz¹, B. George¹, M. Patil², A.M. George¹, A. S Padavil¹ ¹St. John's Medical College Hospital, Anaesthesiology, Bangalore, India, 2St. John's Medical College Hospital, Gastroenterology, Bangalore, India

Background: SpyGlass cholangioscopy is an advanced tool for diagnosing and treating complex biliopancreatic diseases. It allows direct visualization, biopsy sampling, and electrohydraulic or laser lithotripsy. While minimally invasive, the procedure causes significant discomfort, necessitating deep sedation. Target-Controlled Infusion (TCI) of propofol, coupled with Transnasal Humidified Rapid Insufflation and Ventilatory Exchange (THRIVE), provides stable sedation with spontaneous ventilation, hemodynamic stability, and rapid recovery.

Case Report: Four patients underwent SpyGlass cholangioscopy under deep sedation using TCI propofol with THRIVE. Propofol was titrated using the Schneider model to achieve a Bispectral Index (BIS) target of 40-50. Oxygen flow via THRIVE started at 10 L/min and increased to 50 L/min during scope insertion. Fentanyl boluses (1 mcg/kg) were administered intermittently for pain. Hemodynamics, BIS, and propofol concentrations were continuously monitored. After the procedure, propofol was stopped, and patients were observed until fully awake.

Case	Gender	Age (yrs)	Weight (kg)	Propofol (mL)	Procedure Time (min)	Max Propofol (mcg/mL)	Recovery Time (min)	Complica- tions
1	F	48	49	110	140	5.65	25	Nil
2	F	34	55	45	60	3.96	10	Nausea
3	M	25	50	45	40	6.30	15	Vomiting
4	M	72	50	50	70	4.01	20	Nausea

Discussion: THRIVE provides excellent oxygenation and allows spontaneous breathing during shared airway procedures. Studies confirm its efficacy in reducing hypoxia and procedural interruptions. TCI propofol offers precise sedation control, as shown by Schneider model-guided dosing and BIS monitoring. Despite risks of gastric insufflation with THRIVE, no distension was noted, and prophylactic antiemetics mitigated post-procedure symptoms. Combining THRIVE and TCI propofol ensures optimal sedation, minimal airway intervention, and rapid recovery during SpyGlass cholangioscopy.

References:

The SpyGlass direct visualisation system for diagnostic & therapeutic procedures during endoscopy of the biliary system.2015 www.nice.org.uk/guidance/mib21 Motiaa Y,et al. Anesthesia for endoscopic retrograde cholangiopancreatography: target-controlled infusion versus st&ard volatile anesthesia. Ann Gastroenterol. 2016 doi:10.20524/aog.2016.0071

Learning points: TCI with THRIVE with adequate monitoring is an optimal choice for Spyglass cholangioscopy allowing short recovery time & less peri-operative complications compared to standard anaesthetic techniques.

13AP02-7

Efficacy and safety of cipepofol versus remimazolam combined with low-dose sufentanil in painless gastroscopy: a prospective, single-center, single-blind, randomized controlled trial

H. Tang¹, Z. Pi¹, G. Hu¹, L. Tang¹, Z. Xia¹, S. Lei¹ ¹Wuhan University, Renmin Hospital of Wuhan University, Wuhan, China

Background and Goal of Study: Cipepofol is an innovative drug developed independently in China, known for its effective anesthetic and sedative properties. Remimazolam is believed to provide adequate sedation for gastrointestinal endoscopy. However, there are no studies comparing the effectiveness and safety of cipepofol with remimazolam for the diagnosis and treatment of painless gastroscopy in adults.

This study was intended to compare the effectiveness and safety of remimazolam and cipepofol in adult outpatients undergoing painless gastroscopy.

Materials and Methods: This study included a total of 194 patients, who were allocated into the remimazolam group and the cipepofol group in a 1:1 ratio. The remimazolam group received $0.3 \text{ mg/kg remimazolam} + 0.1 \,\mu\text{g/kg sufentanil}$, while the cipepofol group received 0.4 mg/kg cipepofol + 0.1 µg/kg sufentanil. The primary outcome measure was the sedation success rate, while adverse events were recorded to evaluate safety. Continuous variables are presented as N, Mean ± SD, M (Q1, Q3), Min, Max, and differences between groups are analyzed using the T test. Categorical variables are reported as N (%), with differences between groups assessed using the Chi-square test.

Results and Discussion: The sedation success rate was 99% in the remimazolam group and 100% in the cipepofol group. The success rate for the first dose of sedation was 91.75% for cipepofol, compared to 64.95% for the remimazolam group.

The incidence of apnea (1.03% vs. 6.19%; P = 0.124), respiratory depression (6.19% vs. 5.15%; P = 1.000), hypoxemia (8.25% vs. 7.22%; P = 1.000), hypotension (4.12% vs. 2.06%; P = 0.678), bradycardia (4.12% vs. 2.06%; P = 1.000), dreams (12.37% vs. 20.62%; P = 0.176), and injection pain (5.15% vs. 1.03%; P = 0.213) showed no statistical significance.

The incidence of body movements was higher in the remimazolam group (31.96% vs. 14.43%; P = 0.006), as was the incidence of choking (25.77% vs. 13.40%; P = 0.047) and hiccups (13.40% vs. 2.06%; P = 0.007).

Both remimazolam and cipepofol exhibit promising applications in the diagnosis and treatment of painless gastroscopy in adults, with cipepofol demonstrating superior safety.

Conclusion(s): Both 0.3 mg/kg remimazolam and 0.4 mg/kg cipepofol combined with 0.1 µg/kg sufentanil exhibit effective sedative properties. Cipepofol has lower incidence of adverse events, especially body movements, choking and hiccups, as compared to remimazolam.

Anaesthetic risk factors of delayed discharge after appendectomy performed in ambulatory surgery

A. Donck¹, F. Verdonk¹ ¹Hopital Saint Antoine APHP, Anesthesiology and Intensive Care, Paris, France

Background and Goal of Study: Acute appendicitis is the first emergency in digestive surgery. Its treatment can be performed in an outpatient surgery unit. It requires optimized management from both surgical and anaesthetic perspectives. The main objective of this study is to identify the anaesthetic factors that may prolong the length of stay after an appendectomy performed in ambulatory unit.

Materials and Methods: This is a five years retrospective monocentric study conducted at Saint Antoine Hospital in Paris. All adult patients who underwent appendectomy for acute appendicitis in the ambulatory unit were included. Demographic data, ASA score, and administered anaesthetic products were studied, as well as the operative times and durations in the post-anaesthesia care unit. The primary endpoint was the discharge time, defined as the time between the end of surgery and discharge. Results and Discussion: Six hundred eighty-two (682) patients were included. The mean time before discharge was 1,71 hours ± 0,027. Factors statistically associated with a prolonged discharge time were the non-use of ketamine (p=0,041), desflurane use as maintenance of anaesthesia (p=0.045) and the perioperative dose of sufentanil (p=0,010). Thirty-one patients (4,54%) experi-

Conclusion(s): This study showed that anaesthetic practices influence the time to discharge after appendectomy performed in an ambulatory unit.

enced unplanned hospitalization postoperatively.

13AP02-9

Evaluation of the effectiveness of melatonin for recording ABR in children (Experience from a third-world country)

K. Damaan¹, M.A. Abidi², S. Benhamza¹, M. Lazraq¹, Y. Miloudi¹, A. Bensaid¹ ¹University hospital 20 Août, anesthesiology / intensive care unit, Casablanca, Morocco, ²University Hospital 20 Août, anesthesiology / intensive care unit, Casablanca, Morocco

Background and Goal of Study: In the pediatric population, auditory brainstem response (ABR) testing can be challenging due to the lack of child cooperation. The Goal of study is to evaluate the efficacy of oral melatonin in achieving sleep necessary for conducting threshold auditory brainstem response (ABR) tests in children suspected of having hearing impairments.

Materials and Methods: It's a prospective study. All children over one year of age suspected of hearing impairment.

Outcomes are Percentage of successful ABR examinations, percentage of children achieving sleep with melatonin, and Time required to complete a full ABR examination after the melatonin dose. ABR tests were conducted in a day-hospital setting in ENT. in a single-occupancy room optimized for sleep. After parental consent, 5 mg (or 10 mg for children over 6 years) of melatonin is administered orally, dissolved in 10 mL of water. A dedicated data collection form is used to record parameters from patient files comply with the principles of the Declaration of Helsinki, Study submitted to the ethics committee. Data were analyzed using EX-CFL and SPSS software.

Results and discussion: 18 children aged 2 to 14 years have been included since September 2024.36 ears were tested using threshold ABR under melatonin: in 4 children, both ears were fully explored, resulting in 8 completed tests (22.2% of children): in 6 children, only one ear was explored, leading to 6 completed tests (33.3%); and in 8 children, the test could not be performed (44.4% failure rate).

One child achieved good-quality sleep (5.5%), 10 had brief sleep but remained calm during the test (55.5% of children), and 7 children never reached sleep (38.9%). The average time to achieve effective sleep after melatonin administration was 42 minutes, with an average sleep duration of 24 minutes and an average test duration of 55 minutes after melatonin administration. Therefore, an average of 97 minutes was required to complete a full test.

Conclusion(s): The use of melatonin has indeed enabled us to test at least 55.5% of children on at least one ear. However, the failure rate remains significant at 44.4%. Consequently, we believe that our protocol is not effective and requires adjustments. Additionally, our sample size is limited, which restricts the scope of our study. That said, the study is ongoing as we await more relevant results.

13AP02-11

Trends in anaesthesia for phacoemulsification combined with minimal invasive glaucoma surgery: a case report

M.B.C. Fernandes¹, C.Q.d.S. Cavalcante², B.V.C. Fernandes³, R.V. Fernandes de Souza⁴ ¹CGV Oftalmologia Clinica e Cirurgica, Departamento de Anestesia, Fortaleza, Brazil, 2CGV Oftalmologia Clinica e Cirurgica, Departamento de anestesia, Fortaleza, Brazil, 3UNIFOR-Universidade de Fortaleza, Graduação, Fortaleza, Brazil, 4CGV Oftalmologia Clinica e Cirurgica, Departamento de Oftalmologia, Fortaleza, Brazil

Background: Glaucoma is emerging as one of the main causes of irreversible blindness worldwide. New minimally invasive surgical technologies like iStent® have emerged with satisfactory results 1 and the goals of anesthetic care during micro-invasive glaucoma surgeries are minimization of increased risk of damage to the optic nerve during local anesthetic injection.

Case Report: A 60 years-old male with chronic bilateral glaucoma, underwent phacoemulsification combined with minimal invasive glaucoma surgery with implantation of intraocular lens (IOL) plus angular drainage device for glaucoma iStent®, performed using a minimally invasive technique. He had already undergone cataract and glaucoma surgery (trabeculectomy) with significant visual loss in the other eye, 20/80 and tubular visual field. Eye showed significant worsening of vision due to nuclear and posterior subcapsular cataract. Moderate glaucoma damage with also moderate visual field damage, ocular pressure of 17 mmHg with daily use of latanoprost.

Since it was the better eye, with moderate damage, performed peribulbar block (Ropivacaine 1%- 4mL) avoiding increases in intraocular pressure during anesthesia and admnistered dexmedetomidine for collaborative sedation². Facectomy surgery and IOL implantation were performed without complications. The patient's head was repositioned at an angle of approximately 45 degrees for placement in the nasal trabecular meshwork through temporal access. Surgical procedure lasted 20 minutes, and patient was discharged consciously at same day, with ocular pressure already at 14 mmHg in the first few days.

Discussion: Anesthetic care during glaucoma micro-invasive ambulatorial anesthesia involves risk of transitory increase in intraocular pressure and damage to the optic nerve during local anesthetic injection. The goal of sedation must be minimize anxiety, and dexmedetomidine is an excellent option since provides an awake and cooperative sedation.

Non-operation room anesthesia during polypectomy in colonoscopy for a patient with pattern of Wolff-Parkinson White

M. Naco¹, H. Gani², K. Lilaj¹, E. Kacurri³, I. Refatllari⁴, E. Naco⁵

¹University of Medicine Tirana, General Surgery, Tirane, Albania, ²Hospital university center Tirana, General surgery, Tirane, Albania, ³La vita clinic, Gastroentrology, Tirana, Albania, ⁴Hospital university center Tirana, Cardiology, Tirane, Albania, ⁵University our lady of good council, Student, Tirane, Albania

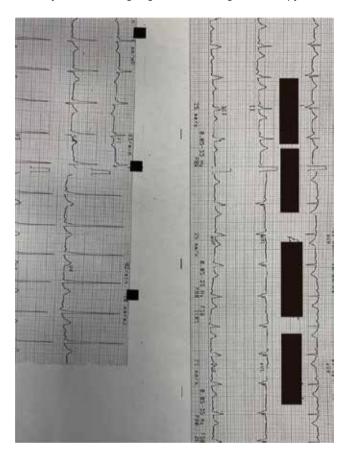

Background: Wolff–Parkinson–White (WPW) syndrome remains still one of the most difficult cardiac arrhythmia to treat in NORA practice. The incidence of the WPW pattern on the electrocardiogram is 0.13% to 0.25% while of WPW syndrome is 0.9-3% of the general population. The risk of sudden death from malignant arrhythmia is estimated at 0.4% /year in patients with WPW syndrome. While colonoscopy is safe, it still carries the risks for cardiac complications.

Case Report: We report a 44 years old male planned for colonoscopy after Fecal occult blood test >25 ng/ml. He was diagnosed with WPW syndrome 9 years ago. A preoperative evaluation showed 12-lead ECG (RS with FC nearly 60bpm, a shortened PR interval and the presence of delta wave) and Rhythm Holter: RS diffused in accessory way (WPW) 40 ESA not significant, without ventricle arrhythmia, maximal frequency 106/min, on average 62/min, minimal 40/min, without disorder of AV diffusing. He was treated in that period with atenolol 50mg x 2 and denied ablation. After i/v cannulation and non-invasive monitoring, oxygenation with 2L was started.

We used dexmedetomidine 3 mcg/kg + ketamine 2 mg/kg i/v for NORA. Adenosine, procainamide, and amiodarone were kept on standby. The procedure lasted 30 minutes and the patient had an early recovery.

Discussion: The perioperative goal of anesthesia is a moderate balance between sympathetic stimulation and vagal tone. Anesthetic medications tent to alter the physiology of atrioventricular (AV) conduction. The recent study have shown Propofol administration is related to arrhythmias that is why we avoided it.

Our case aims to highlight that proper medical knowledge combined with appropriate precautions can avoid sympathetic stimulation. They are the key to a successful outcome in patients with WPW syndrome undergoing sedation during colonoscopy.

Anesthesia management in a 36-year-old pregnant woman with a pituitary macroadenoma: a multidisciplinary approach for endoscopic endonasal resection at 18 weeks gestation

A.B. Guerreiro¹, A. Gil¹, R.R. Calhau¹, S.R. Pereira² ¹Unidade Local de Saude Lisboa Ocidental. Anesthesiology, Lisboa, Portugal, 2Hospital Central do Funchal, Anesthesiology, Funchal, Portugal

Background: Pituitary adenomas (PA) during pregnancy present a unique challenge due to potential complications. Management is complex and multidisciplinary. This case is noteworthy due to the rarity of performing non-obstetric surgery, specifically a pituitary resection.

Case Report: 36-year-old, 18 weeks pregnant ASA II woman, with personal history of hypothyroidism and PA under medical treatment. After cabergoline discontinuation in the beginning of pregnancy she developed visual disturbances. CT scan confirmed a PA extending into the right cavernous sinus and compressing the optic chiasm. Given tumor's progression and symptoms, a decision was made for surgical endonasal resection. The patient was managed by a multidisciplinary team, ensuring both maternal and fetal safety. ASA standard monitoring plus invasive blood pressure was applied. We decided for total intravenous anesthesia (TIVA) with dexmedetomidine, remifentanil, propofol and rocuronium with tracheal intubation. Surgery was uneventful. She was extubated at the end of the procedure. Fetal wellbeing was confirmed through ultrasound. She was transferred to the ICU for further observation and care.

Discussion: PA in pregnancy are rare, particularly those with significant growth or extension to structures like the cavernous sinus. The challenges in this case arose from the need for surgical intervention in pregnancy, which carries the risks of preterm labor, anesthesia complications, and potential fetal harm, underscoring the importance of a multidisciplinary approach. Management required meticulous planning. TIVA was chosen to avoid the risks associated with volatile anesthetics. Dexmedetomidine, although rarely used in pregnancy, provided hemodynamic stability. Fetal monitoring was conducted with careful attention to maternal blood pressure, fluid balance, and avoidance of uterine artery vasoconstriction. Anesthesiologists must be prepared for the unique physiological changes and increased risks during these procedures.

References:

Jia XY, et al. Surgical management of pituitary adenoma during pregnancy. World J Clin Cases 2023; 11(12): 2694-2707

Learning Points: Anesthesia management during non-obstetric surgery in pregnancy requires tailored techniques to minimize risks to both the mother and fetus. TIVA is a safe approach. The importance of preoperative assessment, continuous fetal monitoring, and individualized anesthesia protocols is critical in ensuring a successful outcome.

21AP01-2

Beyond the myths about labour analgesia: level of maternal knowledge in a Portuguese hospital

M. Gutierres¹, F.F. da Costa Rosa¹, C. Salqueirinho¹, R. Sampaio², A.L. Dias¹, C. Sampaio¹ ¹Unidade Local de Saúde (ULS) São João, Anaesthesiology, Porto, Portugal, ²Faculdade de Medicina da Universidade do Porto, Biomedicine, Porto, Portugal

Background and Goal of Study: Labour analgesia plays a critical role in improving childbirth experience. However, misconceptions and limited knowledge among pregnant women regarding labour analgesia often lead to unnecessary anxiety and reluctance toward its use.

Our goal was to analyse the prevalence of these myths and evaluate maternal knowledge about labour analgesia.

Materials and Methods: This cross-sectional study was conducted at the Gynecology and Obstetrics Emergency Department of ULS São João from July to October 2023. A questionnaire addressing sources of information, knowledge levels and common misconceptions about labour analgesia was administered to postpartum women prior to discharge.

Knowledge was scored based on correct answers, with participants classified into high (>6) or low (<3) knowledge levels, defined as mean ±1 standard deviation.

Univariate analysis was performed using Chi-square or Fisher's exact tests with p<0.05 considered statistically significant.

Results and Discussion: A total of 172 postpartum women were included, with a mean age of 31±6 years. Of these, 54.7% were primiparous, 86.6% had a gestational age of 37-40 weeks and 64.5% had an eutocic delivery. 59.6% of the participants reported receiving information about labour analgesia before pregnancy and 32.2% during pregnancy, mainly from health professionals (73.7%) or childbirth preparation classes (43.6%). None of the participants reported a complete lack of knowledge about labour analgesia.

Participants correctly identified as false the statements "Epidural analgesia prevents labour participation" (94.0%) and "Epidural analgesia can harm the baby" (80.2%). However, more than half lacked knowledge or held misconceptions about spinal complications. Only 20 (11.6%) scored >6 (high knowledge), while 110 (64.0%) scored <3 (low knowledge). High knowledge levels were significantly associated with receiving information from health professionals (p=0.01).

Among the participants who reported not receiving labour analgesia (n=3), all had moderate knowledge but held specific misconceptions (e.g., "Epidural analgesia can harm the baby" (p=0.005) vs participants with labour analgesia).

Conclusion(s): This study highlights significant gaps in maternal knowledge about labour analgesia, particularly regarding potential complications and misconceptions. Information provided by health professionals is strongly associated with better knowledge, underlining the importance of antenatal education and counseling.

21AP01-3 Labour Regional Analgesia QIP

H. Gulati¹, R. Goyal¹, C. Cardus²

¹Princess Alexandra Hospital, NHS Trust, Department of Anaesthesia, Harlow, United Kingdom, 2Broomfield Hospital, Mid and South Essex NHS Foundation Trust, Department of Anaesthesia, Chelmsford, United Kingdom

Background and Goal of Study: Standards for the provision of labour analgesia have been defined by the RCoA(Royal college of Anaesthetist) and include:

More than 85% blocks successful, re-sites during labour less than 15%, accidental dura puncture rate less than 1%, satisfaction at follow-up greater than 98% and adequate analgesia at 45 minutes after start of procedure over 88%.

Aims: Collect data over a 3 month period.

Compare our data to the standards and indicators set out in 'Raising the Standards: RCoA Quality Improvement Compendium'.

Materials and Methods: Data was collected over 2 separate audits which were performed between 3rd February - 5th May 2022 and the second audit in 16th April 2023 - 16th July 2023. This re audit gives the details of data from the audit in 2023 and compares it with the data in 2022.

The data was collected from the recordkeeping in the labour ward. The characteristics of the data were as follows:

- · Descriptive data: Date, time, grade of anaesthetist, technique of epidural, complications in follow up, satisfactory analgesia at 45mins or not.
- Incidence of re-siting epidural, accidental dura puncture(ADP), post dural puncture headache(PDPH) was recorded.

Results and Discussion:

- 1) Total 223 epidurals documented, incidence of ADP was 1/223 (0.44%), 1 patient developed **PDPH** and got epidural blood patch. 2) Technique of epidural: In 2022, some anaesthetist were using loss of resistance to air(LORA), while in 2023, all were doing Loss of resistance to saline(LORS).
- 3) The ADP rate in the first audit in 2022 was 3.2%, which decreased to 0.44% in 2023. The reduced incidence of ADP may be due to practicing LORS rather than LORA. Additionally, practicing on mannequins to perform epidural contributed to the decreased ADP rate.
- 4) How did our practice measure up as compared to the 'RCOA standard':
- More than 85% blocks successful. (our rate 93.7%)
- Re-sites during labour less than 15%. (our rate 5.4%)
- Accidental dural puncture rate less than 1% (our rate 0.44%)
- · Satisfaction at follow-up greater than 98%. (93.7%)
- 5) The number of epidurals done in the night are as much in number as in daytime with no difference in complication rate.

Conclusion:

- 1) LORS technique leads to less incidence of ADP.
- 2) Using mannequin to practice epidurals can lead to decreased
- 3) The complication rate is the same in night as compared to the
- 4) Better follow up to quantify satisfactory analgesia

21AP01-4

Navigating the adrenal storm: C-section in a pregnant patient with pheochromocytoma

F. C. Santos¹, I. A. Neves¹, S. Ferraz¹ ¹Unidade Local de Saúde de Lisboa Ocidental. Anesthesiology, Lisboa, Portugal

Background: Pheochromocytoma during pregnancy is a rare, lifethreatening condition requiring multidisciplinary management due to the risk of hypertensive crisis and adverse outcomes. Preoperative optimisation and tailored intraoperative care are essential for improving prognosis.

Case Report: We describe a 41-year-old female, ASA III, G3P1, diagnosed with pheochromocytoma during the third trimester of pregnancy. Prior to an elective cesarean section, an alpha-adrenergic blockade was performed with administration of phenoxybenzamine 10mg during 10 days, under continuous maternal-fetal monitoring. Intraoperative management included ASA-standard and invasive arterial pressure monitoring. Epidural anesthesia with 15mL of ropivacaine 7,5mg/mL was administered without significant complications.

Two transient hypertensive episodes occurred intraoperatively, resolving spontaneously. The neonate had Apgar scores of 9/10/10 and was transferred to level 2 neonatal care for closer observation. The mother was monitored postoperatively in a level 3 intensive care unit, maintaining alpha-blockade and blood pressure surveillance. She was discharged on postoperative day 4, hemodynamically stable, and later underwent laparoscopic resection of the pheochromocytoma without anesthetic or surgical complications.

Discussion: This case highlights the importance of preoperative alpha-adrenergic blockade in controlling hemodynamics and mitigating intraoperative risks. Epidural anesthesia, with invasive arterial monitoring, allowed for stable intraoperative conditions. Postoperative ICU care ensured early identification and management of potential complications, and prompt surgical resection minimized long-term risks.

References:

Clifton-Bligh RJ. The diagnosis and management of pheochromocytoma and paraganglioma during pregnancy. Rev Endocr Metab Disord. 2023 Feb. doi: 10.1007/s11154-022-09773-2.

Learning points: A multidisciplinary approach is critical in managing pheochromocytoma during pregnancy and preoperative alpha-adrenergic blockade is essential for reducing perioperative maternal and fetal risks. Epidural anesthesia is effective in ensuring hemodynamic stability during cesarean section; nonetheless postoperative ICU monitoring is crucial for maternal safety. Definitive pheochromocytoma resection should follow maternal stabilization.

21AP01-5 Preoperative fasting in obstetrics: a comprehensive review

M.A. Zerafa Simler¹, A.M. Camilleri Podesta², K. Bunger³, F. Bilotta⁴, ESAIC Task Force on Perioperative Fasting in Adults

¹Leicester NSH Trust, Intensive Care, Theatres, Anaesthesia, Pain and Sleep, Leicester, United Kingdom, ²Mater Dei Hospital, Department of Anaesthesia, Intensive Care, and Pain Medicine, Msida, Malta, 3Queen Mary University of London, Barts, Faculty of Medicine and Surgery, London, United Kingdom, 4Policlinico Umberto I Hospital, La Sapienza University of Rome, Department of Anaesthesiology and Critical Care, Rome, Italy

Background and Goal of Study: Historically, preoperative fasting guidelines were shaped by expert opinion rather than evidence. These guidelines evolved from antiquated practices that encouraged prolonged fasting driven by concerns over aspiration intraoperatively and postoperative vomiting. Modern recommendations in obstetrics now support the intake of clear fluids up to two hours before elective anaesthesia, however this practice is seldom seen. This practice of unnecessarily prolonged preoperative fasting for liquids has negative effects on the perioperative experience of the obstetric patient. It can also compromise intraoperative safety through effects such as hypovolaemia, poor glucose control, and increased stress response. It is also responsible for issues with breastfeeding postoperatively.

The objective of this literature review is to investigate the recommended duration of liquid fasting before caesarean section, observe type of liquid that can be ingested prior to caesarean section, and the maternal and neonatal outcomes following reduced preoperative fasting.

Materials and Methods: This is a literature review, carried out as an adjunct to the literature review of clinical evidence by the ESAIC Task Force on Perioperative Fasting in Adults (in print). A systematic literature search was conducted between 1st January 2010 to 6th January 2023. Bibliographic databases were used, including MEDLINE (OVID), Embase (OVID), CINAHL, Web of Science, the Cochrane Database of Systematic Reviews (CDSR), and the Cochrane Central Register of Controlled Trials (CENTRAL).

Eligible manuscripts were original studies published in English between 1st January 2010 and 6th January 2023 reporting on safety, physiological effects, and patient experience-related effects of preoperative fasting in pregnancy women undergoing caesarean section.

Results and Discussion: A total of 12312 records were retrieved. of which 11 RCTs met the inclusion criteria. Four distinct interventions were identified: administration of carbohydrate drinks, water, chewing gum, and no intervention (control groups). The studies reported on four key outcomes: prevalence of regurgitation, time to first breastfeeding, glucose control, and maternal well-being. Conclusion(s): Shorter preoperative fasting times have no effect on regurgitation prevalence. This also reduces time to first breastfeed, improves glucose control, and maternal well-being.

21AP01-6

Maternal considerations in postoperative fasting: a comprehensive review

S. Farrugia¹, M.A. Zerafa Simler², K. Bunger³. A.M. Camilleri Podesta¹, S. Sciberras^{4,1}, F. Bilotta⁵, ESAIC Task Force on Perioperative Fasting in Adults ¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care and Pain, Msida, Malta, ²Leicester NHS Trust, Intensive Care, Theatres, Anaesthesia, Pain and Sleep, Leicester, United Kingdom, 3Queen Mary University of London, Barts, Faculty of Medicine and Surgery, London. United Kingdom, ⁴Mater Dei Hospital, Anaesthesia, Intensive Care and Pain, Msida, Malta, 5Policlinico Umberto I Hospital, La Sapienza University of Rome, Department of Anaesthesiology and Critical Care, Rome, Italy

Background and Goal of Study: International guidelines on the resumption of postoperative intake of liquids and solids remain scarce. Obstetric patients recovering from cesarian section are subjected to unnecessarily prolonged postoperative fasting times, resulting in increased postoperative maternal and neonatal morbidity. Reduced length of postoperative fasting has been shown to enhance postoperative recovery, improve rehabilitation, and alleviate the psychological burden of major surgery in such patients. These benefits may result in decreased length of hospital stay, which in turn may benefit healthcare sustainability. Given these potential benefits, this literature review aimed to examine and synthesize the current literature on this topic.

Materials and Methods: This is a literature review, carried out as an adjunct to the literature review of clinical evidence by the ESAIC Task Force on Perioperative Fasting in Adults (in print). A systematic literature search was conducted between 1st January 2010 to 6th January 2023. Bibliographic databases were used, including MEDLINE (OVID), Embase (OVID), CINAHL. Web of Science, the Cochrane Database of Systematic Reviews (CDSR) and the Cochrane Central Register of Controlled Trials (CENTRAL).

Eligible manuscripts were original studies published in English between 1st January 2010 and 6th January 2023 describing the use of chewing gym, post-operative fasting duration, and recovery in obstetric patients following caesarean section.

Results and Discussion: A total of 12312 records were retrieved. of which 12 randomised controlled trials met the inclusion criteria. Four distinct interventions were identified: administration of chewing gum, clear fluids, coffee, and no intervention (control). The studies reported on 4 distinct outcomes, including resumption of oral intake, bowel recovery, length of hospital stay, and maternal satisfaction.

Conclusion(s): Shorter postoperative fasting and chewing gum use enhance bowel recovery, improve oral intake tolerance, reduce hospital stay, and boost maternal satisfaction.

Perioperative management of giant liver haemangioma elective resection in a pregnant woman: a case report

C. Santos Farre¹, A. Jimenez Carrion¹, E. Moret Ruiz¹, A. Martí Acebedo¹, I.D. Jahnke López¹, N.L. Pacheco Comino¹

"University Hospital Germans Trias i Pujol, Anaesthesiology, Perioperative ICU and Pain Management Department, Badalona, Spain

Background: Non-obstetric surgeries during pregnancy require specialized anaesthetic management. Regional anaesthesia is preferred to minimize foetal drug exposure and optimize maternal haemodynamic, but certain surgeries must be performed under general anaesthesia, with more maternal-foetal risks. Unoperated giant haemangiomas can lead to obstructive symptoms, spontaneous rupture and excessive bleeding¹.

Case Report: We present a 29-years-old pregnant woman (19 weeks), without comorbidities, scheduled for elective laparoscopic resection of a giant hepatic haemangioma (85mm x 48mm) detected during the first trimester through abdominal mass palpation. A multidisciplinary team (gynaecology, anaesthesiology, surgery, hepatology, interventional radiology) designed an action plan consensus. Given the high risk of tumour growth and haemorrhage during pregnancy, surgical intervention was considered to be indicated despite the risk of foetal loss. A general anaesthesia with intradural morphine under invasive blood pressure monitoring, ECG and oxygen saturation was performed. No intraoperative foetus monitoring was done due to technical limitations and the foetus age. A pedunculated haemangioma was resected with minimal hepatic transection. The patient remained haemodynamically stable during the procedure and was extubated in the OR. No transfusion was required. Discharge took place after 5 days without complications.

At 39th weeks of pregnancy, an elective c-section was performed due to maternal risk factors, which proceeded without complications

Discussion: Nowadays there are only 11 similar cases published in the literature and there is still no international guideline about the best management of haemangiomas in pregnancy. Multidisciplinary preoperative evaluation is necessary in pregnant women. The very high risk of tumour rupture due to an increased intraabdominal pressure associated to haemangiomas' rapid growth is crucial in decision-making. Surgical intervention should be mandatory when risk of tumour rupture, bleeding or worsening symptoms are present.

Learning Points: Careful anaesthetic planning and close multidisciplinary coordination between specialists are essential to ensure the safety of mother and child in the management of complex cases like liver haemangioma resection during pregnancy.

Lumbar extradural hematoma after labor analgesia in an anticoagulated patient, followed by a pulmonary embolism

I. Reis Ferreira¹, <u>E. Sochirca</u>¹, M. Azevedo Coutinho¹, A.M. Ferreira¹

¹Unidade Local de Saúde do Estuário do Tejo EPE, Department of Anesthesiology, Vila Franca de Xira, Portugal

Background: Pregnancy and puerperium increase the risk of venous thromboembolic disease (VTD), with systemic anticoagulation being the primary prophylactic or treatment option¹.

Anticoagulation raises the risk of spinal hematoma (SH) after a central neuraxial block (CNB), with an incidence of 1:200000 in obstetric patients².

We report a case of a large extradural SH after labor analgesia in an anticoagulated patient, complicated by a pulmonary emholism

Case Report: A 38-year-old parturient, G4P3, 36w+4d twin gestation, requested labor analgesia. History of obesity (BMI 38), venous insufficiency and deep venous thrombosis of left internal saphenous vein (SV) in the first trimester, anticoagulated with enoxaparin 80mg 2x/day. Normal routine laboratory evaluation. Epidural analgesia was performed at L3-L4, non-traumatic technique, >24h after the last enoxaparin administration. Anticoagulation resumed 6h post catheter removal. Discharged at D4, without complications.

One week postpartum, presented severe lower back pain radiating to the right leg and paresthesia, without weakness. MRI revealed a large extradural SH at L2-L4. Admitted for conservative treatment of SH, anticoagulation suspended. Improvement was noted until D4, when a superficial venous thrombosis of the right anterior accessory SV occurred. Enoxaparin was not resumed due to SH. Two days later she had a massive pulmonary embolism with cardio-respiratory arrest - 45min of advanced life support were performed with return of spontaneous circulation 15min after thrombolysis with alteplase 100mg. Admitted to ICU.

The patient developed hemorrhagic complications after thrombolysis including an upper airway hematoma, requiring intubation. Due to the high thrombotic risk and contraindication for anticoagulation an inferior vena cava (IVC) filter was placed; later, anticoagulation was gradually started and the filter removed. Discharged a month after admission, without neurological deficits. Complaints of generalized weakness, fatigue, throat discomfort, dysphonic voice and stridor at follow-up.

Discussion: SH can occur even with an appropriate timing of enoxaparin suspension. Stopping the anticoagulation can lead to a major thrombotic complication, showing the need to balance the benefits and risks of anticoagulation and its suspension.

Learning points: Pregnancy and puerperium are VTD risk factors. Anticoagulation increases SH risk after CNB. IVC filters are valuable options in complex cases.

Peripartum management of a pregnant woman with uncorrected coarctation of the aorta: a case report

C. Sousa¹, T. Pereira da Silva¹, H. Seabra¹, F. Barros¹ ¹Unidade Local de Saude de Santo António, Serviço de Anestesiologia, Porto, Portugal

Background: Congenital coarctation of the aorta (CoA) is usually treated in childhood, with rare cases persisting into adulthood. Untreated CoA can cause severe complications, and pregnancyrelated risks, though rare, may be life-threatening. This report details the perioperative management of a C-section in a pregnant woman with untreated CoA.

Case Report: A 29-year-old pregnant woman with uncorrected CoA had systemic hypertension and exaggerated hypertensive response to exertion, without other severity markers. Additional anomalies included a bicuspid aortic valve and residual patent ductus arteriosus. Imaging showed normal cardiac function, and stress testing confirmed normal functional capacity.

The patient was admitted at 33 weeks for fetal monitoring, with a planned cesarean section. Due to the onset of labor during hospitalization, an urgent cesarean section was performed.

Standard ASA monitoring and invasive arterial blood pressure were used. Epidural anesthesia was administered at L3-L4 interspace in a seated position, without complications. Fractionated boluses of ropivacaine were delivered to minimize hemodynamic lability. The initial bolus consisted of 6 mL of 0.75% ropivacaine combined with 10µg of sufentanil, followed by three additional boluses of ropivacaine, totaling 14mL over 20 minutes. A sensory block up to the T6 level was achieved, with no further local anesthetic required during surgery.

About 20 minutes after epidural onset, mean arterial pressure dropped to 60 mmHg, requiring three 10 µg norepinephrine boluses to resolve. No other complications occurred during surgery. Postoperative analgesia was managed with the epidural catheter, supplemented by 1g paracetamol and 30mg ketorolac. The patient was discharged on postoperative day three without complications.

Discussion: Coarctation of the aorta in pregnancy poses unique challenges, requiring tailored anesthetic and obstetric care. Epidural anesthesia was used to ensure hemodynamic stability, minimize labor stress, and reduce hypertensive crisis risk. Fractionated ropivacaine allowed gradual sensory blockade, avoiding abrupt hemodynamic changes. Transient hypotension was promptly managed with norepinephrine boluses, ensuring maternal and fetal stability.

Management of epidural analgesia in a pregnant patient with suspected local anesthetic allergy

S. Bojic^{1,2}, M. Radovic³, M. Stojanovic^{4,1}, N. Radovanovic^{5,1}, K. Jovanovic^{5,1} ¹Medical University, Anesthesiology, Belgrade, Serbia, ²UCHC Dr Dragisa Misovic Dedinje, Anesthesiology, Belgrade, Serbia, 3UCHC Zemun, Internal ICU, Belgrade, Serbia, ⁴Institute for Cardiovascular Diseases Dedinje, Anesthesiology, Belgrade, Serbia, 5UCSC, Anesthesiology, Belgrade, Serbia

Background: Allergic reactions to local anesthetics (LAs) in dental procedures are reported in approximately 1% of cases. However, true immediate hypersensitivity reactions to LAs are exceedingly uncommon, with diagnostic tests frequently vielding negative results for suspected cases.

This case highlights the challenges of managing labor analgesia in a patient with a reported but undocumented allergy to LAs.

Case Report: A 30-year-old primigravida presented at full term for spontaneous labor. During pre-anesthetic evaluation, she reported a severe allergic reaction following a dental procedure involving an LA but could not specify the drug or provide supporting documentation. Due to these concerns, a decision was made to proceed with epidural analgesia using fentanyl (10 mcg/ mL), delivered as an initial 10 mL bolus followed by a continuous infusion of 5-7 mL/h. Pain relief was initially effective, reducing her Numeric Rating Scale (NRS) score from 8 to 3. However, after oxytocin infusion initiation, pain escalated, reaching 10 on the NRS. To manage this, on-demand boluses of 5 mL meperidine (5 mg/mL) were administered at a minimum interval of 30 minutes. Labor proceeded uneventfully, but the patient's satisfaction with pain management was partial, rated at 4/10 on a Likert scale. The postpartum period was uneventful, and the patient was discharged after 48 hours.

Discussion: This case underscores the importance of early referral to anesthesiology and allergology consultation for patients with suspected LA allergies, especially when no prior testing or documentation exists. A tailored approach to labor analgesia, incorporating non-LA options, is critical in such scenarios. Although fentanyl-based epidural analgesia provided initial pain relief, the escalation of pain during labor highlights the limitations of this approach.

Learning points: Effective communication and early multidisciplinary involvement are key in managing labor analgesia in patients with suspected LA allergies. This case emphasizes the need for preemptive allergology evaluation and the development of individualized pain management strategies to optimize outcomes and patient satisfaction.

Perioperative anesthetic management for a scheduled cesarean section in a patient with Stiff Person syndrome (SPS) and positive anti-GAD antibodies

M. Boned Garcia¹, M.C. Lopez Ponce¹, D. Rodriguez Delgado¹, S. Cuervo Escribano¹, P. Garcia Robledo¹, P. Garcia Pimentel¹ ¹Hospital 12 de Octubre, Servicio de Anestesiologia y Reanimacion, Madrid, Spain

Background: Stiff Person Syndrome (SPS) is a rare autoimmune neurological disorder characterized by muscle rigidity and tonic spasms, particularly in the abdominal and lumbar regions, which is triggered by stress, cold, or auditory and tactile stimuli. Patients with SPS can present significant challenges during surgical procedures due to the risk of triggering crises.

This report describes the anesthetic management of a pregnant patient with SPS and positive anti-GAD antibodies undergoing a scheduled cesarean section (C-section).

Case Report: A 25-year-old pregnant woman at 36 weeks of gestation, allergic to Propofol, was diagnosed with SPS. Her usual treatment included diazepam 10 mg/12 hours, pregabalin 150 mg/24 hours, baclofen 10 mg/12 hours, and rituximab (discontinued at the start of pregnancy).

A scheduled C-section was chosen due to the risk of complications with vaginal delivery. The anesthetic management involved spinal anesthesia with 0.5% bupivacaine 11 mg and fentanyl 10 mcg. The surgical team was prepared to minimize the procedure time. The patient was monitored with ECG, SpO2, and NIBP. A warming blanket was used to prevent hypothermia, monitor volumes were adjusted, and the presence of a companion was allowed throughout the procedure.

During the C-section, the patient did not experience muscle rigidity or spasms. In the Postanesthesia Care Unit (PACU), the patient experienced lumbar spasms and moderate muscle contractions. which were treated with 10 mg IV diazepam. She was taken to the obstetric ward 6 hours later.

Discussion: Anesthetic management of patients with SPS reguires avoiding triggers of crises such as stress, pain, and hypothermia. Regional anesthesia is the preferred option, as it allows adequate pain control without the use of muscle relaxants or inhalation agents, which could induce postoperative hypotonia. General anesthesia, with the use of GABAergic drugs or muscle relaxants, has been associated with postoperative hypotonia. Additionally, maintaining the patient's usual treatment regimen is essential to prevent withdrawal syndrome.

Reference:

Pinto et al. Emergent Anesthetic Management in a Patient Recently Diagnosed with Stiff Person Syndrome. 2023 Oct 5; 16(10): e70899.

Learning Points: Regional anesthesia is ideal for patients with SPS, as it avoids avoids the use of muscle relaxants. Controlling stress, pain, and hypothermia during surgery is crucial to prevent spasms and other complications.

21AP02-1

Anesthesia management of a pregnant patient with pulmonary hypertension due to congenital heart disease: a case report

I. Gedik¹, P. Şen¹, C. Balcı¹ ¹Health Sciences University, Umraniye, Anesthesiology, Istanbul, Turkey

Background: Congenital heart disease can lead to the development of pulmonary hypertension (PH-CHD) in 3%-10% of cases. According to the 2022 guidelines of the European Society of Cardiologyand Respiratory Societies, PH-CHD carries a high perioperative mortality andmorbidity risk, requiring multidisciplinary planning before surgery. This case report discusses the anesthesia management of a pregnant patient with PH-CHD.

Case Report: A 28-year-old pregnant woman at 30W2D gestation was referred from an external hospital toour obstetrics and gynecology clinic due to a threat of preterm labor, and C/S wasplanned. During the preoperative evaluation by our anesthesia and intensive care team, it was revealed that the patient had undergone a "Senning" procedure in childhood due to a diagnosisof transposition of the great arteries and ventricular septal defect, and she had a diagnosis of PH-CHD. Echocardiography showed an EF: 69% and pulmonary artery pressure (PAP) of 100 mmHg. The patient was transferred to the operating room, and standard monitoring was applied. SpO2 was increased from 84% to 89% with 3-4 lt/min oxygen supportvia nasal cannula. Radial arterial cannulation was performed, and the arterial blood pressurewas measured as 91/42 mmHq. A lumbar epidural catheter was placed in the sitting position. The epidural block extended up to the T8 level, and C/S was initiated. NO and O2 inhalation were administered vianasal delivery. An intravenous infusion of alprostadil at 0.1 µg/kg/min was started. The 37-minute C/S procedure was completed without any complications.

Discussion: Pregnant women with PH-CHD have a 30-40% risk of maternal mortality. Ongoing researchis focused on anesthesia techniques that can reduce high mortality and morbidity rates. In this case, we aim to contribute to the literature by presenting the anesthesia management of a pregnant patient with PH-CHD, which resulted in a favorable outcome without any mortalityor morbidity.

Reference:

J Cardiothorac Vasc. Anesth. 2021 Jul;35(7):2201-2211.doi: 10.1053/j.jvca.2020.06.062. Epub 2020 Jun 24.

Learning points: Multidisciplinary planning and careful preoperative evaluation are essential for managing pregnant patients with PH-CHD, as they face significant perioperative risks. Epidural anesthesia, combined with nitric oxide and alprostadil administration, can provide a safe and effective approach in high-risk PH-CHD cases.

Novel technique for managing a rare complication: a case report of epidural catheter retention

L. Abella de la Torre¹, M. Raynard¹, R. Borras¹, M. Homs¹, R. Valdes1

¹Hospital Universitari Dexeus, Anestesiologia y Reanimacion y Terapeutica Dolor, Barcelona, Spain

Background: Epidural catheter placement carries a low risk of complications, including catheter retention or rupture, occurring in approximately 1 in 20,000-30,000 cases. No standard protocol exists for this rare issue.

We report a case of catheter retention during labor, successfully resolved using interventional radiology (IR).ur IR-guided technique offers a minimally invasive alternative to surgery, reducing morbidity and risks. To our knowledge, similar approaches are rarely reported.

Case Report: A 37-year-old primiparous woman at 39 weeks' gestation presented for labor. With no significant medical history, she requested epidural analgesia at 4 cm dilation. An epidural catheter was placed at the L3-L4 interspace using an 18G Tuohy needle. Resistance was encountered when withdrawing the catheter to the 10 cm mark, causing lumbar pain. Despite attempts including saline injections and positional changes, removal failed. To manage labor, we administered an initial 10-mL bolus of levobupivacaine 0.25% and fentanyl, achieving temporary analgesia. Patchy distribution later required placing a second catheter, which provided effective pain relief through delivery. Postpartum imaging revealed the retained catheter looped around the L2 spinous process in the paravertebral lumbar space without kinking or nerve involvement. After reviewing management options, we opted for a minimally invasive IR approach. The patient, sedated with midazolam and propofol, underwent catheter removal using a 0.014 FR guidewire inserted past the catheter tip. The procedure was successful, avoiding complications.

Discussion: Catheter retention may result from coiling, knotting, or entrapment in the vertebrae, lumbar fascia, or nerve roots. Removal attempts should include saline injection, positional adjustments, and waiting before applying excessive force. Imaging is essential if resistance persists or neurological symptoms occur. While retained catheters are often asymptomatic, complications like radicular pain, subdural hematoma, or stenosis may require laminectomy, which carries risks including CSF leaks, infection, or nerve injury.

Comparison of gastric volume using ultrasound in term pregnant patients undergoing elective cesarean delivery and patients undergoing pregnancy termination

D. Senberber¹, M. Oltulu², U. Balcı³, E. Bilicen³, B. Kuvaki Balkan¹

¹Dokuz Eylul University, Anaesthesiology and Reanimation, Izmir, Turkey, ²Dokuz Eylul University, Anaesthesiology and Reanimation, İzmir, Turkey, 3Dokuz Eylul University, Obstetrics and Gynecology, Izmir, Turkey

Background and Goal of Study: Physiological changes caused by increased progesterone and estrogen, along with anatomical changes that occur in later weeks of pregnancy, make pregnancy a standalone risk factor for pulmonary aspiration, which is a rare but serious complication of anesthesia for CS.

This study aims to compare preoperative pulmonary aspiration risks by measuring gastric diameters using ultrasound in term and early pregnant patients, and to evaluate the practicality of this method in routine clinical practice.

Materials and Methods: This study included 40 term pregnant patients undergoing elective cesarean section and 33 patients undergoing dilation and curettage for pregnancy termination before 12 weeks of gestation. In addition to gastric ultrasound measurements,data on height, age, weight, BMI,and ASA classification were recorded.

Patients were evaluated using ultrasound in supine and right lateral decubitus positions, with two different measurements taken from the epigastric region. Qualitative assessment of gastric fluid content was performed during imaging and graded as Grade 0,1 or 2. For quantitative analysis of gastric content, the anteroposterior and cranio-caudal diameters of the gastric antrum were

Cross-sectional area was calculated using the ellipse area formula CSA=AP×CC×π/4.

Gastric volume was calculated as GV(mL)=27+(14.6×CSA (cm2))-(1.28×age).

Results and Discussion: Patients in the CS group had significantly higher weight and BMI compared to the D/C group. The majority of patients in both groups exhibited Grade 0 findings (CS:85.0%,D/C:88.2%),with no significant differences in grade distribution.

There were no significant differences in CSA supine (p=0.195) or lateral (p=0.147) between groups. Gastric volumes (supine and lateral) were also comparable (p>0.05). A significant, moderate positive correlation was found between BMI and both CSA supine (p=0.0025) and lateral (p=0.0044).

Positive correlation between BMI and gastric CSA in both supine and lateral positions, suggests that higher BMI is associated with increased gastric CSA which may not be specific for pregnancy. The ultrasound duration showed no significant difference between the C/S and D/C groups, with both averaging 3.40 ± 1.55 minutes.

Conclusion: Despite demographic differences, the similarity in gastric measurements and qualitative grades across groups suggests that term pregnancy does not significantly affect preoperative gastric parameters or risk profiles.

21APO2-7 Efficacy, side effects and safety of intrathecal clonidine for caesarean delivery

intrathecal clonidine for caesarean delivery: a 12-year retrospective study

L.A. Miggelbrink¹, U. Roorda¹, K. van Loon¹, L. van Wolfswinkel¹, W. Buhre¹, O. van den Bosch¹
¹Academic Hospital Utrecht, Anesthesiology, Utrecht, Netherlands

Background and Goal of Study: To ensure optimal maternal well-being during caesarean delivery, off-label intrathecal additives such as lipophilic opioids or alpha-agonists are often used to intensify and prolong anaesthetic block. However, evidence regarding benefits and potential harms of intrathecal clonidine is limited to smaller randomized controlled trials.¹²

This study aimed to evaluate the efficacy, side effects and safety of intrathecal clonidine for caesarean delivery.

Materials and Methods: This single-centre retrospective cohort study was conducted at a university hospital in the Netherlands. Data from all caesarean deliveries with spinal anaesthesia, performed between July 1, 2011 and January 1, 2023, were extracted from electronic records (AnStat and HiX). Deliveries were grouped: hyperbaric bupivacaine (HB) with clonidine (clonidine group), HB with lipophilic opioids (sufentanil or fentanyl) (opioid group) and HB only (HB-only group). Hypotension was defined as systolic arterial pressure of <80% of the last pre-operative value or systolic arterial pressure <90 mmHg, across at least two consecutive measurements.

Results and Discussion: 6,103 caesarean deliveries under spinal anaesthesia were included: 31.4% in the clonidine group, 11.2% in the opioid group and 57.3% in the HB-only group. Intravenous additives and/or conversion to general anaesthesia was less frequent (p<0.001) in the clonidine group (13%), as well asin the opioid group (12%), both compared to the HB-only group (21%). Intraoperative hypotension was significantly more frequent in the clonidine compared to both the opioid group (65% vs 56%, p<0.001) and the HB-only group (65% vs 59%, p<0.001). Recovery room hypotension was more frequent in the clonidine group than in both the opioid and the HB-only group (43% vs 20% vs 19%, p<0.001). The need for neurology consultation was rare (0.3% in all groups).

Conclusion: Intrathecal clonidine and lipophilic opioids provide similar improvements to anaesthetic block. However, intrathecal clonidine increases the risk of hypotension. We suggest that its use should be reserved for selected cases.

21AP02-8

A rare confluence: Intestinal obstruction and cesarean section at 33 weeks

C. Garcia Sobral¹, <u>L. Umanets</u>², D. Ribeiro¹, A. Paulino¹

1Hospital Beatriz Ângelo, Anaesthesia, Lisboa, Portugal,

2Hospital Santa Maria, Anaesthesia, Lisboa, Portugal

Background: We present a case of a 36-year-old woman at 33 weeks of gestation with intestinal obstruction following bariatric surgery. This scenario required urgent cesarean section, exploratory laparotomy, and segmental bowel resection, performed under combined spinal-epidural-general anesthesia

The case highlights the challenges of managing intestinal obstruction during pregnancy and the importance of tailored anesthetic strategies to optimize outcomes¹.

Case Report: A 36-year-old woman with a history recurrent intestinal obstruction following bariatric surgery developed a new episode of intestinal obstruction at 33 weeks of gestation requiring urgent surgery. She had no other comorbidities, and her pregnancy had been uneventful. After a multidisciplinary discussion, the following approach was decided. A thoracic epidural catheter was placed at T8-T9 for intraoperative and postoperative analgesia, then a spinal anesthesia at L4-L5 with bupivacaine (8 mg), sufentanil (2.5 μ g), and morphine (100 μ g) was performed for the cesarean section, which resulted in the delivery of a healthy neonate. General anesthesia was induced with fentanyl, propofol TCl, and rocuronium, and the patient was intubated using videolaryngoscopy. A total of ropivacaine 0,375% 12 ml was administered epidurally during surgery. The patient surgery and recovery underwent without complications.

Discussion: Acute abdomen during pregnancy is a diagnostic and therapeutic challenge. Around 2% of parturients require surgery for non-pregnancy-related indications. This case underscores the importance of individualized anesthetic planning in managing the rare combination of advanced pregnancy and intestinal obstruction. Regional anesthesia techniques enabled the mother to maintain her airway, minimize fetal drug exposure, and provide effective postoperative analgesia. This approach allowed the mother to remain awake during the cesarean section, ensuring safety for both mother and child.

Reference:

1. Wonte, M.M., Bantie, A.T., & Tadesse, M. (2023). A pregnant lady with compound bowel obstruction managed with thoracic epidural as sole anesthesia in a resource-restricted setting: A case report. *Journal of Medical Case Reports*, 17(231).

Learning Points: Surgical procedures during pregnancy require careful perioperative planning.

Posterior reversible encephalopathy syndrome (PRES) as a complication of eclampsia in two young primigravida patients

A.L. Gradinariu¹, J.L. Crăcană², I. Radu³ ¹Municipal Hospital St. Dr. Cosma & Damian, Anaesthesia and Intensive Care, Radauti, Romania, 2Municipal Hospital St. Dr. Cosma & Damian, Neurology, Radauti, Romania, ³Municipal Hospital St. Dr. Cosma & Damian, Obstetric/ Gynecology, Radauti, Romania

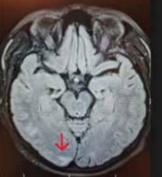

Background: Posterior reversible encephalopathy syndrome (PRES) was first described in 1996 by Hinchey et al. It is characterized by headaches, impaired consciousness, visual symptoms, nausea/vomiting, and focal neurological signs. As the name suggests, it is typically reversible once the underlying cause is treated.

Case Report: We report two cases involving 24 and 27-year-old primigravida women at 24/36 weeks of gestational age, with no medical history and otherwise normal pregnancies. Both presented to the emergency department with severe seizures, unconsciousness, and high blood pressure (both >180/90 mmHg), with laboratory tests suggestive of eclampsia. After stabilization, an emergency C-section was performed, followed by the transfer of the patients to intensive care. After extubation an early neurological evaluation with an emergency MRI were performed, because symptoms such as intense headache, vision disorder (blindness and photopsia) and agitation were presented on both patients. Reversibility of the symptoms after proper management and characteristic imaging on MRI led us to a diagnosis of PRES. Both patients were discharged after 5 days.

Discussion: In this cases PRES was a complication off eclampsia. PRES has generally good prognosis but severe complications can arise.

References:

- 1. A Reversible Posterior Leukoencephalopathy Syndrome | New **England Journal of Medicine**
- 2. Legriel: Understanding posterior reversible encephalopath... -Google Academic
- 3. Posterior reversible encephalopathy syndrome (PRES) in a patient with late postpartum eclampsia - PMC

Learning Points: PRES syndrome is a reversible entity when the aetiology is properly recognised and guickly treated. MRI of the brain is crucial to make a diferential diagnosis.

21AP02-10

Rare case of second-trimester termination of pregnancy due to severe pulmonary arterial hypertension (PAH)

P. Simons¹, F. Roelants¹, M. Momeni¹, F. Debiève², A.-C. Pouleur³, Q. Souberbielle¹

¹Clinique Universitaire Saint-Luc, Anaesthesiology Department, Bruxelles, Belgium, 2Clinique Universitaire Saint-Luc, Obstetric Department, Bruxelles, Belgium, ³Clinique Universitaire Saint-Luc, Cardiovascular Department, Bruxelles, Belgium

Background: Maternal mortality rates up to 33% are reported in case of PAH (mean pulmonary artery pressure (mPAP) > 20 mmHq)1. We describe the case of a second-trimester medical termination of pregnancy (MTP) in a patient belonging to group 1 (among 5 groups) PAH.

Case Report: A 39-year-old woman with severe PAH (mPAP of 73 mmHg) due to congenital right pulmonary artery agenesis and right lung hypoplasia presented at 15 weeks of gestation. She presented with mild dilation and moderate impairment of right ventricular function, pre-pregnancy six-minute walk test of 440 m, post-test oxygen saturation of 87%, and NT-proBNP of 168 pg/ml. Medications included macitentan, tadalafil, and spironolactone. After multidisciplinary counselling (patient classified mWHO Class IV), a MTP was decided.

An arterial line and a central venous catheter were placed in the cardiac intensive care unit (ICU), then an epidural analgesia with ropivacaine 0.1% and sufentanil 0.25 µg/mL was initiated after a test dose of 2% lidocaine without adrenaline.

Labour induction started with anti-progesterone mifepristone, then misoprostol (prostaglandin). Oxygen and low dose noradrenaline were administered. Delivery was planned in the cardiac ICU and occurred after six hours of labour. Oxytocin agonist Carbetocin was given.

Post-delivery, signs of pulmonary congestion and right heart decompensation required increased oxygen therapy and furosemide. The patient was discharged on day 8. Long-term contraception was proposed.

Discussion: Management of maternal PAH is critical, and multidisciplinary approach is essential. We chose vaginal delivery over curettage to reduce blood loss despite challenges associated with haemodynamic fluctuations during labour. Epidural analgesia provided effective pain control and stable haemodynamics, avoiding general anaesthesia, which could exacerbate pulmonary pressures and precipitate right ventricular failure.

Access to advanced monitoring and critical care facilities, including extracorporel membrane oxygenation in the ICU ensured patient safety.

1. Int J Obstet Anesth. 2024;59:104210

Learning Points: This report underscores the importance of tailored anaesthetic and obstetric planning for high-risk pregnancies due to PAH. Current literature predominantly focuses on term outcomes or first-trimester terminations. Limited data on second-trimester MTP requires the need for further research and clinical reporting to guide future management strategies.

21AP02-11

Anesthetic management of hereditary angioedema in pregnancy: a case report

P.I. Branco¹, M. Guarda¹, N. Santos¹, J. Jesus¹, T. Seixas¹ Hospital Professor Doutor Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Hereditary angioedema (HA) is a rare condition characterized by recurrent episodes of swelling due to C1 esterase inhibitor deficiency or dysfunction. Multidisciplinary care, short-term prophylaxis and postpartum surveillance must be carefully considered to avoid a life-threatening upper respiratory and laryngeal angioedema attack¹.

Case Report: We present a case of a pregnant 30-year-old woman with a personal history of type II HA scheduled for an elective caesarean. As prophylaxis, intravenous 1000 Units of plasma derived C1 inhibitor concentrate (pdC1-INH) were administered 1 hour before the caesarean. A combined spinal-epidural anaesthesia was performed and the caesarean proceeded without complications. The patient was transferred to the intensive care unit for postpartum monitoring and 24 hours after the caesarean additional intravenous 1000 Units of pdC1-INH were administered. There were no angioedema related complications.

Discussion: Pregnancy can increase the frequency and severity of angioedema attacks alongside with the physical and emotional trauma of labour and lactation. Angioedema typically occurs immediately after or within 48 hours of delivery². In case caesarean is needed regional anaesthesia is preferred to reduce the risk of an acute attack. Evidence based guidelines recommend prophylaxis with pdC1-INH before caesarean³ but few cases are described in the literature.

Additionally, clear communication with the Immunology consultant, emergency airway equipment and two additional doses of pdC1-INH should be available at all times.

2. Clark K, Givens J, Smith B, et al. Obstetric anesthetic management for parturients with hereditary angioedema: A case report and suggested protocol. Pain Med. 2021;22(8):1878–1882. 3. Magen E, Alesi G, El-Matary W, et al. Hereditary Angioedema During Pregnancy: Considerations in Management. Immunol Allergy Clin North Am. 2023;43:145-157.

Learning Points: A multidisciplinary approach and proper planning are essential in the obstetric management of a patient with HA. Short-term prophylaxis with pdC1-INH and careful postpartum monitoring must be considered.

21AP02-12

"Sitting tilt test" predicts hypotension during spinal anesthesia for elective cesarean section: a prospective observational study

H. Khouadja¹, <u>F. Ben Salem¹</u>, N. Boughzela¹, F. Mighri¹, A. Brahim¹, K. Ben Jazia¹

Faculté de Médecine Ibn El Jazzar, Anesthesia and Intensive Care, Sousse, Tunisia

Background: Spinal anesthesia is the technique of choice during cesarean section. However, hypotension remains a major of concern. Accurate prediction of hypotension facilitates early intervention.

Goal of Study: To evaluate the preoperative benefit of a position change test on the occurrence of severe arterial hypotension after spinal anesthesia for scheduled c-section.

Materials and Methods: A prospective observational study was conducted at a tertiary maternity center during a period of 6 months. Parturients at term scheduled for elective c-section were included. "Sitting Tilt Test" (STT) was performed at the operating room: immediately before spinal anesthesia (bupivacaine10mg+s ufentanil2.5μg+morphine100μg), parturients were kept in supine position for 5min, than asked to move to a sitting position for 5min. At each position, a mean of 3 measurements of systolic arterial pressure (SAP) were noted. SAP of reference was considered at the supine position. A rise of the SAP by 10mmHg was considered as a positive STT. During C-section, SAP and heart rate were noted each 2min; total ephedrine consumption and Apgar scores were considered at the end of surgery.

Severe hypotension was defined as the drop of the SAP of reference by 30% and/or a SAP≤90mmHg. A 6mg bolus of ephedrine was administered to maintain 90% of the SAP of reference.

For results analysis, parturients were assigned to group P (positive STT) and group N (negative STT). Both groups were compared for hypotension incidence, total ephedrine consumption and Apgar scores. For statistical analysis p< 0.05 was considered as significant.

Results: A cohort of 220 parturients was included. A positive STT was observed in 36.82% (group P 81 parturients and group N 139 parturients). Mean BMI was significantly different among groups (p<0.001). Hypotension occurred in 114/220 parturients. Incidence of severe hypotension was 65.43% in group P and 19.42% in group N (p<0.001).

Total ephedrine consumption was significantly different among groups (9.28 \pm 8.8mg and 4.01 \pm 5.9 mg in group P and N respectively) (p<0.001). Apgar score was 10 at 5 minutes in the two groups.

Conclusion: Aortocaval syndrome, present in 10% of parturients, may exacerbate spinal block hypotension-sympatholysis. The sitting position alleviates aortocaval compression, enhance hemodynamic status and can predict hypotension. In our study, a positive "sitting tilt test" was associated with severe hypotension after spinal anesthesia.

21AP03-1

Successful management of pregnancy associated atypical hemolytic uremic syndrome (P-aHUS): a case report

D. Yiqit¹, A. Özanbarci¹, İ. Baran Akkuş¹ ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Atypical hemolytic uremic syndrome (aHUS) is a life-threatening condition characterized by microangiopathic hemolytic anemia, thrombocytopenia, and acute kidney injury (AKI). These patients constitute approximately 5-10% of hemolytic uremic syndromes. Pregnancy induced thrombotic microangiopathies (TMA) due to complement dysregulation are called as pregnancy-associated aHUS (p-aHUS) and are generally associated with poor maternal outcomes.

In this case report, we present a patient with p-aHUS, who was successfully treated.

Case Report: A 38-year-old G3P2 Caucasian female with suspicion of preeclampsia and HELLP syndrome, after undergoing a cesarean section at 35 weeks of gestation, was transferred to our hospital with diagnoses of severe thrombocytopenia, anemia and AKI.Initial investigations included special laboratory tests under the preliminary diagnosis of TMA. Due to the presence of marked schistocytosis in the peripheral smear, plasma exchange (PE) was initiated to address a suspected thrombotic thrombocytopenic purpura (TTP) diagnosis until ADAMTS13 activity results became available. Additionally, dialysis was started to manage AKI.

Subsequently ADAMTS13 activity was found to be within normal limits,the diagnosis was revised to aHUS and after vaccination against encapsulated bacterias, Eculizumab therapy, a monoclonal antibody against C5, was administered. With significant clinical improvement, the patient was transferred to the nephrology ward and Eculizumab therapy was continued during next two weeks in the ward and after discharge. Currently she is in clinical remission on eculizimab treatment and doing well.

Discussion: In cases of AKI encountered during pregnancy and the postpartum period, a thorough differential diagnosis must be made and p- aHUS shouldn't be overlooked.

Dashe, Jodi S., Susan M. Ramin, and F. Gary Cunningham." The longterm consequences of thrombotic microangiopathy (thrombotic thrombocytopenic purpura and hemolytic uremic syndrome) in pregnancy." Obstetrics & Gynecology 91.5 Part 1(1998): 662-668. Polo, E. Simón, et al." Management of atypical uremic hemolytic syndrome in pregnant patient." Revista Española de Anestesiología y Reanimación(English Edition) 69.4 (2022):245-248.

Learning Points: Early and accurate diagnosis and treatment, involving prompt PE and Eculizumab, is critically important to improve outcomes.

21AP03-2

Cyclical Horner's syndrome during labour analgesia

J. Oliveira¹, M. Neto Martins², A. Mendes de Castro² ¹Instituto Português de Oncologia do Porto Francisco Gentil, EPE, Anesthesiology, Porto, Portugal, 2Unidade Local de Saúde de São João, E.P.E., Anesthesiology, Porto, Portugal

Background: Horner's syndrome is caused by the interruption of the sympathetic input of head and neck nerves. Lumbar epidural is not expected to reach high thoracic levels associated with this syndrome. Though rare, it seems more likely in the obstetric population.

Case Report: We present the case of a healthy 38-year-old pregnant woman in active labour who underwent uneventful epidural catheter placement at L3-4 (epidural space at 4 cm, catheter advanced to 9 cm). According to local protocol, initial bolus of 14 mL of Ropivacaine 0,1% with 10µg Sufentanyl. As labor progressed, Ropivacaine concentration was increased to 0.2%, with 10 mL boluses given on demand.

After the second bolus, the patient reported a red, aching left eye without discharge or foreign body sensation. After initial try-outs of eye cleaning and hydration, light ptosis and miosis were noted ipsilaterally, but faded out and resolved spontaneously.

Subsequent boluses intensified symptoms, with obvious ptosis, miosis, warmth, and rubor on the ipsilateral hemiface, all of which resolved spontaneously after reassurance. An addition bolus and a new cycle of worsening and resolving symptoms happened. No additional boluses were necessary, and labour occurred without incidents

Discussion: Horner's syndrome from lumbar epidural is rare but more common in obstetric patients, likely due to narrowed epidural space, increased epidural pressure from uterine contractions, and heightened sensitivity to local anesthetics from elevated progesterone. Anatomical variations, with pupil-innervating fibers originating as low as T4, may also contribute.

We report a case of cyclical Horner's syndrome to highlight potential neuraxial block level rise. While our case had no serious outcomes, complications like maternal hypotension or respiratory distress must be considered.

References:

Chambers DJ, Bhatia K. Horner's syndrome after obstetric neuraxial blockade: A systematic review. Int J Obstet Anesth. 2018. doi: 10.1016/j.ijoa.2018.03.005.;Ray BS, Hinsey JC, Geohegan WA. Sympathetic nerve distribution to the pupil and upper extremity via anterior root stimulation. Ann Surg. 1943;118:647-55.

Learning Points: Serious complications of epidural analgesia are rare but become more severe as the level of the block rises. The obstetric population is particularly at risk for high neuraxial blockades, making clinical signs of Horner's syndrome especially concerning in this group. Careful monitoring is essential to ensure the well-being of both the mother and the foetus.

21AP03-5

Intravenous anxiolytic and analgesic administration during intrapartum cesarean delivery under different methods of neuraxial anesthesia: a retrospective study

D. Hoffman¹, Y. Matatov¹, A. Peres¹, S. Fein¹, S. Orbach-Zinger¹, M.Y. Stav¹ ¹Rabin Medical Center, Anesthesia, Petach Tikva, Israel

Background: Intraoperative anxiety, pain, and stress during cesarean deliveries performed under neuraxial anesthesia have been shown to adversely impact both maternal and perinatal outcomes. Consequently, minimizing these negative effects has become a key focus in obstetric anesthesiology.

The aim of this study was to evaluate the risk factors associated with the use of intravenous (IV) anxiolytics and analgesics during intrapartum cesarean deliveries, with specific attention to the method of neuraxial anesthesia employed - whether spinal, epidural, or combined spinal-epidural anesthesia - at our academic medical center.

Methods: This retrospective cohort study included women who underwent cesarean deliveries between January 2017 and June 2022, utilizing spinal anesthesia, epidural anesthesia, or combined spinal-epidural (CSE) anesthesia. Women who required conversion to general anesthesia or who were initially administered general anesthesia were excluded from the analysis. Neuraxial anesthesia and analgesia were administered according to a standardized protocol.

The study focused on the use of Midazolam, the most frequently used anxiolytic agent at our center, and examined the associated risk factors related to the anesthesia technique. The administration of fentanyl, ketamine, and propofol - commonly used intravenous analgesics - was also analyzed.

Results: Of the 7,325 women who underwent cesarean delivery under neuraxial anesthesia. 836 (11.4%) received IV anxiolytics and 400 (5.4%) received IV analgesics. Epidural anesthesia was a significant risk factor for both anxiolytic (OR 2.45) and analgesic (OR 3.33) administration, while spinal anesthesia reduced the likelihood of both (OR 0.45 for anxiolytics, OR 0.30 for analgesics). Combined spinal-epidural anesthesia was a statistically significant risk factor only for analgesic use (OR 1.8).

Conclusions: Around one in nine women received IV anxiolytics, and one in 20 received analgesics during cesarean delivery at our center.

These results suggest that spinal anesthesia is associated with reduced pain and anxiety compared to epidural anesthesia. The findings could inform improvements to epidural protocols for better pain management.

Additionally, they underscore the importance of patient education and the anesthesiologist's role in assessing the need for anxiolytics and analgesics.

21AP03-6

Dexmedetomidine as an adjuvant to local anesthetics in spinal anesthesia for cesarean section: an updated systematic review and metaanalysis of 17 randomized clinical trials

L. Rezende De Freitas¹, E. Maia Pereira², L. Fábio Ribeiro³, S. Lima Ferreira Martins⁴, R. Astigarraga Abreu⁴, M. Gaya da Costa⁵

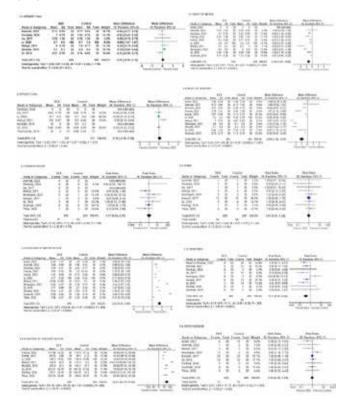

¹Federal University of Juiz de Fora, Department of Medicine, Juiz de Fora, Brazil, ²Federal University of Minas Gerais, Department of Medicine, Belo Horizonte, Brazil. ³Federal University of São João del-Rei, Department of Medicine, Divinópolis, Brazil, ⁴Nove de Julho University, Department of Medicine, São Bernardo do Campo, Brazil, ⁵University Medical Center Groningen, Department of Anesthesiology, Groningen, Netherlands

Background and Goal of Study: Dexmedetomidine (DEX) is increasingly used in spinal anesthesia for cesarean sections due to its potential to enhance sensory and motor blockade and reduce shivering. Despite these potential advantages, its comparative efficacy and safety against placebo or no-intervention remain under-explored.

This meta-analysis assesses its efficacy and safety, focusing on block characteristics and maternal and neonatal outcomes.

Materials and Methods: We conducted a systematic review and meta-analysis comparing DEX versus placebo or no intervention in spinal anesthesia for cesareans. We searched PubMed, Embase, and Cochrane databases up to August, 2024. The primary outcome was shivering incidence.

Secondary outcomes included onset and duration of sensory and motor block, incidence of hypotension, bradycardia, nausea and vomiting, 1 and 5-minute APGAR scores. Review Manager, version 5.4.1, was used for pooled risk ratio (RR), and mean difference (MD) in random effect model.

Results and Discussion: Seventeen RCTs, totaling 1280 patients, were included. DEX significantly decreased the incidence of shivering (RR: 0.37: 95% CI 0.22: 0.62: p<0.001). Its use also prolonged sensory block by 72.21 minutes (95% CI 53.19; 91.22; p<0.001), and motor block by 1.52 hours (95% CI 1.15; 1.89; p<0.001). The onset time for sensory and motor block was significantly reduced by 0.98 minutes (95% CI -1.38; -0.57; p<0.001) and 1.18 minutes (95% CI -1.67; -0.68; p<0.001), respectively.

No significant differences were found for hypotension (RR: 1.01: 95% CI 0.72; 1.41; p=0.96), bradycardia (RR: 1.11; 95% CI 0.52; 2.36; p=0.78), nausea and vomiting (RR: 1.01; 95% CI 0.67; 1.52; p=0.96), 1-minute APGAR (MD: 0.05 points; 95% CI -0.09; 0.19; p=0.51), or 5-minute APGAR (MD: 0.10 points; 95% CI -0.10; 0.30; p=0.34).

Conclusion(s): Dexmedetomidine in spinal anesthesia for cesarean significantly reduced shivering incidence, decreased the onset time and increased the duration of both motor and sensory blocks. There were no differences regarding hypotension, bradycardia, nausea and vomiting, 1 or 5-minute APGAR scores.

21AP03-7

Anaesthetic management of schizencephaly and pregnancy: a case report

T. Afonso Lima¹, D. Caldas Pacheco¹, A.S. Sampaio¹, M. Amoedo Pinto¹

¹Unidade Local de Saúde do Alto Minho, Servico de Anestesiologia, Viana do Castelo, Portugal

Background: Schizencephaly is a rare congenital brain malformation that can lead to neurological deficits, such as hemiparesis. Few case reports have described schizencephaly, and none have focused on anesthetic care. This case is unique due to the combination of schizencephaly and placenta previa in a pregnant woman scheduled for a cesarean section.

Case report: A 30-year-old woman, 37 weeks pregnant, with unilateral schizencephaly and mild right hemiparesis was scheduled for an elective C-section due to placenta previa. A few days before surgery, she reported transient sensory changes in her left upper limb, so a preoperative neurological evaluation was done, which revealed no new deficits and normal cognitive function. Neurology attributed this to probable compressive neuropathy from positioning or pregnancy-related tissue edema, without contraindication for cesarean delivery. Concerned that neuraxial techniques might worsen her condition, the patient opted for general anesthesia, a decision made after discussing the available options. Monitoring consisted of standard ASA, BIS and TOF. Careful positioning was assured to prevent compressive neuropathies during surgery. Rapid sequence induction was used and anesthesia maintained with sevoflurane. Rocuronium mantained neuromuscular blockage; pain was managed with multimodal analgesia, and oxytocin was administered for uterine contraction. The surgery and postoperative period were uneventful, the patient remained neurologically stable and delivered a healthy newborn.

Discussion: Schizencephaly presents an anesthetic challenge due to its rarity and the diverse neurological symptoms. Pregnancy and placenta previa add further complexity to perioperative care. Despite no known contraindications to general or regional anesthesia, the patient's concerns were addressed, and her preference for general anesthesia was respected. To our knowledge, there are no studies on anesthetic management in schizencephaly patients, emphasizing the importance of further reporting to guide anesthetic management in similar future cases. This case highlights the need for individualized anesthetic plans. interdisciplinary collaboration among neurology, anesthesiology, and obstetrics.

Reference:

Halabuda, A. et al.(2015) Childs nerv syst,31(4), 551-556.

Learning points: Schizencephaly is an anesthetic challenge due to its rarity and should be managed multidisciplinary. Patient preferences should be prioritized.

21AP03-9

Right atrial angiosarcoma in a pregnant patient: a rare and complex anesthetic challenge during cesarean delivery

C. Guimarães¹, M. Santos¹, C. Almeida¹ ¹Unidade Local de Saúde de São João, EPE, Anesthesiology, Porto, Portugal

Background: Cardiac tumors during pregnancy are extremely rare diagnoses. Right atrial tumors can cause right atrial enlargement, arrhythmias, functional tricuspid stenosis, and right heart failure due to intracardiac obstruction, presenting challenges during positioning, anesthesia, and surgery1.

Careful planning is essential considering oncological care alongside maternal-fetal safety. Epidural blockade is beneficial for maintaining effective surgical conditions and analgesia, allowing for incremental administration of local anesthetics.

This approach may reduce the speed of onset and extent of sympathectomy, minimizing hemodynamic changes and facilitating compensatory interventions, especially vital for pregnant patients with cardiopulmonary risks.

Case Report: A 39-year-old woman at 32 weeks gestation presented with two weeks of retrosternal pain, dyspnea, and lipothymia. She was tachycardic but normotensive. An echocardiogram was performed due to suspected pulmonary thromboembolism, revealing a large pericardial effusion, prompting urgent pericardiocentesis. Persistent chest pain on day two led to a repeat echocardiogram, which identified two right atrial masses with no obstruction to venous return.

After completing antenatal corticosteroid therapy, she was scheduled for elective cesarean delivery. An epidural block was performed at the L3-L4 level using 10 mL of 0.75% ropivacaine. Standard ASA monitoring and an arterial line in the left radial arterv were established.

The surgery was uneventful, resulting in a successful delivery. The epidural catheter was removed postoperatively to facilitate anticoagulation therapy. Subsequent evaluations confirmed a diagnosis of right atrial angiosarcoma.

Discussion: Data on cardiac angiosarcoma in pregnancy are primarily case reports1. The epidural blockade in this case limited systemic drug exposure while providing effective pain control during cesarean delivery. This case demonstrates the importance of a multidisciplinary approach and highlights appropriate anesthetic techniques in such complex scenarios.

Learning points: Managing a pregnant patient with cardiac tumors necessitates a tailored anesthetic approach, with regional anesthesia being a valuable alternative.

21AP03-10

High-risk pregnancy: multidisciplinary management of severe aortic insufficiency – a case report

G. Lemos Rodrigues Freitas Pinto¹, M.I. Silva Carvalho¹, A. Milheiro¹, S. Alves², F. Rodrigues¹ ¹Unidade Local de Saúde Gaia e Espinho, Department of Anesthesiology, Vila Nova de Gaia, Portugal, ²Unidade Local de Saúde Gaia e Espinho, Department Anesthesiology, Vila Nova de Gaia, Portugal

Background: Valvular heart disease in pregnancy poses significant risks to maternal and fetal health. Management requires a multidisciplinary approach involving precise diagnosis, disease severity assessment, and individualized strategies during pregnancy, labor, and the postpartum period, when complications are most likelv1,2.

Case Report: A 40-year-old woman with severe aortic insufficiency was admitted at 38 weeks and 4 days for labor induction. Cardiology evaluation confirmed no contraindication for vaginal delivery, as criteria such as an aortic diameter >45 mm, severe aortic stenosis, or significant heart failure were absent. Epidural analgesia was initiated with ropivacaine 0.2% (12 mg) and sufentanil (10 mcg), alongside invasive arterial monitoring to ensure hemodynamic stability. Protracted labor and maternal factors necessitated a cesarean section. After weighing the risks of her cardiac condition, epidural anesthesia with ropivacaine 0.75% (75 mg) was administered. Postoperatively, the patient was monitored in the post-anesthetic care unit for 48 hours for signs of cardiac decompensation. She was discharged in stable condition without complications.

Discussion: Severe aortic insufficiency during pregnancy requires careful management due to hemodynamic fluctuations during labor3. Epidural anesthesia provided effective analgesia and hemodynamic control, while invasive monitoring ensured stability. Postpartum monitoring was essential, as this period carries a heightened risk of cardiac decompensation. This case highlights the importance of individualized anesthetic strategies and coordinated multidisciplinary care in high-risk pregnancies with significant cardiac conditions.

References:

- 1. Ducas RA et al. Pregnancy outcomes in women with significant valve disease: a systematic review and meta-analysis. Heart. 2020.
- 2. Mulder BJM et al. Valvular heart disease in pregnancy. N Engl
- 3. Regitz-Zagrosek V et al. 2018 ESC Guidelines for the management of cardiovascular diseases during pregnancy. Eur Heart J. 2018.

Learning points: The rising maternal age and prevalence of comorbidities add complexity to managing high-risk pregnancies. Specialized training in invasive hemodynamic monitoring and a multidisciplinary approach within the labor and delivery unit are essential to optimize outcomes for pregnancies complicated by severe cardiac conditions.

21AP03-11

Peripartum anesthesia management in high-risk pregnancy after heart transplant: mother and child are doing well!

D. Rosenberger¹, C. Lichnog¹ ¹University of Zürich, Anaesthesiology, Zürich, Switzerland

Background: A growing number of female heart transplant recipients is at childbearing age. Pregnancy is considered an immune system sensitizing period and associated with transplant rejection and heart failure.

Multidisciplinary planning is critical for these high-risk pregnancies and anaesthesiologists play a key role in the peripartum period. (1)

Case Report: 32-year-old G2P1, 36 weeks of gestation, status post heart transplant in 2010. First line antirejection medication (ARM) - mycophenolate, cyclosporine, prednisone- was stopped in 2019 and azathioprine initiated after pre-conception counselling. First pregnancy in 2021 was uneventful, however ARM was continued with azathioprine.

The patient's second pregnancy was complicated by heart failure (NYHA III), arrhythmia (epicardial pacemaker since 2010) and therefore suspected rejection. After maximizing heart failure therapy, decision was made to deliver with caesarean section (CS) at 36 weeks in May 2024.

CS was safely performed in spinal anaesthesia, involved invasive arterial blood pressure monitoring, external defibrillation pads, frequent transthoracic echo exams in the peripartum period and biomarker monitoring (NTproBNP).

A cardiac biopsy was negative for rejection and heart failure and arrhythmia improved over time.

Discussion: Second pregnancy after heart transplantation with long-term cessation of standard ARMs is considered high-risk (mWHO classes II-III). Risk of rejection, graft arteriosclerosis are higher with second line ARM, first line ARM pose teratogenic risks, leading to higher miscarriage rates.

Maternal cardiovascular disease is associated with significant maternal-fetal morbidity. However, two-thirds of pregnancies in heart transplant recipients according to large registries have

This case highlights the importance of a multidisciplinary approach, developing a plan, educating the patient and their families. Participation in international registries, further research and guidelines are needed to support these high-risk patients effectively.2,3

- 2. J of Heart Lung Transplant 2020 39(5): Pregnancy outcomes in heart transplant recipients
- 3. JACC Heart Fail 2023(4): Maternal and Pregnancy Outcomes Following Heart Transplantation

Learning points: This case presents perioperative anaesthesia management in a high-risk pregnancy after heart transplantation.

21AP03-12

Effect of transversus abdominis plane block in cesarean section on platelet/lymphocyte ratio

B. Okutan Kaya¹, E.A. Ayyildiz¹, A.S. Şahin¹ ¹Kanuni Sultan Suleiman Training and Research Hospital, Anesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Postoperative pain is associated with tissue trauma and release of inflammatory mediators. The proinflammatory cytokine response due to the surgical stress: causes postoperative pain, increased opioid use, delay in healing and prolongation in recovery time. Platelet/lymphocyte ratio is one of the markers of inflammatory stress response. Transversus abdominis plane (TAP) block is one of the abdominal blocks commonly used in the treatment of acute postoperative pain for lower abdominal surgery.

Our aim was to show the effect of TAP block on postoperative pain, therefore on platelet/lymphocyte ratio.

Materials and Methods: Between January 1st and November 1st 2023, female patients between the ages of 18-45 who were classified as American Society of Anesthesiology (ASA) I-II-III and underwent cesarean section (CS) were included to the study.

After reviewing the data of a total number of 62 patients, it was found that transversus abdominis plane block had been applied to 30 patients.

Age, comorbid diseases, Visual Analog Scale (VAS) scores at 6th-12th-24th. hours postoperatively, platelet/lymphocyte ratios, pre and perioperative arterial blood pressures, heart rates and oxygen saturations were reviewed.

Results and Discussion: No statistically significant difference was found in terms of VAS scores at the 6th, 12th and 24th hours (p>0,05). Time to first postoperative analgesic need was significantly shorter in the no block group (p< 0.001). But, no statistically significant difference was found in terms of platelet/lymphocyte ratio (p>0.05).

Our results on platelet/lymphocyte ratio may be due to the fact that the minimally invasive intervention performed during the block may have increased the inflammation, albeit locally.

Conclusion(s): TAP block performed after CS, is a practical analgesia method with a low side effect profile which is safe for both mother and baby.

Although our results did not show the effect of TAP block on inflammatory stress response, this study will shed light on studies to be conducted in larger groups in order to reduce the use of analgesic agents and related complications.

21AP04-1

Determination of optimal dose of intrathecal morphine for postoperative analgesia after cesarian section using up & down sequential allocation

D. Oikonomou¹, A. Karakosta¹, G. Micha¹, E. Samara¹, C. Ntagkas¹, P. Tzimas¹ ¹University of Ioannina, Medical School, Ioannina, Greece

Background and Goal of Study: Neuraxial blocks are the gold standard in obstetric anesthesia, particularly in cesarean section (CS), which can lead to significant postoperative pain when undertreated. Intrathecal administration of opioids is effective for postoperative pain, allowing lower doses while reducing side effects. Subarachnoid morphine provides prolonged analgesic effects, lasting 18 to 24 hours after administration.

This study aims to investigate the optimal dose of intrathecal morphine in healthy parturients undergoing CS, with the primary goal of assessing effective analgesia (Numerical Rating Scale/ NRS ≤3/10) for at least 12 hours post-administration.

Materials and Methods: We present the preliminary results of a prospective, non-randomized, double-blind trial where a fixed dose of fentanyl and a variable dose of ropivacaine, along with morphine is administered. Morphine dose is determined by a sequential allocation algorithm based on the previous participant's analgesic response. Successful analgesia is defined as a NRS≤3 for at least 12 hours post-injection. If analgesia is successful, the morphine dose for the next participant is decreased by 20mcg; if unsuccessful, it is increased by 40mcg.

All parturients receive the same multimodal analgetic regimen postoperatively, including paracetamol and nonsteroidal anti-inflammatory drugs (NSAIDs).

Results and Discussion: Forty-two ASA II term parturients scheduled for elective CS under spinal anesthesia were included. The first patient was assigned 100mg dose of intrathecal morphine, based on common clinical practice. In our cohort, the lowest dose of morphine was 20 mcg, and the highest dose was 140mcg. Postoperative pain and adverse effects were monitored for 24 hours. No major adverse effects were observed. Most of the participants reported high levels of satisfaction.

Centered Isotonic Regression (CIR) was applied to the dose response data for ED50 determination. All tests were two-tailed and statistical significance was established at 5% (p<0.05). In our cohort, the median effective dose of intrathecal morphine (ED50) was 40mcg with a 90%C.I. (0-67.08).

Conclusion(s): Low doses of intrathecal morphine seem to be an effective approach for postoperative analgesia after CS, minimizing side effects associated with opioids.

21AP04-2

Impact of cesarean section decision-to-delivery intervals on neonatal outcomes: a prospective audit

V. Katerenchuk¹, R. Dos Santos Carvalho², A. Calçada¹, A. Correia Batista¹, A. Capelão¹, I. Ferreira¹ ¹Unidade Local de Saúde da Arrábida, Anaesthesiology, Setúbal, Portugal, ²Unidade Local de Saúde da Arrábida, Pediatrics, Setúbal, Portugal

Background and Goal of Study: Adherence to decision-to-delivery (DDI) recommended intervals for Grade 1 and 2 cesarean sections is a cornerstone of safety in Obstetric Anesthesiology (1). The primary objectives of this study were to audit DDI times for Grade 1 and 2 cesarean sections and assess their association with neonatal outcomes in a district hospital in Portugal.

Materials and Methods: A prospective audit was conducted, including all pregnant women undergoing cesarean sections during August and September of 2023. Using electronic medical records, the DDI intervals for Grade 1 and 2 cesarean sections were reviewed, along with neonatal outcomes, specifically Apgar scores, need for resuscitation, presence of laboratory markers of asphyxia, requirement for admission to the Neonatal Special Care Unit, and complications identified at 1 year.

Results and Discussion: During the audit period, 50 cesarean sections were performed, of which 11 were classified as Grade 1 or 2 (22%). Among these, 3 (27%) were Grade 1 cesarean sections. DDI intervals for Grade 1 and 2 cesarean sections adhered to national and international guidelines in 82% of cases (1,2). The most commonly used anesthetic technique was balanced general anesthesia (45%), and the most frequent indication for cesarean section was non-reassuring cardiotocography (55%). The lowest 1-minute Apgar score (1) was observed in the only Grade 1 cesarean section that did not meet the recommended DDI. For all other cases, the 1-minute Apgar score was ≥8. Among the three neonates requiring resuscitation (all with Apgar scores <8), the stipulated DDI interval was met in two cases. In this sample, no admissions to the Neonatal Special Care Unit or complications at 1 year were reported.

Conclusion(s): The key findings from this audit are:

- 1. DDI intervals partially meet national and international targets, highlighting the need for improvement.
- 2. In Grade 1 cesarean sections, failure to meet the stipulated DDI time was associated with a low 1-minute Apgar score, although recovery to a score of 8 was observed by the 5th minute.
- 3. The absence of long-term complications, even among the three neonates requiring neonatal resuscitation.

21AP04-3

Beyond bleeding: managing hyperthermia in post-cesarean misoprostol use, two case reports

A. Amorim¹, L. Neuparth², L. Gaudêncio³, P. Santos³, M.d.L. Castro³

¹Instituto Português de Oncologia Francisco Gentil, Anesthesiology Department, Lisboa, Portugal, 2Hospital Central do Funchal, Anesthesiology Department, Funchal, Portugal, 3ULS São José, Anesthesiology Department, Lisboa, Portugal

Background: Misoprostol is commonly used for postpartum hemorrhage (PPH). While fever is a well known side effect of misoprostol1, severe hyperthermia with altered mental status is a rare but potentially fatal complication associated with its administration2. We report two cases of hyperthermia after misoprostol administration, to enhance awareness of this potential adverse effect and promote safer clinical practices.

Case Report: We report two cases, a 30 year old and a 34 year old women with no significant medical history. To achieve proper uterine contraction in the setting of PPH, sublingual misoprostol was administered (800 mcg in the first case, 600mcg in the second). Hours later, both developed a clinical tetrad of altered mental status, tachycardia (160-170 bpm), shivering and high temperature (41°C - 42°C measured transtympanic).

Immediate interventions included active cooling measures and intravenous administration of paracetamol and benzodiazepine (10mg diazepam and 3mg midazolam, respectively=. One case was refractory to these measures and required sedation, intubation and ICU transfer for advance care; the other resolved after further administration of IV methamizole, bicarbonate (due to metabolic acidosis in arterial blood gas) and dantrolene. Both patients made a full recovery within 24 hours and were discharged home safely on postpartum day 3.

Discussion: Severe hyperthermia with altered mental status is a major adverse effect of misoprostol. Sublingual and oral administration, compared to vaginal or rectal routes, are preferable but carry a higher risk due to rapid absorption and elevated peak plasma concentrations. Genetic predisposition may be associated with increased susceptibility. Prompt recognition and management of hyperthermia is critical, with dantrolene being a potential option when conventional treatment such as active cooling, antipyretics, and benzodiazepines are ineffective.

References:

- 1. León W, et al.; Dose and Side Effects of Sublingual Misoprostol for Treatment of Postpartum Hemorrhage: What Difference Do They Make?; BMC Pregnancy and Childbirth. 2012
- 2. Kaiser J, et al.; Profound hyperthermia after postpartum rectal misoprostol administration; Obstetrics and Gynecology; 2016

Learning points:

- Enhanced awareness and early recognition of severe hyperthermia can improve patient safety and outcomes
- Supportive care, including antipyretics and active cooling measures, is key in managing misoprostol-induced hyperthermia.

21AP04-4

Evaluation and experience on the application of the internal guideline of walking epidurals in a regional hospital in Barcelona

A. Saenz¹, M. Martínez García¹, C. Manzano Martín¹. A. Massó Giménez-Salinas¹, C. Savuc¹, I. Carreras Auger¹ ¹Consorci Sanitari de Terrassa, Anesthesiology, Barcelona, Spain

Background and Goal of Study: Epidural analgesia is the most effective pain management method during childbirth. However, it has well known secondary effects associated with local anesthetic concentration, such as lower-body motor blockade. A new low-dose approach known as walking epidural (WE) allows patients to move. Studies suggest adopting different positions is beneficial during labor and could even help delivery. WHO and the Spanish Ministry of Health encourage these patients to adopt positions that provide them with the most benefit and comfort. Our hospital developed its own guideline for WE, detailing considerations for appliance and register. The aim of this study was to determine the frequency of WE in our hospital, as well as to summarize population and procedure characteristics and to evaluate quideline compliance.

Materials and Methods: Descriptive data study of patients who underwent WE in our hospital from October 2023 to September 2024. A checklist was applied to verify guideline compliance based on patient assessment, procedures registration and midwife availability. All patients signed informed consent.

Results: 36 WE were registered, 0 - 5 per week, accounting for 4,5% of all deliveries under epidural analgesia for a year. The mean data for age was 33 years old (ages 20-40), 39 weeks gestational age, mostly primigravidae and a mean BMI of 29,1. They requested WE technique at 4 cm of cervical dilation. 22% of cases delivered at WE dose, while the rest required change to conventional doses. A mean of 4 bolus were administered at WE dose in both instances. During this period, 72% of patients changed position, walked or used a ball. 73% of cases were properly registered, complying all checklist items. Of the remaining cases, >60% of items were registered and only lacked motor blockade notes.

Conclusions: Walking epidurals are gaining popularity due to their benefits. Larger centers are not usually able to carry them out due to resource limitations. While epidural analgesia is commonly performed in our regional hospital, WE is still not frequent but it is on the rise. Some improvements need to be made regarding proper registration, through better tools, to provide the best possible care. Patient satisfaction could be included in future evaluation as a quality parameter.

Vaginal delivery in the context of acute aortic dissection: A case report

G. Simó Pons¹, A. Colom Jornet¹, N. Margarit Estragués¹, M. Rodriguez Cornet¹, M. Lamora Tost¹, N. Poch Vall¹ ¹Hospital Mutua de Terrassa, Anesthesiology, Terrassa, Spain

Background: Acute aortic dissection during pregnancy is a rare but life-threatening complication1 often overlooked due to symptom overlap with obstetric conditions. This case highlights the anesthetic and multidisciplinary challenges of managing an undiagnosed type A agrtic dissection during vaginal delivery.

Case Report: A 34-year-old secundipara at 35.2 weeks of gestation presented with four days of persistent left parasternal chest pain radiating to the back, worsened by deep breathing and accompanied by low-grade fever. Initially discharged from another hospital with negative findings, her symptoms persisted. On admission, she was hemodynamically stable, with leukocytosis, elevated D-dimer, and unremarkable imaging and ECG findings. Chorioamnionitis was suspected, and empirical antibiotics were started alongside labor induction. Despite epidural analgesia with low-concentration levobupivacaine (0.125%), she experienced two hypotensive episodes, which were managed with fluids and prompt phenylephrine bolus. After vaginal delivery, persistent chest pain and hypotension prompted further evaluation. Interarm blood pressure differences (95/50 mmHg vs. 125/75 mmHg) and asymmetrical pulses led to a postpartum CT angiogram, confirming a type A aortic dissection involving the ascending aorta. Emergency Bentall surgery was performed, and the patient recovered uneventfully.

Discussion: Pregnancy-induced hemodynamic changes increase the risk of aortic dissection², particularly in the third trimester, and are further heightened in individuals with underlying conditions such as Marfan syndrome. While cesarean delivery is typically preferred in such cases, epidural analgesia and phenylephrine successfully stabilized maternal and fetal hemodynamics in this scenario, enabling a safe vaginal delivery.

References:

1. Yuan SM. Clinical Features and Outcomes of Pregnancy-Related Acute Aortic Dissection. JAMA Cardiol. 2020;5(9):1051 De Martino A, et al. Acute Aortic Dissection and Pregnancy: A Meta-Analysis. J Card Surg. 2019;34(11):1591

Learning points: Delayed diagnosis, attributed to atypical symptoms and imaging challenges, underscores the importance of considering aortic dissection in pregnant patients with persistent chest pain. Multidisciplinary collaboration and prompt diagnosis are essential for managing this rare condition. Epidural analgesia and vasopressors can stabilize hemodynamics, making vaginal delivery a viable option in carefully selected cases.

21AP04-6

Imaging strategies for diagnosing aortic dissection in pregnant women: A systematic review of current evidence

A. Colom Jornet¹, G. Simó Pons¹, M. Rodriguez Cornet¹, M. Lamora Tost¹, N. Poch Vall¹, N. Margarit Estragués¹ ¹Hospital Mutua de Terrassa, Anesthesiology, Terrassa, Spain

Background and Goal of Study: Aortic dissection (AD) during pregnancy is rare but life-threatening, requiring immediate diagnosis to guide treatment. In the third trimester and labor, delays often stem from concerns about fetal radiation exposure, imaging logistics, and overlapping symptoms with obstetric conditions. This review evaluates diagnostic modalities for AD in pregnancy. focusing on safety, accuracy, and feasibility in emergencies.

Materials and Methods: A systematic review was conducted across MEDLINE, Embase, Cochrane Library, and SCOPUS, targeting studies published up to November 2024. Search terms included "Pregnant women," "Aortic dissection," "CT angiography," "MRI," "Echocardiography," and "Fetal radiation exposure." Articles on third-trimester or labor-related protocols were criti-

cally appraised, excluding duplicates and low-quality data.

Results and Discussion: CT angiography (CTA) is the gold standard, with sensitivity and specificity exceeding 95%. Radiation doses (0.01-0.66 mGy) are considered safe for the fetus when beam collimation and shielding are applied. Transthoracic echocardiography (TTE) offers rapid bedside assessment but is operator-dependent and limited for the ascending aorta. Transesophageal echocardiography (TEE) provides superior resolution but requires sedation, complicating use during labor. MRI, though radiation-free and accurate, is less accessible in emergencies due to cost and imaging time. CTA is optimal in acute settings, balancing speed and diagnostic accuracy, while TTE is valuable for initial triage. The lack of standardized protocols contributes to variability in diagnostic approaches, emphasizing the need for tailored strategies.

Conclusion: Early and accurate diagnosis of AD is crucial to prevent severe complications. CTA with beam collimation and appropriate imaging parameters to reduce radiation dose while maintaining adequate image quality may be the most popular modality in emergencies.

Future efforts should focus on developing standardized, pregnancy-specific diagnostic protocols that balance clinical urgency, imaging availability, and safety.

21AP04-7

Peripartum anesthetic management in a patient with C1 inhibitor deficiency hereditary angioedema

M. Pereira¹, J. Carvalhas¹, M. Azenha¹, P. Gomes¹, R. Sotto Mayor¹

¹Unidade Local de Saúde de Coimbra, Anesthesiology department, Coimbra, Portugal

Background: Hereditary angioedema (HAE) is a rare genetic disorder leading to recurrent episodes of swelling. Pregnancy can exacerbate HAE due to estrogen fluctuations, peripartum stress and trauma. We are reporting the peripartum anesthetic management of a patient with HAE due to C1 inhibitor deficiency who underwent labor induction and vaginal delivery with neuraxial analgesia.

Case Report: A 42-year-old patient G2P0 presented to an anesthetic consultation at 36 weeks of gestation with the diagnosis of C1 inhibitor deficiency HAE. Her known triggers were cold exposure, capsaicin, and surgical procedures. During pregnancy, she did not require HAE-specific medication and remained symptom free. She presented predominantly with abdominal crises exacerbated by invasive procedures, including fertility treatments despite prophylactic C1 inhibitor concentrate administration.

After a multidisciplinary meeting involving obstetrics, anesthesiology, and immunoallergology, labor induction at 39 weeks was planned, targeting vaginal delivery with early epidural analgesia. Prophylactic 1000U of C1 esterase inhibitor concentrate was administered prior to labor induction and difficult airway equipment was prepared and nearby throughout her hospital stay.

Vaginal delivery was complicated by fetal distress, requiring obstetric assistance and neonatal resuscitation. Both mother and baby were discharged 5 days later without further complications. **Discussion:** Pregnancy and labour's impact on HAE is variable. with no universally preferred mode of delivery. However, international guidelines report that 90% of births in HAE patients are vaginal.2 The C1 inhibitor deficiency subtype attacks are not caused by histamine and are therefore not responsive to antihistaminic or corticoids. First-line treatment involves C1 esterase inhibitor concentrate, also used prophylactically in high-risk situations. Neuraxial analgesia helps control potential triggers of acute angioedema during delivery. In this case, vaginal delivery was well-tolerated, with no acute angioedema episodes.3

- 2. J Allergy Clin Immunol. 2012;129:308-320.
- 3. J Allergy Clin Immunol. 2004;114:S51-S131

Learning points: Tailored multidisciplinary planning and proactive anesthetic strategies are required in managing pregnant patients with HAE.

21AP04-9

Bronchial artery embolization during pregnancy: an unusual multidisciplinary challenge - case

S. Faria¹, T. Sousa Branca¹, M. Martins¹ ¹Unidade Local de Saúde de Vila Nova de Gaia e Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: Interventional radiology (IR) has an established role in managing conditions and complications in pregnancy 1.

Non-obstetric procedures in pregnancy are a great challenge to anesthesia due to its physiological changes and risks to mother and fetus safety 2.

Case Report: A 30-year-old female, American Society of Anesthesiology (ASA) physical status III, 28 weeks and 1 day pregnant, had a history of alpha-1 antitrypsin deficiency, complicated by frequent hemoptysis due to varicose bronchial ectasia. Due to risk of worsening during labor, elective pre-delivery embolization was decided.

The procedure was planned by the Radiology, Anesthesia and Obstetrics (OB) team with support from the Hospital Physicist and was performed in left lateral decubitus position under monitored anesthesia care with ASA standard monitoring.

To minimize fetal radiation exposure, we used low-dose pulsed fluoroscopy, reduced the number of digital subtraction angiograms, limited the imaging range, and applied digital zoom for clearer images without increasing radiation.

Fetal well-being was confirmed by the OB team before and after the procedure.

The interventional radiology team successfully performed the angiographic embolization through a femoral artery puncture with no complications.

Discussion: Special considerations concerning radiation exposure, drugs for anesthesia, contrast, and timing of IR interventions must be taken 1.

Anesthetist is an advocate of fetus and maternal safety by avoiding potentially harmful drugs, ensuring proper uteroplacental perfusion and preventing or managing preterm labor and delivery2. In case of radiation use, it is adamant a multidisciplinary discussion to optimize iodine contrast and radiation dosing and minimize maternal and fetal exposure, which must be monitored and recorded 1,2. In procedures outside the abdomen/pelvis, the use of a lead shield is currently questioned 1.

References:

- 2. Van De Velde M, De Buck F. (2007). Anesthesia for non-obstetric surgery in the pregnant patient. Minerva Anestesiol, 73(4), 235-240.

Learning points: IR procedures during pregnancy are associated with specific challenges. Close collaboration among anesthesiologists, OB/GYN, and interventional radiologists ensures the best outcomes for both mother and fetus.

21AP04-10

A balancing act: Anesthetic management for aortic dissection in a pregnant patient

M. Santos¹, M.C. Mendes de Vasconcelos Carvalho Guimarães 1, C. Almeida1 ¹Centro Hospitalar Universitário de São João, Anaesthesiology, Porto, Portugal

Background: Aortic dissection in pregnancy is a rare but critical emergency requiring urgent surgical intervention. Physiological changes in pregnancy increase the risk of maternal and fetal morbidity (1). Anesthetic management in these cases is complex and demands meticulous planning.

Case Report: A 35-year-old pregnant woman, with chronic hypertension and an MYH11 gene mutation, was admitted at 34 weeks gestation due to decreased fetal movements and hypertension. She experienced sudden severe chest pain and syncope, leading to the diagnosis of aortic dissection. Upon admission, her hemodynamic instability necessitated urgent transfer to a tertiary care center for cesarean delivery and cardiothoracic surgery. Continuous infusions of labetalol and isosorbide dinitrate were used to manage blood pressure, with fentanyl for acute pain relief. At the surgical site, she was conscious, stable, and had a normal neurological exam. Rapid sequence induction with propofol and remifentanil preceded an urgent C-section, resulting in the birth of a healthy male infant. Post-delivery, the focus was on repairing the ascending aorta while maintaining hemodynamic stability. NIRS monitoring confirmed adequate cerebral perfusion, and procedures utilized total intravenous anesthesia.

Despite successful surgery, including 99 minutes of aorta clamping and resuscitation with noradrenaline, dobutamine, and plasma, the patient was unresponsive on postoperative day one. Neurological imaging indicated extensive brain ischemia, resulting in brain death on day three. The neonate was discharged without complications.

Discussion: This case underscores the importance of anesthetic management in high-risk cardiovascular surgeries during pregnancy. Effective monitoring and medication adjustments are critical to balancing maternal stability and fetal safety.

1. Regitz-Zagrosek V, et al. 2018 ESC Guidelines for the management of cardiovascular diseases during pregnancy. Eur Heart J 2018;39:3165-241. doi:10.1093/eurheartj/ehy340

Learning points: Anesthesiologists must navigate the complexities of emergent surgery in pregnant patients, focusing on neuroprotection and hemodynamic stability. A multidisciplinary approach improves outcomes, though significant risks persist in such high-stakes situations.

21AP04-11 **EBUS-TBNA** in pregnancy: Is airway topicalization the key?

G.L.R. Freitas Pinto¹, S.J. Santos Faria¹, F. Gouveia¹ ¹Unidade Local de Saúde Gaia e Espinho, Department of Anesthesiology, Vila Nova de Gaia, Portugal

Background: Anesthetic management for endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA) in pregnancy presents significant challenges due to physiological changes. altered feto-maternal pharmacokinetics, procedural limitations particularly regarding airway access - and the complexity of performing anesthesia outside the operating room¹.

Case Report: A 28-year-old primigravida at 16 weeks of gestation was referred for urgent EBUS-TBNA due to suspicious mediastinal lymphadenopathy, presenting mild dyspnea but no signs of airway obstruction.

Following a multidisciplinary discussion, general anesthesia was selected as the preferred approach. Obstetric evaluation confirmed normal fetal well-being both pre- and post-procedure. Standard American Society of Anesthesiologists monitoring was applied, and aspiration prophylaxis was administered. Airway topicalizationwas achieved using 10 mL of 2% lidocaine delivered via MADgic®.

Total intravenous anesthesia was induced with target-controlled infusion of Propofol 1%, alongside Lidocaine 1 mg/kg and Rocuronium 1 mg/kg. A size 4 AuraGain™ laryngeal maskairway (LMA) was inserted, with subsequent gastric aspiration revealing nocontents. An additional 5 mL of 2% lidocaine was instilled through the EBUS bronchoscope to enhance airwaytopicalization.

The procedure was completed without complications, and fetalwell-being was preserved throughout. No opioids were administered during the procedure.

Discussion: Performing EBUS-TBNA in pregnant patients presents unique challenges, including airway narrowing, hypoxia, and increased aspiration risk, particularly in later trimesters. However, evidence supports the safe use of a laryngeal mask airway with careful management. Adequate airway topicalization minimizes reflexes and reduces opioid use, enhancing maternal comfort and

With no established anesthesia protocols for pregnant patients, management must prioritize fetal outcomes while addressing risks like prematurity and neonatal complications. A multidisciplinary approach is critical to ensuring the safety of both mother and child throughout the procedure.

Reference:

1. Becker, C. https://doi.org/10.1186/s12871-024-02551-4

Learning points: Laryngeal masks can offer safe airway management for transbronchial biopsy in pregnancy with careful anesthesia, fetal monitoring, and multidisciplinary coordination.

Effective airway topicalization minimizes opioid use, enhancing maternal and fetal safety.

Respiratory distress following spinal anesthesia for cesarean section: a case report

R. Toipa Lopes¹, <u>A.C. Segundo</u>¹, N. Carrillo-Alfonso¹, P. Silva¹, A. Lares¹

¹Unidade Local de Saúde do Algarve - Unidade de Faro, Dept of Anaesthesiology, Faro, Portugal

Background: Neuraxial techniques are the method of choice for cesarean section (CS). During pregnancy, the risk of cephalic spread of the local anesthetic increases leading to a total spinal anesthesia. The symptoms include an ascending sympathetic, sensory and motor block with associated bradycardia, hypotension, dyspnea and loss of conscience.

Case Report: A 40-week pregnant woman, 22 years old, ASA II (gravida and smoker) admitted to the hospital for labor induction. The pregnancy went uneventful. An epidural catheter was placed with an infusion of ropivacaine with sufficient analgesic control. After ten hours, the patient began to complain of back pain with pelvic irradiation. An epidural bolus was given with ropivacaine 2mg/mL and fentanyl 50mcg, which had no effect. An urgent CS was scheduled for the indication of cephalopelvic disproportion. There was no fetal discomfort.

Under ASA standard monitoring, the epidural catheter was removed on suspicion of displacement. A spinal anesthesia was performed with hyperbaric bupivacaine 10mg, fentanyl 15mcg and morphine 80mcg that were slowly injected. The patient was placed in a supine with a slight Trendelenburg. The subsequent mean blood pressure measurements were above 65 mmHg.

The patient started with slurred speech, chest heaviness and difficulty breathing, Ventilation was assisted with 100% oxygen via facemask. There was no desaturation.

After the fetus was delivered uneventfully, a rapid induction sequence and endotracheal intubation were performed without complications. The patient remained hemodynamically stable until the end of the procedure. The patient was transferred to intensive care unit for vigilance and after 2 hours was extubated uneventfully.

Two days after, she was discharged home without any neurological or clinical sequelae.

Discussion: Respiratory distress without hemodynamic instability following spinal anesthesia is uncommon, but it should be considered.

There are case reports in the literature describing total spinal anesthesia without the ascending progression of symptoms. When recognized, supportive treatment, especially airway management, is needed until the patient regains full motor function.

References:

Cureus 15(1): e34198. doi:10.7759/cureus.34198 BMJ Publishing Group Ltd; 2021. p. A30.2-A30.

Learning points: Total spinal anesthesia could present with nontypical clinical progression. Anesthesiologists must be aware of its symptoms and act to ensure the patients safety.

21AP05-1

Successful intrapartum management of Brugada syndrome: A case of safe labor and delivery – A case report

A. De Oliveira¹, C. Cunha da Silva¹, <u>C. Marques¹</u>, J. Dias¹, S. Santos Rodrigues¹

¹Hospital Senhora da Oliveira Guimarães - Unidade Local de Saude do Alto Ave, Serviço de Anestesiologia, Guimarães. Portugal

Background: Brugada syndrome (BS) is an autosomal dominant arrhythmic disorder characterized by an increased risk of ventricular fibrillation and sudden cardiac death in individuals with structurally normal hearts.¹

Labor and delivery in patients with this condition present unique challenges.¹²

We report a successful case of intrapartum care management in a pregnant with BS.

Case Report: A 26-year-old primigravida with BS, a positive family history, a positive ajmaline test, with an implantable cardioverter-defibrillator (ICD) in place and a negative genetic test. She has a history of cardioinhibitory reflex syncope's, but her pregnancy was uneventful.

A pre-anesthetic consultation was held to discuss the risks and potential adverse effects of her condition. At 39 weeks and 4 days of gestation, she presented to the obstetrics department in spontaneous labor.

Epidural analgesia was administered, and the patient was continuously monitored with ECG, oxygen saturation, and noninvasive blood pressure. An initial dose of 5mL of 2% lidocaine with 10mcg of sufentanyl was given without any changes in ECG, heart rate, or blood pressure. Labor progressed favorably, requiring three additional doses of 10mL of 0.1% ropivacaine at ~1-h intervals.

A healthy male neonate was delivered spontaneously 3h after the initiation of epidural analgesia. No hypotension or cardiac arrhythmias were observed during labor.

In accordance with institutional protocol, the patient was monitored for 24h postpartum in the high-care unit, where no arrhythmic events were recorded.

Discussion: BS presents unique challenges during labor, and delivery, primarily due to the increased risk of arrhythmias and sudden cardiac death. In this case, epidural analgesia was effectively used without triggering arrhythmic events, demonstrating its safety for patients with this condition.

References:

Learning points: This case highlights a multidisciplinary approach to intrapartum care in a patient with maternal BS, emphasizing tailored strategies to ensure maternal and fetal safety.

21AP05-2

Cesarean section anesthesia management under thromboelastography in a patient with Glanzmann thrombasthenia

H.N. Günay¹, H. Taspinar¹, R. Yilmaz¹, S. Arican¹, R. Reisli¹, A. Yosunkaya1

¹Necmettin Erbakan University Faculty of Medicine. Anesthesiology and Reanimation, Konya, Turkey

Background: Glanzmann thrombasthenia (GT) is a rare autosomal recessive bleeding disorder characterised by platelet aggregation disorder (1).

We aimed to share the anaesthetic management of a pregnant woman with a known diagnosis of GT with thromboelastography (TEG) guided cesarean section.

Case Report: Known diagnosis of GT and a 38 week pregnant patient with a was planned to be delivered by cesarean section. The patient had massive haematuria, gingival bleeding and haemoptysis. Laboratory parameters were Hg 11 and Plt, INR, aPTZ, PZ, fibrinogen were normal. The patient received intravenous (IV) 1 g Tranexamic acid 6 hours before surgery.

After 2 units of apheresis platelet suspension replacement, TEG was performed because spontaneous bleeding continued. In the TEG evaluation, 90 mcg/kg recombinant factor VIIa (rFVIIa) was administered to the patient in whom hypocoagulation was domi-

Afterwards, the test was repeated and TEG parameters were shown to improve. Intraoperative haemodynamics were stable and no need for blood replacement was observed.

Discussion: The basic feature of GT is the inability of platelets to bind to fibrinogen and aggregate with each other. The molecular basis is abnormality of integrin αIIbβ3 (2).

Preoperative complete blood count, PZ, aPTZ, fibrinogen should be checked and the patient's bleeding history should be guestioned. A long bleeding time and absence of platelet clustering on peripheral smear suggest GT (3).

In minor surgical procedures, bleeding may be stopped with antifibrinolytic therapies; if it cannot be stopped, platelet transfusion is the treatment (4).

It is recommended to administer antifibrinolytic treatment at least 2 hours before the surgical procedure, rFVIIa 90 mcg/kg immediately before the surgical procedure, to repeat at 2-4 hour intervals in case of prolonged surgical intervention. (3,5).

Management of Glanzmann's Thrombasthenia - Guidelines based on an expert panel consensus from gulf cooperation council countries. J Appl Hematol 2019:10:1-9

Learning points: This case demonstrated the benefit of using teg in a patient diagnosed with GT.

21AP05-3

Post-dural puncture headache versus postpartum preeclampsia: a challenging diagnosis

I. Capito¹, K. Paramés Ferreira¹, J. Duarte¹ ¹Unidade Local de Saúde Santa Maria, Anesthesiology, Lisboa, Portugal

Background: In the postpartum period, approximately 40% of the parturients experience postpartum headache. Some of the main risk factors for this condition are sleep deprivation, psychological stress, hormonal changes and the use of neuraxial techniques. Postpartum headache is caused by both benign and life-threatening conditions, and distinguishing between them can be challenging.1

Case Report: We present a 29-year-old on her postpartum day six, admitted to the emergency department due to orthostatic frontal headache, neck stiffness and nausea. She had a known history of accidental dural puncture with a 18-G Touhy needle during a combined spinal-epidural technique performed for cesarian delivery. She had no known history of preeclampsia during a well-monitored pregnancy, and her past medical history was unremarkable.

Upon admission, the blood pressure was 159/89 mmHg, though subsequent readings were within normal limits, appearing consistent with her pain and anxiety rather than a worrisome condi-

Neurologic exam was normal, with no visual disturbances, edema, epigastric pain, or other signs of preeclampsia. Laboratory screening was normal, except for proteinuria, which was initially overlooked in this characteristic post-dural puncture headache (PDPH) framework.

Conservative treatment for PDPH was initiated, with partial symptoms resolution. Six hours after admission she presented with a generalized tonic-clonic seizure. Eclampsia was suspected and magnesium sulphate started. She was admitted to the intensive care unit, where magnesium sulphate was maintained, and antihypertensive drugs initiated. Further laboratory and neuroimaging studies confirmed the diagnosis of eclampsia.

Over the following week, her condition improved, and she was subsequently discharged.

Discussion: Currently, regional anesthesia is the method of choice for providing analgesia/anesthesia in obstetrics. Since PDPH is a potential cause of postpartum headache, the anesthesiologists frequently manage these patients, whose symptoms may be identical to those of life-threatening conditions.1

Reference:

1. Winston AW, Norman D. Late postpartum eclampsia coincident with postdural puncture headache: a case report. AANA J. 2003 Oct;71(5):371-2.

Learning points: Anesthesiologists must be comfortable in diagnosing and managing postpartum headaches to effectively help reduce morbidity and mortality in these patients.

21AP05-4

Anesthetic management of severe postpartum hemorrhage in a high-risk pregnancy: A case of a 39-year-old female with Turner syndrome and cardiovascular abnormalities undergoing elective cesarean section

R.M. da Costa Graça¹, M.T. Boneco¹, F. Lança¹ ¹Unidade Local de Saúde de Santa Maria - ULSSM, Anestesiologia, Lisboa, Portugal

Background: Turner syndrome (TS) is a genetic disorder characterized by the complete or partial absence of one X chromosome and frequently associated with systemic complications, particularly cardiovascular abnormalities1.

Aortic valve replacement (AVR) is often required. Pregnancy in TS patients is high-risk, requiring multidisciplinary management.

Case Report: A 39-year-old woman with TS (ASA III), bioprosthetic AVR, ascending aortic aneurysm, and recent carotid artery dissection was scheduled for elective cesarean delivery at 37 weeks' gestation.

Key concerns included maintaining hemodynamic stability while avoiding hypertensive episodes. ASA-standard monitoring was used complemented by invasive arterial pressure monitoring.

Combined spinal-epidural anesthesia using ropivacaine and sufentanil was successfully administered. Intraoperative management was complicated by uterine atony, with estimated blood loss of 2,5L. Immediate measures included fluid resuscitation, vasopressors, and uterotonics.

Massive hemorrhage protocol was activated, with tranexamic acid administration and thromboelastography to guide blood product transfusion. Hemodynamic stability was achieved without cardiovascular-related complications.

Postoperative care included close hemodynamic monitoring. Recovery was uneventful.

Discussion: Managing parturients with TS and severe cardiovascular pathology poses unique challenges. A multidisciplinary approach is essential to address increased maternal and fetal risks. including hemodynamic and obstetric complications. Anesthesia strategies must be tailored to ensure cardiovascular stability and adequate analgesia.

Combined spinal-epidural anesthesia provided effective anesthesia for cesarean delivery, stable hemodynamics and optimal perioperative pain management. Timely activation of the massive hemorrhage protocol and advanced hemostatic tools were critical in achieving a favorable outcome2.

References:

1. Bondy, C. Pregnancy and cardiovascular risk for women with Turner syndrome. Womens Health(Lond). 2014 Jul;10(4):469-76. 2.Drew,T. et al. Major obstetric haemorrhage. BJAEducation, Volume 22(6):238-244.

Learning points: TS with cardiovascular abnormalities requires tailored obstetric anesthetic management. Anticipating and promptly managing obstetric emergencies is critical in high-risk cases. Combined spinal-epidural anesthesia is a reliable approach for cesarean delivery, ensuring hemodynamic stability in patients with cardiovascular risk.

21AP05-5

Severe preeclampsia complicated by HELLP syndrome: a case report

G. de Miguel¹, I. Castelo², N. Apodaca², G. Gutiérrez³. A. Menéndez², J. García Fernández¹ ¹H.U.Puerta de Hierro, Anesthesiologý, Majadahonda, Spain, ²H.U.Cruces, Anesthesiologý, Barakaldo, Spain, ³H. de la Sant Creu i Sant Pau, Anesthesiologý, Barcelona, Spain

Background: HELLP syndrome is a rare but severe complication of preeclampsia, with a prevalence of 0.1%-1%. Hepatic bleeding and subcapsular hematomas are infrequent, occurring in 0.9%-1.6%. The syndrome is characterized by hemolysis, elevated liver enzymes, and thrombocytopenia.

Case Report: We present a 35-year-old woman with mild asthma. diagnosed with severe preeclampsia during delivery after regular prenatal care. She presented with systolic blood pressure (SBP) >180 mmHg, headache, and epigastric pain, which resolved with analgesia.

Delivery proceeded without complications, and post-delivery, she was admitted to the ICU for management of severe preeclampsia. She was treated with magnesium sulfate and antihypertensive agents. Due to her asthma, labetalol was avoided.

After a sudden BP increase, she developed intense epigastric pain and a drop in BP to 70/40 mmHg, with anemia and a hemoglobin level of 6.8 g/dl. Urgent CT angiography revealed hepatic bleeding in segment VII, subcapsular hematoma, hemoperitoneum, and infarction in the right hepatic lobe.

She was transfused with packed red blood cells (PRBC) and fibrinogen, and embolization was performed. After the procedure, she remained stable, with blood pressure controlled with hydralazine and amlodipine.

Follow-up Doppler ultrasound and CT angiography showed no new bleeding, thrombosis or new infarct areas. Transaminases peaked at 3900 IU/L for ALT and 3500 IU/L for AST, with thrombocytopenia (platelets 50,000) and intravascular hemolysis (LDH 1500 IU/L).

These findings confirmed HELLP syndrome. After one week in the ICU, she was discharged with normalized lab values.

Discussion: HELLP syndrome is a rare but life-threatening complication of severe preeclampsia, marked by liver damage, hemolysis, and thrombocytopenia. Hepatic bleeding and subcapsular hematoma are rare but can be devastating.

Patients with severe epigastric pain or abdominal discomfort should be monitored for liver involvement. Advances in interventional procedures, like embolization, offer effective treatment.

References:

- 1. Norwitz MD PhD MBA E. Preeclampsia: Intrapartum and postpartum management and long-term prognosis
- 2. Sibai BM. HELLP syndrome (hemolysis, elevated liver enzymes, and low platelets)

Learning points: Subcapsular hematoma is a very rare complication of HELLP syndrome. Early diagnosis and timely intervention are crucial for improving outcomes. Embolization is a highly effective therapeutic alternative.

21AP05-6

Breaking new ground: Safe cesarean delivery anesthesia in a patient with Fanconi-Bickel syndrome

L. Freixo¹, V. Eckardt¹, C. Almeida¹, M. Loureiro² ¹Unidade Local de Saúde Lisboa Ocidental, Anesthesiology, Lisbon, Portugal, 2Unidade Local de Saúde Lisboa Ocidental, Obstetrics-gynecology, Lisbon, **Portugal**

Background: Fanconi-Bickel Syndrome (FBS) is a rare autosomal recessive disorder caused by GLUT2 gene mutations, impairing glucose transport. It manifests as hepatorenal glycogen accumulation, proximal renal tubular dysfunction, rickets, osteoporosis, and severe short stature. Reports on reproductive outcomes in FBS are scarce, with only two documented successful pregnan-

This case uniquely describes a tailored anesthetic strategy for cesarean delivery in an FBS patient, highlighting the challenges posed by short stature and associated comorbidities.

Case Report: An 18-year-old woman with FBS at 39 weeks gestation underwent cesarean delivery due to the risk of pelvic fractures. Her history included short stature (148 cm) and multiple renal dysfunction markers - glycosuria, proteinuria, aminoaciduria, hypercalciuria, and hypouricemia - without metabolic acidosis. A spinal anesthetic approach was chosen, using 8 mg of intrathecal hyperbaric bupivacaine, 2.5 mcg of sufentanil, and 100 mcg of morphine.

The surgery proceeded uneventfully with stable hemodynamics, minimal blood loss, and no complications during or after the procedure. The patient's recovery was smooth, meeting discharge criteria promptly.

Discussion: Managing cesarean delivery in FBS patients is complex, requiring strategies tailored to short stature and low prepregnancy BMI. Neuraxial anesthesia was preferred for its benefits, including reduced blood loss, superior postoperative pain control, and immediate maternal-infant bonding.

A reduced spinal dose accounted for anatomical factors like short vertebral column length and abdominal girth, mitigating risks of high spinal block. Intrathecal sufentanil and morphine were administered effectively without respiratory depression during hospitalization. General anesthesia was considered but avoided due to the patient's normal airway and preference for neuraxial techniques.

Due to the scarce clinical data, this case may contribute as a framework for managing similar patients, showcasing how individualized anesthetic plans can achieve successful outcomes even in challenging clinical scenarios.

Respiratory distress due to "anesthesia mumps" after emergency cesarean delivery under spinal anesthesia: a case report

E. Daku¹, R. Nallbani¹, F. Sada²

¹University of Prishtina, Department of Anesthesiology and Reanimation, Prishtine, Kosovo, ²University of Prishtina, Department of Anesthesiology and Reanimation, Prishtina, Kosovo

Background: General anesthesia due to factors like dehydration and prolonged intubation, is more often associated with "Anesthesia Mumps", but this condition following spinal anesthesia is rare. Risk factors such as inadequate hydration and underlying patient comorbidities may contribute to its occurrence in the obstetric population.

Case Report: We present a case of acute parotitis in a 44-yearold woman following an emergency cesarean section performed under spinal anesthesia. The patient, gravida 2, para 1, with a twin pregnancy at 33 weeks and 5 days, had a history of a previous cesarean section and four failed in vitro fertilization (IVF) attempts. An emergency cesarean section was indicated. Postoperatively, the patient developed acute swollen parotid gland, presenting with painful bilateral parotid swelling, this condition causes stress, mouth opening problems and respiratory distress with a drop in SpO2.

Discussion: While spinal anesthesia is less commonly associated with parotitis, this case highlights the importance of adequate perioperative hydration and vigilance in managing high-risk obstetric patients.

Additionally, rare complications such as respiratory distress underscore the need for prompt diagnosis and treatment.

References:

- 2. Günaydın B, Bağcaz S, İnan G, Tekin E, Karcaaltıncaba D. Postoperative Acute Parotitis After Cesarean Delivery Under Spinal Anaesthesia, Turk J Anaesthesiol Reanim, 2021 Apr;49(2):159-162. doi: 10.5152/TJAR.2020.405. Epub 2020 Jun 12. PMID
- 3. Jafra A, Arora S, Dwivedi D. Benign swelling of submandibular glands under general anaesthesia "anaesthesia mumps". J Clin Anesth. 2016:34:325-6.

Learning points:

- 1. Acute parotitis can occur even after spinal anesthesia, though it is rare.
- 2. Life threating respiratory distress can emerge and its need special attention.
- 3. Adequate perioperative hydration is critical in preventing complications like parotitis.

21AP05-8

HELLP syndrome in the context of massive postpartum hemorrhage: where every minute counts

Á.V. Bautista Cañas¹, E. Aguado Saster¹, A. Melero Palencia¹, R. Pérez González¹, L. Gómez Martínez¹, C. Aldecoa Álvarez Santullano¹ ¹Hospital Universitario Río Hortega, Anesthesiology and Postoperative Critical Care Unit, Valladolid, Spain

Background: This work emphasizes the importance of timely intervention in pregnant women at risk of postpartum hemorrhage (PPH), a leading cause of maternal mortality. Women with risk factors like preeclampsia, HELLP syndrome, or placenta previa are particularly vulnerable. Early identification during prenatal care allows for planned delivery in specialized centers. Swift action protects mothers from long-term consequences and enhances recovery, making prevention and management key in this obstetric emergency.

Case Report: 33-year-old primigravida after in vitro fertilization with egg donation. The patient has gestational hypertension and antiphospholipid syndrome (diagnosed due to recurrent miscarriages, treated with LMWH and ASA).

A third-trimester screening indicated high risk for preeclampsia, which was diagnosed based on positive proteinuria (protein/creatinine ratio of 0.32 mg/mg). She was admitted for a scheduled induction of labor due to SGA. After a spontaneous vaginal delivery, manual removal of the placenta was required. Subsequently, moderate vaginal bleeding escalated into massive obstetric hemorrhage.

The hospital's emergency response protocol was activated to save the patient's life and manage hemorrhagic shock (with hemoglobin dropping from 13 to 6.9). Initial stabilization included intubation, massive transfusion, administration of tranexamic acid, fibrinogen, uterotonics, and placement of a Bakri balloon, guided by blood gas analysis and Quantra.

The patient was transferred to the Intensive Care Unit. There, our patient developed HELLP syndrome in the first hours of admission (platelets 25,000/µL, AST 75 U/L, LDH 622 U/L, total bilirubin 1.27 mg/dL).

Treatment with labetalol and magnesium sulfate was initiated. PO-CUS and a CT were performed. After detecting a large amount of free fluid in the abdomen, an embolization of the arterial branches of the deep femoral arteries was carried out.

Discussion: According to literature, PPH in high-risk pregnancies requires rapid and coordinated management. Prompt identification of risk factors allows for timely interventions, such as uterotonics, blood transfusion, fluid resuscitation and multidisciplinary treatment, which are vital to preventing complications such as hypovolemic shock, CID, and multi-organ failure, which can lead to maternal death.

Urgent cesarean anesthetic management in a pre-eclamptic patient with new-onset neurological symptoms: balancing the risks of regional vs. general anesthesia

M. Martínez Morales¹, M. Raynard¹, R. Valdés¹ ¹Hospital Universitario Dexeus, Anaesthesiology department, Barcelona, Spain

Background: Bell's palsy (BP) is a rare condition, but its incidence increases in the obstetric population, especially associated with hypertensive states of pregnancy such as preeclampsia (PE) and studies suggest that BP increases the severity of PE.

Neuraxial anaesthesia (NA) remains the technique of choice for the majority of c-sections (CS) because of its multiple benefits. Despite that, in parturients with intracranial lesions or suspected intracranial hypertension (ICHT), the theoretical risk of herniation due to dural puncture is cited as a contraindication to NA.

In preeclamptic patients, the presence of headache and facial paralysis (FP) further complicates the decision-making process, as both symptoms could indicate ICHT or simply be part of clinical presentation of PE.

There are no clinical guidelines that address the safety of performing NA in the presence of de novo neurologic focality related to PE. The objective of this case report is to highlight the need to develop clinical guidelines that address the anesthetic management (AM) of obstetric patients with new-onset neurologic focality in the context of PE.

Case Report: A 32-year-old primiparous woman at 36.6 weeks of gestation was admitted for PE with occipital and retroorbital headaches, scapulohumeral pain, and new-onset facial paralysis (FP). Neurological exam revealed right facial hemihypoesthesia and hemiparesis, labial commissure deviation, and eyelid weakness with preserved ocular occlusion. Long-tract involvement and nuchal rigidity were ruled out.

Due to suspected worsening clinical condition and the need for rapid delivery, an urgent c-section was indicated. Given stable hemodynamics, intradural spinal anesthesia was chosen. Postoperatively, MRI showed demyelinating lesions in the callosal-septal interface and right corona radiata, likely unrelated to current symptoms.

Discussion: AM in patients with PE and acute neurological symptoms presume significant challenges. Although guidelines suggest avoiding NA in the presence of signs of ICHT, PE headache, as well as FP, can confuse the clinical picture, leading to controversy over the use of GA or NA in the anesthetic management of CS. GA avoids risk of brain herniation, but NA avoids general anaesthesia's complications.

Learning points: AM guidelines for urgent CS in patients with PE and neurological symptoms.

21AP05-12

Comparison of standard versus walking epidural anesthesia: clinical implications for labor pain management. A prospective cohort study

Á. Mingote Lladó^{1,2}, L. Fernández González^{3,2}, C. García Gil3,2, A. Gutiérrez Garcia2,3, I. Fornet Ruiz2,3, J. García Fernández^{2,3}

¹Universidad CEU San Pablo, Cirugia, Madrid, Spain, ²Puerta de Hierro Maiadahonda Universitary Hospital. Anesthesia and Intensive Care, Majadahonda, Spain, ³Universidad Autónoma de Madrid, Cirugia, Madrid, Spain

Background and Goal of Study: Epidural anesthesia is the gold standard for labor pain management, offering analgesia while reducing discomfort. Recent advancements have prioritized minimizing motor blockade, aligning with the demand for walking epidural. These techniques utilize low concentrations of local anesthetics combined with opioids to balance analgesia and functional preservation. This study evaluates the analgesic effectiveness, motor blockade, and maternal satisfaction of standard epidural versus walking epidural.

Materials and Methods: This prospective, blind cohort, observational study included 90 laboring parturients, divided into three groups: 30 received standard epidural (SE) anesthesia (levobupivacaine 0.125% + 1 mcg/ml fentanyl or ropivacaine 0.15% + 1mcg/ ml of fentanyl), while 60 received walking epidural (WE) anesthesia (30 with levobupivacaine 0.0625% + fentanyl 2 mcg/mL, and 30 with ropivacaine 0.075% + fentanyl 2 mcg/mL). We received approval from our local Ethical Committee (74/21). All participants provided written informed consent. Epidural infusions were standardized based on patient height. Pain (VAS), motor blockade, and satisfaction (10-point scale) were assessed.

Results and Discussion: After 2 hours, patients who received SE showed a mean VAS of 0.3 [0.0 to 1.0] vs 2.0 [1.0 to 3.5] (p < 0.01) in patients who received WE. Patients who received SE showed a punctuation in Bromage scale after 2 hours of 0.0 [0.0 to 1.0] vs 0.0 [0.0 to 0.0] (p = 0.01) in patients who received WE. Patients who received SE scored a mean satisfaction index of 10.0 [10.0 to 10.0] versus 9.0 [8.0 to 10.0] (P < 0.01) in those who received WE. SE group required 0.3 rescue bolus per hour [0.1 - 0.6] versus 0.3 rescue bolus per hour [0.2 to 0.5] (P = 0.94) in the WE group. SE provided more analgesia and satisfaction compared to WE. Motor blockade observed with both techniques suggests WE remains a viable option for those prioritizing mobility. Hence, it is reasonable to tailor anesthesia choices to individual patient preferences and clinical contexts.

Conclusion: SE anesthesia offers superior analgesia and slightly higher satisfaction compared to WE, albeit with reduced mobility. Both techniques are safe and effective. These findings support individualized anesthesia choices, balancing the desire for mobility with the need for optimal pain relief.

Unusual epidural catheter knot during its removal

A. Abdyli¹, G. Huti¹, D. Hoxha¹, F. Coniglione¹, R. Domi^{1,2}, K. Lilai2

¹American Hospital Tirana, Anesthesia and Intensive Care, Tirana, Albania, ²University of Medicine Tirana, Anesthesia and Intensive Care, Tirana, Albania

Background: Epidural analgesia for vaginal delivery is considered the gold standard today. It is regarded as a safe procedure, with contraindications including patient refusal, infection at the puncture site, and coagulopathies.

While the complications of epidural analgesia are well-documented, our case is unique and has not been previously reported in

Case Report: A 29-year-old woman in her first pregnancy was admitted to the hospital for labor. The anesthesiologist was called to administer an epidural for analgesia during the planned vaginal delivery. The epidural catheter was inserted without complications, and its correct placement was confirmed by administering three doses of ropivacaine/sufentanil over 8 hours until the patient delivered.

Several hours after delivery, the anesthesiologist was requested to remove the catheter. During the removal, resistance was encountered, and the catheter could not be easily withdrawn.

After applying slight force, the catheter was successfully removed, and it was found to be fully intact. Upon inspection, an unusual eight-loop knot was discovered in the catheter.

Discussion: Epidural analgesia is currently the method of choice for pain relief during vaginal delivery. Several technical and physiological changes in pregnant women, such as obesity, obscured anatomical landmarks, a tendency for higher blocks, and the need for smaller volumes of local anesthetics, can complicate the pro-

In our case, the epidural procedure was uneventful, and an eightloop knot in the catheter was only discovered during removal. It is possible that the catheter took an unusual path through the tissues, with the knot forming at the outset and tightening during its removal. We wish to share these intriguing photos with our colleagues to highlight this unusual complication.

References:

1. Halliday L, Nelson SM, Kearns RJ. Epidural analgesia in labor: A narrative review. Int J Gynaecol Obstet. 2022;159(2):356-364. 2. Callahan EC, Lee W, Aleshi P, George RB. Modern labor epidural analgesia: implications for labor outcomes and maternal-fetal health. Am J Obstet Gynecol. 2023;228(5S):S1260-S1269.

Learning Points:

- 1. Epidural analgesia is a safe procedure and is considered the gold standard for pain relief during normal delivery.
- 2. Epidural aids in facilitating the normal delivery process.
- 3. The anesthesiologist in charge must be vigilant and evaluate every step carefully.

Cesarian section in pregnant woman suffering from idiopathic spinal cord ischemia

G. Huti¹, A. Abdyli¹, R. Domi¹, D. Hoxha¹, K. Lilaj², F. Coniglione¹

¹American Hospital Tirana, Anesthesia and Intensive Care, Tirana, Albania, ²University of Medicine Tirana, Anesthesia and Intensive Care, Tirana, Albania

Background: Pregnant women have different pathophysiological changes, and often current diseases. We present a rare case of a pregnant women suffering from spinal tumor diagnosed during her second pregnancy. The progressive neurological deficit makes inevitable the tumor removal in the 29-th week of preg-

Case Report: A 21-year-old pregnant women was diagnosed in the 29-th week of pregnancy of spinal tumor based on her clinical signs (backache, and progressive neurological deficit of her legs) and on IMR examination.

These examinations revealed a spinal tumor on TH10-L1 level. The progressive motor deficit of her legs makes the surgery inevitable. A multidimensional team (obstetrician, neonatologists, anesthetists, and neurosurgeons) consulted the patient, concluding of neurosurgical approach and strict fetal monitoring in perioperative period.

This conclusion was appreciated by the women which did not permit to deliver the baby prior of term. Betamethasone, nifedipine, and magnesium sulfate) were started. Careful positioning of pregnant women in prone position was realized. Fetus monitoring was perioperatively realized taking care of maintaining fetal heart rate over 120.

The procedure was uneventful, and the women discharged from hospital without deficits and normal pregnancy course.

Discussion: This rare case presents an unusual situation of a pregnant women undergoing non-obstetrical surgery. Being in 29th week of pregnancy minimize the risk of anesthetic effects on organogenesis, and the anesthesiologist must take care about fetal monitoring, maternal hemodynamic, and tocolysis.

Case report of atypical eclampsia with progression to PRES

M. Keresztes¹, R.C. Nicolau², S. Maier³, B. Baroti⁴, J. Szederiesi5

¹Emergency County Hospital Targu Mures, Anaesthesiology and Intensive Care, Targu Mures, Romania, ²George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Târgu Mures, Obstetrics and Gynecology, Targu Mures. Romania. ³George Emil Palade University of Medicine, Pharmacy, Science and Technology of Târgu Mureș, Neurology, Targu Mures, Romania, 4Emergency County Hospital Targu Mures, Radiology, Targu Mures, Romania, 5George Emil Palade University of Medicine, Pharmacy, Science, and Technology of Târgu Mureş, Anaesthesiology and Intensive Care, Targu Mures, Romania

Background: Posterior reversible encephalopathy syndrome (PRES) is a neuro-radiological syndrome characterized by transient brain dysfunction (headache, seizures, visual disturbances), often associated with reversible subcortical vasogenic edema. primarily affecting the parieto-occipital regions of the brain. This condition can be associated with hypertensive disorders, including eclampsia during pregnancy. PRES can occur even in the absence of prior hypertensive disorders during pregnancy, presenting as an atypical eclamptic crisis which poses a diagnostic and management challenge.

Case Report: A 30 year old primigravida, 40 weeks of gestation presented in the hospital for labor and delivery, no prior history of hypertensive disorders during pregnancy. Three hours after admission she complains of a headache, her blood pressure is measured at 127/85 mmHg, an increase of 20% from her baseline blood pressure.

During labor, twelve hours since admission she experienced a sudden onset of a generalized seizure. She was urgently taken to the operating room for an emergency cesarean section under general anesthesia to ensure maternal and fetal safety.

During emergence from anesthesia, she had a second seizure, prompting the administration of magnesium sulfate and a request for a neurology consultation and imaging evaluation. Imaging studies, including computed tomography (CT) and magnetic resonance imaging (MRI) of the brain, revealed findings consistent with PRES. She also required postoperative antihypertensive treatment with methyldopa and nifedipine. She was discharged after 15 days with no neurological deficits.

Discussion: This case highlights the need for heightened awareness of atypical presentations of eclampsia, particularly when neurological symptoms such as seizures occur without overt hypertension. Early recognition and timely management are crucial to prevent complications and ensure optimal maternal and fetal outcomes.

Reference:

Anant Parasher, Rajat Jhamb. Posterior reversible encephalopathy syndrome (PRES): presentation, diagnosis and treatment. Postgraduate Medical Journal, Volume 96, Issue 1140, October 2020

Learning Points: Blood pressure in pregnant patients during hospitalization should be compared with their baseline values. An increase of 20% may warrant closer monitoring.

21AP06-4

Machine learning approach to predict postoperative pain after spinal morphine administration in caesarean delivery

S.A.L. Ang1, C.W. Tan1, J.Z. Koh2, H. Jin2, H.L. Goh2, B.L. Sng1

1KK Women's and Children's Hospital, Department of Women's Anaesthesia, Singapore, Singapore, ²Synapxe Pte Ltd, Data Analytics and Al, Singapore, Singapore

Background and Goal of Study: Current pain service workflow and electronic medical records do not allow clinicians to risk stratify women with significant pain in wards after caesarean delivery and may lead to delayed reviews and workflow disruption. We compared the predictive performance of six modelling techniques (ridge regression, LASSO, Elastic net, Random Forest, XGBoost, LightGBM) in predicting significant pain defined as the maximum pain score on movement of at least 3 at the 13th to 24th hour after spinal morphine administration after caesarean delivery.

Materials and Methods: This is a retrospective cohort study conducted in a specialist maternity hospital in Singapore between August 2019 and August 2022 on parturients administered postoperative spinal morphine after caesarean delivery.

The study received a waiver of consent from the SingHealth Centralised Institutional Review Board (reference number CIRB 2022/2505).

A total of 120 clinical variables were extracted from the medical records of eligible patients, with 23 further selected to enhance the accuracy of the tested algorithms. We randomly selected 80% of the patients (n = 5,248) as training cohort, followed by validation using the remaining 20% (n = 1,313).

Results and Discussion: The study cohort comprised 6,561 patients with an incidence of significant postoperative pain of 7.9%. Ridge regression demonstrated the best performance with both the full (AUC: 0.649) and selected (AUC: 0.719) feature sets.

By reducing the number of features, Ridge regression, LASSO, Elastic net, and XGBoost showed similar in AUC (0.704-0.719), sensitivity (0.644-0.695), specificity (0.644-0.705), positive predictive value (0.155-0.179), and negative predictive value (0.949-0.955) in predicting significant postoperative pain. These were attributed to the top three variables, mainly the last recorded postoperative pain score (on movement) before the prediction point, mean and standard deviation of the hourly maximum postoperative pain score (at rest) at 0th to 12th hour.

Conclusion(s): Future work will focus on prospective validation and integration into risk stratification practices for clinical practice. This will benefit caesarean patients and healthcare professionals by streamlining clinical workflows with risk stratification, enabling enhanced responses to patients at high risk of significant postoperative pain, and improving patient outcomes and experience.

21AP06-5

Incidence of Epidural-Related Maternal Fever: findings from a prospective study in a Czech **Maternity Hospital**

Q.G. Nguyenová¹, K. Kapralova¹, Z. Kapustova¹, L. Smatlakova², T. Bartosova¹, J. Blaha¹ ¹General University Hospital in Prague, Anesthesiology, Resuscitation and Intensive Medicine, Prague, Czech Republic, ²General University Hospital in Prague, Gynaecology, Obstetrics and Neonatology, Prague, Czech Republic

Background: Although epidural-related maternal fever (ERMF) was first described in 1989, it remains controversial and its aetiology unclear. The incidence of ERMF varies widely between studies, ranging from 1.6% to 46%, but typically occurs in 15% to 25% of patients who receive an epidural during labour.

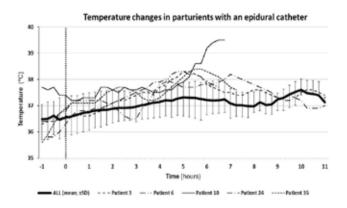

The wide variation in reported incidence may be due to differences in study design, populations studied and definitions of fever used. Data confirming ERMF come from studies on different continents, and several meta-analyses have shown that ERMF is a clinical phenomenon that is unlikely to be caused by selection bias. However, the existence of ERMF has never been recorded in Czech maternity hospitals, nor has it been studied.

Therefore, we designed a study on the occurrence of ERMF at our hospital using continuous maternal temperature monitors to exclude that it is only caused by our poor monitoring.

Materials and Methods: We performed a prospective observational study at a university obstetric department with 3800 deliveries/year and the use of epidural labour analgesia in 56% of parturients.

The aim was to determine the incidence of maternal fever (axial temperature ≥ 38°C for 1 hour or more) and to monitor temperature in labouring women with an epidural catheter. The study included 110 parturients whose temperature (T) was continuously monitored with the SteadyTemp system. Of these, 51 with epidural catheter inserted for > 3 hours were analysed.

Results: The mean T rise after catheter insertion was 0.9 ±0.7°C, with a mean pre-catheter T of 36.5 ±0.5°C and a maximum T of 37.4 ±0.6°C. Fever for more than 1 h was recorded in only 1 case (1.9%), but this was in a mother with an entry temperature of 37.7°C. Five other parturients had a short-term rise above 38°C with a spontaneous decrease in T before epidural catheter removal.

Conclusion: Our results show that, for some unknown reason. ERMF is not found in our area. The Czech population is not genetically unique to explain it in such a way, rather a different-way of delivering babies in our hospitals could be suggested. In relation to our observations, a multicentre national study is currently being drafted.

21AP06-6

Enhanced recovery after planned caesarean birth, Improved discharge rates within 36 hours after the delivery

S.K. Timalapur¹

¹Royal Alexandra Hospital, Anaesthesia, Paisley, United Kingdom

Background and Goal of Study: Planned Caesarean births constitute 45% of all our Caesarean births in our institution. As the pressure on the healthcare system is very high and non availability of ward beds in common, 6 years ago we introduced enhanced recovery after planned caesarean births at our institute with the aim to send women who had a planned caesarean births within 24-30 hours after the child birth (1st postoperative day). Most of our planned caesarean births were going home on the 2nd postoperative day previously.

We introduced a antenatal EROSS class to all women who were having planned caesarean births a week before their delivery and they were informed about Anaesthesia, neonatal care, breast feeding, physiotherapy and early mobility. Any questions and enquires were answered. The class was attended by an Anaesthetist, a midwife and a physiotherapist.

Materials and Methods: We analysed the data for all the caesarean births for 2 years, Jan 1st 2022 to Dec 31st 2023.

Results and Discussion: We analysed 1100 cases where data was available. The length of stay was (1-6 days) with mode 1 day. 660 women were discharged on the 1st post operative day.

Conclusion(s): After the introduction of the Enhanced recovery pathway for the planned caesarean births, we have reduced the length of stay in the hospital after planned caesarean births.

21AP06-7

Anaesthetic considerations congenital complete heart block in pregnancy

M. Venditti¹, T. Gower¹, P. Krishnan¹, K. Kamarai¹ ¹Medway Maritime Hospital, Perioperative Medicine, Gillingham, Kent, United Kingdom

Background: The presence of cardiovascular disease in pregnancy has increased because of multiple factors including advanced maternal age and more women with congenital heart conditions entering childbearing years. Some of these cases might effectly be managed in distric hospitals with maternal medicine network support.

Case report: A 26-year-old primigravida presented at 37+4 weeks with reduced foetal movements. On examination, heart rate (HR) of 40bpm triggered an ECG which revealed narrow complex Complete Heart Block (CHB). Otherwise asymptomatic, she underwent exercise tollerance test which showed maximum HR achieved was 58% of the target.

A multidisciplinary team (MDT) meeting involving obstetricians, cardiologist, anaesthetists, and midwives from our regional maternal network resulted in a comprehensive care plan defining place of birth, method of delivery, equipment needed, anaesthetic management and pharmacologic consideration for both emergency and anaesthetic interventions as well as for third stage of delivery. This allowed to manage this case in our general distric hospital.

Decision was for vaginal delivery with induction of labour and Csection reserved for obstetric reasons. Patient was counselled for insertion of early labour epidural. Epidural slow top up was felt to be the safest option in case of C-section, with spinal being preferred to general anaesthetic. Cardiologists determined that temporary pacemaker insertion was not necessary before delivery.

Patient represented at 39+5 weeks in labour, she underwent an early labour epidural and she was delivered uneventfully by category 2 C-section for failure to progress with slow epidural top up and noradrenaline via peripheral infusion.

Discussion: About one third of the cases of congenital CHB remain undiscovered until adulthood and may present during pregnancy for the first time, posing unique challenges. A MDT approach and liaison with tertiary centres is imperative for successful outcomes in complex cases (1).

Reference:

1. Agarwal A, Murkey S P, Pandit P, et al. (December 23, 2023) Navigating the Complexity: A Comprehensive Review of Managing Pregnancy in Complete Heart Block Cases. Cureus 15(12): e50977

Learning points:

- · ECG during prenatal care for high-risk pregnancies
- Importance of a regional MDT network
- · Strategic use of epidural anaesthesia for stable cardiovascular function
- · Considerations for jugular venous access electively for facilitating insertion of temporary pacemaker

21AP06-8

Anaesthesia management in a pregnant woman with Brugada syndrome

P. García Robledo¹, M. Santiago Sánchez¹,

V. Reig Calabuig¹, M. Boned García¹, I. Verges Montano¹, P. García Pimentel¹

¹Hospital Universitario 12 de Octubre, Servicio de Anestesiología y Reanimación, Madrid, Spain

Background: Brugada syndrome (BS) is a rare heart rhythm disorder, with AD inheritance, that increases the risk of malignant arrhythmias. Due to its low prevalence and predominance in men, there is little information on anesthesic management in pregnant women, with some contradictory reports about it.

Case Report: A 36 year-old primigravida woman with asymptomatic drug-induced BS, at 39w+6d gestation, is admitted with labor in maternal ICU for monitoring. A cardiological study performed at age 13, following her father's diagnosis of BS, showed a positive pharmacological provocation test and negative electrophysiological induction study. Currently, she had baseline ECG in high leads without Brugada criteria and normal echocardiogram. A multidisciplinary team made recommendations for labor induction, analgesia and cardiac considerations, with the aim of avoiding contraindicated drugs and normothermia control. Epidural anesthesia (EA) was chosen for labor and L-bupivacaine indicated as it has reduced cardiotoxic profile.

During labor, an external defibrillator was available in the delivery room. Puncture at L3-L4 of EA was performed without incidents; test dose of 4 mL 1% lidocaine was negative. An initial bolus of Lbupivacaine 0.15% 8 mL + fentanyl 50 mcg was given, followed by perfusion of L-bupivacaine 0.0625% + fentanyl 2 mcg at 8 mL/h + PCA (patient-controlled analgesia) 6 mL (blocking time of 20

The birth ocurred spontaneuously, eutocically, with directed delivery. A grade II tears occurred, with subsequent dehiscence of the episiotomy suture that required intradural anesthesia instilling prilocaine 10 mg + fentanyl 20 mcg. The patient remained monitored 24 hrs after delivery, with defibrillator stickers placed and isoproterenol and quinidine available. Throughout the process, she remained hemodynamically stable.

Discussion: To date, in the absense of consistent clinical studies in pregnant women with BS, there is no general recommendation for anesthesia, so it is important to communicate experiences. Some local anesthesics as bupivacaine and procaine are conflicted in these patients. Our case shows the anesthesic management of a high-risk pregnant with BS, using L-bupivacaína for EA y prilocaine for intradural without complications.

References:

Minerva Anestesiol. 2019;85:173-88.

Learning Points: Pregnancy represents a risk situation in women with BS that requires special anesthetic considerations that should be familiar to the anesthetist.

21AP06-9

Anesthetic considerations in the management of anticoagulation in pregnant woman with mechanical heart valves

P. García Robledo¹, S. Cuervo Escribano¹, M. Santiago Sánchez¹, V. Reig Calabuig¹, P. González Pérez¹, P. García Pimentel¹ ¹Hospital Universitario 12 de Octubre, Servicio de Anestesiología y Reanimación, Madrid, Spain

Background: Currently, there is no consensus on the optimal anticoagulation (AC) strategy for pregnant women with mechanical heart valves (MHVs). Cumarin derivatives (CD) can cause embryopathies. Low molecular weight heparin (LMWH) is safer for the fetus but whether it is as effective as CD has been questioned. It is important for the anesthetist to understand the AC regimens as they have anaesthetic implications. We report our peripartum AC management in a woman with mitral MHV.

Case Report: A 26 year-old woman underwent mechanical mitral valve replacement at the age of 13. When she became pregnant her therapeutic AC with acenocumarol (A) was replaced by enoxaparin. At 16 wks of gestation she suffered a cerebral stroke, as a result of mitral valve thrombosis. Due to the difficulty in achieving therapeutic levels of enoxaparin it was decided to

A multidisciplinary team scheduled a cesarean section (CS) at 37 weeks' gestation, and made recommendations for peripartum AC. Regional anaesthesia during labor was chosen. At 35 wks, A was switched to LMWH twice daily (target anti-Xa 1-1.2 IU/mL), which was replaced by non-fractionated heparin (NFH -sodium heparin iv-) 36 hrs before CS. The infusión was stopped 6 hrs before the surgery. aTTP was analysed to ensure reversal of AC. Puncture at L4-L5 of intradural anaesthesia was performed without incidents. Intraoperative bleeding was low and a healthy baby was delivered. 6 hrs later, NFH was restarted monitorized by aTTP. On the 3rd day, the patient suffered hemodynamic instability related to bleeding in the CS area, which required urgent surgery. 2 L of hemoperitoneum were removed and the hysterorrhaphy was reinforced. Subsequentely, the evolution was favorable.

Discussion: The high thrombotic and hemorrhagic risk of pregnant women with MHVs can be reduced by a planned CS and modifying the AC regimen close to term. The main concern about regional anesthesia and AC are complications such as spinal hematoma.

In our case, due to the previous thrombotic event, CS was chosen to reduce the period without AC compared to vaginal delivery, and to facilitate the neuraxial procedure we favor AC with LMWH near the labor, switching to NFH before delivery. The risk of second surgey due to postpartum bleeding requires close monitoring of hemostasis.

References:

Br J Hosp Med. 2021;82:1-7

Learning Points: Parturients with MHVs carry a high risk of complications that require detailed planning of their peripartum AC needs

21AP06-10

Navigating Safe Anesthetic Management in a **Pregnant Woman with a Malignant Hyperthermia Diagnosis**

I. Mendes Leitão¹, L. Godinho¹, F. Gil¹, J. Magalhães Fernandes¹, D. Sepúlveda¹, S. dos Santos Rodrigues¹ ¹Unidade Local de Saúde do Alto Ave, Anesthesiology, Guimarães, Portugal

Background: Malignant hyperthermia (MH) is a rare pharmacogenetic skeletal muscle disorder triggered by halogenated inhalational anesthetic agents and succinylcholine, leading to a life-threatening hypermetabolic crisis. Despite its rarity and the limited use of general anesthesia in obstetrics, recent research supports maintaining dantrolene in maternity units, as MH susceptibility during cesarean delivery (1/125,000) matches rates in non-obstetric settings.1,2

Preventing exposure to triggering agents requires meticulous perioperative planning and equipment preparation.

Case Report: A 38yo primigravid woman at 41 weeks gestation with a confirmed diagnosis of MH susceptibility underwent labor induction. Anesthesiology was consulted in advance, ensuring safety protocols were in place. The anesthesia workstation was prepared by removing vaporizers, replacing breathing circuits and soda lime canisters, and flushing the system with 100% oxygen. Dantrolene was readily available in the maternity floor.

Labor was induced with oxytocin and an epidural catheter was placed at L2-L3. Analgesia was provided using 8mL of 0.2% ropivacaine and 10mcg of sufentanil, with additional 0.2% ropivacaine boluses as needed.

After 20h of labor, due to cephalopelvic disproportion, a c-section was performed. An additional 15mL of 0.75% ropivacaine and 10mcg of sufentanil were administered. The intraoperative course was uneventful, with administration of 30mg ketorolac, 1g paracetamol, 4mg ondansetron and 25IU oxytocin. Both mother and neonate were discharged 5 days later.

Discussion: Although rare, MH is an anesthetic emergency that requires logistical readiness, including availability of dantrolene, established protocols, and trained multidisciplinary teams. Avoidance of triggering agents is imperative.

The anesthesia workstation must be fully prepared for MH-susceptible patients, even if regional anesthesia is planned, to facilitate a prompt conversion to general anesthesia if necessary.

References:

1. Larach MG et al. Succinylcholine use & dantrolene availability for MH: analysis & review. *Anesthesiology.* 2019;130:41–54.
2. Guglielminotti J et al. MH prevalence in obstetric patients, US 2003–2014. *BMC Anesthesiol.* 2020;20:19.

Learning Points: MH requires preparation in obstetric units, including dantrolene availability and trained teams. The anesthesia workstation must always be prepared for MH management, even if general anesthesia is not initially planned.

21AP06-11 PDPH and CVST - different sides of the same coin

M. Zdravkova Borislavova¹, E. Ochin¹, E. Ivanova², O. Lovhvinenko³

¹CH Hopital Simoneveil, Anesthesia and Intensive Care, Eaubonne, France, ²University Hospital "Pirogov", Pediatric Anesthesia ICU, Sofia, Bulgaria, ³AP HP NECKER, Pediatric aneshtesia, Paris, France

Background: Cerebral venous sinus thrombosis (CVST) is a rare but potentially fatal complication in the post-partum period. A recent review of 58 case reports in obstetric patients diagnosed with CVST found that 79.3% of the cases had an antecedent postdural puncture headache (PDPH) and concluded a possible association between the two. A proposed mechanism of its pathogenesis can be explained by the components of Virchow's triad.

According to this review, the most consistent and common symptom of CVST is headache (98% of cases) as it is in PDPH, which can pose a serious diagnostical challenge and delay treatment. By publishing this recent clinical case, we want to raise awareness of this association and emphasize the importance of a careful differential diagnosis of postpartum headaches.

Case Report: A 31years old patient G2P1 with a BMI-37.5 presented at 41w gestation for a vaginal delivery after a normal pregnancy. She had a past medical history of obesity and previous uncomplicated vaginal delivery with epidural anesthesia.

For the current delivery, a successful epidural catheter was placed on the second attempt after an inadvertent dural puncture during the first one. Three days after the delivery, the patient presented typical postural headache with photophobia and neck stiffness consistent with PDPH.

Following local protocols - a blood patch(BP) was performed twice, with some transient relief of the symptoms. Because of the persistent headache, the patient underwent brain MRI 24h after the second BP, which revealed thrombosis of the sagittal sinus. Anticoagulation was initiated. At 6 month follow-up, the patient was asymptomatic and the control MRI showed complete resorption.

Discussion: The post-partum period is an independent risk factor for CVT and a PDPH possibly augments the risk of this serious complication.

References: https://www.bjanaesthesia.org/action/showPdf?pii=S0007-0912%2822%2900647-X, https://pubmed.ncbi.nlm.nih.gov/34598860/

Learning Points: Women with post delivery headache should be carefully evaluated by a multidisciplinary team with a low threshold for neuroimaging, particularly if the headache persists or changes its pattern.

21AP06-12

Anticipated difficult airway and thrombocytopenia in an obstetric patient undergoing cesarean section: a case report

K. Králová¹, P. Nosková¹

¹General University Hospital in Prague, Department of Anaesthesiology and Intensive Care Medicine, Prague, Czech Republic

Background: Anesthetic management of parturients with anticipated difficult airways is challenging due to pregnancy-related airway changes and potential for urgent cesarean sections¹.

Thrombocytopenia further complicates the choice of neuraxial anesthesia, requiring careful assessment within a clinical context. Current evidence suggests that the risk of spinal epidural hematoma with a platelet count ≥70,000/µL is likely to be very low in the obstetric patient over a range of thrombocytopenia diagnoses in the absence of other risk factors².

Case Report: A 27-year-old primigravida with trismus from multiple temporomandibular joint surgeries and thrombocytopenia (platelets ~60,000/µL) was scheduled for elective cesarean section at 34 weeks. Her medical history included congenital deafness, acute myocardial infarction, and polyvalent allergies (analgesics, soya, latex).

The patient was well known to our department, and early planning with cardiology and hematology was carried out, also in case of emergency surgery. Spinal anesthesia with 0.5% bupivacaine without morphine was administered.

A difficult airway specialist was available if general anesthesia became necessary. Surgery was uneventful, the neonate's Apgar scores were 10-10-10.

Discussion: Anesthetic planning for cesarean delivery in a patient with a difficult airway, thrombocytopenia, cardiac history, and severe allergies requires careful consideration of physiological and situational factors. Elective cesarean allowed for preparation, but emergency readiness was essential.

Due to airway management limitations - trismus, inability to use supraglottic devices, uncertain awake intubation - we preferred neuraxial anesthesia, accepting lower platelet counts as there were no bleeding symptoms present.

References:

1. Mushambi, M. C., et al. (2020). Anaesthesia, 75(7):945-961. 2. Bauer, M. E., et al. (2021). Anesthesia & Analgesia, 132(6):1531-1544.

Learning Points: In complex cases, early recognition of high-risk patients, multidisciplinary teamwork, and antenatal planning contribute to a safe outcome.

21AP07-2

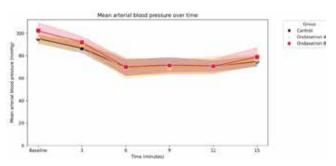

The role of ondansetron in prevention of hypotension during caesarean section under spinal anaesthesia: randomized double-blind study

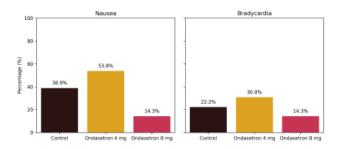

O. Ožegić¹, I. Pažur¹, K. Kličan-Jaić¹, M. Ciglar¹, L. Lijović¹ ¹University Hospital Centre Sestre Milosrdnice, Department of Anaesthesiology, Intensive Medicine and Pain Management, Zagreb, Croatia

Background and Goal of Study: Maternal hypotension is the most frequent complication of spinal anaesthesia for caesarean section (CS). Serotonin- sensitive receptors in cardiac chambers are provoked by decreased venus return during spinal anaesthesia resuting in activation of Bezold-Jarisch reflex leading to worsening of hypotension and bradycardia.

The aim of our study was to investigate the efficacy of 5-hydroxytriptamine antagonist ondansetron in maintaining maternal haemodynamic stability during spinal anaesthesia for CS.

Materials and Methods: This randomized double-blind study was conducted on 45 healthy parturients who were scheduled for elective CS under spinal anaesthesia. They were randomly assigned into three groups. Control group received saline, while experimental groups were administered ondansetron 4 mg and 8 mg respectively. All drugs were given in 10 ml syringes and the attending anaesthesiologist was unaware of syringe content. In all groups drug was given five minutes before spinal anaesthesia. The baseline mean arterial pressure (MAP) and heart rate were measured before spinal and then in three minutes interval until delivery. All participants were given metoclopramide before spinal as antiemetic prophylaxis. The overall vasopressor and atropine requirement was recorded.

Results and Discussion: Demographic characteristics were comparable. There was no significant difference between groups in terms of mean blood pressure. Moreover, the incidence of bradycardia and nausea did not reach statistical significance among groups.

Conclusion(s): Ondansetron does not affect haemodynamic parameters such as MAP and heart rate during spinal anaesthesia for CS.

Rosuvastatin changes the transport function of OATP2B1 across the blood-placental barrier and the placental permeability rate of remimazolam

S. Sato¹, T. Chaki¹, T. Hirahata¹, K. Narumi², M. Kobayashi², M. Yamakage¹ ¹Sapporo Medical University School of Medicine, Department of Anesthesiology, Sapporo, Japan, ²Hokkaido University, Laboratory of Clinical Pharmaceutics, Faculty of Pharmaceutical Sciences, Sapporo, Japan

Background and Goal of Study: We hypothesized and verified that the interaction of drugs in combination with each other would change the transport rate by transporter on the blood-placental barrier and control the placental permeability of remimazolam (RMZ) during general anesthesia

Materials and Methods: The Organic Anion Transporting Polypeptide 2B1(OATP2B1) transports specific substances from outside to inside the cell as carriers. Using an in vitro 3D bloodplacental barrier model (Fig.A), we compared the permeability of RMZ between the single administration group of RMZ 100 nM only and the coadministration group of RMZ 100 nM and rosuvastatin. Next, we compared the amount of RMZ taken up into the HEK293 cells overexpressing OATP2B1(HEK-OATP2B1) and the HEK293 cells not expressing OATP2B1(HEK-pcDNA) upon exposure to RMZ, to evaluate the competitive inhibitory effect of the two drugs, administered with simultaneously Estrone-3-Sulfate(E3S) for the high-affinity binding site and rosuvastatin for the intermediate-affinity binding site (H579), as known sitespecific binding agents. The site within OATP2B1 transporting RMZ was identified from changes in intracellular uptake of RMZ. Statistics were analyzed using Kruskal-Wallis test for comparison between groups at each time point and within groups over time. Results and Discussion: In an in vitro 3D blood-placental bar-

rier model, the permeability rate of RMZ increased over time in the single administration group of RMZ, and decreased in the coadministration group with rosuvastatin concentrations of 10 nM (Fig.B). Uptake of RMZ into cells in HEK-OATP2B1 was not reduced in combination with E3S and was significantly decreased in combination with rosuvastatin, compared to the single administration group (Fig.D), suggesting carrier transport of RMZ via the H579 site, which is same as that of rosuvastatin.

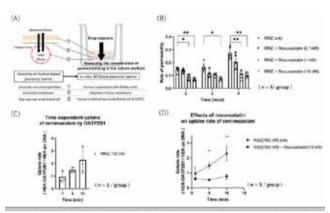

Figure. (A) Overview of the *in* rains 3D roodel. The three-layer structure is mimicked with human-derived cells similar to in vivo. (B) Permeability or RMZ 100 nM. Permeability of RMZ 100 nM increased over time in the monotherapy group and decreased in the cambination group at concentrations of rossentatin greater than 10 nM. (C) Validation of OATP2B1 mediated carrier transport of reminaculam. Reminatelam uptake increased in the REX-OATP2B1 group compared to the REX-pc DNA group. (D) Effects of the coadministration with concreatation of the transport rate of reminazulam. The uptake of syminazulam was significantly decreased in the rosservatatio group compared to the terminazulam and group.

Data are presented as error bar; mean = 58M, *p<0.05, **p<0.01. Remimazolam, RMZ.

Conclusion(s): Rosuvastatin can change the placental transfer rate of RMZ by modifying the transport rate of OATP2B1 on the blood-placental barrier.

21AP07-4

Undiagnosed placenta accreta disorder in a uterus transplanted patient presenting with a spontaneous miscarriage

<u>J. Sheffield</u>¹, A. Söderberg¹, A. Kollmann Camaiora¹

¹Akademiska Sjukhuset, Anesthesia and Intensive Care, Uppsala, Sweden

Background: Over the past 11 years uterus transplant surgery (UTx) has become a relevant, albeit rare option for patients with uterine factor infertility. The first child born to a uterus transplanted woman was in 2014 in Sweden in 2014¹, and just over 60 babies have been born via this method.

UTx consist of transplant surgery, IVF, c-section and hysterectomy (after maximum 2 children)². There are no reports of placenta accreta disorders (PAD) in these patients, but it is well known that women with previous uterine surgery have a higher incidence of this condition. Hysterectomies in UTx patients showed prolonged surgical times, typically 2-3h, but ranging up to 5 hours³.

Case report: 39 y.o. ASA 2 woman with a UTx in 2017 due to Rokitansky Sd and cervix stenosis. She had a successful pregnancy and CS in 2019 but opted out of a hysterectomy as she wished for a second pregnancy. In 2023 she underwent an uncomplicated CS at w22 due to premature delivery. In her third pregnancy she miscarried at week 18, got epidural for pain relief and the entirety of the fetus was expelled vaginally, however the placenta was retained. Upon her arrival to the OR she had bled 500 ml with minimal active bleeding. The patient wished for a hysterectomy. The primary plan was to remove the retained placenta vaginally and perform

a hysterectomy the following day when an obstetric anesthetist was on-site. After discussion with the team and taking into consideration the patient wishes she received an uncomplicated general anesthesia.

It was not possible to manually remove the placenta. A hysterectomy was performed, total surgical time of 222 min, total bleeding 1050 ml. The patient remained stable throughout. The pathological study confirmed a morbidly adherent placenta accreta, FIGO grade 1.

Discussion: This is the first case of a PAD in UTx and it is unclear what the incidence of PAD will be in this group of patients. Although neuraxial anesthesia in the first choice in patients with placental retention, the lack of an obstetric anesthesiologist and the patient wishes made the team opt for a general anesthesia.

References:

1. The Lancet 2015;385:607-16. 2.Acta Obstet Gynecol Scand 2022;101:355-63. 3. nesth Analg 2018;127:930-8

Learning points: UTx, despite uncommon, is becoming more available, and complications regarding this technique require a team management with an obstetric anesthetist to diminish maternal morbidity and mortality, providing the highest level of care.

21AP07-5

Case of successful thrombolytic therapy during cardiopulmonary resuscitation in a pregnant women with massive pulmonary embolism

E. Kotova¹, A. Bogomolov¹, V. Rimashevsky¹, <u>A. Gritsan²</u>¹Respublican Scientific and Practical Center "Mother and Child", Anaesthesiology and Intensive Care, Minsk, Belarus, ²V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Anaesthesiology and Intensive Care, Krasnoyarsk, Russian Federation

Background: It is known that 11% of maternal deaths during pregnancy are associated with pulmonary embolism (PE), but data on the use of thrombolysis in pregnant women with PE and hemodynamic instability are scarce.

Case Report: In pregnant woman H., 36 years old, 26 weeks, based on clinical of cardiopulmonary shock, D-dimers (3487 ng/ml), and bedside ultrasound examination of the heart, PE was suspected. Intensive care: NIV, dobutamine 5 mcg/kg/min and adrenaline 0.01 mcg/kg/min, morphine 1 mg, heparin: bolus 5000 U, followed by infusion of 1000 U/hour.

Against the background of spontaneous labor, circulatory arrest occurred. CPR was performed three times, each lasting 1 minute. Thrombolysis was performed 15 minutes after the onset of the first episode of asystole: alteplase 50 mg i.v. by jet stream, titrated with 50 mg at a rate of 25 mg/h, followed by heparin infusion (1000 U/h) in the postoperative period.

After 30 min., spontaneous circulation was restored, but bleeding began in a volume of 1000 ml. In order to stop the bleeding, postpartum uterine extirpation was performed against the background of an activated hemostatic resuscitation protocol under the control of a coagulogram and ROTEM.

Three hours after its implementation FIBTEM: A5=0, MCF=0; INTEM: CT=1057, FT=1577, A%=5 mm; EXTEM: CT=269, CFT=817, A5=9 mm; HEPTEM: CT=474, CFT=930, A5=18 mm.

Further correction DIC syndrome was carried out purposefully under the control of ROTEM. The increase in the D-dimer level to 58125 ng/ml served as an additional laboratory marker of the

effectiveness of thrombolysis. The total volume of blood loss was 3100 ml. In the postoperative period, the volume of infusion-transfusion therapy was 6940 ml. 24 hours, a complete absence of neurological deficit was recorded and extubation was performed. CT with contrast was performed, massive pulmonary embolism with 60% lung involvement was established.

Discussion: The use of thrombolytic therapy during labor, on the one hand, is contraindicated, on the other hand, it is the only effective method of saving pulmonary embolism: the number of reports on thrombolytic therapy for massive PE in pregnant women is extremely small.

Learning Points: Thrombolytic therapy provides excellent effect in case of circulatory arrest caused by PE in obstetric patients. It is advisable to manage hemocoagulation after thrombolytic therapy for PE with subsequent bleeding in pregnant women not only using standard tests, but also using ROTEM.

21AP07-6

Managing pregnancy with severe mitral regurgitation: insights into anesthetic and postpartum strategies

A. Silva¹, M. Carvalho¹, G. Nogueira¹, A. Milheiro¹, J. Rebelo¹. I. Vieira¹

¹Unidade Local de Saúde de Gaia Espinho, Anesthesiology Department, Vila Nova de Gaia, Portugal

Background: Valvular heart disease during pregnancy poses significant risks to both the mother and fetus. Multidisciplinary care is essential for optimizing outcomes, which includes accurate diagnosis, evaluation of severity, and management during pregnancy, labor, and postpartum1.

Limited evidence-based guidelines reflect the need for individualized care.

Case Report: 40-year-old pregnant woman (3G2P) at 27 weeks of gestation, former drug addict presented in the ER with exertional dyspnea for 2 months. Her first two pregnancies were uneventful and had no history of cardiac diseases.

She was diagnosed with severe mitral regurgitation and pulmonary hypertension complicated by a respiratory infection that precipitated decompensated heart failure. She was stabilized in the ICU, and scheduled for an elective c-section at 30 weeks.

Epidural anesthesia was selected using 10mcg sufentanyl and incremental doses of ropivacaine 0.75% and lidocaine 2% to achieve T4 sensitive block, guided by invasive arterial monitoring. The cesarean delivery was uneventful, and both the mother and newborn were admitted postoperatively to the ICU and neonatal unit, respectively.

There were no complications, and both were discharged in stable condition, with the patient scheduled for mitral valve replacement postpartum.

Discussion: Cardiac diseases remain a leading cause of maternal mortality due to hemodynamic changes of pregnancy and postpartum².

Epidural anesthesia with incremental boluses of local anesthetics allowed precise level of sensitive block and hemodynamic control during cesarean delivery.

Postpartum care was critical, as rapid hemodynamic shifts increased cardiac stress. Intensive monitoring during the first 72 hours ensured tight surveillance, enabling a stable recovery without complications.

References:

1. Van Berendoncks A, McGhie J, Heidbuchel H. Repetitive out of hospital cardiac arrests following pregnancy: A case report (...). Eur Heart J Case Rep.

2. Chauhan G, Tadi P. Physiology, Postpartum Changes. https://www.ncbi.nlm.nih.gov/books/NBK555904

Learning Points: Multidisciplinary care is critical in managing valvular heart disease in pregnancy. Early diagnosis, symptom control, and strategic delivery planning are key to achieve favorable maternal and fetal outcomes. Individualized anesthetic plans, such as epidural techniques, provide hemodynamic control during delivery, and intensive postpartum monitoring mitigates risks associated with rapid hemodynamic changes.

21AP07-7

Enhancing epidural analgesia: a technical overview of the dural puncture epidural technique

T. Asimakopoulos¹, C. Georgakopoulos², O. Katsiorkhi², P. Oikonomopoulou², M. Paximadi² ¹Johns Hopkins University, JHU Koliatsos Laboratory, Baltimore, United States, 2General Hospital of Patras. Anesthesiology, Patras, Greece

Background and Goal of Study: The dural puncture epidural (DPE) technique has gained attention as an alternative to standard epidural analgesia. By using a spinal needle to create a dural perforation without intrathecal drug injection, DPE enhances cerebrospinal fluid (CSF) exchange and promotes the spread of epidural medication, improving analgesic efficacy.

Here, we aim to review and summarize the procedural aspects and clinical outcomes associated with DPE.

Materials and Methods: A literature review was conducted using PubMed and Google Scholar to evaluate DPE compared to traditional epidural and combined spinal-epidural (CSE) techniques. We focused on analgesic onset, sacral nerve block quality, patient outcomes, and procedural complications.

Results and Discussion: DPE improves analgesic onset and sacral nerve coverage while mitigating risks such as fetal bradycardia and profound hypotension, often seen with CSE. Factors influencing its efficacy include needle gauge, local anesthetic selection, and patient positioning.

Despite these benefits, procedural challenges such as accidental dural puncture and post-dural puncture headache necessitate standardized protocols to optimize its safety and effectiveness.

Conclusion(s): DPE offers improved block quality and safety over epidural while avoiding the hemodynamic instability and fetal risks associated with CSE.

Further studies should focus on optimizing its procedural protocols and exploring its broader applications beyond obstetric anesthesia.

21AP07-8

Insights into postpartum haemorrhage cause and management in an Albanian University hospital

A. Soxhuku Isufi¹, V. Shpata¹, Z. Delia¹, I. Guranjaku¹, A. Abdyli², R. Domi¹

¹University of Medicine Tirana, Anesthesia and Intensive Care, Tirana, Albania, ²American Hospital Tirana, Anesthesia and Intensive Care, Tirana, Albania

Background and goal of the study: Postpartum haemorrhage (PPH) continues to be the leading preventable cause of maternal illness and deaths globally, accounting for 8%-20% of maternal deaths. The study aims to identify the cause of postpartum haemorrhage regarding the time and modes of delivery and their

Materials and methods: A prospective study in healthy pregnant women ASA II, admitted during 2023-2024, in UHOG "Koço Gliozheni". The study enrolled patients who had blood loss ≥ 1000 ml or that was accompanied by signs or symptoms of hypovolemia, occurring within 24 h after birth, regardless of the mode of delivery. The volumetric, gravimetric and area methods were combined to assess the PPH amount quantitatively.

Exclusion criteria: women with renal and hepatic insufficiency, hematologic disease, gestational age < 26 weeks. SPPS 20 was used for statistical analysis.

Results and discussion: 159 patients with a mean age of 31 years, 28-42 weeks of gestation, had PPH.The most common cause of PPH was uterine atony in 44.7%, followed by placental factors in 42.8%. The haemoglobin before was 11.06 mg/dL and after PPH 7.41 mg/dL.

In term delivery, the most common causes of postpartum haemorrhage were uterine atony (55.55%) and the retained placenta (11.96), while in preterm delivery, placental abruption and placenta previa (33.33% each). Patients with placenta percreta had the more significant blood loss and consequently, the highest number of transfused blood units, followed by uterine dehiscence, retained placenta and uterine atony.

The estimated blood loss was more significant in MP than in PP and, according to the time of delivery, in term delivery than in preterm delivery. There was no significant difference in blood loss according to the mode of delivery or type of anaesthesia used.

Conclusions: Uterine atony and placental factors remain the most common causes of postpartum haemorrhage. The management of PPH is still a challenge and needs close patient monitoring, early intervention and the collaboration of the professional team.

Midwives experience with and subjective impressions of spinal analgesia for vaginal delivery, a single centre survey study

E. Kesek Björkman¹, A. Kollmann Camaiora¹ ¹Akademiska Sjukhuset, Anesthesia and Intensive Care, Uppsala, Sweden

Background and Goal of Study: Sweden has approximately 100 000 deliveries per year and 1-3% of the patients (mostly multiparous women) get a delivery spinal (DSPA). To study the opinion of the MW regarding DSPA and relate it to their experience, we conducted a survey at our tertiary centre, performing about 4000 deliveries annualv1.

Materials and Methods: An anonymous survey was distributed among MW working at the delivery unit during a 3-week period. It included questions on their professional background, their beliefs regarding pain relief and negative effects of DSPA, their comparison with epidural analgesia (EDA), complications and examples of different clinical scenarios. Statistics was computed with PSPP. Chi2-test was used for comparison between groups, p≤0,05 was considered significant.

Results and Discussion: 38/45 MW answered the survey. They were split into two groups: 16/38 with <6 years of experience and 22/38 with ≥6 years of experience. 9/38 have worked at least at two delivery units. 19/38 have managed ≤5 patients with DSPA, 19/38 had experience of ≥6 DSPA. 24/38 considered DSPA to be technically easier than EDA. DSPA was considered very effective by 29/38, effective by 8/38 and moderately effective by 1/38.

A positive opinion regarding efficacy of DSPA was related to MW's greater experience as expressed both in years of experience and as number of managed DSPA (p=0,005 and p=0,027, respectively). The positive association might be related to a calmer situation in the delivery room due to greater experience.

Regarding clinical scenarios, the majority of the MW's considered DSPA preferable in multipara with a cervix opening of ≥8 cm and when the fetus was at the spinae level. All MW considered EDA preferable in primipara, regardless of cervix dilation and fetal position.

Adverse situations mentioned with DSPA included: poor pain relief, uterine hypertonus, fetal bradycardia, delayed labor, affected motor skills in the mother and need for episiotomy. Several MW had concerns regarding limited duration of DSPA effect, resulting in a need for speeding up delivery.

Conclusions: MW with greater experience tended to consider DSPA to be more effective. Some survey answers expressed fears that DSPA would increase the risk of episiotomy and other adverse effects not supported by scientific knowledge.

Anaesthetic management of a parturient with hypertrophic cardiomyopathy: a case report of two gestations and respective deliveries

S. Ribeiro¹, M. Guimaraes Adams¹, A. Brito², J. Almeida¹,

N. Lages¹, H. Machado¹

¹Centro Hospitalar Universitário de Santo António, Unidade Local de Santo António, Servico de Anestesiología, Clinica de Anestesiología, Medicina Intensiva, Emergência e Urgência, Porto, Portugal, ²Unidade Local de Saúde de Entre-o-Douro e Vouga. Serviço de Anestesiologia, Santa Maria da Feira, **Portugal**

Background: Hypertrophic cardiomyopathy (HCM) is an autosomal dominant genetic disorder characterized by asymmetric hypertrophy of the interventricular septum causing intermittent obstruction of the left ventricular outflow tract (LVOT). During pregnancy, the risk of decompensation depends on the severity of the outflow tract obstruction and ventricular dysfunction or presence of symptomatic arrhythmias. Therefore, affected patients should be managed by a multidisciplinary team.

This case report presents the anaesthetic plan of two labours of a parturient with HCM.

Case report: A 39-year-old patient presented for induced vaginal delivery at 39 weeks of gestation. The patient had a history of eutocic delivery 5 years prior, under epidural analgesia, which was uneventful. The patient had since been diagnosed with HCM but had remained stable throughout the gestation.

Labor induction at 39 weeks with vaginal misoprostol, early labour analgesia and invasive hemodynamic monitoring were planned. A continuous spinal catheter was placed for labour analgesia, with a 0.1% ropivacaine infusion titrated according to effect.

At 24-hours postpartum the patient presented with post-dural puncture headache (PDPH) and was treated with an epidural blood patch. The patient and the newborn were discharged on the fourth day after delivery.

The second delivery occurred two years after the above-described case. The patient presented for induced vaginal delivery at 38 weeks and 5 days gestation. An epidural analgesia technique was chosen. Patient-controlled epidural analgesia (PCEA) was set up with an infusion of 0.1% ropivacaine and 0.25mcg/ ml sufentanil at 5ml/h and a 5ml bolus with a 30-minute lockout. Vacuum-assisted vaginal delivery occurred 10 hours after induction, with discharge on the second day after delivery.

Discussion: The optimal analgesia modality for labour in patients with HCM is unknown. CSA and conventional epidural analgesia were both effective in maintaining hemodynamic stability and provided adequate pain relief.

However, the occurrence of PDPH with CSA was a drawback and contributed to a less positive patient experience. Ropivacaine was the local anaesthetic of choice for both techniques due to its lower cardiotoxicity and ease of titration to reduce cardiovascular effects.

Reference:

Eur Heart J. 3165-3241(2018.

Learning points: CSA and conventional epidural analgesia were both effective in maintaining hemodynamic stability and controlling labor pain.

21AP07-11

Patient satisfaction with epidural compared to combined spinal - epidural analgesia during labor - retrospective observational study

V. Banovic¹, S. Sobot-Novakovic¹, D. Rakanovic¹ ¹University Clinical Center of Republic of Srpska, Clinic for Anesthesiology, Intensive Medicine and Pain Therapy, Banja Luka, Bosnia and Herzegovina

Background and Goal of Study: Epidural analgesia and combined spinal-epidural analgesia are widely used techniques in labor analgesia. This study aimed to compare patient satisfaction and side effects between epidural (E) and combined spinalepidural (CSE) analgesia during labor.

Materials and Methods: Data was collected retrospectively thorough electronic hospital medical records and interviewing the patients after delivery during their hospitalization.

The study included sixty-five patients allocated into groups: Group E (n = 24) and Group CSE (n = 41). Patient satisfaction was measured using five-point Likert scale. Pain scores were measured with visual analogue scale (VAS). Data on episodes of fetal bradycardia and Apgar scores in neonates, along with itching, postdural puncture headache (PDPH), nausea, vomiting, and pain scores in mothers, were analyzed. The Mann-Whitney U test and Chi-square test were applied where appropriate. Statistical significance was determined at a p-value threshold of 0.05.

Results and Discussion: The data on patient satisfaction showed high satisfaction that exceeded 95% in both groups (p > 0,05). Itching was reported to be higher in CSE group (70.7% vs 29.1%, p< 0.001). Pain scores were lower in CSE compared to E group (0.93±1.68 vs. 2.5±2.3; p <0.001). There were no statistically significant differences among other measured variables (PDPH, nausea and vomiting, fetal bradycardia, Apgar scores). More than 95% of patients in both groups expressed that they would opt for labor analgesia in their next delivery.

Conclusion(s): There were no significant differences in overall patient satisfaction between the groups. CSE group experienced less pain but more side effects such as itching. These findings highlight the need to balance analgesic efficacy with potential side effects when selecting the most appropriate method for labor analgesia.

21AP07-12

Streamlining category one caesarean section WHO checklist

A. Jandu¹, S. Hawkins¹, P. Nadarajah¹ ¹Royal Free Hospital, Anaesthetics, London, United Kingdom

Background and Goal of Study: Category one (CAT1) lower segment caesarean sections (LSCS) are time critical with national guidance dictating that surgery be performed within 30 minutes of decision being made. The World Health Organisation (WHO) checklists are designed to ensure staff and patient safety however can result in delays to surgery.

The purpose of this project was to minimise time taken from decision of a CAT1 LSCS being made to KTS, whilst also ensuring patient safety. We aimed to shorten the WHO checklist process and design an abridged CAT1 LSCS checklist.

Materials and Methods: We conducted a survey with the faculty of anaesthetics and obstetrics to assess what information from the existing checklists the teams deemed was essential to be asked prior to KTS for a time critical CAT1 LSCS with the proviso that remaining questions be asked once baby delivered and mother stable.

Results and Discussion: Response rate of 19 (12 anaesthetists and 7 obstetricians). Eighty five percent believed that a shorter checklist will streamline the process whilst simultaneously preserving patient safety. The following 6 points were deemed absolutely essential to be clarified by consensus; conformation of patient details, consent (verbal or written) confirmed, allergy status, anaesthetic plan agreed, blood products available and in maternity fridge, neonatal registrar informed and resuscitaire checked.

ANSWER CHOICES	*	RESPONSES	
 So the shaulthets, muchine and modification check complaint? 		3.28%	1
 Difficult sinesy risk? 		38.8%	. 1
Antacid prophylasis gliver?		15.79%	1
Figure tales phechael?		10000%	1
 Team members introduced themselves by name and role? 		5.36%	-1
 Additional absorbit procedures plureself. 		D.00%	
 Any official or animal step\$1 		3138%	. 0
Any placental concernit?		36.32%	.1
Any insentiteits consens?		21,05%	.4
Antineira grant		5.36%	1
Any equipment lances or concerns?		0.00%	(gr
Cathebar in and drawing?		15.79%	1
Till servini?		1.00%	1
 YTE prophylazis ? 		0.00%	- 12
Configurate conduct*		3.36%	1
Total Respondence 19			

Thirty one percent felt enquiring about critical or unusual steps should be included. Further question of bladder catheterisation was added after direct discussions with obstetric safety lead. The remaining points on the check list were only deemed essential by <26% of participants. Based on these results - a new shorter check list was created. We opted to only include points where the positive response rate was >30%.

Conclusion(s): A formal CAT1 LSCS checklist would streamline the timeline from decision to operate to KTS and highlight critical information to uphold patient safety.

This allows for emergency delivery of anaesthesia, surgery and delivery of baby. Outstanding information from the WHO checklist to be collated retrospectively rather than a substitution for this information

21AP07-13

Anesthesia challenges in eclampsia: a case report

I. Carrapatoso¹, P. Gaspar¹, T. Estevens¹, A. Delgado¹ ¹Hospital Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Eclampsia is a rare but life-threatening obstetric emergency requiring prompt seizure control, blood pressure stabilization, and urgent delivery. Anesthesia plays a pivotal role, with regional techniques preferred to minimize airway risks. This case highlights the challenges and crucial role of anesthesia management in eclampsia.

Case Report: 32-year-old woman, 39+1 weeks of gestation with hypertension, presented with new-onset seizures at home. On admission, she was postictal, blood pressure 169/99 mmHg, sinus tachycardia (110 bpm), peripheral oxygen saturation 94%, with bilateral lower limb edema.

Eclampsia was suspected, and magnesium sulfate (MgSO4) therapy was initiated (6g bolus plus 2g/h infusion). Labs showed hemoglobin 10.1 g/dL, platelets 161,000/µL. Another seizure occurred 20 minutes after admission, requiring diazepam (10mg) for cessation.

Another bolus of 4g MgSO4 was administered, and the infusion rate was increased to 3g/h. An urgent cesarean section under spinal anesthesia (SA) (morphine 100µg, sufentanil 2.5µg, bupivacaine 8mg) proceeded without complications. ASA monitoring, radial arterial line, oxygen therapy (2 L/min), blood typing, and two 18G intravenous accesses were established.

Multimodal analgesia (paracetamol 1g, ketorolac 30mg, ropivacaine 150mg), antiemetics (dexamethasone 8mg, ondansetron 4mg), aspiration prophylaxis (metoclopramide 10mg), and cefazolin 2g were used. Arterial blood gases showed pH 7.38, lactate

The newborn's Apgar scores were 8/9/10. Postoperatively, the patient was transferred to the intensive care unit. Her blood pressure stabilized, and no further seizures occurred.

Discussion: This case highlights the importance of MgSO4 as the cornerstone of eclampsia management to prevent recurrent seizures. Emergency cesarean section under SA, supported by comprehensive perioperative management, ensured maternal and neonatal safety. The absence of thrombocytopenia allowed the safe use of SA.

References:

1. Smith, J., et al. Anesthesia for cesarean delivery in eclampsia: A review of techniques and outcomes. Anesthesia & Analgesia. 2022;134(3):575-582

Learning Points:

- 1. Eclampsia requires immediate diagnosis and treatment with MgSO4 to prevent maternal and fetal complications.
- 2. SA is a viable option for cesarean delivery in eclamptic patients with hemodynamic stability and without thrombocytopenia.
- 3. Multidisciplinary coordination and timely intervention ensure favorable outcomes in cases of eclampsia.

21AP08-2 **High Anion Gap Metabolic Acidosis caused** by starvation ketoacidosis in pregnancy

M. Krupova¹

¹Cavan Monaghan Hospital, Anaesthesiology Department, Cavan, Ireland

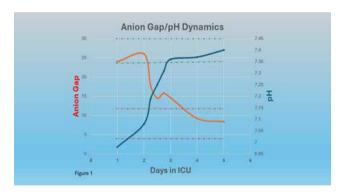

Background: Pregnancy leads to notable physiological changes, including an exaggerated fasting response due to relative insulin resistance and elevated counter-regulatory hormones like placental glucagon and lactogen. Inadequate caloric intake may trigger starvation ketoacidosis.

This report details a case where overlooked ketonuria in the 3rd trimester advanced to severe high anion gap metabolic acidosis (HAGMA), culminating in intrauterine demise (IUD).

Case report: A 33-year-old multiparous woman(36+2) presented with shortness of breath. Recent medical history: a dental abscess on antibiotics, not eating/+sleeping well. ED: markedly agitated. Afebrile. Tachypneic. Tachycardic, Hypertensive. Lab. results: Hb:15.8, WBC:28.3, Plt: 339; Creat: 67µmol/L, K:5.2mmol/L. Urinalysis: Ketones:150mg/dL, Proteins:500mg/dL. ABG: pH: 6.98, pCO2:1.52kPa, pO2:17.2kPa, BE: -28.8mmol/L, AG: 25.4mmol/L, Lactate:1.49mmol/L. Glu:4.4mmol/L. Bedside ultrasound: no foetal heartbeat. Following patient's stabilization using i.v. bicarbonate+ crystalloids+ MgSO4, an emergency C-section under GA was performed without complications.

It was revealed only after the procedure in the ICU, the patient hadn't eaten adequately for over 3 weeks, with ketonuria persisting for a similar duration.

To suppress further ketogenesis, an immediate source of glucose was administered with insulin and precautions for refeeding syndrome. The patient achieved complete homeostasis after 4 days. (Fig.1)

Discussion: After excluding pre-eclampsia and placental abruption, all potential causes of HAGMA, including intoxication, sepsis, renal failure and diabetic/starvation ketoacidosis, were considered. The most significant clue came from a thorough anamnesis, confirming long-term malnutrition. Regrettably, eminent ketonuria was already present during routine check-ups. Its oversight ultimately led to IUD.

Reference:

Abraham L.et al, Starvation Ketoacidosis in Pregnancy: An Unusual Presentation and Brief Literature Review, JCEM Case Reports, Volume 2, Issue 9, 2024.

Learning points: Early recognition and management of patients at risk of starvation ketoacidosis are crucial to ensure optimal foetal development.

21AP08-3

PCA remifentanil versus intermittent epidural boluses for labor analgesia: pain scores and patient satisfaction

D. Karadjova¹, A. Sivevski¹, E. Ivanov¹, S. Spasovski¹, M. Zlatkova¹, S. Simevska¹

¹University Clinic for Gynecology and Obstetrics, Department for Anesthesia and Intensive Care, Skopje, North Macedonia, The Republic of

Background and Goal of Study: In labor analgesia remifentanil is becoming very popular as an alternative to epidural analgesia. In this study, we compared pain scores and patient satisfaction in different time points during labor.

Materials and Methods: We analyzed 120 patients, ASA I, admitted for spontaneous labor and divided into two groups. The first group (60 patients) received intravenous patient-controlled analgesia with remifentanil titrated from 20 mcg up to a maximum bolus dose of 50 mcg with a lockout interval of 2 minutes. The second group, epidural group (60 patients) received intermittent epidural boluses. We evaluated pain scores and patient satisfaction scores through 2 VAS scales in different time points. Oxygen saturation (SpO₂) and respiration rate were monitored continuously.

Results and Discussion: VAS pain scores were significantly higher in the remifentanil group at all time points, mean values of the VAS pain scores after onset of analgesia were 4.1±1.2 in remifentanil group, 2.3±1.1 in the epidural group (p<0.0001). On the other hand, VAS satisfaction scores did not differ between the two groups. The average VAS satisfaction score during the entire monitoring period was 9.2 ± 0.9 in the remifentanil group, and 9.3 ± 0.8 in the epidural group, without statistically significant difference between the two groups (p = 0.69). Mean VAS score after delivery was 9.68±0.5 in the remifentanil group and 9.72±0.5 in the epidural group (p=0.8).

Conclusion(s): PCA with remiferatnil is less effective for pain relief in patients during labor compared to epidural analgesia, but the satisfaction of patients is equal in both groups. It could be a viable alternative to epidural analgesia in moments when it is contraindicated, unwanted by the patient or simply unavailable. Continuous respiratory monitoring is mandatory.

Uterine rupture following medical termination in a 21-week twin pregnancy with previous cesarean sections: a case report on management and outcomes

S. Tavares¹, H. Azevedo Duarte¹, L. Ramos¹, L. Silva¹, L. Castro1

¹Unidade Local de Saúde São José, Anesthesiology Department, Lisboa, Portugal

Background: Uterine rupture during medical termination of pregnancy is an uncommon but severe complication. This is a case of a medical interruption of a 21 weeks gestation that resulted in uterine rupture.

Case report: 41 year old female G3P1 (one prior abortion and two previous cesarean sections), presented for pregnancy termination due to Down syndrome in both fetuses. Medical induction was initiated with mifepristone, followed by hospitalization two days later due to heavy vaginal bleeding. at admission, ultrasound revealed pelvic fetal presentation with head retention and intraabdominal blood, uterine rupture was suspected.

Upon emergency arrival, the patient was hemodynamically unstable and was immediately transferred to the operating room. Due to the high suspicion of rupture, rapid sequence induction was performed, and massive hemorrhage protocol was activated due to continued blood loss and hypotension. Exploratory laparotomy confirmed rupture at the previous hysterotomy site. Resuscitation with blood products was tailored via real-time ROTEM analysis and included 6 plasma, 7 units of blood, 1 platelet pool, 6 g of fibrinogen, and 2 g of tranexamic acid. Additionally, 5 liters of crystalloids, ionic reposition and vasopressor support (ephedrine, phenylephrine, and norepinephrine) were required to stabilize the patient.

Despite uterine repair attempts, persistent hemodynamic instability prompted an emergency hysterectomy. The patient was then transferred to the ICU, and later recovered in the general ward without complications.

Discussion: The incidence of uterine rupture in pregnant patients with unscarred uterus is 0.3-0.8% for patients, increasing to 1.4% and 3.3% in patients with history of one or more C-sections. There is a higher risk of uterine rupture with medical termination in scarred uteri, particularly with the use of mifepristone. Unfortunately, at the time of this event, cell-saver with amniotic fluid filter wasn't available and was the only additional intervention that could decrease transfusional needs

References:

Heather Frey, MD, MSCI, Mark B Landon, MD. Uterine rupture: After previous cesarean birth. In: UpToDate, Connor RF (Ed), Wolters Kluwer. (Accessed on December 1, 2024.

Learning points: Uterine rupture in second-trimester medical terminations is rare but possible, especially in scarred uteri and multiple gestations. Local protocols must be in place with a trained multidisciplinary team.

21AP08-5

The long-term effects of unintentional dural puncture in obstetrics: a seven year prospective observational study

A. Weiss¹, Y. Binyamin², Y. Gozal¹, A. loscovich¹ ¹Shaare Zedek Medical Center affiliated with the Hebrew University Hadassah Medical School, Anesthesiology, Jerusalem, Israel, 2Soroka University Medical Center and the Faculty of Health Sciences, Ben-Gurion University of the Negev, Anesthesiology, Beer Sheva, Israel

Background: Post dural puncture headache (PDPH) is a debilitating condition that occurs following puncture of the dura. Little to no investigation has been done regarding the long-term morbidity of this condition. The widespread use of epidural analgesia for childbirth comes with a substantial incidence of unintentional dural punctures of 0.5%-1.5%. In a previous study we looked at the presence of chronic headache and backache in women 18-24 months following dural puncture and found a high incidence rate (16-23%).

In this study we examine the occurrence of chronic headache and chronic backache seven years post dural puncture, a significantly extended time period for post puncture sequelae.

Our study, and the previous one we conducted, is the first to exclude women with preexisting headaches or backaches.

Methods: 233 parturients were included in the analysis distributed across four groups: those who underwent a dural puncture and were treated conservatively, not with a blood patch (DP-no BP, n = 53), those who underwent a dural puncture treated with blood patch (DP-BP, n = 58), a control group of women without an epidural (n = 58), and a control group with uncomplicated epidural (n = 63). All women had delivered vaginally, and those with pre-existing chronic headache or backache prior to delivery were excluded from the analysis.

Results: In the DP-BP group, 12/58 (20.7%) women reported chronic headache, while 10/58 (17.2%) women in the DP-no BP group reported chronic headache. For chronic backache, 14/58 (24.1%) women in the DP-BP group and 12/58 (20.7%) in the DPno BP group reported chronic symptoms.

In comparison, no participants in the control without epidural group and 2/63 (3.2%) in the control with uncomplicated epidural group reported chronic headache. Chronic backache was reported by 7/63 (11.1%) in the uncomplicated epidural group and by 0 women in the control without epidural group. Statistical analysis revealed significant differences in the incidence of chronic headache between the groups (p = 0.0067), as well as in chronic backache (p = 0.0029). Women in the DP-BP group had lower odds of developing chronic headache and backache compared to both control groups.

Conclusion: PDPH poses long-lasting morbidity for years following dural puncture as we found a high incidence of chronic back pain and chronic headache in a seven year time-frame. Using epidural blood patch for treatment did not show a great advantage over conservative treatment.

Brain tumour during pregnancy: Clinical and surgical management of a challenging case

J. Caldeira¹, R. Silva¹, D. Henriques¹, A. Sá¹, J. Carvalhas¹ Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: The incidence of brain tumours during pregnancy is slightly lower than in non-pregnant women, about 2,6 cases per 100,000¹. The resulting increase in intracranial pressure can mimic common pregnancy-related conditions like hyperemesis gravidarum, delaying its diagnosis and posing additional challenges to maternal and fetal health¹.

Case Report: We describe a case of a 19-year-old primigravida, diagnosed with persistent hyperemesis gravidarum since the first trimester. In the 3rd trimester, she developed severe nausea and vomiting associated with psychomotor impairment. A CT scan showed a right medial cerebellar tumour with a cystic component. Obstetric and fetal examinations were reassuring.

At 31 weeks and 6 days of gestation, an Ommaya chamber was implanted to drain the cystic lesion and control intracranial pressure, under general anesthesia. We used rapid sequence induction (RSI), videolaryngoscopy for tracheal intubation, and maintenance with volatile anesthetics. During the 4-hour procedure, left lateral tilt and strict hemodynamic control were kept. Periodic fetal monitoring and tocolytic infusion with atosiban were maintained throughout.

Drainage through the Ommaya chamber provided symptom relieve, and a c-section was planned at 37th week of gestation.

Cesarian was performed under total intravenous anesthesia (TIVA) using propofol target-controlled infusion, RSI and videolaryngoscopy to secure the airway. Gastric aspiration and triple antiemetic prophylaxis were given. Multimodal analgesia included a bilateral ultrasound-guided TAP block. C-section was uneventful, and a healthy male newborn was delivered.

Two months later, the mother was submitted to suboccipital craniotomy with excision of the posterior fossa lesion, a pilocytic astrocytoma, and removal of the Ommaya reservoir, under TIVA, with no complications.

Discussion: An experienced team involving Neurosurgery, Obstetrics, Neonatology and Anesthesiology was crucial to ensure mother, fetus and neonate health. Optimal timing, coordination and accurate anesthetic management of the surgical procedures minimized the risk of complications and allowed a positive outcome.

Reference:

1. Molina-Botello D, et al. Pregnancy and brain tumors: a systematic review. J Clin Neurosci. 2021;86:211-216.

Learning points: The complexity and rarity of this case highlights the need for standardized guidelines and interdisciplinary teamwork to maximize safety for brain tumour management during pregnancy.

21AP08-8

Noise during anesthetic induction in obstetric operating rooms: a prospective observational

V. Ashok¹, A. Moses¹, I. Bhukal¹, V. Jain² ¹Postgraduate Institute of Medical Education and Research, Anaesthesia and Intensive Care, Chandigarh, India, ²Postgraduate Institute of Medical Education and Research, Obstetrics and Gynaecology, Chandigarh, India

Background and Goal of Study: Excessive noise in the operating room (OR) during anesthetic induction has shown to have negative consequences for healthcare workers and patients. Data regarding noise levels during anesthetic induction in obstetric ORs is currently lacking.

This study was conducted to measure and report noise during anesthetic induction for cesarean deliveries, with the hypothesis that noise levels during anesthetic induction in our obstetric ORs would be higher than existing Occupational Safety and Health Administration (OSHA) recommendations.

Materials and Methods: 100 ASA II/III parturients scheduled for cesarean delivery under either neuraxial or general anesthesia were consecutively recruited in this observational study. Baseline noise, time-weighted (TW) maximum and average noise, and peak noise levels were measured during the time of anaesthetic induction using a decibel meter (Decibel X Software, SkyPaw Co Ltd, Hanoi, Vietnam) running on a dedicated android mobile device placed discretely at the head end of the operating table.

At the end of surgery, patients reported their satisfaction with OR noise on a simple 5 point Likert scale. Data was analyzed using measures of central tendency and dispersion.

Results and Discussion: The overall mean TW average and maximum noise were 32.4±7.51 dBA and 56.02±6.74 dBA, respectively. The mean TW average and maximum noise levels did not differ significantly between elective (n=47) and emergency (n=53) caesarean deliveries [32.64+4.32 vs 32.18+9.46, MD(95%CI) -0.46(-3.33 to 2.52), p=0.76 and 55.39+4.72 vs 56.58+8.13, MD(95%CI) 1.19(-1.49 to 3.87), p=0.38]. The median[IQR] number of personnel in the OR during anaesthetic induction was 9[8-11], which had a weak correlation with the TW average noise [r(95% CI)=0.25(0.05 to 0.42), p=0.01].

In our study, 92(92%) patients reported being satisfied with the noise levels during anesthetic induction. The mean TW average noise level reported in our study was within the recommended OSHA threshold of ≤45 dBA for hospitals, which reflected on the overall greater patient satisfaction levels regarding OR noise.

Conclusion: Mean TW average noise level during anesthetic induction in our obstetric ORs was less than OSHA thresholds, and did not differ significantly between elective and emergency cesareans.

Maintaining noise levels below OSHA threshold recommendations could result in higher patient satisfaction scores, which requires further exploration.

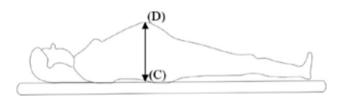

The relationship of back length and sagittal abdominal diameter with the level of sensorial block during spinal anesthesia for cesarean section: a prospective observational study

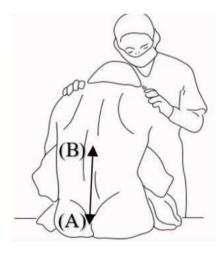

E. Altunbag¹, E. Tugcugil², A. Besir² ¹Republic of Turkey Ministry of Health Zonguldak Atatürk State Hospital, Anesthesiology and Reanimation, Zonguldak, Turkey, 2Karadeniz Technical University, Anesthesiology and Reanimation, Trabzon, Turkey

Purpose: In this study, we aimed to investigate the relationship of sensory block level with back length and sagittal abdominal diameter in spinal anesthesia for cesarean section using anthropometric measurements.

Materials and Methods: This study was conducted in 45 patients of 18-40 ages included in the ASA II classification. The patients' abdominal circumference (AC) and sagittal abdominal diameter (SAD) were measured in the supine position.

Height, weight, body mass index (BMI) and body roundness index (BRI) were noted. Trunk length (TL) and back length (BL) were measured in the sitting position. 0.5% hyperbaric bupivacaine 2 ml was administered with a 25 G Quincke needle at the $L_{4.5}$ level. The level of sensory block, heart rate, blood pressure, ephedrine doses, frequency of hypotension were noted.

Results: There was no correlation between height, weight, BMI, BRI, TL, AC, BL, SAD with maximum block level or hypotension (p>0.05). There was no correlation between BL, SAD and BL/ SAD2 with maximum sensory block level time, T, time and hypotension (p>0.05). There was a negative correlation between T₄ time and BRI (r:-0.338, p<0.05), AC (r:-0.350, p<0.05), TL/AC2 (r:0.349, p<0.05).

There was a positive correlation between T₄ time and TL (r:0.442, p<0.01). There was a negative correlation between maximum sensory block time and BRI (r:-0.300, p<0.05) and a positive correlation with TL (r:0.550, p<0.01).

Conclusion: In our study, anthropometric measurements were shown to be effective parameters for the rise time of sensory block level in pregnancy.

Our study showed that not BL, which is the regional spine length, but TL, which is the length of the entire spine, is more effective; therefore, it is not correct to evaluate the compression only mechanically. AC width, TL shortness, and high BRI are warning parameters for rapidly rising spinal block in pregnant women.

21AP08-11

Infection with parvovirus B19 and maternal mirror syndrome: A case report

L. Vifian¹, P. Rölli¹, C.T. Vetter¹ ¹Inselspital, University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background: Acute parvovirus B19 infection in pregnant women remains asymptomatic in up to 50%, and the infections increases worldwide. Fetal infection with parvovirus B19 and subsequent fetal hydrops (FH) is among the life-threatening manifestations of the infection. FH describes the presence of excessive fluid accumulation in at least two fetal body cavities. In 5-30% of cases of FH, the child's symptoms are reflected on the mother as mirror

In these cases, women present with non-specific signs and symptoms such as peripheral edema, weight gain, dyspnea, hypertension, headache, and visual disturbances.

Case Report: We describe the case of a 37-year-old patient (ASA2, G1/P0) at 26 weeks pregnant at admission (fetal weight: 810g), presenting with fetal hydrops due to parvovirus B19 infection (verified with PCR) and sudden onset of acute myoperocarditis during hospital stay.

Fetal ultrasound showed FH with pericardial effusion, ascites, and skin edema, as well as intrauterine growth restriction with pathological venous hemodynamics, placentomegaly and oligohydramnios.

During the two fetal transfusions hemoglobin of the fetus significantly improved from 27 g/L at the beginning to 138 g/L after the second procedure and one fetal ascites puncture were performed. One day after the procedures, the patient first complained of tremor, dizziness, headache, shortness of breath, and left-sided chest pain.

These symptoms became more severe during the course of the day. The patient was being unable to tolerate the supine position due to dyspnea. Correspondingly, the O2 saturation in the supine position decreased from 98% to 92% with oxygen 2 L/min. An ECG showed diffuse concave ST-elevations. Troponin was elevated NT-pro BNP at 6171 pg/ml. An CT-scan ruled out lung embolism. The patient was monitored, and supportive therapy was initiated, which led to a rapid improvement in symptoms.

Discussion: The potentially overlapping symptoms of mirror syndrome and acute myopericarditis of the mother in combination with the FH emphasizes the importance of close monitoring of the baby but also the woman herself, and differential diagnoses must be ruled out. Multiparity, elevated BMI, hemodilution, hypoalbuminemia, anemia, and hyperuricemia are risk factors for the development of FH, and it can also develop after the treatment of the fetus. Delivery is frequently required for fetal and/or maternal indications, and symptoms usually improve rapidly after delivery.

A network meta-analysis comparing the efficacy of epidural blood patch and neostigmine with atropine for the treatment of post-dural puncture headache

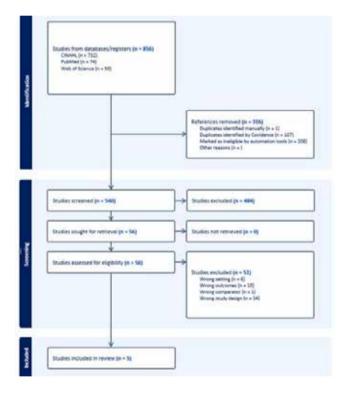

T.-J. Kuo¹, C. Kuo²

¹Taichung Veterans General Hospital, Department of Anesthesiology, Taichung City, Taiwan, 2Independent Researcher, Chia-Yi City, Taiwan

Background and Goal of Study: Post-dural puncture headache (PDPH) is a common complication of neuraxial anesthesia in obstetric patients. The epidural blood patch (EBP) is the most effective treatment, but its invasive nature has led to the exploration of alternatives such as neostigmine combined with atropine.

This study compares the effectiveness of neostigmine/atropine. EBP, and placebo in managing PDPH using a network meta-analysis.

Materials and Methods: This network meta-analysis included 5 RCTs with a total of 331 patients.

Participants were divided into 3 groups: neostigmine/ atropine(n=71), placebo (n=90), and various doses of EBP (n=170). Headache severity was assessed at baseline and 24 hours post-treatment. The primary outcome was the mean difference in headache severity between groups, with 95% confidence intervals (CI) calculated for each comparison.

Results and Discussion: At baseline, the neostigmine/atropine group exhibited slightly lower pain severity compared to the EBP group. No significant differences were observed between the EBP and placebo groups at this time point. At 24 hours post-treatment, the EBP group demonstrated significantly greater efficacy in reducing headache severity compared to both the neostigmine/atropine group and the placebo group. While neostigmine/atropine provided notable pain relief compared to placebo, it was less effective than EBP in achieving headache reduction at 24 hours.

Comparison	Mean Difference	95% CI	p-value
Epidural vs. Neostigmine (0hr)	1.0209	[0.3904, 1.6514]	0.0015*
Epidural vs. Placebo (0hr)	0.2676	[-0.1960, 0.7312]	0.258
Epidural vs. Neostigmine (24hr)	-4.1753	[-4.9614, -3.3892]	<0.0001*
Epidural vs. Placebo (24hr)	-6.5759	[-6.9794, -6.1724]	<0.0001*

Table 1. Efficacy of EBP vs Neostigmine/atropine and Placebo

Conclusion(s): Although neostigmine/atropine provides notable pain relief, it is less effective than EBP in reducing PDPH severity at 24 hours after treatment. Given its non-invasive nature, neostigmine/atropine may be a viable alternative for patients unable or unwilling to undergo EBP. Future research is necessary to optimize Neostigmine in clinical settings.

21AP08-13

The peripartum anesthesia management of placenta accrete treated via Resuscitative **Endovascular Balloon Occlusion of the Aorta** (REBOA)

L.m. Vegas isasi¹, S. Fein¹, A. Karam¹, A. Ioscovich², I. Valbuena Gomez³, Y. Binyamin⁴ ¹Rabin Medical Center, Anesthesiology, Petah Tikva, Israel, ²Shaare Zedek Medical Center, Anesthesiology, Jerusalem, Israel, 3Hospital Universitario La Paz, Anesthesiology, Madrid, Spain, 4Soroka Medical Center, Anesthesiology, Beersheba, Israel

Background and Goal of Study: Placenta accreta spectrum (PAS) disorders are associated with abnormal placental attachment to the uterine wall and pose a significant risk of severe postpartum hemorrhage. The rising incidence of PAS has prompted the exploration of advanced management techniques. Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) has emerged as a promising approach for managing hemorrhage in PAS cases, yet, optimal anesthetic strategy in these high-risk situations remains unclear.

This study aims to evaluate the anesthetic management and surgical outcomes of PAS patients treated with REBOA across four international centers, with a particular focus on factors influencing anesthesia choice, conversion to general anesthesia, intraoperative pain management, and overall surgical outcomes.

Materials and Methods: A retrospective analysis was conducted of PAS patients who underwent cesarean delivery with REBOA inflation between 2018, and 2021, at four medical centers (Soroka, Beilinson, Sharei Zedek, and La Paz). Data were collected from medical records, including demographic details, anesthetic techniques, blood loss, transfusion data, surgical details, and maternal and neonatal outcomes.

Results and Discussion: The choice of anesthetic technique varied significantly across centers, with combined spinal-epidural (CSE) being the most common (47.7%). Conversion to general anesthesia (GA) was highest in spinal anesthesia cases (60%) and lowest in CSE cases (23.8%).

Intraoperative pain was a significant issue, with 33.3% of patients experiencing breakthrough pain. REBOA was successfully used in all cases, with no related complications, although blood loss varied significantly across centers (1000-3000 ml).

The transfusion rate also showed considerable variation (14.3% to 88.9%). Maternal ICU admission rates and neonatal outcomes, including APGAR scores, varied across centers.

Conclusion(s): REBOA appears to be a safe and effective intervention for managing PAS-related hemorrhage, with minimal complications in our cohort. However, significant variability in anesthesia protocols and surgical management across centers highlights the need for evidence-based guidelines. Combined spinal-epidural anesthesia may offer advantages over single-shot spinal anesthesia, with a lower rate of conversion to general anesthesia. Ongoing research is essential to standardize anesthetic approaches, optimize pain management, and refine REBOA use in PAS cases.

The Paediatric Patient

22AP01-1

Paraoesophageal hernia type II in preterm critical ill newborn: a case report

L. Tantsiura¹, A. Biliaiev¹, I. Kyselova¹, I. Yachnyk^{1,2}, I. Stadnik³

¹Shupyk National Healthcare University of Ukraine. Paediatric Anaesthesiology and Intensive Care, Kyiv, Ukraine, ²National Children's Specialized Hospital Okhmatdyt, ICU, Kyiv, Ukraine, 3Municipal Children's Hospital #1, NICU, Kyiv, Ukraine

Background: Gastro-oesophageal reflux (GER) is common in children in the first months of life. Among the causes of GER, paraesophageal hernias are rare; they are primarily congenital and require timely diagnosis and urgent surgical intervention [1].

Case report: A preterm newborn, was admitted to the NICU on the 2-nd day of life with respiratory disorders, the need for mechanical ventilation (MV) and massive gastric bleeding. Diagnosis of haemorrhagic disease of the newborn was confirmed. As he stabilized and improved, feeding a small amount of infant formula through the gastric tube resumed. After weaning from MV and commencing full-volume feeding in the third week of life, he exhibited symptoms of GER, including vomiting with haematemesis. Anti-reflux therapy was unsuccessful. OGD revealed signs of esophagitis and hiatus hernia. A contrast swallow test confirmed the diagnosis, which assumed a type II paraesophageal hernia. The patient underwent Nissen fundoplication and crurorrhaphy.

Discussion: We presented a clinical case of a rare disease for children - paraesophageal hernia type 2, which was the cause of GER and vomiting in a neonate after reaching the age-appropriate feeding volume. Unlike most cases in adults, the mechanism of this pathology in neonates is congenital and apparently a variation in the failure of the central tendon of the diaphragm development. Factors associated with intensive care could cause a delay in identifying the actual congenital anomaly of the upper Gl. Such factors could be a pause in feeding, MV, intestinal paresis, another severe disease that manifests bleeding from the Gl,etc. Although haematemesis is one of the so-called "red flags" to rule out disorders other than GER, the simultaneous presence of other conditions, such as DIC syndrome or stress ulcers, may reduce vigilance in searching for surgical pathology.

References:

1. Garvey EM, Ostlie DJ. Hiatal and paraesophageal hernia repair in pediatric patients. Semin Pediatr Surg. 2017 Apr;26(2):61-66. Learning points: Hiatal hernia is a rare condition for newborns. In the differential diagnosis consider the possibility of a congenital diseases of the upper GI.

22AP01-2

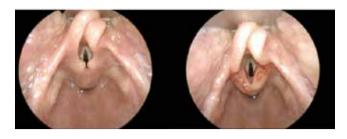

Pediatric airway management in cold-steel supraglottoplasty: a case report

M. Antunes¹, P. Alves¹, C. Gomes¹ ¹Unidade Local de Saúde de Braga, Anaesthesiology Department, Braga, Portugal

Background: Laryngomalacia is the leading cause of chronic inspiratory stridor in children, with 10% of cases requiring surgical intervention¹. Reduced airway diameter can make manual ventilation and orotracheal intubation challenging.

Case Report: A 2-year-old girl with congenital laryngomalacia was scheduled for cold-steel supraglottoplasty. Standard ASA monitoring was applied, along with anesthetic depth monitoring with BIS® and cerebral oximetry with INVOS®. We used intravenous anesthesia (TIVA) with propofol and remifentanil and high-flow nasal oxygen therapy (HFNO) while maintaining spontaneous ventilation. The procedure was uneventful, maintaining hemodynamic stability and spontaneous ventilation without desaturation.

Discussion: Laryngomalacia presents significant challenges due to airway management complexity. This case demonstrates a successful approach using TIVA, HFNO and maintenance of spontaneous ventilation. HFNO prolongs apnea tolerance, allowing deeper anesthesia during periods of heightened stimulation and reducing interruptions for rescue oxygenation².

TIVA allows unobstructed surgical access to the airway, anesthetic depth independent of the airway and avoids environmental contamination, though it increases risks of apnea and patient movement3

References:

- 1. Robbins A. Operative Techniques in Otolaryngology-Head and Neck Surgery. 2022;33(3):175-178;
- 2. Kim JY. Medicine. 2021;100(49):e28102-e28102; [3] Oshan V. Continuing Education in Anaesthesia Critical Care & Pain. 2013:13(2):47-51.

Learning points:

- · Laryngotracheal surgeries present challenges for anesthesiologists due to the shared airway, increasing the risk of perioperative airway compromise;
- · Due to the rarity of this condition, no standard anesthetic protocols exist, making thorough preoperative planning and multidisciplinary coordination essential.

22AP01-3

The phenomena of arrhythmia-induced cardiomyopathies (AICM): what comes first, the chicken or the egg?

M. Krmzova Gjorgjioska¹, V. Chadikovski¹, L. Malinovska Nikolovska¹ ¹Acibadem Sistina Hospital. Pediatric Cardiac Surgery. Skopje, North Macedonia, The Republic of

Background: AiCM is an important reversible cause of heart failure that is likely underestimated in clinical practice due to the uncertainty in diagnosis. Diagnosis can only be made after witnessing ventricular function recovery with successful rhythm or rate control, or the very clear onset of cardiomyopathy temporally associated with the onset of arrhythmia.

Case Report: A 7-year-old male patient came to our pediatric ED for palpitations, fatigue and chest pain. One week ago the patient had symptoms of flu, but at the moment of hospitalization no evidence of viral or bacterial infection was found. Electrocardiogram (ECG) revealed atrioventricular dissociation with atrial rate faster than the ventricular, and average heart rate of around 190 bpm. Transthoracic echocardiogram was performed and severe congestive heart failure was diagnosed with global hypokinesia and dilation of the left ventricle. The NT-Pro-BNP was 26725pg/ml. Consequently, a therapy with amiodarone and beta blocker was gradually designed to control the arrhythmic pattern. After the decrease of heart rate, we continued to treat the heart failure with beta blocker carvedilol, digoxin, ACE inhibitor and diuretics. At the first check-up after discharge there were still no signs of sinus rhythm on EKG, but the heart function was easily improved.

Discussion: Reversible forms of cardiomyopathies due to arrhythmic causes in pediatric patient represent a rare event. Even if the causative arrhythmia is apparent, the clarification of a causeeffect relationship sometimes provokes a diagnostic "headache" for the treating physician, since diagnosis may be confirmed only retrospectively. Raising awareness of the difficulties of diagnosis and all available treatment options is essential for a better management of dysrhythmia in children.

22AP01-4

The whistling boy: an anesthetic challenge

S. Faria¹, P. Sequeira¹, J. Rodrigues¹, F. Gouveia¹, C. Monteiro¹, G. Araújo¹

¹Unidade Local de Saúde de Vila Nova de Gaia e Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: This case highlights the importance of flexible adaptation in airway management, including the use of jet ventilation and emphasizing its value in pediatric bronchoscopy.

Case Report: A 5-year-old male patient, 20 kg, ASA I, went to the pediatric department 1 day after swallowing a small whistle. A whistle sound was audible on physical examination when the patient deep breathed. His vital signs were stable, he had no respiratory distress and did not require supplemental oxygen. After a thoracic x-ray, the foreign body was found to be in middle trachea. The initial plan was a flexible bronchoscopy through a laryngeal mask airway (LMA) under intravenous general anesthesia.

After standard ASA monitoring, anesthesia was induced using 60 µg of fentanyl, 60 mg of propofol and 15 mg of rocuronium. Once a sufficiently deep level of anesthesia was achieved, a size 2.5 Igel® LMA was successfully inserted. Anesthesia was maintained using continuous infusion of 1% Propofol.

Flexible bronchoscopy was unsuccessful in removing the foreign body, and a rigid bronchoscopy was required. The airway management was modified to manual jet ventilation using the Manujet III® system. The maximum driving pressure was 1.4 bar, frequency of 30 breaths per minute, FIO₂ of 100%. Over the course of 10 minutes, a rigid bronchoscopy was performed, successfully removing the foreign body. The patient maintained stable vital signs, including a SpO2 of 100%.

After completing the bronchoscopy, the patient was transitioned from jet ventilation to facial mask ventilation, and neuromuscular blockade was reversed with 40 mg of sugammadex. Spontaneous ventilation resumed within 5 minutes. The perioperative course was uncomplicated, and the patient was discharged 1 day following the procedure.

Discussion: Rigid bronchoscopy requires a clear and stable operative field. Anesthesia using manual jet ventilation has proved a valuable technique in procedures where thoracic immobility is required.

Reference:

Miyawaki, J. https://doi.org/10.1016/s0952-8180(03)00023-0 Li, S.(2010), https://doi.org/10.1016/i.iiporl.2010.09.018 Learning points: Manual jet ventilation can maintain a stable and unobstructed operative field, enabling the successful removal of a foreign body in a child with a previously stable presentation.

22AP01-5

Exploring anesthetic strategies in rare disorders: a case of molybdenum cofactor deficiency

A. Silva¹, G. Araújo¹, M. Duque¹ ¹Unidade Local de Saúde de Gaia Espinho, Anesthesiology Department, Vila Nova de Gaia, Portugal

Background: Molybdenum cofactor deficiency (MoCD) is a rare autosomal recessive disorder characterized by disrupted metabolic pathways and neurotoxic sulfite accumulation. MoCD leads to neurological impairment, including seizures. Prognosis is poor, with high mortality and limited treatment options.

Limited cases have been reported, and evidence on anesthetic management remains sparse, posing challenges in managing these patients1.

Case Report: We present a nonoperation room anesthesia (NORA) case of a 15-month-old female with MoCD Type A who underwent brain MRI under deep sedation. The patient weighed 9 kg and displayed severe neurological symptoms, spasticity and intractable seizures, despite a regimen of anticonvulsants (vigabatrin, levetiracetam, phenytoin, and diazepam).

No premedication was given, and sedation was achieved with sevoflurane administered via a facial mask under spontaneous ventilation.

Continuous monitoring included oxygen saturation, heart rate, and capnography. The procedure lasted 37 minutes and went without complications. Following sedation, the patient was closely observed for three hours, with recovery assessed using the Modified Aldrete Score, being discharged home after.

Discussion: This case underscores the importance of individualized plan in MoCD. Perioperative continuation of anticonvulsants and a proactive plan was in place for managing intraoperative seizures to mitigate risk, highlights the importance of preemptive measures in high-risk patients.

Sevoflurane was chosen for its ability to enhance GABA-mediated neuronal inhibition, reducing excitability and seizure risk, while supporting spontaneous ventilation. It offers an alternative to agents like propofol, which should be avoided due to its high lipid content2.

References:

1. Alkan M. Choice of anesthesia in molybdenum cofactor deficiency: A case report. J Res Med Sci. 2014 Nov 2. Prasun P. Multiple Acyl-CoA Dehydrogenase Deficiency. GeneReviews® [Internet] https://www.ncbi.nlm.nih.gov/books/ NBK558236/

Learning Points: While a simple plan such as deep sedation with sevoflurane may seem effective, it doesn't mean it's safe. Pediatric NORA presents unique challenges that require anesthesiologists to remain vigilant for complications.

Awareness of the patient's underlying condition and readiness to address unexpected events are paramount to ensure optimal outcomes. We postulate that sevoflurane can be a relatively safe drug to utilize in patients with MoCD deficiency.

22AP01-6

Anesthetic management for syndactyly correction in a toddler with Poland syndrome: a case report

L. Cortes Pacheco¹, M. Brízido¹, M. Cardiga¹, J. Figueiredo¹ ¹Hospital da Luz Lisboa, Anesthesiology, Lisboa, Portugal

Background: Poland syndrome (PS) is a rare congenital condition affecting 1:30,000 to 1:80,000 live births, characterized by hypoplasia/agenesis of the pectoralis major muscle, often associated with upper limb and thoracic abnormalities. It poses specific anesthetic challenges, including risks of malignant hyperthermia (MH) and ventilation problems.1

We report the anesthetic approach for outpatient syndactyly correction in a toddler with PS, emphasizing the safe and valuable use of ketamine-dexmedetomidine (Ketodex) premedication.

Case Report: A 19-month-old boy with PS presented for outpatient correction of syndactyly of the right hand. He had agenesis of the pectoralis major, hypoplastic hand and syndactyly of the second and third fingers at the right side of the body. Medical history was significant for recurrent bronchiolitis.

Preoperative sedation with intramuscular ketamine (1mg/kg) and dexmedetomidine (1mcg/kg) facilitated operating room admission and enabled venous access cannulation and regional anesthesia. An axillary brachial plexus block with levobupivacaine 0.25%/5mL was performed under ultrasound guidance. Sedation was maintained with propofol target-controlled infusion, monitored by Bispectral Index™.

The 75-minute procedure was uneventful. Spontaneous ventilation was preserved, and SpO2 >98% was maintained with supplemental oxygen at 2L/min through nasal cannula.

Postoperative analgesia was supplemented with paracetamol 20mg/kg, ketorolac 0.5mg/kg and dexamethasone 0.2mg/kg. Recovery was smooth and the patient was able to feed within 40 minutes, being discharged home 5.5 hours post-surgery.

Discussion: PS requires individualized anesthetic strategies to avoid MH triggers, such as succinylcholine and halogenated agents, as well as close ventilatory vigilance if a spontaneous ventilation strategy is chosen. This is the first report demonstrating the safety and efficacy of Ketodex premedication in PS1. Regional techniques and intravenous agents are ideal to safely manage these patients and optimize recovery.

Reference:

1. Gui L, Shen S, Mei W. BMC Anesthesiol. 2018;18:57. Learning points:

- · Avoidance of MH triggers is a priority in PS patients.
- · Regional anesthesia combined with intravenous anesthesia provide effective perioperative management, minimizing risks and enabling rapid recovery in outpatient surgeries.
- · Ketodex premedication provides safe sedation, reducing healthcare associated distress and facilitating regional anesthesia.

22AP01-8

Effect of head position on nasotracheal intubation with video-laryngoscope in pediatric patients: a randomized controlled trial

Y.J. Chae¹, T.K. Kim¹, H.B. Joe¹, J.Y. Kim¹, S.Y. Park¹ ¹Ajou University School of Medicine, Anesthesiology and Pain Medicine, Suwon, Korea, Republic of

Background and Goal of Study: Nasotracheal intubation requires precise control of the tube tip for successful placement. In pediatric patients, anatomical differences pose additional challenges. The flexibility of wire-reinforced tubes further complicates tube manipulation in children. While head position adjustments have been shown to aid nasotracheal intubation in adults, their effects in pediatric patients remain unexamined.

This study aimed to evaluate the impact of different head positions (sniffing, neutral, and flexion) on the ease of nasotracheal intubation in children using a video laryngoscope (AceScope®).

Materials and Methods: This randomized trial included pediatric patients aged 1-10 years assigned to sniffing, neutral, or flexion positions. Intubation was performed using a video laryngoscope and wire-reinforced tubes.

The primary endpoint was the total intubation time, defined as the duration from the moment the tube was inserted into the nostril to the detection of end-tidal CO₂ on the monitor.

Secondary endpoints included time for each intubation stage (nostril to oropharynx, oropharynx to glottic opening, glottic opening to trachea and intubation difficulty assessed with IDS and subjective scores.

Results and Discussion: No significant differences were observed in total intubation time or stage-specific times among the three groups (median [IQR]: 67.5 [60.3-83.3] s, 66.5 [60.0-76.0] s, 74.5 [63.5–90.8] s; P = 0.149). Stage-specific and overall intubation difficulty showed no significant differences. The use of the cuff inflation method did not differ significantly among the three

However, in the flexion group, two cases required Magill forceps because the tube tip could not be positioned at the glottic entrance even after the maximum cuff inflation.

Conclusion(s): This study found no statistically significant differences among the three head positions in terms of total intubation time, stage-specific intubation times, or intubation difficulty in pediatric patients using a video laryngoscope.

However, the flexion position was less practical for routine anesthesia practice and offered no notable advantages.

These findings suggest that the sniffing and neutral positions are recommended for effective and practical nasotracheal intubation in pediatric patients.

22AP01-9 **Pediatric Anaesthesia Management in Advanced Pelvic Ewing Sarcoma Resection**

T. Zupanc¹, S. Djordjević Stanković² ¹Institute of Oncology Ljubljana, The Department of Anaesthesiology and Intensive Therapy, Ljubljana, Slovenia, ²University Medical Center of Ljubljana, The Department of Anaesthesiology and Surgical Intensive Care, Ljubljana, Slovenia

Background: Administering regional anaesthesia in pediatric patients presents unique challenges, and has potential adverse effects of opioid use in the perioperative period, especially in cancer patients. Increased opioid administration has been associated with immunomodulatory effects, including prolonged immunosuppression post-surgery. This suppression increases the risk of postoperative infections, posing challenges to recovery.

Our case report details the perioperative analgesia of a pediatric patient undergoing radical pelvic resection.

Case Report: We present the case of a 12-year-old boy with advanced pelvic Ewing sarcoma. After a favourable response to neoadjuvant chemotherapy, he underwent a radical pelvic resection. To manage pain effectively, we employed combined epidural and spinal anaesthesia alongside general anaesthesia.

The patient received standard preoperative monitoring. An epidural catheter was placed at L2-L3, followed by a subarachnoid block at L4-L5, administering 2.4 mL of 0.5% bupivacaine and 20 ug fentanyl. Both procedures adhered to guidelines.

General anaesthesia was induced with propofol, remifentanil (TIVA) and rocuronium. The patient remained hemodynamically stable during the 11-hour surgery, requiring only a single bolus of 10 mL of 0.25% levobupivacaine via the epidural catheter.

Postoperatively, he was extubated and transferred to the ICU. A continuous infusion of 1 mL/h of 0.2% levobupivacaine was initiated, with 7.5 mL boluses every 180 minutes.

The patient reported effective pain control and satisfaction with the regimen. The epidural catheter was removed on fifth postoperative day without complications.

Discussion: The latest studies show a connection between opioid analgesia and immunomodulation. We were able to provide successful pain management while minimizing the potential adverse effects of opioids. By first administering an epidural catheter and then a spinal block we were able, in the absence of a CSE needle, to position the catheter correctly.

Our analgesia technique provided excellent pain relief while maintaining stable hemodynamics, minimizing the need for additional analgesics, especially opioids, reducing the risk of immunomodulatory side effects.

Learning points: This case highlights the efficacy of combined epidural and spinal anaesthesia as a perioperative adjuvant analgesia strategy in pediatric cancer patients undergoing complex surgeries.

22AP01-10

Does a change in optic nerve sheath diameter have an association with postoperative emergence delirium in paediatric patients undergoing laparoscopic surgeries?

K. Sundaram¹, S.B. Shah¹, G. Prasad¹, P. Khanna¹, K. Prakash¹, N. Patel¹ ¹All India Institute of Medical Sciences, Anaesthesiology, Pain medicine and critical care, New delhi, India

Background and Goal of Study: Emergence delirium(ED) is one of the most common postoperative problem in paediatric population. The optic nerve sheath is linked to meninges, enabling cerebrospinal fluid to flow freely between the subarachnoid spaces of both intracranial and intraorbital regions. So patients with an elevated intracranial pressure(ICP) demonstrate an increase in optic nerve sheath diameter(ONSD). Due to the use of pneumoperitoneum during laparoscopic surgery, there is an increased risk of elevated ICP and ONSD.

The hypothesis is that an intraoperative change of ONSD will have an association with postoperative ED in paediatric patients undergoing laparoscopic surgeries.

Materials and Methods: A Prospective observational cohort study. Children between 2-8 years of age were premedicated with 0.1mg/kg midazolam before wheeling to the OR.

After induction of anaesthesia, three measurements of ONSD was acquired in both horizontal and vertical planes in each eye at 3 timepoints- T1, immediately after induction; T2, 15 minutes after intraperitoneal CO2 insufflation; T3, 10 minutes after releasing pneumoperitoneum. The mean value of ONSD from both eyes was calculated at each time point. In PACU, ED was assessed using PAED scale at each 5 minute interval till 30 minutes from the time of awakening. A score >10 will qualify to be presence of ED. Pain assessment was done using Face, Legs, Activity, Cry and Consolability(FLACC) scale.

Results and Discussion: Total 60 patients were recruited. No significant association was observed in percentage change in ONSD with emergence delirium at T2 (10.29 [4.668-18.068]% in patients with emergence delirium vs. 12.8 [6.383-16.806]% in patients without emergence delirium, p value = 0.594) and T3 (15.51 [8.181-23.387]% vs. 22.97 [10.65-30.91]%, p value=0.196). Median (25-75th percentile) FLACC score on arrival to PACU was significantly higher in patients with ED (6[5.25-6.75]) compared to patients without ED(0[0-0]) (p value <0.0001).

Non significant very weak negative correlation was seen between percentage change in EtCO2 at T2 with percentage change in ONSD at T2 with correlation coefficient of -0.053 and at T3 with correlation coefficient of -0.074.

Conclusion(s): There is no significant association between intraoperative change in ONSD and postoperative delirium in paediatric patients undergoing laparoscopic surgeries.

The study has to be conducted in large sample size to prove statistical significance.

22AP01-11

Evaluation of factors affecting the need for postoperative ICU care in pediatric patients undergoing Nissen Fundoplication surgery: a retrospective study from anesthetic perspective

G. Daghan¹, F. Uzümcügil¹, I.R. User², O. Boybeyi², T. Sover², S. Ekinci²

¹Hacettepe University, Department of Anesthesiology and Reanimation, Ankara, Turkey, 2Hacettepe University, Department of Pediatric Surgery, Ankara, Turkey

Background and Goal of Study: Nissen fundoplication (NF) surgery is a high-risk surgery in terms of postoperative respiratory failure and the need for intensive care due to the frequently co-existing neurological and lung-related diseases in the patient population, the low functional capacity of the patients, and the fact that it constitutes a major intervention to upper abdomen.

Our aim in this study is to investigate the factors that may affect the need for postoperative ICU care of pediatric patients undergoing NF surgery.

Materials and Methods: Between January 2018 and January 2023, 98 cases under the age of 18 who had NF surgery in our hospital were included. Data were obtained by retrospectively examining the hospital database system and anesthesiology followup forms in patient files. The patients' age, gender, body weight, preoperative BUN, albumin values, as well as surgery type, accompanying neurological disease, cardiac disease, recurrent lung infection and preoperative antibiotic use were obtained after approval from our university IRB (24.10.23, SBA-23/236).

Results and Discussion: While the total intensive care unit admission rate was 33.7%, the endotracheally intubated transfer to ICU with a mechanical ventilation requirement was 11.2% and the rate of postoperative respiratory failure was 5.1%.

The incidence of neurological disease, recurrent lung infection. and the co-existence of both neurological disorder and recurrent lung infection were found to be higher in the postoperative intensive care unit group (p=0,095; p=0,115 and p=0,102), despite revealing no statistical significance.

Similarly, although the frequency of antibiotic use due to preoperative pneumonia was higher in the postoperative intensive care unit group, the difference was not statistically significant (p=0,272).

Low albumin level (<3.5 g/dl) was a risk factor independent of other factors in predicting the need for intensive care after surgery (p=0.014). As the albumin level increased, the need for ICU care after surgery decreased (OR=0,186; %95 CI: 0,061-0,564 p=0.003).

Conclusion(s): It has been shown that preoperative albumin level may be a significant risk factor in determining the need for postoperative intensive care in pediatric patients undergoing NF surgery, and that co-existing recurrent lung infection or neurological disease may also be important factors in determining the need for postoperative intensive care.

22AP02-1

COPPER study: An RCT comparing cryoanalgesia with epidural in children undergoing pectus excavatum repair. A personalized approach through digital

E. Massaro¹, M. Bastianello¹, M. Rehman², G. Bonatti¹, A. Wolfler³, R. Bonfiglio¹

¹IRCCS Istituto Giannina Gaslini, Unit for Research in Anesthesia, Genoa, Italy, 2 Johns Hopkins All Children's Hospital, Department of Anesthesia and Pain Medicine. St. Petersburg, United States, 3IRCCS Istituto Giannina Gaslini, Unit of Anesthesia, Genoa, Italy

Background and Goal of Study: Pectus Excavatum is the most common pediatric chest wall deformity. Post-operative pain can be managed with a multimodal approach, including thoracic epidural analgesia. Intercostal cryoanalgesia is a promising alternative but further validation is needed.

We designed an RCT comparing cryoanalgesia with epidural integrating a clinical follow up and a more personalized approach: the digital twin.

Materials and Methods: This RCT study was developed in two stages. The first stage was a clinical follow-up with PedsQL score at 14 days after surgery integrated, in the second stage, with realtime physiological measures (such as heart rate, sleep quality, activity levels before and after surgery) provided by a wearable digital health technology (DHT).

The aim was to develop a patient's digital twin to personalize post-operative recovery tracking. Both stages were conducted at IRCCS G. Gaslini Hospital, Genoa, enrolling participants aged 12 and older to receive either cryoanalgesia or epidural analgesia.

Results and Discussion: Results of this abstract are focused on the second stage of the COPPER study. 20 patients were included with a median age of 14.50 years. PedsQL score was comparable between the two arms of treatment (81 in study group vs 80 in epidural group).

Patients in the study group experienced delayed onset of analgesic effect, often requiring supplementary pain management within the first 24-48 hours post-surgery, but they were discharged earlier than patients in the epidural group (3.5 days vs 4 days, respectively, p-value=0.031).

Digital twins analysis showed that patients in the cryoanalgesia group had higher daily step counts, suggesting a potentially faster return to activity (Figure 1).

Challenges, such as variable patient's compliance to wearable devices, might have influenced data accuracy and analysis.

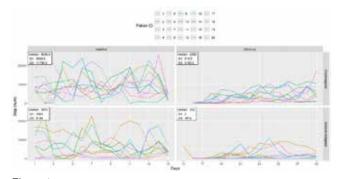

Figure 1.

Conclusions: Cryoanalgesia and epidural showed comparable efficacy in terms of quality of life 14 days after surgery. The use of wearable DHTs provided valuable insights into individualized recovery patterns, including tailored pain management strategies to facilitate early return to preoperative activities.

22AP02-2

They keep bleeding: von Willebrand disease and tonsillectomy - a case report

F. Zigman¹, I. Balenović¹, T. Tomić Mahečić¹, R. Curić Radivojević¹ ¹University Hospital Centre Zagreb, Department of anesthesiology, reanimatology, intensive care and pain therapy, Zagreb, Croatia

Background: Von Willebrand disease (VWD) is an inherited bleeding disorder characterized by reduced levels or dysfunction of von Willebrand factor (VWF), which due to impaired blood clotting, poses a significant risk of severe bleeding during surgery. This case report details the treatment of a 9-year-old with VWD Type 1 undergoing a tonsillectomy, reviewing the current guidelines.

Case Report: A 9-year-old girl with Type 1 VWD was scheduled to undergo a tonsillectomy. Diagnosed at birth due to intraparenchymal bleeding, she was under regular hematology care. Preoperative testing confirmed low VWF and factor VIII levels. She received 40 IU/kg of plasma-derived VWF before surgery and an additional 20 IU/kg 8 hours postoperatively. The initial recovery was uneventful. However, on the 15th postoperative day, she experienced significant bleeding from the right tonsil, requiring emergency surgery. Upon induction of anesthesia, she was given 20 IU/kg of plasma-derived VWF and 20 mg/kg of tranexamic acid. A follow-up dose of 20 IU/kg VWF was administered three days later to maintain VWF activity above 50%. The patient recovered well and was discharged on the third day after her second hospitalization.

Discussion: Tonsillectomy, though considered routine, presents a heightened bleeding risk in VWD patients. While DDAVP may suffice for minor to moderate bleeding, it may be inadequate for the significant bleeding risks associated with tonsillectomy and carries potential side effects. Thus, the combination of tranexamic acid with plasma-derived or recombinant VWF is preferred for major surgeries. Cryoprecipitate should be reserved for situations where other VWF products are unavailable.

Ensuring adequate preoperative VWF and factor VIII therapeutic levels together with an interdisciplinary approach is crucial for optimizing outcomes.

Haemostasis prophylaxis using single dose desmopressin acetate and extended use epsilon aminocaproic acid for adenotonsillectomy in patients with type 1 von Willebrand disease. Haemophilia. 2012 Mar;18(2):200-4. Learning points: Preoperative VWF and factor VIII monitoring is crucial. VWF and tranexamic acid are effective for major bleeding. Interdisciplinary care is essential

22AP02-3

Impact of dedicated paediatric trauma lists on out of hours emergency surgical caseload in a tertiary paediatric hospital, 10 years on

T. Nour¹, K. Daga¹, A. Mishra¹ ¹Royal Alexandra Children's Hospital, Anaesthesia, Brighton, United Kingdom

Background and Goal of Study: Following the introduction of thrice weekly (Mon, Thurs, Fri) dedicated trauma lists in May 2011, we witnessed a drop in 'out of hours' (OOH) orthopaedic trauma cases as a proportion of all OOH operating from 35% in 2010 to 29% in 2011

In this study, we aimed to follow up on whether this improvement has been sustained in post-pandemic years.

Materials and Methods: We interrogated the theatre management software for all emergency operations from October 2018 to June 2024, dividing them into orthopaedic and non-orthopaedic surgery. We classified cases as OOH if they occurred over weekends, public holidays and weekdays on or after 17:30 and before 08:30 hours. To counter the effects of seasonal variations, we focused on 2019-2023, where data was available for complete vears

Results and Discussion: The number of cases for individual years are shown in Table 1. 3898 emergency operations were conducted in the period, including 1301 orthopaedic and 2597 non-orthopaedic cases. 1101 cases were performed out of hours, made up of 218 orthopaedic cases and 883 non orthopaedic cases.

OOH cases only	2019	2020	2021	2022	2023	Total
All OOH cases	208	255	191	223	224	1101
Orthopaedic OOH cases	40	55	39	43	41	218
Percentage Ortho / All cases	19.2	21.6	20.4	19.3	18.3	19.8

Table 1.

The percentage of all out of hours operating which was emergency orthopaedic averaged at 19.8% (range 18.3 - 21.6%). This shows a further improvement since the previous study (in 2012). Increased provision of emergency surgery in hours has widereaching benefits1.

Dedicated trauma lists at the Royal Alexandra Children's Hospital mean more children are discharged from the emergency department to return for day case procedures, reducing overnight admissions, risk of hospital acquired infection, cost of admission and improving the patient experience.

Conclusion(s): This study has demonstrated sustained improvement in OOH orthopaedic case numbers since the introduction of dedicated in-hours trauma lists, with positive implications for elective list staffing, staff wellbeing and patient safety.

Tunneled central venous catheters - beyond scholastic education

R. Abdullavev¹, G.E. Kilicaslan², D. Tas³, A. Kararmaz¹ ¹Marmara University, Anesthesiology and Reanimation, Istanbul, Turkey, 2Dr. Yaşar Eryılmaz Doğubeyazıt Hospital, Anesthesiology and Reanimation, Ağrı, Turkey, 3Ercis Sehit Ridvan Çevik Hospital, Anesthesiology and Reanimation, Van, Turkey

Background and Goal of Study: Intravascular catheters are used for infusion of hyperalimentation fluids, blood products, antimicrobial and chemotherapeutics; hemodialysis and plasmapheresis. Complications include arterial puncture, pneumothorax, air embolism, catheter malposition or kinking, infection and thrombosis. [1] Tunneled catheters are generally performed by interventional radiology and pediatric surgery, but in recent years they have also been used by anesthesiologists.

The aim of this study was to investigate the complication rates of tunneled catheters inserted in our clinic in a 4-month period.

Materials and Methods: In this retrospective observational study, 15 pediatric patients having tunneled catheter insertion were included. Demographic data, data about the catheter insertion procedure and complications were obtained. Jamovi software was used for analysis.

Results and Discussion: Seven of the fifteen patients were male (47.7%). Mean age was 12.8 years (range 5-17). The internal jugular vein was used in all patients, eleven right and three left. The procedure was successful in all but one. Complications such as thrombosis, pneumothorax, subcutaneous emphysema were not observed. Catheter-related infections were observed in three patients and catheter dysfunction in four.

Mean procedure time was 52 minutes (range 28 to 85). Catheter thicknesses were selected according to current guidelines by evaluating the age and body weight of the patients. Catheter lengths were adjusted by taking measurements from thoracic Xrays. At the end of the procedure, confirmation was performed with C-armed scopy.

Conclusion(s): Tunneled central venous catheter placement is associated with some difficulties and complications. Taking the necessary precautions, performing the procedure in accordance with the current literature and guidelines, performing the catheterization procedure with a planned strategy and appropriate imaging methods, and applying the correct catheter care may reduce the risk of complications.

We should follow surgical discipline, learn the technique well and teach it well for this procedure that we anesthesiologists have just started to learn.

Anesthesia management in Smith-Lemli-Opitz syndrome: a case report

S.I. Türkel¹, E. Öçmen¹

¹Dokuz Eylul University School of Medicine,
Anesthesiology and Reanimation, Izmir, Turkey

Background: Smith-Lemli-Opitz Syndrome (SLOS) is a rare autosomal recessive disorder caused by a deficiency in the enzyme 7-dehydrocholesterol reductase, resulting in multiple congenital anomalies and cognitive impairment. It affects multiple organ systems including the airway, gastrointestinal, genitourinary and central nervous systems.¹

Anesthesia management in SLOS is challenging, especially due to the increased risk of muscle rigidity and malignant hyperthermia.

Case Report: A 5-year-old 15 kg male child, was scheduled for an adenotonsillectomy. He had been diagnosed with SLOS type 1 at birth and had undergone a trigonocephaly surgery at 15 months. The patient also had autism spectrum disorder and dysphagia with solid foods. Systemic examinations and laboratory tests were normal. Preoperative vital signs were normal.

Total intravenous anesthesia (TIVA) was planned using 2% propofol and remifentanil, avoiding inhalational agents due to the risks associated with SLOS. The patient was scheduled as the first case.Premedication with 0.5 mg/kg midazolam was given.

In the operating room standard monitoring was applied,followed by induction with 0.1 mg/kg atropine,2 mg/kg propofol and 0.3 mg/kg rocuronium. To prevent nausea-vomiting and for antiedema traetment,3 mg of dexamethasone was administered.

Endotracheal intubation was successfully achieved with a 4.0 cuffed tube on the first attempt. Maintenance anesthesia consisted of 0.5 mcg/kg/min remifentanil and 6 mg/kg/hr 2% propofol.which was later increased to 8 mg/kg/hr.

Postoperative analgesia included 100 mg of paracetamol and 0.5 mg of intravenous morphine. Extubation was uneventful.

Discussion: Careful preoperative evaluation is essential for patients with SLOS, given the potential for difficult airway management.²

In this case, direct laryngoscopy facilitated successful intubation, although videolaryngoscopy and supraglottic airway devices may also be effective. For patients at high risk for malignant hyperthermia, TIVA is preferred to avoid inhalational anesthetics.

This case underscores the need for a tailored anesthetic approach in SLOS, highlighting the importance of a multidisciplinary team to ensure safe outcomes for this complex patient population.

Dexmedetomidine sedation in children undergoing magnetic resonance imaging: doses, effectiveness and side effects

N. Markovic¹, G. Rakić¹, D. Turanjanin¹, S. Starčević¹, M. Preveden¹

¹University of Novi Sad, Faculty of Medicine, Anesthesia and perioperative medicine, Novi Sad, Serbia

Background and the Aim of the Study: Sedation and general anesthesia have facilitated magnetic resonance imaging examinations in children. Soon after the procedure is performed, the patient can be safely discharged from the hospital on the same day. Dexmedetomidine is a new drug, that causes loss of consciousness similar to normal sleep, which makes it a suitable alternative to general anesthesia for pediatric MRI. It reduces the level of exposure to conventional anesthetic agents and invasive ventilation. Previous studies have shown that there is an extensive range of doses of this drug that can achieve adequate sedation in children. However, high doses can lead to hemodynamic instability, accompanied by bradycardia and hypotension.

This study aimed to examine dexmedetomidine effectiveness and cardiopulmonary safety as a sedative drug for children undergoing MRI.

Methods/materials: This was a prospective study where data was analyzed from 177 consecutive patients who were sedated with dexmedetomidine for MRI from October 2023 to September 2024

Results and discussion: The 10-minute loading dose, according to our dexmedetomidine protocol varied from 1 to 4 mcg/kg with an average dose of 1,83 mcg/kg, and the infusion rate varied from 0,7 to 5 mcg/kg/h with an average dose of 1,75 mcg/kg/h.

Our results showed a 24,3% lower heart rate than the age-adjusted normal range after the loading dose and a 21,54 % lower heart rate during the infusion dose. Mean arterial blood pressure was within 15,6 % of the age-adjusted normal range after the loading dose and 17,6% lower than the age-adjusted normal range during the infusion dose. Oxygen saturations measured by pulse oximetry were 98% or higher. Additional drugs were needed in 5% of natients

Conclusion: Dexmedetomidine is useful as the sole sedative for pediatric MRI. Using dexmedetomidine in high doses is associated with a decrease in heart rate and blood pressure, but it did not cause severe side effects.

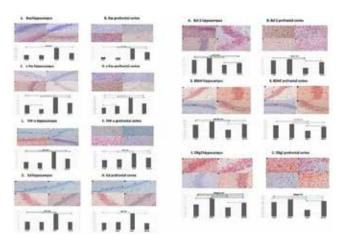

22AP02-10

Effects of prophylactic vitamin D on behavioral hyperactivity and neurotoxicity in mice exposed to sevoflurane on postnatal day 10

E. Biricik¹, M. Ünverdi¹, <u>F. Karacaer¹</u>, D. Tunay¹ ¹Çukurova University, Anesthesiology, Adana, Turkey

Background and Goal of Study: Sevoflurane is a GABA-A receptor agonist. GABA can induce excitatory postsynaptic responses in young neurons Sevoflurane-induced neuronal activation and behavioural hyperactivity may contribute to the agitation observed in children. Exposure to anaesthetics may lead to neuroinflammation and neuroapoptosis.

Materials and Methods: Vitamin D (vit D) is a regulator in various physiological pathways such as brain development, immunomodulation. This study investigated the effects of vit D on behavioural hyperactivity and neurotoxicity in young mice exposed to sevoflurane.

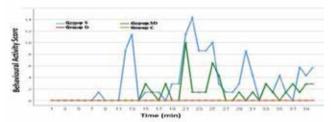

Fig 1a. Sevoflurane induced behavioral hyperactivity

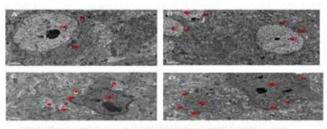

Fig 1b. EM views of hippocampus. A. Group C B. Group D C. Group S D. Group SD

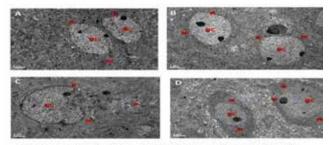

Fig 1c. EM views of prefrontal cortex. A. Group C B. Group D C. Group S D. Group SD

Results and Discussion: Twenty-eight Swiss albino mice were randomly divided into four groups: Vitamin D (GD), control (GC), sevoflurane (GS) and vitamin D+sevoflurane (GSD) groups. Mice in GD and GSD received daily intraperitoneal injections of 5 µg/ kg calcitriol from PN to PN10, while mice in GC and GS received saline injections. On PN10, mice in GS and GSD were placed in an anaesthesia chamber (35x15x15 cm) for 5 min to habituate to the environment. Mice in GS and GSD were exposed to 2% sevoflurane in 100% O₂ at a flow rate of 2 L/min for 10 min. Mice in GC and GD received 100% O_a. After exposure, all mice were allowed to recover in a chamber for 40 min.

Behavioural activity of each mouse was recorded and scored using the Behavioural Activity Score. Hippocampus and prefrontal cortex sections from six mice per group were examined by immunohistochemical methods (IHM) and electron microscopy (EM). IHM was used to assess the expression of IL6, BDNF, TNF-α, c-Fos. Bcl-2. Bax and Olig2.

Conclusion(s): Vit D treatment reduced behavioral hyperactivity in GSD compared to GS. In GSD, Bax, IL6, TNF-α and c-Fos expressions were decreased, whereas BcI-2, Olig2 and BDNF expressions were increased compared to group S (p<0.0001). EM images supported these data.

22AP02-11

Anesthetic management challenges in pediatric patients with Congenital Long QT Syndrome

G. Carreira¹, M. Pascoal¹, F. Figueiredo¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Congenital long QT syndrome (LQTS) is a cardiac condition marked by a prolonged heart rate-corrected QT interval (QTc) in the absence of structural heart disease. It commonly manifests in childhood and presents significant perioperative risks due to sympathetic stimulation or exposure to QT-prolonging drugs, increasing the chance of life-threatening arrhythmias.

Case Report: A 5-year-old female undergoing elective Morgagni hernia repair under general anesthesia was found to have a QTc of 467 ms, suggestive of LQTS. Propranolol therapy was initiated, and oral midazolam was used as premedication. Poor cooperation required sevoflurane induction, which resulted in QTc prolongation and transient ST segment depression that resolved upon discontinuation.

Intravenous induction was subsequently performed with lidocaine, fentanyl, propofol, and rocuronium. Maintenance was achieved with total intravenous anesthesia (TIVA) using propofol. The patient recovered uneventfully.

Discussion: This case highlights the anesthetic challenges in pediatric LQTS patients, emphasizing the importance of avoiding sympathetic stimulation during induction. Premedication with midazolam can attenuate the sympathetic response without affecting QTc. While inhalational agents like sevoflurane may be necessary for induction in uncooperative patients, they must be used cautiously due to their QT-prolonging effects. TIVA emerges as a safer alternative, minimizing arrhythmia risk.

Perioperative management requires strict avoidance of hemodynamic and respiratory instability, including hypertension, bradycardia, tachycardia, hypoxemia, and hypocapnia or hypercapnia, to optimize safety.

- 3. Yaman, F. et al., Anesthesia for a Child with Congenital Long QT Syndrome, a Case Report and Literature Review. Anesthesia, essays and researches, 15(1), 149-151

Learning Points:

- Congenital LQTS demands careful perioperative planning to mitigate arrhythmia risks.
- TIVA is the preferred anesthetic technique to minimize QT prolongation.
- 3. Beta-blockers and appropriate premedication are essential in the perioperative management.
- Ensuring adequate analgesia and monitoring is critical to prevent hemodynamic and ventilatory instability.

22AP02-12

Simplifying pediatric CVC placement: Ketodex and superficial plexus block in Rothmund-Thomson syndrome

V. Eckardt¹, <u>A.B. Guerreiro</u>¹, J. Pelicano Paulos² ¹Unidade Local de Saúde Lisboa Ocidental, Anesthesiology, Lisboa, Portugal, ²Unidade Local de Saúde São José, Anesthesiology, Lisboa, Portugal

Rothmund-Thomson syndrome (RTS) is a rare genodermatosis with about 300 reported cases in the literature. It includes premature aging, facial rash, predisposition to osteossarcoma, skeletal abnormalities and radial ray defects that can cause airway challenges (1).

This case describes CVC insertion in a 10-year-old RTS patient for prolonged osteossarcoma chemotherapy.

The patient exhibited hallmark features of RTS, including areas of hypo and hyperpigmentation, as well as dental anomalies, high-arched palate and restricted mouth opening. Cooperation was challenging due to the patient's anxiety and developmental limitations. Given the potential airway difficulty, we opted for sedoanalgesia with ketodex and a superficial cervical plexus block.

Standard ASA monitoring including ventilation assessment via nasal capnography was initiated, and oxygen therapy at 2L/min. Ketodex (combination of ketamine 1 mg/kg and dexmedetomidine 1 mcg/kg) was administered as a bolus over 10 minutes. The superficial cervical plexus block was performed under ultrasound guidance using a 26G needle, injecting 10 mL of 2% lignocaine. An initial desaturation episode resolved with supplemental oxygen via a facial mask. The remainder of the procedure occurred uneventfully without the need for additional local infiltration, including cannulation, tunneling and catheter fixation.

Ketodex ensured hemodynamic stability, absence of respiratory depression, analgesia and anxiolysis. Superficial cervical plexus block resulted in blockade of neural conduction in the ventral rami of the C1-4 nerve roots, providing an effective analgesia to CVC cannulation and obviating the need for additional IV sedation or airway manipulation (2). Here we preserved spontaneous breathing and airway patency while providing sufficient analgesia and anxiolysis to ensure procedural success.

We add to the growing body of evidence supporting the use of ketodex, a simple approach offering a safe and effective alternative for CVC placement in complex pediatric cases.

Rare complication of scalp block in pediatric neurosurgery: transient facial nerve palsy

S. Açici Çakıroğlu¹, <u>U.C. Ozagar</u>¹, G. Keskin¹, A. Dönmez¹ ¹Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Scalp block is regional technique used in neurosurgery to block sensory nerves innervating scalp. While routinely employed in adults, use in pediatric is rare. It targets sensory branches of trigeminal nerve greater and lesser occipital nerves. In our pediatric anesthesia clinic, this technique is routinely used to reduce pain during pin placement and scalp incision, decrease opioid use, and early neurological assessment. However, scalp blocks carry risk of complications,including rare facial nerve palsy. Few pediatric cases have been reported.

This article discusses a pediatric case of transient peripheral facial nerve palsy following scalp block, in addition to central facial palsy due to neurosurgery.

Case Report:11-year-old male,weighing 50 kg,presented with 3-month history of headaches and was diagnosed with right parietal AVM. Preoperative evaluations were normal. After premedication with oral midazolam, general anesthesia was induced with propofol (2mg/kg), lidocaine (1mg/kg), fentanyl (1µg/kg), and rocuronium(0.6mg/kg). Scalp blocks were performed using technique described by Pinosky et al.[1] with 1-2 mL of 0.5% bupivacaine mixed with 0.015 mg adrenaline.

Surgery lasted 4 hours without complications and was reversed with sugammadex. Postoperatively, patient exhibited grade 3 left facial paralysis and mild left arm weakness. Imaging studies,temporal CT and MRI, showed no abnormalities. Pediatric neurology diagnosed peripheral facial paralysis and initiated corticosteroid therapy.

Over following two weeks, upper facial paralysis resolved, but lower facial weakness and arm weakness persisted. By one month, all symptoms had resolved, and at a two-month follow-up, the patient resumed normal activities.

Discussion:This case highlights rare complication of peripheral facial nerve palsy following auriculotemporal nerve block during pediatric neurosurgery. Although technique was performed according to established methods, anatomical variations may contribute to complications.

Facial nerve block is typically self-limiting, but it may delay assessment of surgical nerve damage. To minimize complications, volume of anesthetic can be reduced, and injection site adjusted 1 cm above tragus, as suggested by Bebawy et al.(2).

This modification could lower the risk of adverse effects while maintaining effective anesthesia.

22AP03-2

Effect of instillation of intranasal dexmedetomidine on the duration of caudal analgesia in pediatric infra-umbilical surgeries

S.S. Mathew¹, G. Prasad¹, A. Gupta¹, L. Kashyap¹ ¹All India Institute of Medical Sciences, New Delhi, Anaesthesiology, Pain medicine and Critical Care, New Delhi, India

Background and Goal of Study: Caudal block is considered gold standard technique of analgesia in paediatric infra-umbilical surgeries due to its ease of placement and lesser adverse effects but the major flaw of single shot caudal block is the short duration which necessitates adjuvants. Dexmedetomidine, a highly specific α_0 agonist, in recent times have been explored as an adjuvant in prolonging the duration of caudal anesthesia. Our research guestion was, does dexmedetomidine, applied via intra nasal route prolong the duration of caudal block in such surgeries.

Primary Objective: To assess first analgesic requirement in the postoperative period

Secondary Objectives: To assess for post-operative sedation (Ramsey score), Readiness for discharge from PACU (Mod. Aldrete score)

Materials and Methods: We conducted a prospective randomized double-blind comparative interventional study. 60 patients among the age of 1-7 years undergoing elective infra-umbilical surgeries were randomised into two groups Group A - Caudal block with 0.25% Ropivacaine (1ml/kg)+ intranasal dexmedetomidine of 1mcg/kg and Group B Caudal block with 0.25% Ropivacaine (1ml/kg)+ intranasal saline. Intraoperative parameters and postoperative (PO) outcomes were recorded.

Patients were assessed on OR table for pain, sedation & PO agitation on extubation. All patients were monitored in post anaesthesia care unit (PACU) for 6 h and in the ward or telephonically till the first analgesic request.

This study was registered in national clinical trial registry of India on 9th September 2021(CTRI/2021/09/036376).

Results and Discussion: Demographic data and duration of surgery were comparable between both groups. No episodes of bradycardia or hypotension were noted in both groups. The mean (SD) time to first analgesic request in Group A was 562.57 ± 126.02 min and was 324.27 ± 81.77 min in Group B, significant prolongation was noted in the intervention group p valve <0.001 (un-paired t-test).

Longer periods of PO sedation (Ramsey score) were noted in Group A but all of the children were easily arousable score, but readiness to be discharged from PACU at end of 6 hours were comparable among the 2 groups.

Conclusion(s): Intranasal dexmedetomidine significantly prolongs the duration of caudal analgesia without any significant adverse events. It also gives a good quality recovery in children after surgery by reducing the incidence of delirium and anxiety in PO period.

22AP03-3

Perioperative management with manual exchange transfusion of a patient with a congenital heart disease and undiagnosed Sickle Cell Disease

L. Abella de La Torre¹, E. Abella¹, M. Raynard¹, R. Borras¹, T. De la Torre Garcia²

¹Hospital Universitari Dexeus, Anestesiologia y Reanimacion y Terapeutica Dolor, Barcelona, Spain, ²Hospital Vall d'Hebron, Anestesiologia y Reanimacion y Terapeutica del Dolor, Barcelona, Spain

Background: Sickle cell disease (SCD) involves a hemoglobin mutation, where HbS leads to vascular occlusion. Triggers such as hypoxia, acidosis, hypothermia, and low blood flow during cardiac surgery can provoke a sickle cell crisis. This report highlights the perioperative management of a 5-year-old girl with undiagnosed SCD undergoing atrial septal defect closure, emphasizing manual exchange transfusion as an alternative to automated exchange or simple transfusion.

Case: A 5-year-old, 15-kg girl from a developing country presented with SCD (82% HbS) and atrial septal defect. Initial anemia (Hb 6.9 g/dL) was clinically tolerated, with normal neurological, abdominal, and hepatosplenic findings. A simple blood transfusion (15-20 mL/kg RBC) was administered at 2 mL/kg/h due to Hb <7 g/dL. Continuous monitoring of blood counts, reticulocytes, and HbS levels followed. Under general anesthesia, femoral artery and right internal jugular vein access were obtained, while peripheral venous access in the lower extremities was avoided. Prophylactic antibiotics and tranexamic acid were given. Manual exchange transfusion was initiated: the first 10 mL/kg (150 mL) of blood was replaced with saline, followed by 30 mL/kg (450 mL) of RBC in two sessions. Calcium and glycemia were monitored every 30 minutes. Dopamine and milrinone ensured hemodynamic stability, and 10 mL/kg plasma was transfused. Post-surgery, the patient was extubated within 2 hours, with HbS reduced to 15% and no complications.

Discussion: Blood transfusion is critical in preventing strokes in SCD patients. The optimal transfusion method is debated. Simple transfusions raise ferritin levels (250 mg iron/unit RBC), increasing risks of liver cirrhosis, myocardial dysfunction, and mortality. Automated RBC exchange reduces ferritin levels but requires costly equipment and specialized personnel, limiting its accessibility. Manual exchange transfusion offers a practical alternative, mitigating ferritin-related risks and being feasible in resourcelimited settings.

Learning Points:

- · Anesthetic management of SCD in congenital heart disease.
- Practical application of manual exchange transfusion.

Short video viewing for preoperative anxiety and post-procedure recovery in the pediatric endoscopy unit: a prospective randomized study

C. Genc¹, O. Komurcu¹, B. Ciftci¹, F. Suna², O. Yuce² Samsun University, Faculty of Medicine, Department of Anesthesiology and Reanimation, Samsun, Turkey, ²Samsun Educational and Research Hospital, Department of Pediatric Gastroenterology, Samsun, Turkey

Background and Goal of Study: This study aimed to evaluate the impact of watching short videos on social media as a nonpharmacological intervention for reducing preoperative anxiety and its effect on recovery time in pediatric patients undergoing endoscopic procedures.

Materials and Methods: This prospective, randomized study was conducted in a tertiary care pediatric endoscopy unit. 102 patients were screened for eligibility between September 17 and November 27, 2024. A total of 22 patients were excluded, leaving 80 children who were randomly assigned to the video (Group V) or control (Group C) group. The primary outcome was anxiety scores, assessed using the Modified Yale Preoperative Anxiety Scale (mYPAS) at four-time points: upon arrival in the waiting room (T1), just before entering the operating room (T2), upon entering the operating room (T3), and during anesthesia induction (T4). The secondary outcome was recovery time, measured from the end of the procedure until the Aldrete score reached 9 or higher. Statistical analyses were conducted to compare anxiety scores and recovery times.

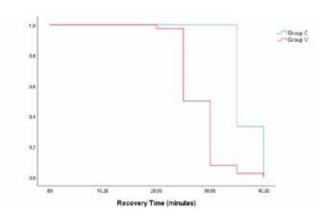

Results and Discussion: mYPAS scores were comparable at T1 (P=0.969); however, at T2, T3, and T4, Group V demonstrated lower scores than Group C (P < 0.001). mYPAS scores stayed relatively consistent in Group V, whereas they increased significantly over time in Group C (P < 0.001). Recovery times were shorter in Group V (p<0.001).

Comparison of The Perioperative mYPAS Scores

	Group V (n=38)	Group C (n=42)	p
mYPAS			
T1	39.9 (3.3) ^a	39.9 (5) ^a	0.969
T2	28.6 (3.3)b	43.2 (5)b	< 0.001
T3	35 (4.5)°	49.8 (4.1)6	< 0.001
T4	36.7 (4)4	53.9 (4.6)8	< 0.001
p	< 0.001	< 0.001	

mYPAS, modified Yale Preoperative Anxiety Scale. Data are expressed as median (interquartile range). +No significant difference was observed between measurement times with the same letter in within-group compa Entrance to the waiting room (T1), before being taken to the procedure room (T2), upon entering the procedure

Conclusion: Watching short videos on social media reduces preoperative anxiety and recovery time in pediatric patients undergoing endoscopic procedures.

22AP03-5

Retrospective evaluation of demographic characteristics, types of surgical procedures, postoperative hospitalization and mortality rates of pediatric patients undergoing surgery under general anesthesia

S. Hisarkava¹, F. Üzümcügil¹, F. Sarıcaoğlu¹, S. Ekinci² ¹Hacettepe University School of Medicine, Department of Anaesthesiology and Reanimation, Ankara, Turkey, ²Hacettepe University School of Medicine, Department of Pediatric Surgery, Ankara, Turkey

Background and Goal of Study: The risk of anesthesia is higher in pediatric patients than in adults, and this risk increases inversely with the age of the pediatric patient. This study aims to determine the gender and age group distribution, the most common surgery procedures, and to define the postoperative length of stay and mortality rates in patients operated on by pediatric surgery.

Materials and Methods: The data of patients who underwent pediatric surgery in the period from 01.01.2022 to 31.12.2022 were obtained from hospital digital database after university IRB approval (24.10.23, SBA-23/243). Gender, age at the time of the operation, type of the surgical procedure, the number of surgeries each patient undergone, postoperative hospitalization, the length of stay (LOS), and mortality within 30 days postoperatively were recorded.

Results and Discussion: The study encompassed 1,553 surgical procedures performed on 1,274 patients (70.7% male and 29.3% female) under the age of 18 who underwent surgery under general anesthesia. The most common age group for surgery was young children (4-12 years) (49.0%) and the least common was neonates (2.3%). The most common surgical procedure was abdominal surgery (21.7%) and the least common was trauma surgery (0.1%).

Postoperatively, 810 (52%) were hospitalized. Toddlers (57.2%) and children of walking age (53.4%) were most frequently admitted to day surgery, while neonatal group (8.6%) was the least. Of the 35 neonates, 32 (91.4%) were hospitalized with a mean LOS of 11 days.

The hospitalization rate was significantly higher in neonates (p<0.001). The longest LOS was found in neonates (p<0.001). Postoperative 30-day mortality was evaluated for medium/highrisk surgeries in which body cavities such as the abdomen and/or thorax were opened, as well as, tumor and port procedures. In this group, 30-day mortality rate was 10/655 (152 per 10.000). There was no significant correlation between mortality and gender and number of previous operations.

Hospital mortality was significantly higher in neonatal surgeries (OR=10.221; 95% CI: 2.561-40.797, p<0.001). As the LOS prolonged, the likelihood of hospital mortality continued to rise significantly (OR=1.015: 95% CI: 1.002-1.028, p=0.029).

Conclusion(s): In our study, neonates undergoing surgeries under general anesthesia had the highest rate of postoperative hospitalization, the longest postoperative stay and highest mortality rate.

22AP03-6

VA-ECMO as a lifeline: managing severe intoxication after speedball

F.N. Duruk Erkent¹, S.N. Aydin Kussan¹, A. Guven¹, F.C. Yerebakan¹, O.N. Altinisik¹, O. Selvi Can¹ ¹Ankara University, Anesthesiology and Reanimation, Ankara, Turkey

Background: Speedball, a combination of an opioid and a stimulant (cocaine or methamphetamine), is associated with high mortality due to respiratory and cardiac arrest.

This case highlights the rare occurrence of severe speedball intoxication in a pediatric patient requiring extracorporeal membrane oxygenation(ECMO).

Case Report: A 15-year-old female presented to the emergency department in a comatose state with clinical signs of shock. She was intubated and admitted to the pediatric intensive care unit. Physical examination revealed fever, nuchal rigidity, positive Kernig and Brudzinski signs, and ecchymotic and cyanotic skin lesions. Laboratory findings indicated elevated creatinine, thrombocytopenia, and severe metabolic acidosis. Toxicology screening confirmed significant elevations in amphetamine, methamphetamine, ketamine and lidocaine levels. Initial management included broad-spectrum antibiotics for presumptive septic shock, highdose vasopressors, and aggressive fluid resuscitation.

Despite these interventions, the patient remained in refractory shock. Femoral veno-arterial ECMO was initiated two hours postadmission, along with intravenous lipid emulsion therapy for intoxication management. On day 6, worsening renal failure and severe acidosis necessitated the initiation of continuous renal replacement therapy. Neuroimaging on day 7 revealed an intraparenchymal hematoma, prompting decompressive craniectomy. Transcalvarial herniation necessitated a fronto-temporo-parietal lobectomy. Despite maximal therapeutic efforts, the patient succumbed to meningococcal meningitis and vasopressor-resistant septic shock on postoperative day 10.

Discussion: This case presentation highlights the potential utility of VA-ECMO in managing severe intoxication with hemodynamic instability. While data on ECMO use in poisoning remains limited1, this case underscores its potential role as a bridge to definitive therapy by maintaining adequate perfusion. Notably, this case exemplifies the rare presentation of severe pediatric speedball intoxication leading to multi-organ failure, intracranial hemorrhage, and superimposed sepsis. While ECMO is a potential salvage therapy for adult drug intoxication, its use in critically ill children presents unique challenges and requires further study.

Learning points: VA-ECMO can stabilize hemodynamically unstable patients in severe intoxication cases.

22AP03-7

A tailored approach to paediatric airway management: lessons from a Goldenhar syndrome case

C. Cardante¹, M. Almeida¹, C. Gomes¹, J. Borges¹ ¹Unidade Local de Saúde de Braga, Anesthesiology, Braga, Portugal

Background: Goldenhar syndrome (oculo-auriculo-vertebral spectrum) results from a developmental disturbance in the first two branchial arches, that leads to craniofacial and vertebral anomalies that pose challenges in ventilation and intubation. Patients may have cardiac and renal defects of varying severity.1 Difficult airway management in children is particularly complex due to their higher oxygen consumption and limited cooperation in awake intubation.2

This case report describes a successful orotracheal intubation in children with Goldenhar syndrome.

Case Report: An 8-year-old female patient, ASA III, was scheduled for bone-anchored hearing aid implantation under general anesthesia. Preoperative physical exam revealed right-sided hemifacial microsomia with ear atresia and mandibular hypoplasia, resulting in limited mouth opening, a narrow oral cavity, and marked retrognathism. There was no history of other medical disorders. Laboratory tests were unremarkable.

After parental consent, the patient was transferred to the OR and monitored using ASA standard measurements, with additional monitoring of neuromuscular function and anesthesia depth.

Spontaneous ventilation was maintained with propofol boluses. An initial attempt with videolaryngoscopy was unsuccessful. A bronchofibroscopy was associated to guide our approach and, despite marked airway structure distortion, careful technique and patience, led to successful intubation.

The child was maintained on TIVA and the procedure went uneventfully. She was extubated once fully awake in the OR, recovered without complications and was discharged after 2 days.

Discussion: Goldenhar syndrome is linked to predictable difficult airway. The ESAIC-BJA new guidelines aim to address this gap in paediatric anticipated difficult airway management; however, they emphasize the need for adaptation, as there is no "one size fits all".3

In our case, combining videolaryngoscopy and bronchofibroscopy while maintaining spontaneous ventilation ensured safe intubation, emphasizing that adequate preparation and adaptability are essential. Trained anesthesiologist in paediatric airway management is also a crucial key to success.

Mastering anesthesia: a delicate dance with osteogenesis imperfecta – a case report

C. Pereira Pinto¹, A. Nogueira¹, J. Ramos¹, L. Ormonde¹ ¹ULS Santa Maria, Anesthesiology Department, Lisboa, Portugal

Background: Osteogenesis imperfecta (OI) is a group of hereditary disorders primarily characterized by bone fragility and is the most common cause of heritable bone weakness. It is associated with significant anatomical and physiological abnormalities, including mitral valve prolapse, a predisposition to malignant hyperthermia, abnormal cervical spine mobility, and an increased risk of mandibular and facial fractures.

These complexities present unique challenges for anesthetic management, requiring meticulous planning and care to ensure patient safety.1,2

Case Report: We present the case of an 11-year-old male with OI, ASA III, who underwent intramedullary nailing of the cubital bone due to an infected fracture osteosynthesis. His clinical features included short stature, blue sclerae, a barrel-shaped chest, and thoracodorsal kyphoscoliosis. He had no additional comorbidities.

The procedure was performed under balanced general anesthesia using sevoflurane, with the placement of a second-generation supraglottic airway (SGA). Special attention was given to gentle SGA placement to avoid cervical spine manipulation, and meticulous patient positioning was maintained to prevent fractures or soft tissue injury.

The surgery proceeded smoothly, without major complications or significant fluctuations in vital signs, and the patient experienced a successful, uneventful recovery.

Discussion: This case hopes to demonstrate a successful intervention in a patient with OI under balanced general anesthesia with sevoflurane, using a second-generation SGA. It also underscores the critical importance of a meticulous, multidisciplinary approach to anesthetic management in these patients to ensure optimal outcomes.

- 2. Gupta D, Purohit A. Anesthetic management in a patient with osteogenesis imperfecta for rush nail removal in femur. Anesth Essays Res. 2016 Sep-Dec;10(3):677-679.

Learning points: It is essential to adopt a flexible anesthetic and surgical approach when managing rare diseases with potentially severe anesthetic implications, guided by the best available scientific evidence and a thorough understanding of the disease's relevant pathophysiological features.

22AP03-9

Day-case paediatric anesthesia for dental surgery in children with autism spectrum disorder

I. Yovenko¹, D. Gavrychenko¹, M. Belyakov² ¹Odesa National Medical University, Dept of Anaesthesiology & Intensive Care, Odesa, Ukraine, ²Medical Home Odrex, Dept of Anaesthesiology & Intensive Care, Odesa, Ukraine

Background: Autism Spectrum Disorder (ASD) is a neurodevelopmental disorder. Social ties and interactions are persistently disrupted, communication difficulties, stereotyped behavior, and unusual responses to sensory stimuli occur, there are characteristic aggression, hysteria, self-harm. This makes it difficult to perform dental procedures in awake patients with ASD and requires the choice of anesthesia.

Case Report: Under our observation in 2022-2024 there were 87 patients aged 3 to 17 years with ASD, who required significant and very significant support (DSM-5). Patients underwent outpatient sanitizing dental interventions for infections of the teeth, periodontium and paranasal sinuses.

Discussion: Our local protocol for the anesthetic support is based on our experience and analysis of literature data [1]. The main rules on the day of surgery are: ensuring the maximum presence of the patient's parents (guardians) in the perioperative period; exclusion of a delay in the start of the surgery and the patient's waiting time in the clinic; support of the observance of the patient's household habits and taking the usual medications; minimization of sensory stimuli (light, sound) and the number of personnel involved in the procedure.

All of our patients received oral midazolam (0.5 mg/kg) 15 min. before the start of the procedure. Sedative effect (deep sedation) developed during 5-10 min. and lasted 35-45 min. After reaching a sufficient level of sedation, patients underwent peripheral vein catheterization. If it was necessary to potentiate sedation (37% of patients), we used intravenous administration of ketamine 0.1-

For patients monitoring we used a pulseoximeter, capnograph, and electrocardiogram. When deeper anesthesia was needed (17% of patients), we used induction with intravenous propofol 2-3 mg/kg.

For maintain of anesthesia we used propofol infusion 9-15 mg/ kg/h. Oxygen support was given through nasal cannulas. Also we used regional anesthesia with 2% lidocaine/adrenaline 1:100000. After reaching an adequate level of awakening, we practice fast discharge of patients from the clinic and their telemedicine support if it was necessary.

Reference:

1. Vallogini G, et al. Conscious Sedation in Dentistry for the Management of Pediatric Patients with Autism: A Narrative Review of the Literature. Children (Basel). 2022 Mar 24;9(4):460. Learning points: This approach provided for patients with ASD effective and safe sedation for dental surgery.

22AP03-10

A case of complex congenital heart disease posted for non-cardiac surgery: An extremely rare challenging case

T. Jamir¹, S. Mehta¹, R.K. Rajeev¹, H. Medikondu¹ ¹All India Institute of Medical Sciences, Anaesthesiology, Pain medicine and critical care, New Delhi, India

Background: We report a rare case of tricuspid atresia, hypoplastic left ventricle, unrestricted ostium secundum atrial septal defect, a large inlet ventricular septal defect, malposition of the great arteries, with aorta arising from the right ventricle, and a large patent ductus arteriosus (PDA), discussing the anesthetic management of the patient scheduled for non-cardiac surgery.

Case Report: An 8 month old female child, a follow-up case of necrotizing enterocolitis and a double-barrel stoma, along with complex congenital heart disease (CHD), was scheduled for stoma closure. On physical examination, the child presented with cyanosis, blood oxygen saturation of 73%, and a continuous grade III murmur on auscultation.

Laboratory investigations revealed hemoglobin level of 19g/dl and hematocrit of 61.2%. Intraoperatively, patient was induced with intravenous(IV) fentanyl, ketamine, and atracurium. An arterial line was placed in the left radial artery for strict blood pressure monitoring.

Analgesia was provided via caudal anesthesia and IV paracetamol. To maintain baseline systemic vascular resistance(SVR), phenylephrine infusion was initiated at 0.05-1.5mcg/kg/min to keep blood pressure within the 50th-90th percentile for the patient's age.

During the procedure, the patient remained hemodynamically stable. At the end of procedure, she was extubated and shifted to postoperative recovery room

Discussion: This case report demonstrates the intricate anesthetic management of patient with PDA dependent complex congenital heart disease. Pulmonary stenosis or disruption in the flow through a PDA can result in pulmonary hypoperfusion and progressive hypoxemia1.

In our case, pulmonary perfusion was dependent on heart rate²

The primary objective of our management was to prevent complications associated with complex CHD and maintain stable hemodynamics.

References:

- 1. Tyagi S et al. Stent implantation in right sided patent ductus arteriosus to relieve severe cyanosis in adult patient with pulmonary atresia and ventricular septal defect. Catheter Cardiovasc Interv.2004 Feb;61(2):271-4.
- 2. Ueda N et al. Anesthetic management of pheochromocytoma associated with tricuspid atresia. Can J Anaesth. 1991 Sep;38(6):780-4.

Learning points: Pediatric population with uncorrected CHD presents significant challenges. However, understanding the pathophysiology of the disease, meticulous management, appropriate use of drugs, and stringent monitoring can lead to a safe outcome.

22AP03-12

Analgesia for paediatric hip dysplasia surgery in the under 6 age group: a single centre 8-year experience

K. Daga¹, R. Tresman¹, C. Bounds¹, O. Ward¹, A. Mishra¹ ¹Royal Alexandra Children's Hospital, Anaesthesia, Brighton, United Kingdom

Background and Goal of Study: Analgesia for hip dysplasia surgery (femoral osteotomy or open hip reductions) varies significantly between institutions (1). Traditionally our service used epidural/caudal infusions for post-operative analgesia, requiring admission to high dependency unit (HDU). Due to reduced HDU bed availability during the COVID-19 pandemic, single-shot neuraxial techniques (spinal, epidural, or caudal injections) became more common. This retrospective service evaluation compares outcomes of patients with caudal/epidural infusions to those without infusion.

Materials and Methods: We reviewed patients aged under 6 years of age from October 2015 to August 2024. Data on analgesic technique, epidural/caudal infusion duration, nurse/patientcontrolled analgesia (NCA/PCA) usage (morphine 20 micrograms/kg/ml), length of stay and pain scores were collected. All patients received oral analgesics.

Results and Discussion: We identified 46 patient episodes. 42 patients were ASA 1, 4 were ASA 2. Analgesic techniques used were epidural infusion (n=13), caudal infusion (n=22), single shot caudal injection (n=6), spinal injection (n=1) and caudal catheter inserted but removed at the end of surgery (n=4). Neuraxial infusions were used for a mean duration of 1.6 days. Results are presented in Table 1.

Pain scores were similar in both groups. There was lower mean NCA/PCA dosage in the non-infusion group which may be secondary to reduced length of stay.

	Mean age (years) (range)	Mean weight (kg) (range)	NCA / PCA use (%)	Mean NCA / PCA dose (mL) (range)	Mean length of stay (days) (range)	Mean worst pain score (recovery) (range)	Mean worst pain score (ward) (range)	Nausea / vomiting (%)
Neuraxial infusion (n=35)	1.6 (0-5)	11.1 (7.7-16.7)	20	22.8 (0-77)	2.9 (1-13)	0.2 (0-5)	3.5 (0-7)	32
No neuraxial infusion (n=11)	2 (0-5)	13.5 (7.7-21.6)	64	14.75 (0-28)	1.5 (1-2)	0 (0-0)	3.6 (0-8)	27

Table 1.

Conclusion(s): Single-shot neuraxial injections given intra-operatively are an acceptable alternative to post-operative caudal/ epidural infusions and may even lead to better outcomes in the form of reduced HDU admissions, NCA/PCA dosage, nausea and vomiting and overall length of stay for children under 6 years undergoing hip dysplasia surgery.

22AP04-1

From womb to cath-lab: Anesthetic management for balloon atrial septostomy within two hours of birth

H.D. Ozcanoglu¹, B.B. Kurt¹, E.D. Yucel¹, M.H.H. Toprak², F. Gumus Ozcan¹

¹Basaksehir Cam and Sakura City Hospital, Anesthesiology and Reanimation, Istanbul, Turkey, ²Basaksehir Cam and Sakura City Hospital, Pediatric Cardiology, Istanbul, Turkey

Background: Balloon Atrial Septostomy (BAS) is an emergent life-saving intervention for cyanotic neonates with dextro-Transposition of the Great Arteries (d-TGA) and restrictive atrial sep-

This report presents a 2 hours-old neonate who was timely and effectively given perioperative anesthesia care for BAS and consequently able to live to have arterial switch operation (ASO).

Case Report: Classified as ASA IVE, the patient was one of antenatally diagnosed male twins, born by planned cesarean section at 36 weeks, weighing 2690 grams. Prostaglandin-1 infusion was initiated immediately after birth. He was transferred to the pediatric cardiac intensive care unit with blood oxygen saturation (SpO2) of 70% on continuous positive airway pressure.

The initial echocardiography showed d-TGA, patent ductus arteriosus and a 1.5 mm restrictive atrial level communication. Presenting deepening hypoxaemia and acidosis, he was taken to the catheterization laboratory (cath-lab) for BAS 1.5 hours after his birth. Cath-lab temperature was maintained at 29°C.

Before induction while on adrenaline and dextrose infusions, haemodynamic monitorization showed his SpO2 was 22%, heart rate was 120 beats/min, blood pressure was 70/35 mmHg. He was uneventfully intubated. Near-infrared spectroscopy cerebral oxygenation showed 54%.

Mild hyperventilation was applied. His SpO2 raised to 55% after intubation and to 91% after placement of balloon catheter. The echocardiography after BAS showed a 6.5 mm atrial communication, allowing adequate intercirculatory mixing. He was extubated the next day and scheduled for ASO the following week.

Discussion: Restoring adequate systemic perfusion of severely cyanotic patient can call for BAS1 and its perioperative anesthetic management, which starts with preoperative collaboration with the pediatrics team, includes intraoperative interventions to maintain cardiac output while keeping a lower pulmonary vascular resistance than systemic vascular resistance¹ and extends to postoperative follow up.

Learning points: The quick collaboration across disciplines and a well prepared experienced pediatric cardiac anesthesiology team are crucial for perioperative care for BAS.

22AP04-2

Incidence of and risk factors for acute kidney injury in neonates with congenital diaphragmatic

A. Andersson^{1,2}, B. Sedlacek¹, J. Berner^{3,2}, J. Mårtensson^{4,2}, Å. Norberg^{4,5}, U. Fläring^{1,2} ¹Astrid Lindgren Children 's Hospital, Karolinska University Hospital, Department of Pediatric Perioperative Medicine and Intensive Care, Stockholm, Sweden, 2Karolinska Institute. Department of Physiology and Pharmacology. Stockholm, Sweden, ³Astrid Lindgren Children 's Hospital, Karolinska University Hospital, Ecmo Centre, Pediatric Perioperative Medicine and Intensive Care, Stockholm, Sweden, 4Karolinska University Hospital, Department of Perioperative Medicine and Intensive Care, Stockholm. Sweden. 5Karolinska Institute, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden

Background and Goal of Study: Congential diaphragmatic hernia (CDH) is a severe congenital malformation requiring surgery in the neonatal period. The reported mortality is 25-30%, often due to severe pulmonary hypertension. Neonates with CDH are exposed to several risk factors for acute kidney injury (AKI), including strict fluid restriction. Still, data on the incidence of AKI is sparse in this group of patients.

Our aim was to investigate the AKI incidence and identify modifiable risk factors for AKI development in a cohort of CDH-patients thoroughly characterized in physiological/clinical variables.

Materials and Methods: This was a retrospective cohort study from a tertiary pediatric referral center for CDH patients. CDH patients born January 2015-May 2022 with birth weight ≥2 kg, GA ≥32 weeks and invasive ventilation initiated within 2 days were included. Patients with congenital kidney disease and patients who died within the first 2 days were excluded.

The primary outcome was frequency of AKI according to the KDIGO definition. Patients with complete data from day 1 were included in a step-wise forward regression analysis of risk factors

Results and Discussion: Out of 109 patients, 31 (28%) developed AKI. Among AKI patients 17 (55%) had stage 1, 1 (3%) stage 2 and 13 (42%) stage 3 AKI. The AKI incidence was higher in ECMO patients compared to non-ECMO: 15/24 (62%) and 16/85 (19%), respectively (p<0.0001). Thirteen (42%) AKI patients received CRRT, 12 of these during ECMO treatment.

On admission, PIM-3 score was higher in the AKI group compared to no AKI patients, 17 (13-26) and 12 (9.2-16), respectively (p=0.0001). ECMO treatment was required in 24/109 patients (22%). In included patients, the mortality was 6/109 (5.5%).

In multivariate analysis of risk factors prior to AKI development (n=100), the duration of hyperchloremia (p=0.0006), peak Oxygenation Index (OI)(p=0.02) and peak Vasoactive-inotropic score (VIS)(p=0.0004) were significantly associated with AKI. Using the KDIGO definition there was complete resolution of AKI at PICU discharge in all surviving patients.

Conclusion(s): AKI is common in CDH patients. Duration of hyperchloremia prior to AKI development was found to be a potentially modifiable risk factor for AKI.

The impact of OI and VIS likely reflects renal effects of the hypoxic respiratory failure and severe hemodynamic effects related to CDH. In this study, AKI had resolved at PICU discharge in all surviving patients.

22AP04-3 **MDMA** intoxication

H. Darouich¹, K. El Fakhr², S. Kalouch¹ FMPC. Anesthésie-réanimation, Casablanca, Morocco. ²Casablanca, Anesthésie, Casablanca, Morocco

Background: intoxication with 3,4 methylenedioxymethamphetamine (MDMA), commonly known as "ecstasy," although rare in children, represents a potentially serious medical emergency. This substance, primarily used recreationally by adults, can be accidentally ingested by children, who are exposed to toxic doses due to their low body weight and immature metabolism. These intoxications are often characterized by severe symptoms such as seizures, hyperthermia, or multiorgan failure, requiring prompt and appropriate management.

With the rising number of reported cases, it is crucial to better understand the clinical features and therapeutic strategies to improve prevention and treatment.

Case Report: This case involves a 13-month-old male infant with no significant medical history, admitted to the pediatric emergency department of the Mother-Child Hospital at CHU Ibn Rochd in Casablanca for generalized tonic-clonic seizures, complicated by status epilepticus.

These symptoms occurred following the accidental ingestion of MDMA. The diagnosis was confirmed through the patient's history, supported by law enforcement officials who brought the child in and reported the discovery of MDMA tablets at the scene.

The child was admitted to the pediatric intensive care unit due to his comatose state. Upon admission, a comprehensive biological workup was conducted to assess metabolic parameters and identify potential complications.

Discussion: This case highlights the potential severity of MDMA intoxication in children, emphasizing the importance of prompt recognition of clinical signs and appropriate management. Neurological instability and systemic complications observed in such cases require urgent intervention to prevent fatal outcomes. Early intubation, sedation, and hemodynamic support are crucial in these situations.

This incident also underscores the need to strengthen preventive measures, particularly by raising awareness among families about the dangers of accidental exposure to psychoactive substances. A multidisciplinary approach, involving pediatricians, toxicologists, and intensive care teams, is essential to optimize the chances of full recovery and reduce the risk of long-term sequelae.

22AP04-4

Intraoperative physiologic interventions associated with postoperative neurological complications in neonates: a secondary analysis of the NECTARINE registry

V. Tangel^{1,2}, S.E. Hoeks¹, L. Vutskits^{3,4}, R.J. Stolker¹, N. Disma⁵, J.C. de Graaff^{1,2,6}

¹Erasmus MC, Anesthesiology, Rotterdam, Netherlands, ²Weill Cornell Medicine, Anesthesiology, New York, United States, 3University Hospitals of Geneva, Anesthesiology. Pharmacology, Intensive Care, and Emergency Medicine. Geneva, Switzerland, 4University of Geneva, Geneva Neuroscience Centre, Geneva, Switzerland, 5IRCCS Istituto Giannina Gaslini, Anesthesia, Genoa, Italy, 6Adrz-Erasmus MC, Anesthesiology, Goes, Netherlands

Background and Goal of Study: Neonates and infants are at risk for severe postoperative neurologic complications following anaesthesia. The exact cause of these neurologic complications is unknown, but intraoperative physiologic disturbances have been suggested to play a role in the aetiology.

The objective of this study was to assess the relationship between unexpected intraoperative instability of systemic homeostasis necessitating a corrective action and the development of postoperative neurological complications in neonates undergoing operative and non-operative procedures.

Materials and Methods: Data for this secondary analysis were extracted from the NECTARINE registry: a prospective cohort of neonates up to 60 weeks postmenstrual age from 165 participating centres in 31 countries. The primary outcome was a binary measure indicating the development of any neurological complication up to 30 days postoperatively.

Neurological complications included: hypertonia (new onset), hypotonia (new onset), intracranial bleeding (ultrasound, CT, or MRI), intracranial ischemia (ultrasound, CT, or MRI), and occurrence of seizures (clinically or EEG).

Exposures of interest were binary indicators of unexpected intraoperative instability of systemic homeostasis necessitating a corrective action. Descriptive statistics were calculated, and a multivariable logistic regression model was fit using complete case analysis.

Results and Discussion: 140/5,504 (2.5%) neonates developed a postoperative neurologic complication; of those with a neurologic complication, 40.7% experienced at least one episode of intraoperative hypotension which necessitated corrective action. In a multivariable analysis, no exposures of interest were significantly associated with the outcome (Table 1).

	N (%) among cases withour nesteologic complication(i)	N (%) among cases with noneologic complication(s)	Adjusted odds ratio (aCR)	95% confidence interval (CI)	P value
learn entten for:					
Typocapous or Trypeerapean	464 (5.7%)	23 (16.4%)	1.00	(0.60,1.67)	0.990
Hypotessou	1.132 (21.1%)	57 (40:7%)	1.33	(0.89, 1.99)	0.160
Oradycardia or tarityenrdia	122 (2.3%)	11 (2.9%)	1.70	(0.53,3.51)	0.149
Hyperplycaessus	31 (1.0%)	3 (2.1%)	1.02	(0.28.3.73)	0.972
Hypoglycomia	104 (1.9%)	4 (2.9%)	0.63	(0.21,1.83)	0.394
Hypernatremia	8 (0.2%)	1 (0.7%)	2.43	(0.22,26.82)	0.470
Hypoustrema	14 (0.3%)	2 (1.4%)	1.23	(0.18.8.32)	0.832
N .	5,364	146	5,504		

Table 1. Results from bivariate and multivariable analyses of neurologic complications.

Conclusion(s): In this retrospective study of neonates undergoing operative and non-operative procedures, there was no association between unexpected intraoperative instability of systemic homeostasis necessitating a corrective action and subsequent neurologic complications.

22AP04-5

Anesthesia for pediatric radiotherapy and its effect on patient outcomes

P. Owusu-Agyemang¹, J. Mani¹, T. Idowu¹, D. Kaur¹, R. Kapoor¹, A. Zavala^{2,1}

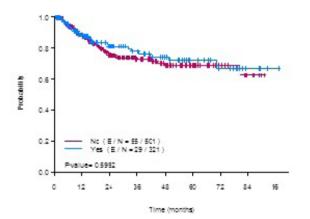

¹MD Anderson Cancer Center, Anesthesiology, Houston, United States, 2The University of Texas MD Anderson Cancer Center, Anesthesiology, Houston, United States

Background and Goal of Study: Patient motion poses significant challenges for accurate delivery of radiotherapy. In younger children limited to no motion is often accomplished by performing treatments under general anesthesia (GA). In children undergoing proton beam therapy (PBT), this may require up to 30 treatments under GA over a period of 6 to 8 weeks.1

To date, the impact of this many iterative anesthetic (IA) exposures on the short and long-term outcomes of children undergoing PBT remains unclear. The primary objective of this study was to assess the association between IA exposure and the occurrence of an unplanned admission (UA) or emergency room (ER) encounter within 30 days of treatment start. The secondary objective assessed the impact of IA on overall survival (OS).

Materials and Methods: Retrospective study of children (≤ 19 yrs.) who had undergone PBT (with or without anesthesia). Multivariable logistic regression was used to assess factors associated with an UA and survival.

Overall Survival by Froton with Anesthesia

Results and Discussion: The average age of the 822 children was 9.3 yrs. (SD±5.2). The majority 458/822 (55.7%) were female, and 501/822 (60.9%) had undergone PBT without anesthesia. The group who underwent PBT under IA were younger (4.4 yrs. vs. 12.4 yrs., p<0.001), and had higher proportions of treatment interruptions (55.5% vs. 44.3%, p=0.001), chemotherapy history (41.1% vs. 9.8%, p<0.001), and UA/ER encounters (12.5% vs. 1%, p<0.001).

In the multivariable analysis, IA (OR, 13.91: 95%CI, 5.39-35.85: p<0.001), concurrent chemotherapy (OR, 2.69: 95%Cl, 1.39-5.24: p=0.004), and treatment interruptions (OR, 1.97; 95%Cl, 1.02-3.89: p=0.045) were each associated with increased odds of an UA/ER encounter. However, there was no difference in OS rates (IA vs. no-anesthesia) at 1yr (88% vs. 87%), 3 yrs. (81% vs. 75%), or 5yrs. (73% vs. 77%), p=0.599.

Conclusion(s): In this retrospective study, undergoing PBT under anesthesia was associated with an increased risk of an unplanned admission or emergency room visit within 30 days of treatment start. However, there was no association between anesthesia exposure and patient survival.

Pulmonary hypertensive crisis following release of lung torsion: a case report

K. Yagi^{1,2}, Y. Chida², S. Nishibe², K. Miyasaka¹, T. Hayashi¹, N. Fuiita¹

¹St. Luke's International Hospital, Anesthesiology, Tokyo, Japan, ²Tokyo Metropolitan Children's Medical Center, Anesthesiology, Tokyo, Japan

Background: Lung torsion is an extremely rare postoperative complication of MICS (minimally invasive cardiac surgery), Pulmonary hypertensive (PH) crisis is characterized by acute elevation of pulmonary vascular resistance, accompanied by decompensation of right ventricular systolic function.1

We experienced a PH crisis precipitated by alveolar hypoventilation as a result of airway obstruction by massive hemosputum following release of lung torsion.

Case report: A 4-year-old boy underwent MICS via a right minithoracotomy for ventricular septal defect. Postoperative progression of anemia and chest CT suggested pulmonary hemorrhage. An exploratory re-thoracotomy revealed no apparent cause. The boy was transferred to a tertiary facility for further evaluation on POD8. Surgery was performed the following day under general anesthesia with one-lung ventilation by a bronchial blocker in the right main bronchus.

Preoperative transoesophageal echocardiography (TEE) suggested elevated right ventricular systolic pressure, with no blood flow in the right upper pulmonary vein. The superior and middle lobes of the right lung were rotated. Upon detorsion, tidal volume, SpO_a, and blood pressure dropped, with a D-shaped left ventricle on TEE indicating an acute increase in right ventricular preload. Hemosputum had overflown the bronchial blocker, causing alveolar hypoventilation, triggering a PH crisis. Repetitive suctioning of bloody secretions from the trachea greatly improved ventilation and helped stabilize hemodynamic fluctuations. The superior and middle lobes of the right lung were resected, and the boy made a smooth recovery.

Discussion and Learning points: We experienced a case of lung torsion following MICS VSD repair. Despite placement of a bronchial blocker and ligation of the pulmonary vessels prior to detorsion, hemosputum expectorated from the rotated lung lobes obstructed the airway, overloaded the right ventricle and precipitated a PH crisis. Availability of devices for one-lung ventilation in pediatric patients is limited. Bronchial blockers require careful management of placement and sealing effectiveness.

Long-term risk of chronic kidney disease after pediatric CRRT in the PICU - data from the Swedish National Patient Register

I. Szeps^{1,2}, M. Herthelius^{3,4}, Å. Norberg^{3,5}, A. Löf Granström^{6,7}, U. Fläring^{1,8}, A. Andersson^{1,8} ¹Karolinska Institutet, Department of Physiology and Pharmacology, Stockholm, Sweden, 2Stockholm South General Hospital, Department of Perioperative Care and Intensive Care, Stockholm, Sweden, 3Karolinska Institutet, Department of Clinical Science, Intervention and Technology, Stockholm, Sweden, 4Karolinska University Hospital, Astrid Lindgren Children's Hospital, Stockholm, Sweden, 5Karolinska University Hospital, Department of Perioperative Medicine and Intensive Care, Stockholm, Sweden, 6Karolinska Institutet, Department of Women's and Children's Health, Stockholm, Sweden, ⁷Karolinska University Hospital, Unit of Pediatric Surgery. Stockholm, Sweden, 8Astrid Lindgren Children's Hospital. Karolinska University Hospital, Department of Paediatric Perioperative Medicine and Intensive Care, Stockholm, Sweden

Background and Goal of Study: Continuous renal replacement therapy (CRRT) is the preferred therapy for critically ill children with severe acute kidney injury (AKI) or multiple organ failure (MOF) with fluid overload (FO). Mortality in this cohort is high, but the longterm risk for chronic kidney disease (CKD) in survivors is unclear. Also, risk factors for the development of CKD are unknown, and there is no consensus regarding post-ICU follow-up.

We aimed to describe the long-term risk of developing CKD after CRRT in the PICU, and to identify risk factors for CKD development.

Materials and Methods: This was a register-based study from a tertiary pediatric centre. Patients 0-18 years old receiving CRRT due to AKI or MOF with FO between 2008-2021 were included if they survived PICU stay.

The primary outcome was frequency of CKD diagnosis in the national register. PICU data was collected from patient charts. Patients diagnosed with CKD, hypertension or kidney transplantation after ICU discharge were identified through the Swedish National Patient Register.

Results and Discussion: 156 patients were included. Median age at CRRT initiation was 3.5 months (IQR 0-69). Twenty-one (13.5%) patients were diagnosed with CKD after ICU discharge. Median follow-up time was 8.7 years in patients with CKD and 6.3 years in no-CKD patients (p=0.04). AKI as indication for CRRT was significantly more common in the CKD group (95.3% vs 67.4%, p<0.01).

Moreover, in the CKD group severe AKI (KDIGO stage 2-3) at CRRT initiation was more frequent (90.5% vs 64.4%; p=0.02) and GFR at hospital discharge was lower (38.5 vs 82.1 ml/min/1.73 m², p<0.01) compared to the no-CKD group. However, the no-CKD group was younger at CRRT initiation (p=0.01) and had higher PIM-scores (p=0.01). During follow-up, hypertension occurred in 11.5% of patients and 1.9% needed a kidney transplant.

Variable	All patients (156)	No CKD (135)	(21)	P-value	
Age at CRRT initiation, months	3.5 (0-69)	1 (0-62)	48 (7-133.5)	0.01	
PIM-3, PDR (%), n=152	22.4 (8.3-54.4)	25.1 (9.9-60)	8.6 (3.8-30)	< 0.01	
KDIGO stage at CRRT initiation - 0-1 - 2-3	50 (32.1) 106 (67.9)	48 (35.6) 87 (64.4)	2 (9.5) 19 (90.5)	0.02	
GFR at hospital discharge	76.1 (45.3-107.6)	82.1 (52.4-120.3)	38.5 (20.9-65)	< 0.01	
CRRT indication (%) - AKI - MOF	111 (71.2) 45 (28.8)	91 (67.4) 44 (32.6)	20 (95.3) 1 (4.7)	<0.01	

All values are presented as n (%) or as median (interquartile range). P values are calculated by Fisher exact test or Mann-Whitney U test. CKD+chronic kidney disease, CRRT+continuous renal replacement therapy, PIM+pediatric index of mortality, PDR+predicted death rate, KDIGO+kidney disease improving global outcome, GFR-glomerular filtration rate.

Table 1.

Conclusion(s): In this long-term follow-up using a national diagnosis register 13.5% of patients developed CKD. CKD development was associated with more severe AKI, but not with severity of disease or low age. Adequate post-ICU follow-up is important for pediatric CRRT patients, especially for those with severe AKI.

22AP04-8

Efficacy and safety of an ultrasound guided single shot paravertebral block in reconstruction of oesophageal atresia in neonates

C. Linnarsson^{1,2}, A. Andersson^{1,2}, A. Tollne³, J.F. Svensson^{3,4}, M. Anell Olofsson^{1,2} ¹Karolinska Insitutet, Department of Physiology and Pharmacology, Stockholm, Sweden, 2Karolinska University Hospital, Pediatric Perioperative Medicine and Intensive Care, Stockholm, Sweden, 3Karolinska University Hospital, Pediatric Surgery, Stockholm, Sweden, 4Karolinska Intitutet, Department of Women's and Children's Health, Stockholm, Sweden

Background and Goal of Study: Neonates with oesophageal atresia (OA) needs surgery early in life and hence appropriate peri- and postoperative pain treatment. In our institution primary repair of OA is performed with a right-sided thoracotomy. A single shot paravertebral block (sPVB) is administrated before thoracotomy. The use of sPVB has several benefits including reduced need for general anesthetics, reduced surgical stress response, reduced opioid analgesia and shorter postoperative recovery time. However, the efficacy and risks of using sPVB in neonatal OA surgery has not previously been described.

The primary aims were to investigate if sPVB reduced the perioperative opioid consumption and postoperative time on mechanical ventilation. Secondary aims were the rates of sPVB complications, length of PICU stay and need of pain treatment at PICU discharge.

Materials and Methods: Retrospective study including 30 neonates undergoing repair of OA. The patients were divided in two groups based on the type of pain treatment received during surgery, sPVB or opioid based intravenous therapy (IV). The sPVB was performed after induction using an ultrasound-guided inplane transverse approach. Levobupivacaine 2,5 mg/ml, 0,5-0,7 ml/kg, were injected at the T5 level with direct ultrasound visu-

Results and Discussion: 30 neonates undergoing OA surgery were included, 25 patients (11 IV and 14 sPVB) had complete data for the perioperative period and 26 patients (13 IV and 13 sPVB) for the postoperative period.

Significantly lower consumption of fentanyl perioperative was found in the sPVB group compared to the IV-group [median] (range) 4,65 mg/kg (1,49 - 9,62) vs. 8,59 mg/kg (4,38 - 13,50) p=0,0005]. There was a trend towards shorter time on mechanical ventilation postoperatively in the sPVB group, however not significant [median (range) 21,3 hours (18,6 - 43,8) vs. 26,4 hours (19,0 - 68,0) p=0,099].

No complications due to the sPVB or the administration of the local anaesthetic was detected. There was no significant difference in length of PICU stay or need for pain treatment after PICU

Conclusion(s): sPVB is an effective and safe method for neonates undergoing primary repair of OA. sPVB significantly reduced perioperative fentanyl consumption, but postoperative mechanical ventilation was not significantly shortened. sPVB could be a valuable help to reduce surgical stress and the need of general anesthetics in this vulnerable group of patients.

The influence of depth of anaesthesia on motor evoked potentials monitoring during scoliosis surgery in children and adolescents (SCOL study): a prospective observational study

J. Hudec^{1,2}, M. Kosinová^{2,3}, T. Prokopová^{1,2}, H. Zelinková⁴, R. Gál¹, P. Štourač^{2,3}

¹University Hospital Brno and Faculty of Medicine, Masaryk University Brno, Department of Anaesthesiology and Intensive Care Medicine, Brno, Czech Republic, ²Faculty of Medicine, Masaryk University, Department of Simulation Medicine, Brno, Czech Republic, 3University Hospital Brno and Faculty of Medicine, Masaryk University Brno. Department of Paediatric Anaesthesiology and Intensive Care Medicine, Brno, Czech Republic, 4Faculty of Medicine, Masaryk University, Institute of Biostatistics and Analyses, Brno, Czech Republic

Background and Goal of Study: Intraoperative neurophysiological monitoring (IONM) is frequently used in high-risk spinal surgeries. The Scoliosis Research Society recommends IONM application during scoliosis surgery, specifically motor-evoked potentials (MEP) and somatosensory-evoked potentials (SEP) directed by neurophysiologists (1).

However, the lack of neurophysiologists leads to the alternative, which is only MEP monitoring directed by surgeons. Anaesthesia can affect MEP reproducibility and potentially MEP interpretation. This study aims to evaluate the influence of total intravenous anaesthesia (TIVA) depth on transcranial MEP reproducibility and interpretation by surgeons.

Materials and Methods: In this prospective observational study, we aimed to enrol 150 children and adolescent patients indicated for elective scoliosis surgery with surgeon-directed MEP monitoring under TIVA. We maintained TIVA respecting local protocol for scoliosis anaesthesia and titrated TIVA to the bispectral index (BIS) level 60 ± 5 after the pronation when MEP were monitored. We deepened the anaesthesia to the BIS level of 40 ± 5 before the skin incision and repeated MEP measurement respecting local protocol (2).

Results and Discussion: We enrolled all patients from September 2020 to August 2024. The initial MEP latencies and amplitudes on BIS level 60 ± 5 were baselines, resp. 100 %. The MEP parameters at the BIS level of 40 ± 5 were proportionally compared with the baseline. The MEP latencies were 103 % (97-110), median (minimum-maximum), and the MEP amplitudes were 78 % (40-118) at the BIS level of 40 ± 5 .

Although MEP parameter changes at the BIS level of 40 ± 5 were statistically significant, the interpretations by surgeons were not altered and not clinically significant.

Conclusion(s): Our study data shows statistically significant differences in latency and amplitude in dependence on the TIVA depth. However, these changes are not clinically significant for interpretation by surgeons in MEP if TIVA depth is maintained in the recommended BIS range of 40-60.

Evaluating the efficacy of clonidine premedication in reducing emergence delirium in children: a retrospective analysis

<u>A.L.d.B. Garioud</u>^{1,2}, A. Taplin^{3,4,5,6}, D. Evans^{3,4,5,6}, N. Khan^{5,7}. A. Sommerfield^{3,4,5,8}, B.S. von Ungern-Sternberg^{3,4,5,8} ¹Copenhagen University Hospital - Rigshospitalet, Department of Anesthesiology, Juliane Marie Center, Copenhagen, Denmark, 2University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark. ³Perth Children's Hospital, Department of Anaesthesia and Pain Medicine, Perth, Australia, 4The Kids Research Institute Australia, Perioperative Medicine Team, Perth, Australia, 5The University of Western Australia, Institute for Paediatric Perioperative Excellence, Perth, Australia, 6The University of Western Australia, Shool of Physics, Mathematics and Computing, Perth, Australia, ⁷The University of Western Australia, Department of Mathematics and Statistics, Perth, Australia, 8The University of Western Australia, Medical School, Perth, Australia

Background and Goal of Study: Emergence delirium (ED) is a common and distressing postoperative complication in children, characterized by agitation and disorientation, with potential implications for recovery, safety, and postoperative behavior. Evidence suggests that preoperative anxiety increases the risk of ED. Clonidine, an alpha-2 adrenergic receptor agonist with sedative and analgesic properties, has shown potential for reducing ED incidence. Therefore, we aimed to evaluate the impact of clonidine premedication on ED in pediatric patients undergoing general anesthesia.

Materials and Methods: This retrospective cohort study analyzed data from 36 clinical studies involving 11,450 pediatric patients aged 0-16 years from Perth Children's Hospital, Australia. Propensity score matching was used to adjust for baseline covariates including age, sex, surgery type, and anesthetic maintenance method. Emergence delirium was assessed using validated scales including PAED, Watcha, and CAPD[ALdBG1] [DE2] . The outcome for patients receiving clonidine premedication was compared to those who did not.

Results and Discussion: Of the 4,742 children with available ED data, 7.2% (n=341) experienced emergence delirium, including 36 (10.6%) who had received clonidine. Oral clonidine premedication was administered to a total of 330 children. Following propensity score matching, we found a slightly higher incidence of ED in patients who received clonidine premedication (11%) compared to 9% in the matched non-clonidine group, consistent with the unmatched rates of 11% and 6.9% respectively. However, this difference was not statistically significant (OR 1.23, 95% CI 0.74-2.05, p=0.436). These findings suggest that clonidine may not be effective for mitigating ED when used as a premedication.

Conclusion(s): Clonidine premedication was not significantly associated with a reduced incidence of emergence delirium in pediatric patients in this retrospective analysis with propensity matching. However, compared to other common premedications such as midazolam, its potential benefits in analgesic sparing and postoperative recovery warrant further investigation in targeted populations. These findings can contribute to preoperative management strategies in pediatric anesthesia.

22AP04-11

Investigating the association between clonidine premedication and the risk of perioperative respiratory adverse events in children: A retrospective cohort study

A.L.d.B. Garioud^{1,2}, A. Taplin^{3,4,5,6}, D. Evans^{3,4,5,6}, N. Khan^{5,7}. A. Sommerfield^{3,4,5,8}, B.S. von Ungern-Sternberg^{3,4,5,8} ¹Copenhagen University Hospital - Rigshospitalet, Department of Anesthesiology, Juliane Marie Center, Copenhagen, Denmark, ²University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark, ³Perth Children's Hospital, Department of Anaesthesia and Pain Medicine, Perth, Australia, 4The Kids Research Institute Australia, Perioperative Medicine Team, Perth, Australia, 5The University of Western Australia, Institute for Paediatric Perioperative Excellence, Perth. Australia, 6The University of Western Australia, Shool of Physics, Mathematics and Computing, Perth, Australia, ⁷The University of Western Australia, Department of Mathematics and Statistics, Perth, Australia, 8The University of Western Australia, Medical School, Perth. Australia

Background and Goal of Study: Perioperative respiratory adverse events (PRAE) are the major cause of critical incidents in pediatric anesthesia. They can lead to long-term neurological damage or even death. Sedative premedications such as clonidine are frequently used preoperatively for treatment of preoperative anxiety and as an analgesia adjunct. We aimed to investigate the association between clonidine premedication and the risk of PRAE in pediatric patients.

Materials and Methods: We conducted a retrospective propensity-score matched analysis by combining data from 36 clinical studies, encompassing 11,450 surgeries in pediatric patients aged 0-16 years at Perth Children's Hospital (and its predecessor, Princess Margaret Hospital), Australia. Propensity scores for the probability of treatment with clonidine were estimated using administrative (year of surgery, trial), patient-related (age, sex, weight, ASA, respiratory sensitivity), and surgical factors (induction type, maintenance type, airway device, and surgical specialty). Surgeries were matched 1:1 for clonidine and no-clonidine groups. The overall incidence of PRAE and the incidence of postoperative PRAE i.e., occurring at emergence from anesthesia or in the post-anesthetic care unit (PACU), were compared between matched groups.

Results and Discussion: 8,629 surgeries with full data sets were available for analysis, of which 7.7% have received clonidine as a premedication. The 1:1 matched dataset contained 1,324 surgeries (662 in each treatment group). Clonidine premedication was not associated with a statistically significant difference in overall PRAE incidence (18.3% in the clonidine group vs. 17.7% in the noclonidine group; OR 1.04 95% CI 0.79-1.38, p=0.775). Similarly, no statistically significant difference was observed for postoperative PRAE (11.2% vs. 10.6% in clonidine and no-clonidine groups respectively; OR 1.07 95% CI 0.75-1.51, p=0.722). Our results suggest that clonidine premedication does not significantly alter the risk of PRAE in pediatric patients.

Conclusion(s): Clonidine premedication was not significantly associated with the incidence of perioperative respiratory adverse events, either overall or during the immediate postoperative period. These findings from our retrospective propensity scorematched analysis contribute to evidence supporting the safety profile of clonidine, suggesting that it does not increase the risk of PRAE in pediatric patients.

22AP04-12

Non-operating room anesthesia for pediatric cardiac catheterization, including newborns: a comprehensive ten-year analysis of 665 cases at a single institution

S.I. Türkel¹, Ç.G. Olguner¹, L. İyilikçi Karaoğlan¹, D.G. İnal¹, i.E. ince1

¹Dokuz Eylul University School of Medicine, Anesthesiology and Reanimation, Izmir, Turkey

Background and Goal of Study: Pediatric cardiac catheterization and angiography are essential for diagnosing and treating congenital heart diseases. Anesthesia management is challenging due to variations in childeren age and medical conditions.1

This study presents demographic data, procedures, anesthesia management, and complications in pediatric patients who underwent diagnostic or therapeutic catheterization between 2014 and 2024 at Dokuz Eylul University, Department of Anesthesiology.

Materials and Methods: 665 pediatric patients who underwent procedures with NORA between 2014 and 2024 and had accessible data were included in this retrospective study.

First results of this research are here.

Results and Discussion: Initial results were evaluated. Patients' ages ranged from 1 day to 18 years. Of the 665 patients, 13 were newborn,147 were infant. Weights ranged from 1700 g to 107 kg. The gender distribution was equal (330 girls/ 335 boys). ASA classification:658 patients ASA 2-4 and total 7 patients ASA 1 and 5E.18 patients (2.7%) received general anesthesia and 647 patients (97.3%) received sedation. Among 13 newborn, 12 received general anesthesia (GA):147 babies aged 1-12 months received GA and sedation (n:8/n:139).

Sedative drugs included midazolam (0.03-0.1 mg/kg), ketamine(1–2 mg/kg), propofol(0.5–1 mg/kg), fentanyl(0.5–1 mcg/kg) and dexmedetomidine (0.5 mcg/kg). 2 patients had sedation converted to general anesthesia. Youngest patient receiving sedation was a 25-day-old newborn undergoing diagnostic angiography for ASD. All babies under 1 year were monitored postoperatively in the pediatric ICU or ward, regardless of anesthesia type. 13 patients (1.95%) had complications. Procedural complications included failed arterial puncture(3), arrhythmia(1), hypotension(1), hypoxic spell(1), need for IABP(1), and perioperative arrest(2).

Anesthesia-related complications included desaturation(2), nausea and vomiting(1), and local allergic reaction(1). Only one baby

Conclusion(s): Our study differs the literature by using sedation in 97.3% of cases included newborns, covering a wider age range and patient weights. Despite the risks, the low complication rate is likely due to continuous hemodynamic monitoring. The choice between general anesthesia and sedation should consider the pediatric patient's cardiac pathology, hemodynamic-pulmonary status and appropriate drug selection. Sedation at pediatric cardiac procedures seems safe.

22AP05-1

literature review of peri-operative preparation and premedication in children with autism spectrum disorder (ASD)

N. Taghizadeh1

¹Austin Hospital, Anaesthesia, Heidelberg, Australia

Aim: To synthesise existing evidence about perioperative practices for the management of children and young adults with Autism Spectrum Disorder (ASD).

Method: A literature review was carried out of studies published in peer review journals of the current best practices and interventions in children and young adults with ASD undergoing medical procedures.

Results: Fifty-one studies and 17 review articles published between 1997 and 2018 were identified. Emerging priorities were an emphasis on increased attention to individual patient needs. preparation using psychological principles and social stories, engaging parents as experts in the care and having a consistent care giver in the hospital. Flexibility in the hospital setting was identified as advantageous and some innovative practices, for example to getting a service dog to give propofol were reported. The retrospective studies of premedication found a pattern of atypical use with frequent intramuscular or intranasal administration of ketamine. In day case procedures, excellent results were recorded with the use of alpha-2 agonists such as clonidine and dexmedetomidine as the sedative agent in both prospective and retrospective studies.

Conclusion: This review supports the need for better preparation using principles of cognitive behavioural therapy, social stories with individualised reward as motivator and desensitisation using toy/fake cannulation kits. Most of these are low cost strategies that can prevent harm and higher health care costs. We suggest they should be implemented and evaluated in all settings providing procedural care to children and young people with ASD. Having a staff member responsible for the patient and successful implementation of care plan has been successful and effective. Premedication: use of alpha2 agonist has been successful and should be further investigated in randomised trials.

22AP05-3

Dynamic of EEG signatures in children before, under and after general anaesthesia

M. Markus¹, F. Panagiotou¹, C. Spies¹, S. Kramer¹, S. Koch²

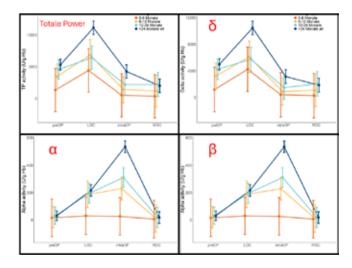

¹Charité - University Medicine Berlin, Anästhesiologie und Intensivmedizin, Berlin, Germany, 2Southern Denmark Odense, Denmark, Department of Anesthesiology and Intensive Care Medicine, University Hospital Siaelland, Campus Nykobing Falster, Nykøbing Falster, Denmark

Background: The benefits of electroencephalographic (EEG) neuromonitoring during anaesthesia in young children remain largely unexplored. Most EEG devices are designed and validated primarily for adults, leaving a gap in understanding their application for young, pre-school children.

However, young children are particularly susceptible to the effects of anaesthesia, and the impact of anaesthetics on brain development in this age group is still unclear.

This study aims to characterize perioperative frontal EEG signatures in preschool children.

Methods: This prospective observational clinical study recorded electroencephalogram (EEG) data from children (NCT02481999), with ethical approval from the Charité - University Medicine Berlin ethics committee (EA2/027/15).A total of 147 frontal EEG recordings from children aged 1 month to 8 years were recorded under general anaesthesia. EEG data was acquired using the Narcotrend Monitor, and the raw EEG files were subsequently analyzed across different frequency bands. The patients were grouped into four age categories (0-5 months, 6-11 months, 12-23 months, and over 24 months) to compare EEG signatures between these age groups.

Results: Delta activity is present across all age groups prior to the induction of anaesthesia. With loss of consciousness, Delta activity increases in all groups, with a more marked increase in older children. Intraoperatively, Alpha activity begins to appear in children aged six months and older, whereas infants (0-5 months) display no Alpha or Beta frequency activity during anaesthesia, maintaining a high level of Delta activity. As consciousness returns, faster frequencies gradually diminish, leaving Delta activity as the predominant rhythm in all age groups.

Conclusion: In conclusion, this study characterizes perioperative EEG signatures in children aged 1 month to 8 years from induction to emergence phases of general anaesthesia. The findings reveal distinct differences in EEG signatures across age groups, highlighting the need for age-adapted monitoring systems to safeguard this vulnerable population from the risks of over- and under-sedation.

22AP05-4

Ventricular tachycardia refractory to cardioversion in a pediatric patient without congenital cardiac anomaly: case report

M. Krmzova Gjorgjioska1, V. Chadikovski1,

- L. Malinovska Nikolovska¹, V. Stojanovikj¹, V. Trpkovska¹, J. Madzovska¹
- ¹Acibadem Sistina Hospital, Pediatric Cardiac Surgery, Skopie. North Macedonia. The Republic of

Background: Ventricular tachycardia (VT) in a pediatric patient without congenital cardiac anomaly is a rare entity and althought generally associated with a good prognosis, it can sometimes cause serious complications.

Case Report: We report a case of a 3-years-old girl who presented to our emergency department following a flu-like illness with palpitations.

On examination the child was found to be normotensive with irregular pulse. The EKG showed a polymorphic wide QRS tachycardia at a rate of 240-280 bpm. Immediately adenosine was given as a safe diagnostic and therapeutic agent.

There was no response and a diagnosis of a ventricular tachycardia was made and initially intravenous amiodarone was tried and synchronized cardioversion was planned. Sinus rhythm was not restored following three repeated attempts at synchronized cardioversion and bolus dose of amiodarone 5mg/kg.

The child was then put on amiodarone infusion and intravenous xylocaine 1.5mg/kg was given as a last resort to convert to sinus rhythm. When the heart rate began to slow as a response to this therapy we deside to continue with a xylocaine infusion until desired effect.

After 2 hours sinus rhythm was restored and the xylocaine infusion was discontinued. No recurrences of VT were seen in one month and six months follow-up time, with several isolated premature ventricular contractions on Holter exam.

Discussion: VT is a rarity that can cause sudden death in children with an otherwise normal heart and it is of utmost importance to detect and treat these children.

It can occur in children with cardiomyopathy, following some heart surgeries, and with inherited diseases that affect the heart's electrical system (e.g. Long QT syndrome, Brugada's syndrome), also metabolic or electrolyte abnormalities and medication toxicity. In the case of our patient on futher investigation Human coronavirus OC43 infection was detected with molecular PCR testing and the patient was discharged with oral beta blocker for rhythm control.

22AP05-5

Hydromorphone reduced the incidence of emergence agitation after adenotonsillectomy in children with obstructive sleep apnea: a randomized, double-blind study

Q. Huang¹, Y. Chen¹, X. Sun², R. Zhou², G. Chen¹, T. Zhu² ¹Sichuan University; West China Hospital of Sichuan University, Department of Anesthesiology, Chendu, China, ²West China Hospital; Sichuan University/West China School of Nursing, Sichuan University, Department of Anesthesiology and Operation Center, Chengdu, China

Background and Goal of Study: Emergence agitation (EA) after (adeno)tonsillectomy (AT) surgery impairs the quality of recovery in children. Adequate analgesia plays a crucial role in reducing the incidence of EA. This study validated that anesthesia induction with hydromorphone infusion could reduce the incidence of EA following AT surgery for obstructive sleep apnea (OSA) in children.

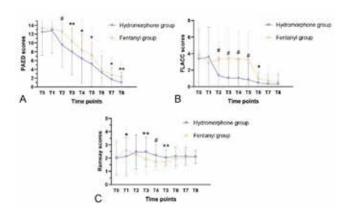

Materials and Methods: 183 ASA physical status I to III children aged 3 to 7 years undergoing AT surgery were enrolled in a blinded randomized controlled trial of hydromorphone (30 µg/kg) versus fentanyl (4 µg/kg) infusion during anesthesia induction.

The primary outcome was the incidence of EA within 30 minutes after extubation.

Secondary outcomes included the pediatric anesthesia emergence delirium (PAED) scores, the face, legs, activity, crying, consolability (FLACC) scores, Ramsay sedation scores, extubation time, duration of post-anesthesia care unit stay, the incidence of rescue analgesia, and perioperative adverse events.

Results and Discussion: Compared with the fentanyl group, the incidence of EA within 30 min after extubation in the hydromorphone group was significantly lower [48.4% (45/93) vs. 64.5% (60/93); absolute difference, 16.1%; 95% confidence interval, 18.9% to 29.5%; P=0.027], with decreased PAED, FLACC and Ramsay scores in post-anesthesia care unit. In subgroup postanalysis by age, the difference in incidence of EA between hydromorphone and fentanyl was only observed in children aged 3-5 years old (51.7% vs. 77.6%, P = 0.006).

However, this difference became insignificant in elder children aged 6-7 years old (42.9% vs. 50.0%, P = 0.527). The proportion of patients with postoperative moderate-to-severe pain (FLACC scores > 3 at any time point) was significantly lower in the hydromorphone group than in the fentanyl group (57.0% vs.77.4%, χ^2 = 8.806, P = 0.003). Neither of the two groups experienced postoperative complications.

Conclusion(s): Hydromorphone at 30 µg/kg effectively reduces the incidence of EA within 30 minutes post-extubation in children after AT surgery, providing superior analgesia and a high safety profile compared to fentanyl.

22AP05-6

Optimal electrode positions for electromyographic neuromuscular monitoring by posterior tibial nerve stimulation in infants

T. Sonoyama¹, M. Hara¹, O. Uchida² ¹Chiba Children's Hospital, Department of Anaesthesia. Chiba, Japan, 2Kansai Medical University, Department of Anaesthesia, Hirakata, Japan

Background and Goal of Study: Monitoring neuromuscular blockade (NMB) is strongly recommended when muscle relaxant is used in general anaesthesia. In infants or small children, NMB monitoring at the adductor pollicis muscle is occasionally unavailable due to the interference by vascular lines. Therefore, the sole is a potential monitoring site in these patients. In monitoring NMB by electromyographic (EMG) technology, reliable EMG signals must be obtained.

In this study, we have placed multiple electrodes on the sole and measured evoked EMG signals to investigate the optimal electrode positions

Materials and Methods: After IRB and parental consent, fifteen infants without neuromuscular disease were enrolled. Anaesthesia was maintained with sevoflurane or propofol and remifentanil. Rocuronium was administered before the intratracheal intubation. After the end of surgery and the confirmation of train-of-four ratio > 0.9 at the adductor pollicis muscle, eight surface electrodes were placed on the sole (Figure).

Supramaximal stimulation was applied on the posterior tibial nerve at the ankle, and the EMG amplitudes from eight electrodes against the ground electrode (placed at the base of the great toe, G in Figure) were recorded simultaneously. Amplitudes were compared between electrodes using one-way ANOVA or Student's t test as appropriate. A p value < 0.05 was considered

Results and Discussion: The age and weight of the patients were 6.5±3.8 months and 7.3±1.7kg, respectively. The intensity of supramaximal nerve stimulation was 57.5±11.4mA. EMG amplitudes from eight electrodes were shown in Table. The amplitude was higher at the heel-side (A3, A4, A7, and A8) than at the toe-side (A1, A2, A5, and A6). There was no statistical difference between medial (A3, A4) and lateral (A7, A8) electrodes.

Electrode	A1	A2	А3	A4	A5	A6	Α7	A8
Amplitude(mV)	0.8	11.2	16.5	15.4	5.0	12.6	15.3	15.6
Ampillude(mv)	±0.6	±3.1	±3.2	±3.1	±1.8	±2.8	±2.4	±3.1

Table. Evoked EMG amplitudes at each electrode

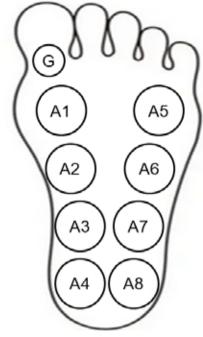

Figure. Positions of electrodes.

Conclusions: Sufficient amplitudes for NMB monitoring were obtained at sole electrodes by posterior tibial nerve stimulation. The heel of the sole can be a preferable position for NMB monitoring by EMG in infants.

22AP05-7

A rare case of pediatric temporomandibular joint ossifying myositis: customized airway strategies

R. Chesa i Martí¹, S. Casares Acuña², E. Martinez Garcia², N. De Luis Cabezon¹

¹Hospital Universitario Basurto, Anestesiología y Reanimación, Bilbao, Spain, ²Hospital Universitario Infantil Niño Jesús, Anestesiología y Reanimación, Madrid, Spain

Background: Ossifving myositis (OM) is a rare condition involving heterotopic bone formation, often post-trauma. OM in the temporomandibular joint (TMJ) is particularly rare in pediatric patients, with fewer than 1% of cases under 10 years old. TMJ OM can severely limit mouth opening, creating a difficult airway. This case highlights the challenges of managing airway and anaesthesia in paediatric OM with severe restrictions.

Case Report: An 8-year-old boy presented for coronoidectomy and pterygoidectomy due to progressive TMJ OM, with a mouth opening of <1 cm. This condition followed facial trauma at 18 months and required two previous surgeries for TMJ ankylosis, with recurrence after each.

Given the severe restriction, a difficult airway was anticipated. The patient was uncooperative with awake procedures, so fiberoptic nasotracheal intubation under general anesthesia with spontaneous ventilation was planned. Preparation included nasal topicalization with lidocaine and vasoconstrictor, IV induction agents, and the presence of a paediatric ENT specialist. A custom-modified nasotracheal tube was prepared by connecting two 5.5-sized tubes to ensure proper length and diameter.

Following sevoflurane induction and IV cannulation, sedation with ketamine and fentanyl maintained spontaneous ventilation, ensuring patient tolerance to the procedure. The tube was successfully placed under fiberoptic guidance, and the surgery proceeded without complications.

Discussion: This case illustrates the challenges of managing paediatric TMJ OM with severe airway restrictions. Tailored equipment and preoperative topicalization combined with IV induction agents enabled spontaneous ventilation and a safe fiberoptic intubation while ensuring correct sedation and tolerance to the procedure. OM's rarity highlights the importance of individualized strategies in such cases.

- 2. Simmonds, J., et al. (2016). Pediatric nontraumatic myositis ossificans. Int J Pediatr Otorhinolaryngol, 84, 116-118.

Learning Points:

- 1. TMJ OM in paediatric patients presents unique and complex airway challenges.
- 2. Customizing airway material and planning is crucial for managing specific difficult airway situations.
- 3. Effective topicalization and sedation ensure safe fiberoptic intubation with spontaneous ventilation in paediatric patients.

22AP05-8

Successful airway management in a pediatric patient with a large melanotic neuroectodermal tumor of infancy affected with his oral cavity stenosis

M. Omoto¹, M. Yagihara¹, Y. Nakajima¹ ¹Hamamatsu University School of Medicine, Department of Anesthesiology and Intensive Care, Hamamatsu, Japan

Background: Melanotic neuroectodermal tumor of infancy (MNTI) is a rare tumor arising from the neural crest cells. It occurs mainly in the maxilla of the infants and grows rapidly [1].

Although it is challenging to secure the airway in a patient with a tumor-occupied oral cavity, we achieved successful airway management in an infant with a large MNTI in his mouth.

Case Report: A 6-month-old boy presented with his right-sided upper jaw swelling. The swelling rapidly grew to a large mass which occupied more than half of his oral cavity, and the surgical resection was scheduled. He was able to suck milk until the surgery. He suffered from bleeding of the tumor and needed astriction frequently in the preoperative period. At the preoperative visit, there was space in his oral cavity for manipulation when he bent backward. We used low-dose remimazolam and sevoflurane as induction agents. After we confirmed facemask ventilation under deep sedation, we used rocuronium and performed the oral intubation with the use of the Pentax Airway Scope® from the left side of his mouth.

Discussion: The tumor bled several times before the surgery. and therefore we planned a nasal intubation at first so that we avoid the tumor. Once a tumor bleeds, it is difficult to use a video laryngoscope and/or fiber scope. However, oral intubation was better for the surgeons to perform surgery, and we decided it. We considered facemask ventilation through the nasal cavity would be possible because he could suck milk. Hence, we decided to intubate after we used anesthetic drugs. Also, we administered remimazolam which can be reversed in case of facemask ventilation failure. Dose of remimazolam increased step by step. After adequate depth of anesthesia with additional sevoflurane inhalation, we checked the patency of the airway again and administered rocuronium.

References:

1. Rachidi Saleh et al. Melanotic Neuroectodermal Tumor of Infancy: A Systematic Review. Journal of Oral and Maxillofacial Surgery, 2015:73:1946-56.

Learning Points: This case showed that it is essential to perform an airway risk assessment and have a preformulated strategy for the management of the tumor-occupied oral cavity.

22AP05-9

Difficult airway management in an infant with severe lingual tonsillar hypertrophy

N. de Luis Cabezón 1, D. Ly-Liu1,

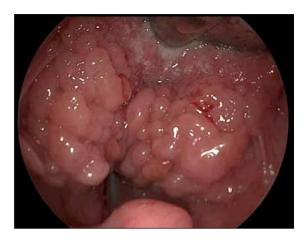

Madrid, Spain

P. Renedo-Corcóstegui¹, O. Romero-Menchaca¹, E. Martínez-Hurtado², M.Á. Fernández-Vaguero³ ¹Basurto University Hospital, Anaesthesia and Intensive Care, Bilbao, Spain, ²Hospital Universitario Infanta Leonor, Anaesthesia and Intensive Care, Madrid, Spain, 3Clínica Universidad de Navarra, Anaesthesia and Intensive Care,

Background: Lingual tonsillar hypertrophy (LTH) is a known cause of OSA and paediatric airway obstruction. It can cause varying degrees of airway obstruction and should be considered a potential difficult airway. Severity is determined by the extent to which the lingual tonsil occupies the vallecula and classified by 4 degrees(1).

Case Report: We describe the case of a 9-year-old girl with OSA, nasal speech and dysphagia. Adenotonsillectomy was performed at 3 years old. She has currently been diagnosed with LTH Grade 4 and is scheduled for lingual tonsillectomy surgery. Given the risk of difficulty with both ventilation and tracheal intubation, intubation with a nasal fiberoptic bronchoscope was performed under spontaneous ventilation. Both nostrils were prepared with tetracaine + adrenaline-soaked lentils and 4 ml of nebulized 2% lidocaine were administered. Inhalation induction was performed

with 6% sevoflurane, and once adequate hypnosis was achieved, nasal intubation was performed with a fiberoptic bronchoscopy, with a No. 5 tube. Then, lingual tonsillectomy was carried out. Admission to the ICU intubated for 72 hrs was required to control oedema and bleeding, and maintaining treatment with systemic corticosteroids, successful extubation was achieved.

Discussion: Making the diagnosis of LTH in children with OSA is important, as it can modify anaesthetic approach to a potential unplanned difficult airway management as well as the postoperative care planning in the ICU, which may require up to 4 days of endotracheal intubation due to the risk of oedema and bleeding. including preventive tracheostomy(2).

References:

- 1. Kang KT, et al. Lingual Tonsillectomy for Treatment of Pediatric Obstructive Sleep Apnea: A Meta-analysis. JAMA. 2017.
- 2. Sarmento J, et al. Fiberoptic intubation in a child with previous unexpected difficult airway due to lingual tonsil hypertrophy. Rev Esp Anestesiol Reanim. 2019.

Learning Points: Patient safety is the maximum priority in any medical situation, especially when dealing with a potential difficult airway. These patients must be considered as having a difficult extubation and it's necessary to have a difficult extubation plan.

22AP05-11

The development of a comprehensive pediatric enhanced recovery after surgery (ERAS) program utilizing a pathway development team

T. Glenski¹, C. Taylor¹, N. Doyle¹, E. Weisberg¹, K. Murari², A. Melanson³

¹Children's Mercy Kansas City, Anesthesiology, Kansas City, United States, 2University of Kansas, School of Medicine, Kansas City, United States, 3Children's Mercy Kansas City, Evidence Based Practice, Kansas City, United States

Background: While ERAS pathways are gaining momentum in the pediatric realm, the development, implementation, and maintenance of these pathways can be a time-intensive process that may deter physicians from undertaking the effort.

Fortunately, the Department of Evidence Based Practice (EBP) at our pediatric hospital plays a pivotal role in streamlining and expediting the ERAS pathway development and implementation process.

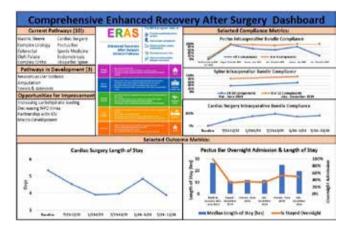

Methods: In a quality improvement collaboration with our hospital's EBP team starting, a total of ten ERAS pathways have been implemented. Each pathway is championed by an anesthesiologist and surgeon in partnership with nursing teams. Current services include cardiac surgery, pediatric surgery, urology, gynecology, orthopedics, sports medicine, and spine surgery.

The development, implementation, and monitoring of the ERAS pathways are coordinated by the EBP team, with all ERAS pathways made accessible externally on the hospital's website. Monthly reports of compliance and outcome measures monitor the success of the pathways.

Results: A comprehensive dashboard was created to help capture the entire program, including our most updated handout to patients. (Image 1).

The dashboard reveals the following intraoperative bundle compliance rates: pectus bar insertion currently achieves 100% compliance for 8 of 9 components and 25% compliance for all 9 components; spine surgery achieves 82% compliance for 9 of 10 components and 38% compliance for all 10 components; and cardiac surgery demonstrates 84% compliance across all components.

This dashboard currently shows a decreased need for overnight admission in the pectus bar pathway (50% vs 100% at baseline) and a decreased length of stay in the cardiac surgery pathway (3.9 days vs 5.3 days at baseline).

Conclusion: Working alongside a dedicated pathway team, ten pediatric ERAS pathways have been successfully implemented and have been associated with certain improved outcome metrics.

This collaborative approach has fostered teamwork across disciplines and reduced the burden on physicians, resulting in a stronger and more effective ERAS program that continues to expand.

22AP05-12

Intraoperative dexmedetomidine and acute kidney injury in paediatric non-cardiac surgery: a retrospective propensity score-matched analysis

R. Luo¹

¹West China Hospital of Sichuan University, Anesthesiology, Chengdu, China

Background and Goal of Study: Paediatric acute kidney injury (AKI) is common and linked to longer hospitalization and mortality. We investigated whether a continuous intraoperative infusion of dexmedetomidine, which increases renal blood flow, was associated with a lower risk of postoperative AKI in paediatric patients undergoing non-cardiac surgery.

Materials and Methods: This retrospective cohort study included paediatric patients undergoing non-cardiac surgery between January 2019 and July 2021. Propensity score matching (PSM), based on the participants' baseline characteristics, was used to minimize the potential bias.

The primary outcome was AKI within 7 days after surgery. The secondary outcomes included intensive care unit (ICU) admission, in-hospital mortality, length of hospitalization, intraoperative bradycardia and hypotension. The exposure of interest was continuous intraoperative infusion of dexmedetomidine at any dosage or duration.

Multivariable logistic regression and linear regression analyses were further employed to adjust for residual imbalanced intraoperative factors in the matched cohort.

Results and Discussion: After propensity score matching, we identified 1858/4091 paediatric patients who had received intraoperative dexmedetomidine infusion. Intraoperative dexmedetomidine infusion was associated with a lower risk of AKI (1.4% vs 3.2%; odds ratio (OR) 0.43; 95% confidence interval (CI) 0.27-0.66: P<0.001), postoperative ICU admission (OR 0.35 95% Cl: 0.3-0.42; P<0.001), and shorter hospitalization (7 vs 9 days; P<0.001). Intraoperative bradycardia, hypotension, and in-hospital mortality were similar between the matched groups.

Conclusion(s): This retrospective analysis of a single-centre paediatric non-cardiac surgery cohort suggests that intraoperative dexmedetomidine infusion was associated with a lower incidence of AKI within 7 days postoperatively.

22AP06-1

The risk of postoperative nausea and vomiting (PONV) in pediatric patients under dental and oral surgery

M. Tsukamoto¹, Y. Oku², R. Nishimura³, T. Yokoyama³ ¹Kagoshima University Hospital, Dental Anesthesiology, Kagoshima, Japan, 2Kagoshima University, Dental Anesthesiology, Kagoshima, Japan, 3Kyushu University, Dental Anesthesiology, Fukuoka, Japan

Background and Goal of Study: Postoperative nausea and vomiting (PONV) is a relatively common complication of general anesthesia. We encountered PONV in pediatric patients after dental and oral maxillofacial surgeries under general anesthesia. In particular, there is a higher incidence of PONV due to bleeding of the oral cavity and aspiration of gastric contents. In addition, it might be difficult for pediatric patients to communicate the intensity and characteristics of their symptoms. However, the few studies have focused on dental and oral maxillofacial surgeries. In this study. we retrospectively investigated the risk factors of PONV on the first postoperative day in pediatric patients.

Materials and Methods: The anesthesia records of patients (aged 0-12 years) were retrospectively reviewed. The patient underwent dental and oral maxillofacial surgeries. The patients' background (gender, age, BMI), anesthesia time, use of anesthetic drugs, nitrous oxide (N_oO), history of PONV, motion sickness, disability, and time to oral intake were investigated. In the univariate analysis, Fisher's exact and χ 2 tests were used, and a multivariable analysis was performed using stepwise logistic regression to determine the risk factors of PONV.

Results and Discussion: A total of 589 patients were enrolled, with a mean age of 5.6 ± 2.8 years, and were divided in two groups based on the presence or absence of PONV. Eighty-six patients (17.0%) complained of PONV. The occurrence of PONV was correlated with age, BMI, anesthesia time, fentanyl, N2O, history of PONV, and motion sickness. Fentanyl was the highest risk factor (odds ratio=1.76; 95% confidence interval=1.33-2.32). Other risk factors included motion sickness, age, duration of anesthesia, BMI, history of PONV, and N₂O.

In many cases of minor surgeries in the oral region, drugs such as acetaminophen can be substituted for opioids. In addition, the use of a gastric tube may have resulted in a lower incidence of PONV compared to previous reports. We thought that PONV can be reduced by changing some aspects of anesthetic management.

Conclusion(s): The highest risk of PONV (17.0%) was determined to be dose of fentanyl for pediatric patients who underwent dental and oral maxillofacial surgeries under general anesthesia.

22AP06-2

Vitamin D attenuates neurotoxicity induced by propofol in offspring mice

H. Solmaz¹, F. Karacaer¹, E. Biricik¹, D. Tunay¹, S. Kara²,

¹Cukurova University, Anesthesiology, Adana, Turkey, ²Çukurova University, Histology, Adana, Turkey

Background and Goal of Study: Propofol is an intravenous agent widely used for the induction and maintenance of anaesthesia. It readily crosses into the placenta and brain and can induce neurotoxicity. Vitamin D, a neuroprotective hormone, inhibits neuroinflammatory and apoptotic processes in the brain and contributes to neurotrophin expression and myelination. We investigated whether vit D could attenuate sevoflurane-induced neurotoxicity in the offspring of mice.

Materials and Methods: Twenty 8-week-old pregnant Swiss albino mice were divided into 4 groups of 5 mice each: Control(group C), vit D (group D), propofol (group P), and propofol with vit D (group PD). Throughout pregnancy, groups D and PD received 5 mcg/kg/day of vit D, while groups P and K received 1 ml of saline. On day 14 of pregnancy, groups P and PD received 200 mg/ kg propofol. Newborn mice from these groups were used in this

Twelve offspring from each group were examined by electron microscopy (EM) and immunohistochemical methods to assess the expression of IL6, BDNF, TNF-alpha, c-Fos, Bcl-2, Bax ,Olig2 in prefrontal cortex and hippocampal tissue sections. Behavioural tests, including the open field and elevated plus maze tests, were performed on day 45.

Results and Discussion: Vit D significantly attenuated the propofol-induced increase in the expression levels of inflammatory cytokines (Figure 1, IL-6, TNF- α ; p < 0.0001) and apoptotic factors (Figure 1,2, Bax, c-Fos; p < 0.0001). Vit D also improved the expression levels of anti-apoptotic factors (Figure 1, Bcl 2; p < 0.0001) and neuroprotective proteins (BDNF, Olig2; p < 0.0001). EM images supported these data.

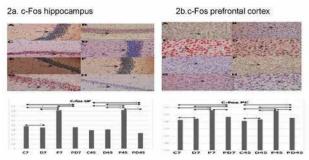

Figure 2. Immunohistochemical reactivity and scoring of c-Fos

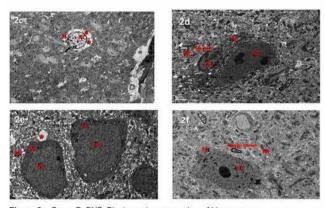

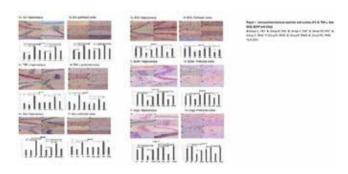

Figure 2c. Group P, PN7, Electron microscopy view of hippocampus Figure 2d. Group PD, PN7, Electron microscopy view of hippocampus Figure 2e. Group P, PN45, Electron microscopy view of hippocampus Figure 2f. Group PD, PN45, Electron microscopy view of hippocampus M: Mitochondria, N: Neuron, NC: Nucleus

Conclusion(s): Our results suggest that neuroinflammation and neurotoxicity induced by maternal propofol exposure on day 14 of gestation can be attenuated by maternal vit D teratment.

22AP06-3

EEG pattern during sevoflurane vs dexmedetomdine-remifentanil low dose sevoflurane based anesthesia in children up to the age of 5 years

<u>F.M. Lembo</u>¹, M. Cataldi², A.C. Lusardi¹, R. Bonfiglio¹, N. Disma³

¹IRCSS Istituto Giannina Gaslini, Anesthesiology and Pain Medicine, Genova, Italy, ²IRCSS Istituto Giannina Gaslini, Unit of Child Neuropsychiatry, Genova, Italy, ³IRCSS Istituto Giannina Gaslini, Unit of Research in Anesthesia, Genova, Italy

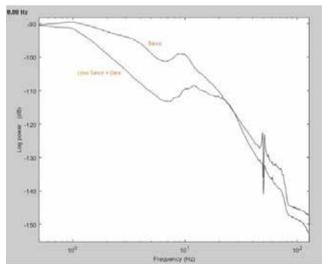

Background and Goal of the Study: Current brain activity monitoring predominantly relies on EEG-derived indices or single-number parameters. However, these indices often diverge from clinical assessments of unconsciousness, as they inadequately reflect the neurophysiological effects of anesthetic drugs.

The aim of this prospective cohort study is to investigate electroencephalographic (EEG) activity, including both periodic and aperiodic components, in children undergoing two different anesthetic regimens: low-dose sevoflurane combined with dexmedetomidine and remifentanil vs standard-dose sevoflurane with remifentanil.

Materials and Methods: During one-year inclusion period, we collected data from 28 pediatric patients. After induction, EEG was recorded continuously, focusing the analysis on spectral power, spatial distribution, and aperiodic components (spectral exponent). Data about BIS (BIspectral Index) and EtSevo (End-Tidal Sevoflurane) were also collected, every five minutes.

Result and Discussion: The low-dose sevoflurane group exhibited oscillatory activity extending to higher frequencies compared to the standard-dose group. The standard-dose group demonstrated greater absolute power in the delta and alpha bands. Delta power predominated in posterior regions in both groups, consistent with the developmental pattern of cortical maturation from posterior to anterior regions in children. The SE was more negative in the standard-dose group, indicating greater neuronal inhibition compared to the low-dose regimen: frontal (p < 0.002), central, and occipital (p < 0.001), respectively.

Spectral power distribution (PSD) analysis and the spectral exponent appear to be promising tools for monitoring the depth of anesthesia in pediatric patients, offering potential advantages over conventional indices like BIS.

Airway management in children with severe scoliotic spinal deformity

I. Smirnov¹, G. Roytberg¹, D.I. Vachnadze¹, N. Kondratova¹, V. Lazarev²

¹JSC "Medicina", Inpatient Department, Moscow, Russian Federation, ²Pirogov Russian National Research Medical University, Department of Pediatric Anesthesiology and Intensive Care of FDPO, Moscow, Russian Federation

Background and Goal of Study: Patients undergoing surgery for severe scoliosis with a Cobb angle exceeding 70 degrees pose significant challenges for anesthesiologists, particularly regarding airway management and tracheal intubation.

This study aimed to determine the risk factors for difficult airways in paediatric patients with severe scoliosis based on spinal curvature severity.

Materials and Methods: This observational, prospective-retrospective study included 86 patients aged 7-18 years, operated for scoliosis with a Cobb angle >70° between 2017 and 2024 at JSC «Medicina», Moscow. Inclusion criteria were: age 7-18 years and planned corrective scoliosis surgery.

Patients were divided into two groups: Group 1 (n=34) with Cobb angle 70-120° and Group 2 (n=51) with Cobb angle >120°. Airways were assessed using the Mallampati classification and the LEMON score.

The frequency of direct laryngoscopy, videolaryngoscopy and bronchoscopy use was analyzed. Statistical analysis was conducted using the Mann-Whitney U test.

Results and Discussion: Mallampati score differed significantly between groups (p<0.05), with Group 1 having a median score of 1.788 ± 0.363 compared to 2.417 ± 0.292 in Group 2. LEMON scores were also higher in Group 2 (2.362 ± 0.422) than in Group 1 (1.394 ± 0.46) (p<0.05). Endoscopic visualization tools were reguired less frequently in Group 1 (6.25%) compared to Group 2 (25.49%) (p<0.05).

Patients with less severe scoliosis more often underwent successful intubation using direct laryngoscopy alone.

Conclusion(s): Patients with a higher Cobb angle have a significantly increased risk of difficult airways. Endoscopic visualization tools, such as videolaryngoscopes and bronchoscopes, are crucial for safe and effective tracheal intubation in this group. Future studies should explore strategies to optimize airway management in this challenging population.

22AP06-6

A fight against sevoflurane emergence delirium in children: does remimazolam use in children following tonsillectomy and adenoidectomy prolongate emergence time and length of PACU stay? A randomized controlled study

F. Peris¹, S. Stojanovic Stipic¹, G. Prizmic¹, A. Bego¹, A. Mitar¹, S. Pavicic Perkovic¹ ¹University Hospital of Split, Anesthesiology, Reanimatology and Intensive Care, Split, Croatia

Background and Goal of Study: A well-known postoperative behavior disorder after sevoflurane anesthesia in the pediatric population, characterized by screaming, kicking and restlessness is emergence delirium. Several interventions, which have been studied to prevent its occurrence, may result in delayed extubation and prolonged PACU stav.

Remimazolam is short-acting benzodiazepine, which used postoperatively, reduces emergence delirium after sevoflurane anesthesia in children following tonsillectomy and adenoidectomy. However, does its use prolongate emergence time and length of PACU stay?

Materials and Methods: One hundred and ten patients between the ages of 1 and 9, who were set to undergo tonsillectomy and adenoidectomy with sevoflurane anesthesia were enrolled.

Patients were randomly allocated to receive either remimazolam at a dosage of 0.1 mg/kg (intervention group, n=57) or 0.9% normal saline (control group, n=53) at the end of the procedure.

Chi square test was used to examine differences in Aldret score upon awakening between groups. The difference in the duration of anesthesia emergence between groups was tested by the Mann-Whitney U test.

Results and Discussion: 30/53 children in the control group had an Aldret score greater than or equal to 9, while in the remimazolam group 28/57 children had an Aldret score greater than or egual to 9. There was no statistically significant difference in the Aldret score upon emergence between group (P=0.552).

The average duration of emergence was 10 (9-13) minutes in the control group, while in the remimazolam group was 10 (9-12) minutes. Data are presented as median (interguartile range).

There was no statistically significant difference in the duration of the emergence between the groups (P=0.674).

Conclusion(s): Intravenous remimazolam, administered at the end of surgery, not only decreases incidence of emergence delirium, as shown in other studies, but it does so by not prolongating emergence time and PACU stay.

With these characteristics remimazolam emerges as a leading drug in a fight against emergence delirium after sevoflurane anesthesia

Challenges for anesthesiologists in patients with Proteus syndrome: case report

M. Ciuplinskas¹, I. Dockiene¹, E. Kontrimaviciute¹, R. Zagorskis²

¹Vilnius University Hospital Santaros Clinics, Children's Emergency Medicine, Intensive Care and Anesthesiology Center, Vilnius, Lithuania, 2Vilnius University Hospital Santaros Clinics, Children's Surgery, Orthopedic and Traumatology Center, Vilnius, Lithuania

Background: Proteus syndrome (PS) is a rare disorder (1 in 1000 000) which is characterized by postnatal overgrowth of various tissues including bones, skin and soft tissues, with about 200 cases of syndrome described in the literature. Syndrome is the result of mosaic mutation in the AKT1 gene. Life expectancy is between 9 months and 27 years depending on the severity of existing anomalies. Characteristic facial phenotype- macrocephaly, abnormal teeth and macroglossia, soft tissue owergrowth with assymetric tonsils and adenoids are commonly found and may be the risk factors for difficult intubation.

Case report: The first case of PS in Lithuania was diagnosed in 2021 for a 14 year old boy. Clinical symptoms of syndrome manifested in second year of life with significant disease progression in adolescence. During past 4 years our patient underwent 10 orthopedic surgeries under general/combined - general and regional anesthesia and diagnosis was confirmed only after genome sequencing testing of biological material was done. Our patient lost his leg due to vein thrombosis and spreading infection of affected limb.

All general anesthesias were uneventful. Despite facial phenotype airway management dificulties did not occur. Ultrasound guided regional anesthesia was performed with minor challeng-

Discussion: The specific symptoms and severity of PS varies a lot and leads to a challenging diagnosis. Although orthopedic manifestations of PS is not the main issue of the disease, it should be taken into account when treating this syndrome.

In case of multiple surgeries difficult airway management might be an issue. Complicated wound healing, blood loss and thrombosis of dilated veins in affected areas are common.

References:

Proteus syndrome: what the anesthetist should know -ScienceDirect

Anesthesia for proteus syndrome - Cekmen - 2004 - Pediatric Anesthesia - Wiley Online Library

ethi D. Proteus syndrome. Sethi Proteus Syndr. 2018 m. kovo;(3-2018):S85-92.

Learning points: A patient with PS may be challenging for the anesthesiologist. The characteristic facial phenotype can lead to difficulties in airway management. Vascular malformations increase both bleeding and thrombosis risk during surgery. Tissue malformations cause difficulties in performing regional anesthesia.

22AP06-8

Re-expansion pulmonary oedema during tube thoracotomy under conscious sedation in a paediatric patient with anterior mediastinal mass

J. Shahani¹

¹KK Women's and Children's Hospital, Anaesthesiology (Peds), Singapore, Singapore

Background: We describe the successful management of a child with large anterior mediastinal mass who developed re-expansion pulmonary oedema during surgery of chest drain insertion, line insertion and lymph node biopsy under conscious sedation in our

Case report: A 14 years old male child weighing 43 kgs with large anterior mediastinal mass with pleural effusion and superior vena naval obstruction was planned to have chest drain insertion, tunnelled femoral line insertion and cervical lymph node biopsy under conscious sedation. He presented with a short history of 1 week with cough, shortness of breath and loss of weight. Radiological investigation showed large anterior mediastinal mass. He was admitted in ICU where 2 large bore peripheral IV lines and IA line were inserted in lower limbs.

The child was brought to OT in a slight head up position and monitoring lines were attached. He was sedated with Precedex and Ketamine infusions and positioned head up with supplementary

Local anaesthesia was infiltrated to the skin and a 24 Fr chest drain inserted with initial drainage of 700 mls hemoserous fluid. The chest tube was clamped and the surgeon proceeded with cervical lymph node biopsy. At this juncture, the patient became increasingly breathless and tachypneic with intermittent coughing. The oxygen requirement increased and patient was put on Pressure support of 8/5 cms of water but he remained hypoxic with saturation fluctuating between 85-91. Inj Frusemide 40 mg was given IV and IDC inserted.

A brief trial of BIPAP with pressures of 15/8 with 8L/min of oxygen did not improve the saturation and then it was planned to intubate the child. Chest drain was unclamped intermittently to drain a total of 2200 pls in 105 minutes.

The child was given boluses of IV Midazolam 10 mg and IV Ketamine 140 mg. The Blood pressure was supported with IV Adrenaline 0.2mcg/kg/min and the he was intubated with C-Mac Grade 1 view ETT 6.5 cuffed tube.

The child was the sent to ICU with stable hemodynamics.

Discussion: This child developed re-expansion pulmonary oedema following chest drain. It is a rare iatrogenic complication where chronically collapsed lung quickly re-expands following evacuation of air/fluid from pleural space. The incidence is around 1% and the mortality is as high as 20%.

Learning points: Early detection and planned management of this complication is necessary for good outcome.

22AP06-9

Role of mid-regional fragment of pro-adrenomedullin peptide (MR-proADM) in pediatric patients with severe infection: preliminary analysis of a monocentric prospective study

A. Vivaldo 1, P. Vitale2, B. Cochis1, R.I. Comoretto3, A. Conio², G. Montrucchio^{4,1}

¹University of Turin, Department of Surgical Sciences, Turin, Italy, ²Anestesia e Rianimazione 5U, Department of Anesthesia, Intensive Care and Emergency, Città della Salute e della Scienza Hospital, Turin, Italy, 3University of Turin, Department of Sciences of Public Health and Pediatrics, Turin, Italy, ⁴Anestesia e Rianimazione 1U, Department of Anesthesia, Intensive Care and Emergency. Città della Salute e della Scienza Hospital, Turin, Italy

Background and Goal of Study: The MR-proADM is a biomarker produced by endothelial cells showing a potential for early diagnosis, risk stratification, and prognosis prediction in critically ill patients with infections, including pediatric population.

Our study aimed to investigate its prognostic value and the correlation to severity scores and routine biomarkers in pediatric patients with severe respiratory infections (SRI).

Materials and Methods: We analyzed the retrospective data of patients admitted between December 2023 and June 2024 at the Pediatric Intensive Care Unit of a university hospital in Turin (Italy), for SRI. Among the inclusion criteria, the patients' age (28) davs - 16 years).

Exclusion criteria included pathologies correlated with augmented MR-proADM values according to literature, and hospitalacquired infections. MR-proADM levels were assessed within 24 hours from admission, on days 3 and 6, alongside other routine

Follow-up was conducted up to 60 days after discharge, Descriptive analysis and Spearman correlation analysis between MRproADM and the variables of interest were performed.

Results and Discussion: 20 patients were collected; the sample was homogeneous for sex but not for age (24 months old on average). All infections were respiratory, mainly viral bronchiolitis, with respiratory syncytial virus as the most frequent pathogen. Bacteria were found only in 3 cases, with one case of septic shock. Considering MR-proADM values, our population showed a mean value of 0.84 nmol/L (±0.23) at admission, lower than the comparison literature (cut-off 1.37 nmol/L). No patient died during the observation period and the length of stay in PICU and hospital had a median value of 4 and 18 days respectively.

The exploratory analysis showed a positive, statistically significant correlation between MR-proADM and procalcitonin and with some of the analyzed scores (pSOFA, PRISM III at 12h and 24h). No significant correlation was found with C-reactive protein, white blood count and other scores such as PIM 2 and PIM 3. Considering the ventilation-free days parameter as a primary outcome, the correlation with MR-proADM values was not statistically significant.

Conclusion(s): MR-proADM correlates with some routine biomarkers and scores, supporting its promising role as an early biomarker of severity.

studies are needed to deepen its diagnostic and prognostic role in pediatric patients with severe respiratory infections.

22AP06-10

Anxiolytic and analgetic effect of N₂O:O₂ 50%:50% gas mixture for vein puncture and arterial line placement in pediatric patients: A small prospective observational pilot study

A. Mandras¹, A. Velcev Nastasic¹, A.S. Herrera¹, Z. Paunovic², B. Mojsic¹, S. Vasiljevic¹ ¹Institute for mother and child health care, Anesthesiology and intensive care therapy, Beograd, Novi Beograd, Serbia, ²Institute for mother and child health care. Orthopedics, Beograd, Novi Beograd, Serbia

Background and Goal of Study: Nitrous oxide (NaO) can be efficiently and safely used in pediatric population for sedation in procedures of light to moderate pain intensity. The aim of the study is to observe the effect of N₂O:O₂ 50%:50% fixed gas mixture in children for vein and arterial line placement.

Materials and Methods: A single tertiary center prospective observational study. Ethic committee approval and parental/legal guardian informed consent obtained. Study was performed in accordance to Declaration of Helsinki. Inclusion criteria: age 1-16, planed peripheral vein and arterial.

Exclusion criteria: conditions with gas trapped in body cavity, otitis media, obstructive lung disease, upper airway infection, MTHF deficiency, megaloblastic anemia, bleomycin therapy, neuropathy. Dose of fixed N₂O:O₂ 50%:50% gas was equal to patient minute ventilation.

Outcomes: anxiolytic effect qualified as "cooperative" and "uncooperative", pain assessed using pain scales:1-4 years CHIPPS, 4-9 years FACES, > 9 years NRS, hypotension, bradycardia, desaturation. Pain was categorized as: 0-no pain, 1-3 mild, 4-6 moderate, 7-10 severe.

Results and Discussion: Results are presented in Tables 1 and 2. The majority of patients experienced and was cooperative. In 6 patients anxiety and separation fear were expressed, especially in children 4 years and younger. Pain was assessed as severe in 3 patients. It is possible that in these children emotional experience of pain, separation fear, younger age and cognitive disability were factors that influenced pain perception. Longer duration of application of gas mixture with parental presence might result in satisfactory pain and anxiety control.

	Mean ±sd, min, max / N° (%)
Age,y	4.69 ± 3.75 (1,14)

Table 1. Study population

Pain	Nº (%)	Anxiolysis	N° (%)	Complications	No (%)
No pain	6 (21.4)			Hypotension	0 (0)
Mild	11 (39.3)	Cooperative	22 (78.6)	Bradycardia	0 (0)
Moderate	8 (28.6)	Uncooperative	6 (21.4)	Desaturation	0 (0)
Severe	3 (10.7)				
Σ	28 (100)	Σ	28 (100)	Σ	28

Table 2. Outcomes

Conclusion(s): Application of N2O:O2 50%:50% gas mixture resulted in satisfactory pain control and anxiolysis. Further observation of large cohort is necessary.

22AP06-13 Status dystonicus: case report for monitored anaesthesia care

<u>U. Fabeena Mangaladan</u>¹, S. Kumar¹, A. Ayub¹
¹All India Institute of Medical Sciences, Department of Anaesthesiology, Pain Medicine and Critical Care, Delhi, India

Background: Status dystonicus (SD), often called dystonic storm or dystonic crisis, is a potentially fatal movement condition emergency (1). We performed monitored anaesthesia care for a paediatric patient with status dystonicus for examination of the eye to grade retinoblastoma. Anaesthetic agents itself can precipitate SD. Anaesthetic goal was to avoid any triggers of SD and to prevent the worsening of dystonia.

Case Report: 1.5 year old boy, weight 9kg with status dystonicus, West syndrome and bilateral intraocular retinoblastoma with left eye enucleated and post chemotherapy underwent examination of eye under sedation in our institution. Child had GDD and had underwent left eye enucleation under GA at 13 months of age which was uneventful. Child started having myoclonic seizures and abnormal posturing at 15 months of age and was diagnosed with West syndrome and status dystonicus. He was started on antiseizure medications and baclofen. He was sedated with inj. midazolam and inj. fentanyl.

On preoperative assessment, patient was sedated and had recurrent myotonic spasms despite being on multiple antiepileptics and muscle relaxants. Vitals and cardio-respiratory system examinations were within normal limits. IV access was 24g cannula on left foot.

Procedure planned was examination of right eye to assess status of retinoblastoma. In the OR, standard ASA monitors were attached. Oxygen supplementation was through nasal prongs at 4L/min. IVF Ringer lactate was given according to Holiday and Segar formula. Inj Midazolam 1mg was given at the start of the procedure. Patient had muscle spasms and dystonia during the procedure which was managed with further boluses of inj.midazolam and inj.fentanyl. There was no desaturation during the procedure. He was shifted back to PICU after the procedure with stable vitals.

Discussion: Anaestheic considerations include worsening of neurological symptoms, bulbar palsy and aspiration. Airway management may be complicated due to dystonia of neck.

Main anaesthetic goals are to avoid any triggers for the precipitation of status dystonicus such as pain, dehydration etc and to avoid mechanical ventilation as it can result in difficult weaning from ventilator.

Reference:

Allen NM, Lin JP, Lynch T, King MD. Status dystonicus: a practice guide. Dev Med Child Neurol. 2014;56(2):105–12.

Learning points: Proper preoperative evaluation, identifying dystonia state, treating it and ensuring airway protection and ventilation are crucial.

The Geriatric Patient

23AP01-1

Trends in time-sensitive pathologies in medical ICU patients over 80: a comparison of 2005-2009 and 2015-2019

M. Quisquater¹, E. De Keukeleere², L. De Pauw³, W. Swinnen4

¹OLV Aalst, Department of Anesthesiology and Intensive Care, Aalst, Belgium, 2Ghent University Hospital, Department of Anesthesiology, Ghent, Belgium, 3KU Leuven, Department of Anesthesiology, Leuven, Belgium, ⁴az Sint-Blasius, Department of Anesthesiology and Intensive Care, Dendermonde, Belgium

Background and Goal of Study: 15 years of progress in medical science and technology had a huge impact on how we treat patients. However, it is unclear if this progress results in better outcomes, especially for very old patients. A previous study at our ICU showed time sensitivity in admission of very old patients depending upon admission diagnosis. Early ICU mortality was higher when indirectly admitted for congestive heart failure (CHF), COPD-exacerbation (COPD-E) and pneumonia, but not for acute myocardial infarction (AMI), cerebrovascular accident (CVA) and sepsis. This discrepancy was attributed to the presence of standardized guidelines for the latter.

Our goal was to study changes in demographics, ICU length of stay (LOS), SAPS II and mortality in very old ICU patients (>80y) with APACHE IV-admission diagnoses of AMI, CVA, sepsis, CHF, COPD-E, and pneumonia between 2005-2009 (05-09) and 2015-2019 (15-19).

Materials and Methods: This retrospective cohort study was conducted in az Sint-Blasius, Dendermonde, Belgium, a general hospital with a 12 beds mixed medical-surgical ICU. A query in the ICU database, identified all patients over 80y old admitted between 05-09 and 15-19. Patients diagnosed with CVA, CHF, AMI, sepsis, COPD-E or pneumonia were included. Demographics, LOS, SAPS II and mortality were analyzed using chi-square and Mann-Whitney U tests (p < 0.05).

DRIGINAL COHORT	05-09	25-29

loop tal Mortality (Death in IOL/Death in Hosp/Oscharged alive)	19/23/92	7/26/94	P-0019
DIF, COPD E & Perumenia	N=234	N=173	
Apr (years, median)	85 (ICR 4)	89 (ICA 6)	F = 0.09
les (M/F)	62/62	89/84	P=0.801
.05 ICU (days, median)	4 (10) (8)	3-(CR3)	P=0.324
APS I sore (median)	42.5 (IQR 19)	37 (IC(R 11)	P = 0.0002
toughtal Mortaliny (Seath in ICL) Seath in Houg Studyaged alive!	10/35/99	25/41/117	P+ C-848

Results and Discussion: Patients were older in 15-19, though not clinically significant, and SAPS-II scores indicated higher sickness levels in 05-09. No overall differences were observed in LOS or mortality between the periods. However, LOS was significantly longer in 05-09 for both AMI/CVA/sepsis and CHF/ COPD-E/pneumonia cohorts. Mortality was higher for AMI/ CVA/sepsis during this period, but unchanged for CHF/COPD-E/pneumonia.

Conclusions: ICU patients today are generally older with more comorbidities. Hospitals have become more selective in ICU admissions for the elderly, focusing on cases with realistic treatment benefits. Enhanced guidelines for certain time-sensitive conditions, like AMI and sepsis, have contributed to improved outcomes, reducing mortality rates compared to earlier years.

23AP01-2

Detailed nutritional assessment improves preoperative risk assessment of elderly patients to prevent postoperative complications

A. Kostner¹, S. Hirschberger¹, D. Effinger¹, D. Seidenspinner², T. Saller¹, Projekt Gertrud ¹LMU Munich, Department of Anaesthesiology, Munich, Germany, 2LMU Munich, Clinical Nursing Research Unit, Munich, Germany

Background and Goal of Study: In previous work, malnutrition was shown as a risk for preoperative complications, delirium and mortality. However, screening elderly persons with validated and standardised tests may be challenging and shows low sensitivity especially for deficiency of specific nutrients.

The goal of this subcohort was to identify nutritional biomarkers associated with frailty and delirium.

Materials and Methods: Gertrud is a study project investigating the prevention of the perioperative neurocognitive disorder and postoperative complications by a multi-component, nursery-led intervention. After obtaining informed consent, orthogeriatric patients aged 70 years or older were assessed preoperatively for frailty and cognition.

Patients at risk (frailty or cognitive impairment or a combination of both) were randomised to receive a nurse-led intervention at least 7 days before the day of surgery including a multimodal nutritional assessment. Delirium was assessed with the 4A's Test postoperatively.

Results and Discussion: In total, more than 300 patients were included. Until today, 130 were randomised for an intervention with 40 patients with a full dataset of at least two nutritional assessments before surgery. 24 patients were female, 16 male with a median Clinical Frailty Score of 5 (25th-75 percentile 4-6). They mostly showed a normal or obese body shape with a median body mass index (BMI) of 26.2 kg*m2*-1, (24.7-31.7).

Cognition was slightly impaired (MiniCog 3 out of 5; 1,5-5). Incidence of delirium was not different between the intervention and control group. Detailed results of the nutritional assessments and biomarkers will be analysed and presented in detail. However, regarding its power, the study should be interpreted with caution.

Conclusion(s): A detailed nutritional assessment may help to improve the risk assessment of elderly patients and prevent complications, however the incidence of delirium was not improved by the nutritional intervention.

23AP01-3

Survival with preserved care level after emergency laparotomy in octogenarians and nonagenarian - a retrospective cohort analysis

L. lacubovici¹, S. Zarour¹, Y. Weiss¹, O. Goren¹, I. Matot¹, B. Cohen^{1,2}

¹Tel Aviv Medical Center, Anethesia, Pain and Intensive Care, Tel Aviv-Yafo, Israel, 2 Cleveland Clinic, Outcomes Research Consortium, Cleveland, United States

Background and Goal of Study: Despite the global shift towards patient-centered care and outcomes, most studies evaluating emergency laparotomy in older adults focus on survival, overlooking postoperative quality of life and functional status. We therefore aimed to evaluate the incidence and to identify factors that characterize survival with preserved care level after emergency laparotomy in octogenarians and nonagenarian.

Materials and Methods: We performed a retrospective analysis of patients 80 years and older who underwent emergency laparotomy at a single tertiary academic center from January 2017 to July 2021. Survival with preserved postoperative care level was defined as survival with discharge to the same level of care as the pre-admission level. To avoid non-random exclusion of patients who died during hospitalization, in-hospital mortality was considered as increased level of care.

We conducted several subgroup analyses. First, we explored and characterized maintenance of independence among patients previously living independently at home. We also assessed and described characteristics of preserved care level specifically among survivors

Results and Discussion: Among 283 included patients (median age 87 years), 91 (32%) survived with preserved care level. Of the 192 patients considered to have postoperative increased level of care, 113 (59%) met the outcome definition due to survival with increased level of care at discharge and 79 patients (41%) due to in-hospital mortality.

Among 162 previously independent patients, 39 patients (24%) survived with maintenance of independence. Among 204 survivors, 91 patients (45%) were discharged with preserved level of

Conclusions: Only 1 of 3 patients in our cohort survived with preserved functional status. Moreover, among previously independent patients, only 1 of 4 patients survived with maintenance of independence [SPH1]. Less than half of survivors were discharged with a functional status that allowed them to return to preoperative level of care.

The considerably low rate of survival with reasonable functional outcome found in our study might suggest an unfavorable harmbenefit ratio of surgical interventions in certain cases. Whether surgical treatment in these cases contributes to survival at the cost of diminished quality of life, becomes pertinent.

23AP01-4

Association between postoperative delirium in the post-anesthesia care unit and subsequent delirium in the surgical ward: a retrospective cohort analysis

Y. Weiss¹, S. Zarour¹, D. Hikry¹, A. Zegerman¹, B. Cohen¹, I. Matot¹, CIPOD Study Group

¹Tel Aviv Medical Sourasky Center, Anesthesia, Tel Aviv,

Background and Goal of Study: Postoperative delirium (POD) is a frequent complication among older surgical patients and is associated with increased morbidity, mortality, and healthcare costs. Early identification of POD during the immediate postoperative period offers a critical window for intervention.

We aimed to evaluate the association between POD diagnosed in the post-anesthesia care unit (PACU-POD) and subsequent POD in the surgical ward (ward-POD). We sought to explore the predictive value of 4A's test scores (4AT) in risk stratification.

Materials and Methods: W retrospectively analyzed data of patients ≥70 years who had elective non-cardiac surgery in a tertiary center between 2020 and 2021. Routine POD screening using the 4AT was implemented in the PACU and during the first two postoperative days in surgical wards. The 4AT scoring system ranges from 0 to 12, where a score ≥ 4 indicates POD.

Patients were categorized into four groups based on PACU 4AT scores: (1) no POD (4AT=0), (2) subsyndromal POD (4AT 1-3), (3) early PACU-POD (one hour from admission), (4) and late PACU-POD (at PACU discharge and Aldrete score of 9).

The primary outcome was ward-POD.

Secondary outcomes included discharge to non-home facilities and 1-year mortality. Multivariable logistic regression models were built to adjust for potential confounders.

Results and Discussion: Of 2,764 included patients, 9% (n=238) experienced PACU-POD, and 7% (n=198) had ward-POD, PACU-POD was significantly associated with ward-POD (aOR 4.8; 95% CI 3.3-7.2). Risk stratification revealed a graded relationship between PACU 4AT scores and ward-POD risk: patients with no PACU-POD (4AT=0) had the lowest incidence (4%; n=51).

Subsyndromal POD (7%; aOR 1.6; 95% CI 1.1-2.5), early PACU-POD (27%; aOR 4.8; 95% CI 3.2-7.1), and late PACU-POD (46%; aOR 9.8; 95% CI 4.0-24.2), all compared to the control group with no PACU-POD. PACU-POD was also associated with prolonged hospital stay, higher 1-year mortality (19%; aOR 1.7; 95% CI 1.1-2.7), and a trend toward non-home discharge (14%; aOR 1.2; 95% CI 0.8-1.9).

Conclusion(s): PACU-POD is a strong predictor of ward-POD and other adverse outcomes, emphasizing the importance of routine delirium screening in PACU. Incorporating 4AT-based risk stratification in perioperative protocols could guide early interventions. Further research should focus on targeted prevention strategies for high-risk subgroups identified by PACU 4AT scores.

23AP01-5

Five years of the cognitive impairment and postoperative delirium (CIPOD) quality improvement project: advancing perioperative cognitive, frailty, and delirium care

Y. Weiss¹, S. Zarour¹, L. Zac¹, O. Goren¹, B. Cohen¹, I. Matot¹, CIPOD Study Group ¹Tel Aviv Medical Sourasky Center, Anesthesia, Tel Aviv,

Background and Goal of Study: Postoperative delirium (POD) is a common complication among older surgical patients and is associated with significant morbidity, mortality, and healthcare costs. The Cognitive Impairment and Postoperative Delirium (CI-POD) quality improvement project, initiated in 2020, aimed to routinely identify preoperative cognitive impairment, frailty, and POD using validated tools, monitor POD trends, and improve perioperative care outcomes.

This study summarizes five years of CIPOD data, evaluating its clinical impact and highlighting areas for improvement.

Materials and Methods: This retrospective study included data from 8,081 patients aged ≥70 years who underwent preoperative screening between 2020 and mid-2024 at a tertiary hospital. Screening tools included the Mini-Cog for cognitive impairment (scores ≤2 indicating impairment) and the five-item modified frailty index (5-mFI, scores ≥2 indicating frailty). POD was assessed using the 4A's tool (4AT) in the post-anesthesia care unit (PACU) and on the first and second postoperative days in the surgical wards, with scores ≥4 indicating POD. Trends were analyzed using year-by-year comparisons, with P < 0.05 considered significant.

Results and Discussion: Among 8,081 screened patients, the median age was 76-77 years, with 69-72% aged 70-79. Most patients (44-55%) were ASA II. Frailty prevalence decreased from 43% in 2020 to 38% in 2024 (P = 0.04).

Preoperative cognitive impairment ranged from 17% to 21%, with a downward trend (P = 0.04). POD incidence decreased significantly, with PACU-POD dropping from 8.5% to 4.1% (p<0.001), ward-POD from 3.6% to 2.8% (p=0.17, trend, non-significant), and overall POD incidence fell from 10.9% in 2020 to 6.0% in 2024 (p<0.001) - a 45% reduction.

These trends reflect enhanced preoperative optimization and perioperative management, driven by the CIPOD initiative's emphasis on systematic screening and multidisciplinary awareness, education, and engagement.

Conclusion(s): The CIPOD project demonstrated the value of integrating cognitive, frailty, and delirium screening into routine perioperative workflows, achieving a significant reduction in POD incidence over five years.

While screening compliance remained high (≥89%), challenges persist in managing high-risk and severely frail patients. Future efforts should focus on targeted interventions and broader implementation of quality improvement strategies to improve outcomes.

23AP01-6

Detecting postoperative neurocognitive disorder in older adults following elective surgery: development of a short test battery

A. Gribnau¹, G.J. Geurtsen², H.C. Willems³, J. Hermanides¹, M.L. van Zuylen^{1,4} ¹Amsterdam UMC, Location University of Amsterdam, Department of Anaesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Location University of Amsterdam, Department of Medical Psychology, Amsterdam. Netherlands, ³Amsterdam UMC, Location University of Amsterdam, Department of Geriatrics, Amsterdam, Netherlands, ⁴Amsterdam UMC, Location University of Amsterdam, Department of Paediatric Intensive Care, Amsterdam, Netherlands

Background and Goal of Study: Postoperative neurocognitive disorder often affects older adults following surgery. To date, no practical instrument exists for routine clinical use to diagnose this subtle decline in cognitive function. The gold standard, neuropsychological assessment (NPA), takes 60-90 minutes to administer and existing brief cognitive screeners appear inadequate for the diagnosis of PNCD.

Therefore, the aim of this study was to construct a short test battery of existing cognitive tests for the detection of PNCD.

Materials and Methods: To identify the optimal subset of tests from the NPA, an existing database containing pre- and postoperative NPA data was used. Patients were aged 65 years or older and underwent elective surgery at the Amsterdam University Medical Centre. PNCD was defined as a decline of at least one standard deviation from the preoperative test score in two or more tests.

After checking for multicollinearity, 17 subtests across five cognitive domains were used as candidate predictors in a logistic rearession model.

Backward selection, guided by the Akaike Information Criterion, was used to identify the best subset of tests. Reliability of the model was assessed by evaluating discrimination and calibration.

Results and Discussion: In total, 77 patients completed pre- and postoperative NPA and 32 (42%) patients were diagnosed with PNCD. After backward selection, a combination of three tests (Stroop, Digit Span, and Auditory Verbal Learning Test) was identified as the best subset, requiring 20-24 minutes to administer. This battery achieved an area under the receiver operating characteristic curve of 0.91 (95%Cl 0.83 - 0.98) before and 0.86 (95%CI 0.78 - 0.97) after internal validation.

Conclusion: We have developed a short test battery of three cognitive tests for the diagnosis of PNCD in older adults. Administration of the battery before and after surgery can inform on changes in cognitive function in the perioperative period. Further research is needed to validate this test battery in independent datasets.

23AP01-7

Machine vs anaesthesiologist: who can better predict delirium?

C. Nelissen¹, M. Szyszko du Bois D'Aische², N. Schmutz^{3,4}, B. Walder⁵, M. Olofsson², J. Gaudet²

¹Liege University Hospital, Anesthesiology, Liège, Belgium, ²Lausanne University Hospital, Anesthesiology, Lausanne, Switzerland, 3University Hospital Basel, Anesthesiology, Basel, Switzerland, ⁴PIPRA AG, Anesthesiology, Zurich, Switzerland, ⁵Geneva University Hospital, Anesthesiology, Geneva. Switzerland

Background and Goal of Study: This study aims to compare the effectiveness of the PIPRA algorithm against clinical assessments by anesthesiologists in predicting postoperative delirium (POD).

Materials and Methods: Conducted as a multicentric prospective cohort study (Protocol NCT05639348) across three major hospitals in Switzerland since November 2022, the study includes patients aged 60 years and older with a planned postoperative stay of at least two days.

Exclusion criteria encompassed preoperative delirium, limited proficiency in German or French, recent intracranial or cardiac surgery, or surgery within the past two weeks.

During pre-anesthetic consultations, experienced anesthesiologists independently assessed each patient's risk of delirium, which was also evaluated using the PIPRA algorithm.

Postoperatively, patients were systematically monitored for POD using the 4 "A" Test, with assessments conducted twice daily for the first five days.

Results and Discussion: A total of 993 patients were enrolled, of whom 894 were evaluated using both the PIPRA algorithm and anesthesiologist assessments. The anesthesiologists had a mean of 7.9 years (SD 3.8 years) of medical training, including 4.23 years (SD 4.1 years) in anesthesia. The predictive performance of the anesthesiologists for POD was found to have an area under the curve (AUC) of 0.7 (95% CI: 0.65-0.74), while the PIPRA algorithm achieved an AUC of 0.73 (95% CI: 0.68-0.77).

Conclusion(s): In conclusion, the PIPRA algorithm demonstrates predictive accuracy comparable to that of experienced anesthesiologists, suggesting it is a reliable tool for assessing the risk of delirium in the perioperative setting.

23AP01-8

The protective role of overweight body Mass **Index on Postoperative Delirium: Evidence Supporting the Obesity Paradox**

Y. Weiss¹, M. Axelrod², A. Gal Oz¹, B. Cohen¹, I. Matot¹, S. Zarour¹, CIPOD Study Group

¹Tel Aviv Medical Sourasky Center, Anesthesia, Tel Aviv, Israel, ²Sheba Medical Center, Tel Hashomer, Gynecology and Maternity Center, Ramat-Gan, Israel

Background and Goal of Study: Postoperative delirium (POD) is a common complication in older surgical patients, affecting recovery, healthcare utilization, and mortality. The "obesity paradox," where increased Body Mass Index (BMI) is associated with better outcomes in certain contexts, is underexplored in POD.

This study aimed to evaluate the association between BMI and POD, focusing on the potential protective role of overweight BMI.

Materials and Methods: A retrospective cohort study analyzed data from the Cognitive Impairment Postoperative Delirium (CI-POD) project database (2020-2021) at a tertiary hospital. Patients ≥70 years who had elective surgical procedures were included, excluding those with missing BMI values, preexisting dementia, or direct ICU admissions. Patients were categorized into six BMI groups: underweight (<18.5), normal (18.5-24.9), overweight (25-29.9), obesity class I (30-34.9), class II (35-39.9), and class III (>40).

The primary outcome was overall POD, with secondary outcomes including PACU-POD, ward-POD, one-year mortality, and nonhome discharge. Multivariate logistic regression adjusted for confounders, with normal BMI as the reference group.

Results and Discussion: A total of 2,872 patients were included, with an overall POD incidence of 13% (367 cases). Overweight BMI (25-29.9) was associated with a lower overall POD rate compared to normal-BMI patients (12% vs 14%, adjusted odds ratio (aOR)=0.74; 95% CI [0.6-0.9], p=0.03). All other obesity categories did not demonstrate significantly different POD rates compared to the control group.

Mortality decreased with increasing BMI. Overweight and obesity class I patients had significantly lower mortality compared to normal BMI (11% and 9% vs. 15%; aOR=0.72, 95% CI [0.5-0.9], p=0.017 and aOR=0.51, 95% CI [0.3-0.8], p=0.001, respectively). All other obesity categories did not have significantly different mortality rates compared to the control group. Non-home discharge rates were not different across BMI categories.

Conclusion(s): Our findings support the "obesity paradox," with overweight and obesity class I patients benefiting from reduced risk of POD and mortality, likely due to improved metabolic and nutritional reserves.

However, the benefits diminish in obesity class II and III patients, as well as in underweight patients, where increased frailty and comorbidity burden might offset protective effects. Future research should investigate prehabilitation strategies to optimize BMI and enhance outcomes for older surgical patients.

23AP01-9

Clinical efficacy of hypotension prediction Index based protocolized hemodynamic management in geriatric orthopedic surgery: a prospective randomized controlled trial

P.-J. Chen¹, C.-Y. Wu^{1,2}, C.-T. Lee²

¹National Taiwan University Hospital Hsinchu Branch, Department of Anesthesiology, Hsinchu City, Taiwan, ²National Taiwan University Hospital, Department of Anesthesiology, Taipei City, Taiwan

Background and Goal of Study: Perioperative hypotension is a critical factor influencing postoperative outcomes, such as acute kidney injury (AKI) and postoperative cognitive dysfunction. This issue is particularly concerning in older adults. The Hypotension Prediction Index (HPI) has shown promise in predicting and mitigating intraoperative hypotension.

This study investigates the clinical efficacy of HPI-guided hemodynamic management in older patients undergoing orthopedic

Materials and Methods: This prospective randomized controlled trial enrolled patients aged ≥ 60 years undergoing elective orthopedic surgery under general anesthesia. Participants were randomized into two groups: standard care and HPI-guided therapy. Continuous hemodynamic monitoring was performed using minimally invasive Acumen IQ sensors. Hemodynamic parameters were targeted to maintain a mean arterial pressure (MAP) ≥ 65 mmHg and a stroke volume variation (SVV) < 13% using fluid challenges and intravenous norepinephrine infusion.

Additionally, in the HPI group, the HPI was maintained below 85. Key outcomes included the incidence of AKI, perioperative hemodynamic stability, and perioperative changes in neurocognitive test scores, assessed with the Quick Mild Cognitive Impairment (Qmci) test.

Results and Discussion: A total of 68 patients were enrolled, including 35 in the control group and 33 in the HPI group, with a mean age of 70 years. Patients in the HPI group received nonsignificantly higher doses of norepinephrine [17 (1-54) vs. 12 (1-43) mcg; p = 0.090], but intraoperative MAP was maintained comparably between the two groups (83 \pm 7 vs. 82 \pm 7 mmHg for the control and HPI groups, respectively; p = 0.833). AKI developed in 6 patients in the control group (17.1%) and 2 patients in the HPI group (6.1%) (p = 0.260). No significant differences were observed in perioperative Qmci test scores between the two groups. The lack of significant impacts on clinical outcomes may be due to the HPI alerting only at the MAP threshold of 65 mmHg, which may be too low for geriatric populations. Thus, the current utility of HPI may be limited in older adults unless a more flexible MAP threshold can be tailored to individual patients.

Conclusion(s): The HPI-guided intraoperative hemodynamic protocol was not effective in maintaining higher MAP during surgery or in reducing the incidence of AKI and postoperative neurocognitive decline in geriatric patients undergoing orthopedic surgery.

23AP01-10

Incidence and risk factors of extremely poor functional outcome after burr-hole evacuation of chronic subdural hematoma in octogenarians and nonagenarians - a retrospective cohort analysis

I. Rajmilevich¹, S. Zarour¹, Y. Weiss¹, N. Zohar¹, I. Matot¹, B. Cohen¹

¹Tel Aviv Medical Center, Anesthesiology, Tel Aviv, Israel

Background and Goal of Study: Most studies evaluating burrhole evacuation of chronic subdural hematoma (CSDH) in older adults focus on mortality, and only few describe patient-centered outcomes. Data on survival with extremely poor functional outcome remain scarce. We aimed to evaluate the incidence of extremely poor functional outcome after burr-hole evacuation of CSDH in octogenarians and nonagenarians, and to describe associated risk factors.

Materials and Methods: We performed a retrospective analysis of patients ≥80 years who underwent burr-hole evacuation for the treatment of CSDH at a single tertiary center from January 2017 to July 2021. Extremely poor functional outcome was defined as Glasgow Outcome Scale - Extended (GOSE) ≤ 3. Multivariable logistic regression models were used to identify independent risk factors for the primary outcome.

Results and Discussion: Among 153 included patients (median age 85 years), 64 patients (42%) had extremely poor outcome. Of these, 52 patients (81%) met the outcome definition due to GOSE=3 at discharge (survival with total functional dependency), and 12 patients (19%) due to GOSE=1 (died during hospitalization). Independent risk factors for such poor outcome were prehospitalization non-independent living status and pre-existing high burden of comorbidities, with adjusted odds ratios of 6.80 (95% CI 1.96-23.59) and 5.54 (95% CI 1.71-17.91), respectively.

Conclusion(s): Older adults undergoing burr-hole evacuation of CSDH have a significant rate of extremely poor outcome, mostly due to survival with total functional dependency, suggesting an unfavorable harm-benefit ratio of surgical intervention in certain cases. Future research should aim to further establish and validate patient-centered endpoints among older adults with CSDH.

Changes in electroencephalogram waveforms in elderly patients with severe dementia after administration of midazolam: changes in waveform and amplitude

Y. Morimoto¹

¹Kanagawa Dental University, Department of Geriatric Dentistry, Yokosuka, Japan

Background and Goal of Study: We have previously reported that intravenous sedation using midazolam in elderly patients with dementia often results in different responses from healthy populations. In this study, we measured how electroencephalogram (EEG) components change after administration of midazolam to elderly patients with dementia.

Materials and Methods: The study protocol was approved by the institutional research board and ethics committee of Kanagawa Dental University (approval number 735). Elderly subjects aged 60 years or older were enrolled, and subjects with the Mini Mental State Examination (MMSE) score of 23 or less were considered to have dementia.

Furthermore, patients with Functional Assessment Staging of Alzheimer's Disease stage≥6 and/or Clinical Dementia Rating of "severe" were registered as severe dementia. On the other hand, those with MMSE≥24 were considered to have no dementia. EEGs were measured using MWM20® (GMS Co., Ltd. Japan), and delta, theta, alpha and beta waves were identified by power spectrum analysis.

These parameters were measured and compared at three points: before midazolam administration (baseline value), when midazolam was administered and an OAA/S score of 2 was obtained, and just before the start of dental treatment. These data were compared between the dementia and non-dementia patients. Noise was removed from the EEG data by visual inspection, and the data during 10 seconds when the EEG was stable at each measurement time were used. The non-parametric tests were used as statistical analysis. P<0.05 was considered as significant.

Results and Discussion: The subjects' ages were 83.5 years (median) in the dementia group and 73.0 years in the non-dementia group. There were one male and 10 females in the dementia group, and 4 males and 7 females in the non-dementia group. In comparison between the dementia and the non-dementia group, higher delta and theta waves amplitude and lower alpha wave amplitude at baseline were suggested in the dementia group.

The amplitude of alpha and beta waves were lower and delta wave was higher after administration of midazolam in the dementia group. In comparisons within each group, the amplitude of theta wave in both the dementia group and the non-dementia group reduced after administration of midazolam.

Conclusions: Differences were observed in the changes in EEG waveform and amplitude between the elderly populations with and without dementia after administration of midazolam.

23AP02-2

Alterations in patient profiles without effect on short-term or long-term mortality among elderly intensive care unit patients from 2005 to 2019: a retrospective cohort analysis in Belgium

E. De Keukeleere¹, L. De Pauw², M. Quisquater³, J. Pauwels⁴, T. De Grauwe⁵, W. Swinnen⁴ ¹Ghent University, Anesthesiology, Ghent, Belgium, ²KU Leuven, Anesthesiology, Leuven, Belgium, ³Onze Lieve Vrouw Ziekenhuis, Critical Care, Aalst, Belgium, ⁴az Sint-Blasius, Anesthesia, Dendermonde, Belgium, ⁵az Sint-Blasius, Anesthesia & Critical Care, Dendermonde, Belgium

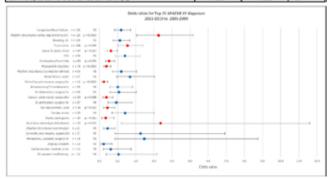

Background and Goal of Study: From 2005 to 2019, ICUs noticed a significant shift in healthcare trends and patient demographics. The intricacy and acuity of ICU patients increased, with more patients with multiple comorbidities and advanced age. Technological progress enabled treatment of increasingly older patients. However, it is unclear whether Very Old Intensive Care Patients (VIPs) benefit from this progress.

Goal: to study changes in demographics, case mix and mortality in VIPs, comparing 2005-2009 (05-09) and 2015-2019 (15-19).

Materials and Methods:

Setting: 12-bed mixed medical-surgical ICU at az Sint-Blasius, Dendermonde, Belgium. A database query identified all VIPs admitted between 05-09 and 15-19. Cross-matching with the Belgian National Register provided actual vital status or date of death. To avoid bias from repeated ICU admissions, we excluded VIPs readmitted within 12 months before final admission. Data: age, sex, APACHE IV admission diagnosis, SAPS II score, mortality. Statistics: Chi-square, Mann-Whitney U-test, Kaplan-Meier survival analysis with log-rank test. Statistical significance: p < 0.05.

Demographics & Outcomes	05-09	15-19	Statistics
Admissions >80 years (n)	747	1066	p < 0.0001
Age (years, median, interquarble range)	83 (IQR 4)	84 (IQR 5)	p = 0.022
Sex (M/F)	333/414	511/555	N5
Length of stay in ICU Idays, median, interquartile range)	3 (10 ft 2)	2 (IQR 2)	p < 0.0001
Hospital Admission Type (Emergency Surg/Planned Surg/Modical)	91/169/487	119/150/797	p < 0.0001
SAPS II score (median, interquartile range)	36 (KLR 20)	35 (ICR 17)	p = 0.091
Hospital Mortality (Death in ICL//Death in Hospital//Discharged alive)	75/116/556	105/140/821	N5
Survival up to 12 months after ICU admission (%)	0.596	0.616	NS

Results and Discussion: 747 vs. 1066 admissions were analyzed. In 15-19 significantly more VIPs were admitted to ICU. Median age was older in 15-19, but length of stay and SAPS II score were

lower. Sex did not differ neither did mortality in ICU, in hospital and survival up to 12 months after ICU admission. Case-mix changed significantly: more admissions for atrial rhythm disturbance, pneumonia, and acid-base electrolyte disturbances, fewer admissions for sepsis/septic shock, cardiogenic shock, COPD exacerbation, AMI, and certain surgical diagnoses (pelvis/hip fracture, colorectal cancer, hip replacement).

Conclusion(s): Because of the aging population, the number of VIPs admitted in ICU is increasing, as is their median age. However, mortality did not change. Our presumption that survival of VIPs improved during 15 years of medical progress, seems incorrect, but could have been influenced by multiple biases. To rule out bias by age, case-mix or acute physiology changes, analysis with logistic regression or propensity score matching is warranted.

23AP02-3

The association between myocardial injury and 90-day mortality after hip fracture surgery- a retrospective cohort analysis

L. lacubovici¹, S. Zarour¹, I. Rajmilevich¹, T. Ben Tov², I. Matot¹, B. Cohen¹,³

¹Tel Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel, ²Tel Aviv Medical Center, Division of Orthopedic surgery, Tel Aviv-Yafo, Israel, ³Cleveland clinic, OUTCOMES RESEARCH Consortium, Cleveland, United States

Background and Goal of Study: The association between myocardial injury after non-cardiac surgery (MINS) and postoperative mortality has been well established in elective surgical patients. However, data regarding this association among elderly patients having hip fracture repair are scarce.

We therefore aimed to investigate the association between MINS and postoperative 90-day mortality in patients≥65 years having surgical hip fracture repair.

Materials and Methods: We conducted a retrospective cohort study in a large volume tertiary medical center between May 2020 And June 2022. MINS was defined as a peak high sensitive cardiac troponin I above the 99th percentile of the upper reference limit, routinely measured in this population during the first 72 postoperative hours, presumed to be of an ischemic origin. The association between MINS and postoperative 90-day mortality was evaluated using multivariable regression models.

Results and Discussion: A total of 698 patients were included (median [interquartile range, IQR] age 84 [77, 90] years; 68% females; 68% ASA physical score 3-4). We found a 24% (165 patients) incidence of MINS. The overall 90-day mortality rate was 6% (n=41 patients).

After adjustment for potential confounding variables, MINS was associated with 90-day postoperative mortality (adjusted odds ratio [aOR] 2.05, 95% confidence interval [CI] 1.05-3.99, p=0.036).

The time from emergency room admission to the operating room was not significantly associated with 90-day post-operative mortality (aOR 1.16, 95% CI 0.44-3.10, p=0.766).

Conclusions: Our results suggest that MINS is independently associated with postoperative 90-day mortality in elderly hip fracture surgical patients, concomitant with previous studies that investigated this association among other surgical populations. Considering the deleterious consequences associated with

MINS, and the high mortality rates following hip fracture surgery repair, routine troponin measurements after these surgeries may have an important role in improving postoperative outcomes.

23AP02-4

The identification of orthostatic hypotension in preassessment

A. Sobahi¹, S. Howell¹

¹University of Leeds, Leeds Institute of Medical Research, Anaesthesia, Leeds, United Kingdom

Background and Goal of Study: Orthostatic hypotension (OH) is a common cardiovascular condition affecting 5-30% of older community-dwelling adults, with higher prevalence in those with comorbidities¹.Despite its potential significance in perioperative outcomes, the implications of OH in surgical settings remain largely unexplored, particularly regarding intraoperative haemodynamics and postoperative complications. Understanding these perioperative implications could help improve risk assessment, patient safety, and outcomes in vulnerable surgical populations.

This work was approved as a service evaluation to examine the practicality and importance of identifying OH in older patients during preassessment clinic visits, determining its incidence, and identifying high-risk groups among patients aged 65 years and older undergoing intermediate or major elective non-cardiac suraerv.

Materials and Methods: A prospective evaluation of 100 patients aged ≥65 years was conducted at St James's University Hospital's preassessment clinics. Data collection included demographics, Clinical Frailty Scale scores, comorbidities, antihypertensive medication use, and orthostatic blood pressure measurements, defined as a ≥20 mmHg drop in systolic or ≥10 mmHg in diastolic blood pressure within 3 minutes of standing. Statistical analysis employed descriptive statistics, chi-square tests, and univariate analyses.

Results and Discussion: OH was present in 42% of participants, significantly higher than community prevalence rates. A strong association was found between OH and frailty levels (p <.001), with higher OH prevalence in vulnerable (41.2%), mildly frail (81.8%), and moderately frail (100%) patients. Diabetes mellitus was significantly associated with OH (p = 0.037), while age, sex, and other comorbidities showed no significant associations.

Conclusion(s): The high prevalence of OH in preoperative older adults, particularly those with increased frailty or diabetes, suggests the need for routine OH screening in preoperative assessments. Special attention should be given to patients with higher Clinical Frailty Scale scores or diabetes mellitus.

Further research is needed to develop risk prediction models and evaluate the impact of preoperative OH management on surgical outcomes.

Combined spinal-epidural anesthesia associated with peripheral nerve blocks for total hip arthroplasty in a patient with decompensated heart failure with reduced ejection fraction (HFrEF) and metastatic lung cancer

A.B. Gondim¹, L. Rodrigues^{1,2}, G. Miná², A. Oliveira¹, B. Almeida², C. Marquez Simões² ¹Hospital Alemão Oswaldo Cruz, Anesthesiology, São Paulo, Brazil, ²Hospital Sírio Libanês, Anesthesiology, São Paulo. Brazil

Background:

Anesthetic management in elderly patients with multiple comorbidities is challenging. This case involves a patient with metastatic lung cancer, decompensated heart failure, COPD, coronary artery disease, and DNI/DNR directives.

Case Report:

A 71-year-old male with metastatic lung carcinoma, heart failure (EF 23%) with 1700 ml of pleural effusion drained the day before surgery, type 2 diabetes, atrial fibrillation, COPD, and an implanted unactivated CDI presented for total hip arthroplasty after a pathological femoral fracture. He had a history of myocardial infarction and was on anticoagulation therapy.

He presented to the OR with 83% SpO2 on room air, 90/50 mmHg blood pressure. Due to cardiovascular instability, spinal anesthesia alone was avoided. The anesthetic approach included:

- 1. Femoral nerve block: 15 ml of 1% lidocaine. allowing adequate patient positioning for neuraxial anesthesia
- 2. PENG block: 20 ml of 0.375% ropivacaine
- 3. Combined spinal-epidural: 5 mg isobaric bupivacaine intrathecally and 4 ml of 0.2% ropivacaine intermittently via epidural catheter, plus 2 mg of morphine at the end of surgery

The surgery was uneventful, with 500 ml of fluid administered and 600 ml of urine output. The epidural catheter was removed promptly to ease the reintroduction of anticoagulants. The patient was transferred to ICU and ambulated 48 hours later with minimal pain and no complications.

Discussion:

Individualized anesthetic management is paramount for high-risk patients. Regional techniques, combined with careful sedation, provide effective analgesia and minimize the risks of general anesthesia and extubation failure. This approach respects the patient's will to avoid invasive interventions and offers a safer alternative to general anesthesia.

Reference:

Bui, Michael et al. "Systematic review and meta-analysis of preoperative predictors for early mortality following hip fracture surgery". Osteoporos Int. 2024;35(4):561-574. doi:10.1007/ s00198-023-06942-0

Learning Points: The dual block technique combines the hemodynamic stability of neuraxial anesthesia with the prolonged analgesia of peripheral nerve blocks.

This approach avoids airway manipulation, reduces systemic risks, and provides effective pain relief. It aligns with palliative care principles by ensuring patient comfort while minimizing invasive interventions, offering a safe and effective strategy for frail patients with severe comorbidities requiring urgent surgical intervention.

23AP02-6 Quality of preoperative patient education in older adults (PREDOL)

J. Myrau¹, L. Plümer¹, C. Olotu¹ ¹University Medical Center Hamburg, Department of Anesthesiology, Hamburg, Germany

Background and Goal of Study: The patient's informed consent to treatment is a prerequisite for any medical intervention and is required by law and by ethical standards. Informed consent is a construct of information exchange, understanding and voluntariness. Little is known how older adults, especially those with cognitive impairment, perceive preoperative education and if the criteria of informed consent are met in these patients.

Here, we evaluated perception of anaesthesiologic education in patients ≥65 years, comparing their views with those of physicians.

Materials and Methods: Patients were enrolled at the University Medical Centre Hamburg, following questionnaires were applied: Information and understanding: COMRADE (Combined Outcome Measure of Risk Communication and Decision Evaluation), DEC (Decision Evaluation Scale); voluntariness, participation: PIC (Perceived Involvement in Care Scale). Autonomy, health literacy and functionality: API (Autonomy Preference Index); HLS (European Health Literacy Survey); WHODAS2.0 (Section one of the WHO disability assessment schedule).

Physicians' perception of informed consent criteria and comparison with the patients' perspective was assessed. Analysis was carried out using Spearman's correlation test and two-sided T-

Results and Discussion: 150 patients (mean age 74, 33% female) and 37 anaesthesist were enrolled. Information and understanding were achieved at a rate of 90% (45/50, SD 5,35, COMRADE), compared to 47% (9/20, SD 3,12, PIC) for participation and voluntariness. While 84% of patients stated a high demand for information (33/35, SD 3,61, API), this was only recognized by 27% of anaesthesists.

Furthermore, physicians were more likely than their patients to believe that the decisions should be physician-led (62% vs 38%, p < 0.01). Patients with self-reported cognitive impairment were less satisfied with received risk education than cognitively unimpaired patients (26/30, SD 4,54, WHODAS; p=0,04).

Criteria of informed consent were more often met in patients with low level of education and health literacy (12/16, SD 5,02, HLS) due to a reduced autonomy preference (33/35, SD 3,5, API; p>0,03).

Conclusion(s): Informed consent has only been partially achieved from elderly patients' perspective due to the lack of involvement; physicians rated their consultations as more informative and interactive than the patients. Accordingly, participation of the elderly in medical decisions should be encouraged.

23AP02-7

Comparison of two different tests in diagnosing postoperative delirium in elderly patients

T. Dinc Dogan¹, F.U. Dogan², Ö. Turhan³, I.H. Gürvit², Z. Sungur³

¹University Hospital Bonn, Department of Anesthesiology and Reanimation, Bonn, Germany, 2Istanbul University, Istanbul Faculty of Medicine, Department of Neurology, Istanbul, Turkey, 3 Istanbul University, Istanbul Faculty of Medicine, Department of Anesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Postoperative delirium is an acute or subacute, usually reversible altered state of consciousness that fluctuates throughout the day. It can occur with a prevalence of up to 55%1.

Delirium is associated with increased mortality, morbidity and healthcare costs2.

Early recognition of delirium in elderly patients undergoing surgery is important to prevent adverse outcomes3.

The aim of the study was to compare the DRS-R-98 and 3D-CAM tests used in the assessment of postoperative delirium, and to evaluate their applicability and power to detect delirium.

Materials and Methods: After obtaining the approval of the ethics committee, 270 patients aged 65 years and older, undergoing elective surgical operation longer than 1 hour were included in the study. Demographic and surgical data and postoperative followup were recorded. DRS-R-98 and 3D-CAM tests were administered on postoperative days 1 and 2 and the diagnosis of delirium was confirmed by DSM-V.

Results and Discussion: The incidence of postoperative delirium was 9. 2% (n=25). The DRS-R-98 test has a sensitivity of 80.9 -81.2% and a specificity of 98. 8-100%; the sensitivity and specificity of the 3D-CAM test were 100% and 98.4- 99 6%, respectively.

A significant difference was observed between the delirium + and - groups in terms of median age, ASA score, history of cerebrovascular events and arrhythmia, hearing aid use, median body mass index, education level, postoperative intensive care unit stay and total hospitalization (p<0.05).

In regression analysis, advanced age, history of cerebrovascular events, low education level, low BMI and long total hospitalization were associated with increased risk of delirium (p<0.05).

Conclusion(s): 3D-CAM and DRS-R-98 tests, whose specificity and sensitivity we compared with the gold standard DSM-V, seem to be reliable diagnostic methods.

Emergency laparotomy in the elderly: A 6-month audit of outcomes in Emergency **Laparotomy and Laparoscopic Scottish Audit** (ELLSA) patients aged 65 and over in a Scottish **Tertiary Major Trauma Centre**

M. Millar¹, R. Dryden¹, M. Rodger¹, S. Hickey¹ ¹Queen Elizabeth University Hospital, Department of Anaesthesia and Critical Care, Glasgow, United Kingdom

Background and Goal of Study: The surgical population is ageing faster than the general population and most emergency laparotomies are performed in patients aged ≥65[1]. This is a high risk group with an increased 30- and 90-day mortality and length of stay[1]. Frailty is associated with poorer outcomes and affects up to 20% of older adults undergoing emergency laparotomy thus frailty scoring is recommended in this group[2.3]. The Emergency Laparotomy and Laparoscopic Scottish Audit (ELLSA) includes frailty scoring as a Key Performance Indicator. Despite this our centre has no formal frailty scoring for emergency laparotomy patients. We aimed to establish the proportion of patients undergoing emergency laparotomy aged ≥65, compare their outcomes with the whole cohort and identify areas for improvement.

Materials and Methods: A subset of data collected for ELLSA from April - September 2024 was reviewed. Data included age, mortality risk scores (≥5% indicating high risk), post-operative critical care stay, 30-day mortality, and length of stay (LOS). Data for patients aged ≥65 were compared with the whole cohort.

Results and Discussion: 121 procedures that met ELLSA criteria were performed in the audit period. Two were excluded for incorrect recording of patient details. 53.8% of patients were aged ≥65. The results are shown in the table:

Patient group	Whole patient cohort	Patients aged ≥65	
Proportion of patients high-risk	50.4%	76.5%	
Post-operative critical care admission (level 2 or 3)	47.1%	57.8%	
30-day mortality	5.0%	7.8%	
Mean LOS	18.7 days	19.0 days	

Table. Comparison of whole patient cohort and patients aged ≥65

Conclusion(s): Over half of patients studied were aged ≥65. This group had higher mortality risk scores, admission rates to critical care, and 30-day mortality. Our data supports the introduction of formal frailty scoring in those undergoing emergency laparotomy allowing targeted interventions for older patients.

23AP02-10

The incidence of postoperative delirium in elderly urological patients, depending on the preoperative condition

H. Gani¹, M. Naco¹, K. Lilaj¹, R. Domi¹, G. Gani², H. Sula¹ ¹UHC "Mother Teresa", Anesthesia, Tirana, Albania, ²Ludwig Maximilian University of Munich, Economics, München, Germany

Background and Goal of Study: Elderly patients are at greater risk than other patients for postoperative delirium. The goal of this study is to assess the role of preoperative morbidity in the incidence of postoperative delirium (POD).

Materials and Methods: All patients over 65 years old who underwent surgery for TUR BT and TUR Prostate under spinal anesthesia were included in the study. The total number of patients was 740. All patients were preoperatively assessed for their mental status using the MMSE (Mini-Mental State Examination). A cutoff score of 23 was used, and patients scoring below this threshold were excluded from the study.

Additionally, for each patient, an evaluation was conducted using the Confusion Assessment Method (CAM). We use Fisher's exact test (statistical significance.p<0.05)

Results and Discussion: Out of these 740 patients, 77 had no underlying illnesses. Of those without illnesses,2 (2.5%) developed (POD). A total of 143 patients had only one illness . POD was observed in 12 (8.3%) patients overall, all of whom were over 80 years old.

On the other hand, 500 patients had two or more illnesses, POD was observed in 88 (17.6%) patients in this group. Out of 740 patients,102 (13.7%) manifested postoperative delirium. Among patients with a single preoperative illness, postoperative delirium was observed at rates between 6% and 16.6%.

Meanwhile, the highest incidence of postoperative delirium was found in patients with more than one illness (12.5% to 31%). Anemia in patients with diabetes was identified as an important factor in the incidence of postoperative delirium (31%). No Disease vs. Any Disease (One or More Diseases),p-0.0013: No Disease vs.≥2 Diseases,p-0.00017.One Disease vs. ≥2 Diseases,p-0.006. Odds Ratios(OR): No Disease vs. Any Disease: OR = 0.15 (Patients with any disease are ~6.7x more likely to develop delirium). No Disease vs. Two or More Diseases: OR = 0.12 (Patients with two or more diseases are ~8.3x more likely to develop delirium). One Disease vs. Two or More Diseases: OR= 0.43 (Patients with two or more diseases are ~2.3x more likely to develop delirium than those with

Conclusion(s): This study revealed that the greater the number of preoperative illnesses a patient has, the higher the likelihood of encountering postoperative delirium.

Additionally, the presence of anemia in patients with diabetes mellitus was identified as a significant factor in the increased frequency of postoperative delirium.(p<0.05)

Post-operative pulmonary complications in elderly sarcopenic patients undergoing thoracic

C. Cambise¹, D. Fusco², L. Petracca Ciavarella³, G. Punzo¹, M.L. Vita³, P. Aceto^{1,4} ¹Fondazione Policlinico Universitario Agostino Gemelli IRCCS, Dipartimento di Scienze dell'Emergenza, Anestesiologiche e della Rianimazione, Roma, Italy, ²Fondazione Policlinico Universitario Agostino Gemelli IRCCS. Dipartimento di Geriatria. Neuroscienze e Ortopedia, Roma, Italy, ³Fondazione Policlinico Universitario Agostino Gemelli IRCCS, UOC di Chirurgia Toracica, Roma, Italy, ⁴Università Cattolica del Sacro Cuore, Dipartimento di Scienze Biotecnologiche di Base, Cliniche Intensivologiche e Perioperatorie, Roma, Italy

Background and Goal of Study: Sarcopenia is a generalized muscle disorder involving strength, muscle quantity/quality and physical performance (European Working Group on Sarcopenia in Older People-EWGSOP2). It is a common pathology in the elderly and it correlates with negative post-operative outcomes such as high mortality, complications, increased hospital stay; therefore, it could be used as an index to identify patients who could benefit from a more conservative surgical approach or post-operative intensive care admission.

Our study is based on the hypothesis that sarcopenic elderly patients undergoing thoracic surgery are exposed to a greater risk of post-operative complications and short- and long-term mortal-

Materials and Methods: Patients candidates for thoracic surgery at Fondazione Policlinico Universitario A. Gemelli IRCCS were enrolled. Inclusion criteria: age ≥ 70 years old. Exclusion criteria: esophageal and emergency surgery. Patients underwent surgical, anaesthesiological, pneumological and geriatric evaluation during pre-hospitalisation, with a subsequent geriatric follow-up visit 30 days after surgery.

Primary endpoint: pulmonary complications 30 days after surgery. Secondary endpoints: other post-operative complications, intensive care unit (ICU) admission, length of stay, falls at 30 days.

Results and Discussion: We enrolled 53 patients: 26 underwent surgery; 13 underwent follow-up after 30 days. The statistical analysis was performed for the 26 operated patients, who were divided into two groups: sarcopenic (14 patients) and non-sarcopenic (12 patients).

According to our knowledge, this is the only study in the literature that analyzes the correlation between pulmonary complications and sarcopenia diagnosed by integrating radiological datas (psoas muscle index [PMI]) with clinical evaluations (hand grip, chair test, short physical performance battery [SPPB], appendicular skeletal muscle mass [AMS]), in patients aged > 70 years undergoing thoracic surgery.

Pulmonary complications (PPCs) 30 days after surgery: 42.8% of sarcopenics vs 0% of non-sarcopenics (p = 0.017). Other postoperative complications: 31.71% of sarcopenics vs 25% of nonsarcopenics (p = 0.683).

Conclusion(s): Sarcopenia diagnosed according to EWGSOP2 correlates with increased PPCs in elderly patients undergoing elective thoracic surgery. Further studies are necessary to confirm this data.

23AP03-1

Analysis of the relationship between preoperative risks in cardiac and abdominal surgery patients, taking into account the Fraility index, CFT, EFT scales and thigh muscle thickness

A. Yakimchuk¹, B. Ferchichi², A. Dzyadzko³, A. Sezina⁴, N. Egorova¹, N. Dzerkach⁵ ¹State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Anesthesiology and Resuscitation #4. Minsk. Belarus. ²State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Cardiosurgery Department #1, Minsk, Belarus, 3State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Anesthesiology and Intensive Care Department, Minsk, Belarus, 4State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Anesthesiology and Resuscitation #4 Chief, Minsk, Belarus, 5State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Anesthesiology and Resuscitation #5, Minsk, Belarus

Background and Goal of Study: In modern surgery, the issue of postoperative risk stratification in patients over 65 years of age is increasingly arising. Numerous studies show that with high-quality surgery, the greatest number of complications in any patient occurs in the postoperative period. This statement is based on peak oxygen consumption, physical fitness and its decline with age. The Clinical Fraility Scale (CFS) and Essential Fraility Toolset (EFT), primarily in elderly patients, are more important in predicting this period.

The main goal of the study is to analyze the prediction of postoperative complications using Fragility indicators and to identify patterns between the thickness of the thigh muscles and the severity of fragility.

Materials and Methods: 144 patients were analyzed, divided according to the profile of the underlying disease and surgical intervention into cardiac surgery and abdominal groups. 91 cardiac surgical patients from 46 to 84 years old (67 ± 6.75 years), including 29 women (31.86%) and 62 men (68.14%), who should undergo coronary bypass surgery or heart valve replacement on a cardiopulmonary bypass or on a beating heart. 53 abdominal patients from 31 to 79 years (57.73 ± 12.76 years), including 27 women (50.95%) and 26 men (49.05%), who should undergo hepatectomy of various volumes, or pancreatic duodenal resec-

The CFS and EFT scores were used to stratify postoperative risks. At the same time, the patients underwent ultrasound diagnostics of the thickness m. rectus femoris and m. vastus medius.

Results and Discussion: In cardiac group the correlation analysis revealed a significant (p <0.05), strong inverse relationship (r = -0.71) between the CFS scale indicators and thickness m. rectus femoris. Significant (p < 0.05), inverse, moderate relationships were also revealed between EFT and thickness m. rectus femoris and m. vastus medius (r= -0.56; r= -0.53), and between SFS thickness m. vastus medius (r= -0.57).

Abdominal group, a significant (p <0.05), weak inverse relationship (r = -0.35) was found between the EFT scale indicators and thickness m. rectus femoris. A significant (p <0.05), inverse, and weak relationship between CFS and thickness m was also revealed. rectus femoris (r= -0.45)

Conclusion(s): The CFS and EFT scales in cooperation with preoperative ultrasound of the thigh muscles can improve the tactics of preoperative preparation of patients in order to minimize postoperative complications.

Impact of continuous pre-induction norepinephrine administration on the incidence of hypotension following propofol induction in elderly patients: the vaso-old study

N. Daum^{1,2}, D. von Wedel², L. Hoff^{1,2}, C. Spies¹, F. Balzer², R. Mörgeli¹

¹Charité - Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt Universität zu Berlin, Department of Anesthesiology and Intensive Care Medicine (CCM/CVK), Berlin, Germany, 2Charité -Universitätsmedizin Berlin, Corporate Member of Freie Universität Berlin and Humboldt Universität zu Berlin. Institute of Medical Informatics, Berlin, Germany

Background and Goal of Study: Postinduction hypotension (PIH) can lead to severe complications1. Older adults may be at an increased risk of PIH, particularly when vasodilatory anesthetic agents are used2.

In elderly patients, continuous vasopressor administration is often employed before anesthesia induction. However, the effect of continuous vasopressors on PIH remains unclear.

This study aimed to evaluate the impact of initiating continuous catecholamine infusion prior to propofol induction on the incidence of PIH.

Materials and Methods: This retrospective cohort study was conducted at Charité-Universitätsmedizin Berlin between December 2019, and August 2023. Patients aged ≥70 years who underwent a preoperative geriatric assessment, and received anesthesia induction with propofol for elective surgery were included. PIH was defined as a mean arterial pressure (MAP) <65 mmHg within 15 minutes after the initial propofol bolus. Continuous catecholamine administration was defined as norepinephrine (NA) delivered via syringe pump.

Multivariable zero-inflated negative binomial regression analyses were used to assess the relationship between pre-induction NA and both the duration and severity of PIH. Analyses were adjusted for age, sex, ASA physical status, MET (Metabolic Equivalent of Tasks), CCI (Charlson Comorbidity Index), antihypertensive medication, and median MAP before induction.

Results and Discussion: A total of 1,824 patients were included, with 739 (41%) receiving continuous NA before anesthesia induction and 1,085 (59%) not receiving (Table 1).

The median duration of hypotension in the NA group was 0.0 [IQR 0.0-1.0] minutes, with a median area under the curve (AUC) of 0.0 [0.0-1.8] mmHg·min-1.

In the non-NA group, the median duration was 0.0 [0.0-1.1] minutes, with a median AUC of 0.0 [0.0-1.7] mmHg·min-1. In adjusted analysis, no significant differences in hypotension duration (IRR 0.94, 95%CI 0.75-1.17, p=0.6) or AUC (IRR 1.12, 95%CI 0.81-1.54, p=0.5) were observed.

Conclusion(s): Continuous pre-induction NA administration did not significantly influence the incidence or severity of PIH following propofol induction in elderly patients.

Category	NA cohort (n = 739)	Non-NA cohort (n = 1085)	Standardized Mean Difference
Age (Years)	77 [73-81]	77 [73-81]	0.083
Sex (male)	420 (57%)	647 (60%)	0.076
ASA-Status	2 [2-3]	2 [2-3]	0.113
MET	4 [4-6]	5 [4-6]	0.2
CCI	5 [4-6]	5 [4-6]	0.118
Antihypertensive Medication	705 (95%)	1019 (94%)	0.057
Anaesthesia induction time (min)	13 [9-21]	13 [9-19]	0.158
Median MAP before anaesthesia induction	99 [91-107]	98 [91-107]	0.012
Propofol amount (mg kg ⁻¹)	1.4 [0.9-1.9]	1.5 [0.8-1.9]	0.023
Noradrenaline amount (µg kg-¹min-¹)	0.05 [0.03-0.05]	N/A	N/A

Dexmedetomidine for elderlies used in one day surgery

A. Kishman¹

¹University Clinic for Traumatology, Orthopedics, Anesthesia and Intensive Care, Emergency Center at Mather Tereza Campus, Department of Anesthesia and Intensive Care, Faculty of Medicine, Ss. Cyril and Methodius University, Skopje, North Macedonia, The Republic of

Background and Goal of Study: The use of combination of local anesthesia and analgosedation with short action drugs, seems that meet the requirements for safe anesthesia for aged patients. Dexmedetomidine (DM), a selective alfa -2 agonist of adrenoreceptors and remifentanil (RM) a synthetic opioid can be used for analgosedation in this type of surgery.

Materials and Methods: The use of combination of local anesthesia and analgosedation with short action drugs, seems that meet the requirements for safe anesthesia for aged patients. DM a selective alfa -2 agonist of adrenoreceptors with sympatholytic effects, and RM can be used for analgosedation in this type of

Some publications in the literature suggest the contribution of DM in peroperative inflammation and stress response and the prevention of postoperative cognitive disfunctions (PCD) in elderly people, which can meet the requirements of this type of anesthesia.

Results and Discussion: The use of optimal doses of DM, as it was advised by some authors, provided stable hemodynamic course of the patients included in this study. The titration of remifentanil also resulted in less respiratory disturbances. The operative trauma, stress factors and the separation from their homes make them liable to PCD. One of the hypotheses of this

occurrence is that an increased amount of cortisol during surgical trauma may be responsible for this. In this study the level of cortisol was increased in the group of patients sedated with RM . **Conclusion(s):** It can be concluded that DM in optimal doses provides stable hemodynamics without respiratory depression. Compared to standard remifentanil infusion DM enables better anti-inflammatory and anti-stress effect. Also can be concluded that DM is a powerful tool against the development of the PCD **References:**

23AP03-4 Opioid-free anesthesia for elderly patients: Is it safe and beneficial?

<u>I. Setiawan</u>¹, A. Chrysantia Melati¹, B. Tutuko¹

¹Premier Bintaro Hospital, Anesthesiology and Intensive Care, Tangerang Selatan, Indonesia

Background and Goal of Study: The physiology and anatomy of the elderly patient undergous many changes, including lower drug metabolism and increasing side effects of most drugs, including opiod. Opioid-free anesthesia is being considered as one option for adequate anesthesia with fewer complications. This study aims to demonstrate the role of opioid-free anesthesia among elderly patients

Materials and Methods: This was a retrospective observational study from September 2023 – October 2024 in Premier Bintaro Hospital. Inclusion criteria was aged more than 65, operative duration more than 30 minutes, under general anesthesia. Exclusion criteria was admitted to ICU postoperatively. Primary outcomes were severe postoperative pain, opioid rescue analgesic needs, incidence of nausea and vomiting, and any desaturation incidence in the recovery.

Results and Discussion: There were 158 patients included in this study with 21 subjects or 13.3% had opioid-free anesthesia. Both groups spent comparable time for observation in the recovery room. Most common surgical type for both groups were spine and orthopedic surgery. As for the primary outcome, the incidence of severe postoperative pain was slightly higher among those who received opioid-free anesthesia (23.8% vs. 18.2%). There was no incidence of nausea and vomiting in opioid-free anesthesia group. There were no adverse events in both groups.

Conclusion(s): Opioid-free anesthesia served as an option for elderly patients undergoing surgery with less incidence of nausea and vomiting. However, the incidence of postoperative pain was slightly higher in comparison with those who received opioid.

23AP03-5

Beyond a numeric index: is it enough to keep patients within the recommended Bispectral (BIS) Index?

A. Gulec Kilic¹, G. Inan¹, Z. Ozkose Satirlar¹
¹Gazi University Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Processed electroencephalogram (pEEG) monitoring is recommended to assess anesthesia depth during total intravenous anesthesia (TIVA). We present a geriatric case of delayed recovery and postoperative delirium (POD), whose BIS index was maintained within the recommended range.

Case Report: A 76-year-old female with coronary artery disease underwent thoracic decompression surgery for spinal mass; received standard monitoring with BIS. TIVA induction and maintenance were performed. The patient remained hemodynamically stable, BIS values were kept between 40–60, no intraoperative complication occured. 15 minutes after cessation of anesthetics, she responded to verbal stimuli and was extubated afterwards. Upon PACU transfer, she was disoriented. POD was diagnosed on day 1; which resolved 48 hours later with supportive therapy.

Discussion: Despite maintaining BIS in the 40s; burst suppression (BS) occurred, particularly and increasingly at values below 50, without hypotension (Figure 1).

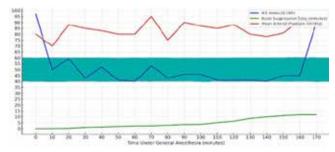

Figure 1.

Retrospective spectrogram analysis showed weak frontal alpha oscillations,a marker of vulnerable brain(1). Advanced age and coronary artery disease, known risk factors for increased burst suppression (BS)(2), heighten the risk of POD. Our case aligns with literature, as the patient developed POD under these conditions. Educating anesthesia providers to identify vulnerable brain physiology, prevent BS and reduce POD through individualized BIS

index and spectrogram-guided monitoring is essential, particularly for those relying solely on BIS values around 40 to remain "safe" and lacking in depth knowledge on spectrogram and raw EEG analysis.

References:

1. Shao YR et al.Low Frontal Alpha Power Is Associated With the Propensity for Burst Suppression: An Electroencephalogram Phenotype for a "Vulnerable Brain". Anesth Analg. 2020 2. Besch G et al. Occurrence of and risk factors for electroencephalogram burst suppression during propofolremifentanil anaesthesia. Br J Anaesth. 2011

Learning Points: BIS index values alone may not suffice in geriatric patients with vulnerable brain physiology. Incorporating raw EEG and spectrogram analysis into practice can mitigate complications in high-risk populations.

23AP03-6

Evaluation of the effect of preoperative iron deficiency anemia on Edmonton Frailty Score in geriatric patients planned for surgery undergoing colorectal cancer

A. Özkan Kaya¹, R. Yilmaz², S. Arican², A. Karakol³, H.N. Gunay², G. Buyukbezirci² ¹Konya City Hospital, Anesthesiology and Reanimation, Konya, Turkey, ²Necmettin Erbakan University Faculty of Medicine. Anesthesiology and Reanimation, Konya.

Turkey, 3Kastamonu City Hospital, Anesthesiology and Reanimation, Kastamonu, Turkey

Background and Goal of Study: Frailty is a predictor of a patient's vulnerability to the stress of a surgical procedure and an increased risk of developing postoperative complications and postoperative adverse events.

Our primary hypothesis is that iron deficiency anemia (IDA) in geriatric patients increases the Edmonton Frailty Scale (EFS) score. Our secondary hypotheses are that a high frailty score increases the length of hospital stay, prolongs recovery time, and increases perioperative complications.

Materials and Methods: Our study included 120 patients over the age of 65 who were scheduled for elective laparoscopic colorectal cancer surgery. All of our patients were evaluated for anemia, and those with a hemoglobin value below 13 were considered anemic.

The patients were divided into 2 groups (anemic, non-anemic). All of our patients were subjected to the EFS during the preoperative evaluation. Heart rate, arterial blood pressure, and peripheral oxygen saturation were recorded at certain time intervals intraoperatively.

In addition; The duration of the operation, the need for inotropic agents, the amount of bleeding and blood transfusion, the duration of intensive care-hospitalization, the postoperative 15th minute Modified Aldrete Score and 30-day mortality were examined. Results and Discussion: In the examination conducted in two groups consisting of patients with and without IDA, it was determined that age (p=0.017), days of intensive care unit stay (p=0.01), total hospital stay days (p=0.016), EFS score (p<0.001) values were higher in patients with IDA.

There was a positive correlation with EFS (p<0.001) and a negative correlation with 15th minute Modified Aldrete Scores (p<0.001) in the duration of intensive care unit stay.

In the group with IDA and high frailty score, respiratory (p=0.047), cardiac (p=0.047) and neuropsychogenic (p=0.046) complications and inotropic agent use were higher (p<0.001).

Conclusion(s): In this prospective observational clinical study: we found that geriatric patients with IDA were associated with higher frailty scores. Perioperative difficulties are possible in geriatric patient group defined as fragile according to EFS.

23AP03-7

The role of vitamin C in postoperative recovery: reducing inflammation and pain after laparoscopic colon surgery in elderly patients - a randomized, double-blind, placebo-controlled trial

V. Gherghina¹, I. Cindea¹, A. Balcan², A. Tabacaru¹, D. Costea¹, B. Samoila³

¹Constanta County Clinical Hospital, ICU, Constanta, Romania, ²Ovidius Faculty of Medicine Constanta, ATI, Constanta, Romania, 3 Jhon Radcliffe Hospital, CardiothoracicAnaesthesia, ICU, Oxford, United Kingdom

Background and Goal of Study: Surgical intervention for colon cancer in elderly patients is often associated with significant inflammatory responses and postoperative pain. Vitamin C, an antioxidant with known anti-inflammatory properties, may offer a potential adjunct to improve postoperative outcomes.

This study aimed to evaluate the effect of intravenous vitamin C on inflammatory markers and postoperative pain in elderly patients undergoing laparoscopic surgery for colon cancer.

Materials and Methods: A total of 100 elderly patients (aged ≥65 years) scheduled for elective laparoscopic surgery for colon cancer were enrolled in a randomized, double-blind, placebocontrolled trial. Patients were randomly assigned to receive either 2 grams of intravenous vitamin C (Group A) or a placebo (Group B) before the surgical incision, with continued administration for 3 days postoperatively.

The primary outcome was the reduction in serum C-reactive protein (CRP) levels 24 hours post-surgery. Secondary outcomes included the assessment of postoperative pain using a numeric rating scale (NRS), opioid consumption, and the incidence of adverse effects such as hyperglycemia or wound infection.

The day before surgery, all patients were taught how to use the patient-controlled analgesia (PCA) system and how to rate pain intensity on the numeric rating scale, 0 indicating no pain and 10 representing the worst pain imaginable.

Results and Discussion: Group A demonstrated a significant reduction in CRP levels compared to Group B (P = 0.01), indicating a lower inflammatory response.

Additionally, postoperative pain scores were significantly lower in Group A at 6, 12, and 24 hours postoperatively (P = 0.02). Opioid consumption was also significantly reduced in Group A compared to Group B (P = 0.03).

There were no significant differences in the incidence of adverse effects between the groups, with no cases of hyperglycemia, fatigue, or wound infection noted in either group, reaffirming the safety of vitamin C in this context.

Conclusion(s): The results of this study underscore the potential of vitamin C as an adjunct in postoperative care. Intravenous administration of vitamin C was found to significantly reduce the

inflammatory response and postoperative pain in elderly patients undergoing laparoscopic surgery for colon cancer. This suggests that vitamin C could be a valuable addition to the postoperative care regimen for this patient population.

23AP03-8

Machine learning-based prediction of postoperative adverse outcomes in super-elderly patients undergoing non-cardiac surgery

T. Talmy^{1,2,3}, R. Eshel¹, V. Rabkin¹, O. Cohen-Rosenboim¹, S. Zarour¹, B. Cohen^{1,4}

¹Tel-Aviv Sourasky Medical Center, Division of Anesthesia, Intensive Care & Pain Management, Tel Aviv, Israel, 2Israel Defense Forces, Medical Corps, Ramat Gan, Israel, ³The Hebrew University of Jerusalem, Department of Military Medicine, Faculty of Medicine, Jerusalem, Israel, ⁴Cleveland Clinic, Outcomes Research Consortium, Cleveland, United States

Background and Goal of Study:Super-elderly individuals are frail and vulnerable to adverse perioperative outcomes. Advancements in geriatric perioperative care allow these patients to undergo more extensive surgery, emphasizing the need for improved risk assessment. Machine learning (ML) has emerged as a powerful approach for individualized risk prediction using preoperative and intraoperative data. We aimed to evaluate ML-based prediction of postoperative complications in this population.

Materials and Methods: Data on super-elderly (≥85 years) surgical patients undergoing non-cardiac surgery at a single tertiary center were collected. ML models were trained using preoperative and intraoperative parameters to predict 30-day mortality as well as a composite of myocardial injury, renal injury, cerebrovascular accident, and 30-day mortality. Model performance was assessed using area under the receiver operating characteristic curves (AUROC). SHapley Additive exPlanations (SHAP) values were used to determine the contribution of variables. An interactive calculator was developed to visualize the models on simulated patients.

Results and Discussion: A total of 5,568 patients undergoing 7,048 surgical procedures were included (median [IQR] age 88 [86-91] years). Thirty-day mortality occurred in 523 cases (7.4%), and the composite outcome in 19.6%. For 30-day mortality, the ML model's AUROC was 0.774 (95% CI 0.738-0.811) when considering preoperative variables only and 0.793 (95% CI 0.759-0.827) when adding intraoperative variables. For the composite outcome. AUROC values were 0.771 (95% CI 0.748-0.794) for both models. SHAP analysis identified several key predictors including ASA physical status, emergency surgery, baseline creatinine, and hemoglobin.

Conclusion: ML models demonstrated moderate performance in predicting postoperative adverse outcomes in super-elderly patients, with limited to negligible contribution of intraoperative data to prediction.

Applying these models to larger datasets and additional perioperative risk factors may enhance accuracy. Interactive calculators could support clinical decision-making and allow individualized risk assessment.

23AP03-9

Factors contributing to increased hospital costs in older surgical patients after hip fracture

P. Apputhura1¹, D. Meyer¹, B. El-Behesy^{2,3}, A. Wu^{2,3}, A class of statistical undergraduate students including McDonald I, O'Dwyer RK, Kotsakis G, Carreras A, Fernando S, Sriratnakumar V, Kumarage A, Dhiruselvam S, Woolcock J, Perera J, Rodrigo B, Chamoun R. ¹Swinburne University of Technology, Department of Health Sciences and Biostatistics, Melbourne, Australia, ²Eastern Health, Anaesthetics, Melbourne, Australia. ³Monash University, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia

Background: Our data (unpublished) indicate that surgical repair of hip fractures is associated with significantly higher hospital costs compared to non-operative treatment, likely due to lower mortality rates and longer hospital stays. Despite over 90% of hip fractures being managed surgically, the specific cost drivers remain unclear.

This study aimed to evaluate the impact of patient characteristics and perioperative factors on hospital costs in older adults undergoing hip fracture surgery.

Methods: This retrospective cohort study included patients aged 65 years or older who underwent primary fixation surgeries for fragility hip fractures at a metropolitan Australian hospital between July 2011 and July 2015. Demographic, perioperative, and cost data were extracted from electronic medical records and hospital administrative databases. A multiple regression model was employed to examine associations between total hospital costs and variables such as patient demographics, ASA scores, comorbidities, surgery type and timing, anaesthesia type, ICU admissions, blood transfusions, postoperative complications, and length of hospital stay (LOS).

Results: A total of 876 patients (73% female; mean age 84 ± 8 years) were included. The mean total hospital cost per patient was AU\$15,396 (95% CI: AU\$14,719-AU\$16,072), covering acute and subacute care until discharge.

On a per-patient basis, ICU admissions were the most expensive component, averaging AU\$5,491 per admission, followed by nursing care (AU\$4,411), medical care (AU\$4,190), and operating theatre costs (AU\$3,863).

The primary cost driver was LOS under acute care, as reflected by the greater beta coefficient (B = 0.609, p < .001). Other significant contributors included ICU admissions (B = 0.299, p < .001), total hip replacement (B = 0.217, p < .001), hemiarthroplasty (B = 0.105, p < .001), general anaesthesia (β = 0.064, p = 0.001), and blood transfusion (β = 0.058, p = 0.004).

Unlike previous studies, neither older age nor higher ASA scores significantly impacted costs.

Conclusions: Hospital costs for surgical management of hip fractures are primarily driven by perioperative factors, particularly acute LOS and ICU admissions, rather than baseline patient characteristics.

These findings highlight opportunities to optimize perioperative care and resource allocation to enhance cost efficiency. Further research is necessary to confirm these results and to address inconsistencies with prior studies.

23AP03-10

Evaluation of an 11-item questionnaire for self-assessment of sleep quality in elderly population

V. Karageorgos^{1,2}, P. Darivianaki^{1,3}, A. Spartinou^{1,3}, D. Kouvidakis³, A. Bogas Manouselis³, A. Papaioannou^{1,3} ¹School of Medicine, University of Crete, Anesthesiology Department, Heraklion, Crete, Greece, 2Onassis Hospital, Department of Anesthesiology, Athens, Greece, ³University Hospital of Heraklion, Anesthesiology Department, Heraklion, Crete, Greece

Background and Aim: Perioperative sleep disturbances are common in surgical patients, often resulting from anxiety, biological stress, and the effects of anaesthetic drugs on the circadian cycle. These disturbances are linked to morbidity and postoperative complications, prompting investigations into their impact. Polysomnography, the gold standard for sleep quality assessment, is complex, expensive, and impractical for routine use outside intensive care settings. Consequently, many studies rely on questionnaires like the Pittsburgh Sleep Quality Index (PSQI), which assesses 24 items related to sleep characteristics and next-day somnolence. While PSQI evaluates average sleep over a month, it is increasingly used for repeated measurements in shorter timeframes pre- and post-surgery.

However, its complexity makes it challenging for elderly patients, particularly those with low education or cognitive impairments. To address this, we developed a shorter, simplified questionnaire based on PSQI.

Methods: The new 11-item questionnaire (SLEEP11) includes 10 binary and one categorical questions assessing sleep initiation, awakenings and their causes, snoring, bad dreams, medication use, next-day somnolence, and overall sleep quality. It was tested on 80 patients preoperatively, immediately postoperatively, and three months postoperatively. Patients also completed the PSQI as a reference questionnaire.

Results: SLEEP11 was easier to complete, with an average completion time of 43±11 seconds compared to 180±29 seconds for PSQI. Correlation analysis showed significant agreement between the two questionnaires across all time points (r>0.7, p<0.001) with Cronbach's a >0.8 signifying good internal consistency.

Conclusion: SLEEP11 is a promising tool for assessing perioperative sleep quality in elderly patients, offering simplicity and efficiency. It could be adopted as a standard screening and follow-up tool in perioperative care. Further validation studies are needed for complete validation of this tool.

23AP03-11

Intraoperative hypotension and postoperative outcomes in super-elderly patients undergoing non-cardiac surgery

R. Eshel¹, T. Talmy^{1,2,3}, V. Rabkin¹, Y. Weiss¹, A. Lustig¹, B. Cohen^{1,4}

¹Tel-Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel, 2Israel Defense Forces Medical Corps, Surgeon General's Headquarters, Ramat Gan, Israel, ³Faculty of Medicine, Hebrew University, Department of Military Medicine, Jerusalem, Israel, ⁴Outcomes Research Consortium, Cleveland Clinic, Cleveland, United States

Background and Goal of Study: Intraoperative hypotension (IOH) is strongly associated with postoperative morbidity and mortality, but this association has not been thoroughly investigated in super-elderly (age >85 years) surgical patients. Considering the growing rate of surgical procedures in this population, we aimed to test the association between various definitions of IOH in patients >85 years of age having noncardiac surgery and postoperative 30-day mortality as well as a composite of postoperative complications.

Materials and Methods: Perioperative data on super-elderly patients (≥85 years) undergoing non-cardiac surgery at a tertiary center between 2011 and 2024 were analyzed. Hypotension was primarily quantified as the area under a mean arterial pressure of 65 mmHg (AUC-MAP65), and secondarily as the time-weighted average MAP<65, and the lowest intraoperative MAP for 5 and 10 cumulative minutes. Area under the receiver operating characteristic curves (AUROC) analyses evaluated prediction of 30day mortality and a composite outcome of acute kidney injury, myocardial infarction, stroke, or mortality using each of the hypotension exposure variables. Optimal thresholds identified by Youden's J statistic were applied in Cox regression models to assess the association between hypotension and outcomes.

Results and Discussion: We analyzed data from 5,568 patients who underwent 7,048 surgeries, with a median age of 88 years (interquartile range [IQR]: 86-91 years). The median AUC-MAP65 was 35 (IQR 0-130) mmHg · min. Predictive accuracy for adverse outcomes was moderate (AUROC range: 0.602-0.612) across all IOH definitions. Survival analysis revealed a significant association between AUC-MAP65 and 30-day mortality (hazard ratio: 2.73; 95% CI: 2.29-3.25), which remained consistent and significant after adjusting for multiple demographic and perioperative confounders.

Conclusions: Individual markers of intraoperative hypotension showed limited predictive accuracy for adverse outcomes. However, survival analysis revealed a significant association between AUC-MAP65 and 30-day mortality, emphasizing its potential relevance in perioperative management. Consideration and management of preoperative risk factors may potentially play a larger role in determining these outcomes compared to the extent of intraoperative hypotension.

24AP01-1

Sweet suprise: unmasking euglycemic diabetic ketoacidosis

S. Stojanovic Stipic¹, J. Vicic¹, A. Goles¹, S. Pavicic Perkovic¹, A.M. Mitar¹, A. Bego¹ ¹University Hospital Split, Department of Anaesthesiology and Intensive Care, Split, Croatia

Background: Euglycemic diabetic ketoacidosis (DKA) is a potentially life-threatening complication of taking dapagliflozin. It belongs to a class of sodium-glucose-linked transporter 2 (SGLT2) inhibitors. It is characterised by euglycemia (blood glucose levels < 250 mg/dL/13.9 mmol/L), ketonemia and metabolic acidosis (pH< 7.3, serum bicarbonate< 18 mmol/L).

Case report: A 66-year-old male was admitted for elective surgery for lung squamous cell carcinoma. He was treating arterial hypertension and DM ty 2.He was also recently diagnosed with squamous cell carcinoma of the larynx (with hoarseness as the primary symptom).

After the surgery, he was stable and was transferred to a department room. Chronic therapy was continued, including dapagliflozin in combination with metformin. On the 3rd postoperative day, he started feeling nauseous, extraordinarily thirsty and with a slight chest pain. His breathing was fast and consistent (indicative of Kussmaul's breathing).

Considering he suffered an acute myocardial infarction 12 years ago, we ruled out an ACS as well as PE. Blood results showed a pH level of 7.05, arterial partial pressure of carbon dioxide (PaCO2) of 1.95 kPa, arterial partial pressure of oxygen (PaO2) of 18.6 kPa, serum glucose levels of 11.5 mmol/L and bicarbonate levels of 7.4 mmol/L.Lactates were normal, and the anion gap was very high (29 mmol/L).

He was intubated by an RSI protocol and transferred to the ICU. He was treated with intravenous crystalloid infusion of 0,9% sodium chloride and 10% glucose solution with continuous insulin infusion. His arterial blood gas (ABG) tests showed a fast improvement.

He was mechanically ventilated for a day, successfully weaned from the respirator, and extubated on the 2nd day. His ABG after extubation showed a pH of 7.43, PaCO2 of 5.51 kPa, PaO2 of 24.5 kPa,a glucose level of 9.8 mmol/L,and bicarbonate level of 27.4 mmol/L.

Discussion: SGLT2 inhibitors should be stopped three to four days before surgery, and we wanted to point out the necessity of that time window.

In this case, the recommended pause in taking dapagliflozin was not done, and it possibly led to the development of eDKA as a severe complication.

Surgery itself is a risk factor for developing an eDKA in patients who are taking SGLT2 inhibitors as it raises cortisol levels and contributes to the cascade leading to ketogenesis. It can also lead to hypovolemia and possible urinary tract infections (UTI), the latter especially linked with dapagliflozin.

24AP01-3

Evaluation of catheter-associated urinary tract infection between latex urinary catheter and metal alloy coated urinary catheter in critically ill patients

M.N. Mokhtar¹, F.A. Mohamed Hassan¹, A. Mohamad Yusof¹, S.K. Cheah¹, F.H. Abdullah¹, W.R. Wan Mat¹ ¹Universiti Kebangsaan Malaysia, Department of Anaesthesiology & Intensive Care, Faculty of Medicine, Bandar Tun Razak, Malaysia

Background and Goal of Study: Catheter-associated urinary tract infection (CAUTI) accounts for 9% of hospital-acquired infection (HAI)1.

This study assessed the incidence of CAUTI between two different types of urinary catheter, the latex urinary catheter and the latex coated metal alloy urinary catheter, used in the intensive care unit (ICU) setting.

Materials and Methods: This was a randomized, prospective, single-blinded study involving 76 ICU patients requiring catheterization and admission for more than 48 hours in ICU. Patients were allocated to the metal alloy catheter group and latex catheter group, with a randomization ratio of 1:1. CAUTI incidence was conducted at study entry, after 48 hours in ICU, day 7 in ICU or any signs or symptoms of CAUTI detected within ICU stay.

For statistical analysis, categorical data were compared using the chi-square or Fischer Exact test, and clinical outcomes were compared using t test.

Results and Discussion: A total of 70 patients were recruited. The majority of admissions to the ICU were due to HAI. Overall the mean age was 48.6 ± 19.2 years old with majority of them being male (61.4%).

The mean APACHE II scores between the latex and metal alloy were 14.20 \pm 4.22 and 12.34 \pm 3.76 respectively. The mean for SOFA scores between the latex and metal alloy cathter were 6.71 \pm 1.93 and 5.57 \pm 1.96 respectively.

The mean ICU length of stay between the latex and metal alloy was 6.20 ± 1.5 and 5.74 ± 1.58 respectively. The mean catheterization days between the latex and metal alloy catheter group were 6.00 ± 1.52 days and 5.74 ± 1.58 .

There was 1 incidence of CAUTI which was only seen in the latex catheter group, and no incidence of CAUTI in the metal alloy group.

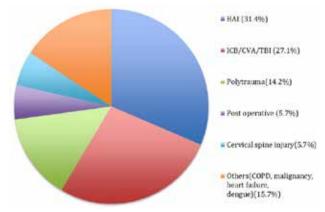

Figure. Diagnosis on admission.

Conclusion(s): In conclusion, there is no statistical difference in the incidence of CAUTI between the latex urinary catheter and the metal alloy urinary catheter group for short-term catheterization in critically-ill patients.

The first China Malignant hyperthermia database based on national remote emergency system for malignant hyperthermia

H. Yu1, L. Tan1, X. Deng1 ¹West China Hospital of Sichuan University, Anesthesiology, Chengdu, China

Background and Objectives: Currently, there is no malignant hyperthermia (MH) database in China. This study establishes the first MH database in China using our developed National Remote Emergency System for MH (MH-NRES).

Methods: The MH clinical database comprises 8 functional modules: patient demographics, clinical information, surgical and anesthesia-related information, treatment, medical history, genetic test, and family history. As of August 30, 2024, a total of 48 patients have been enrolled in this database.

Results: Among the 48 MH patients, 39.6% are under 18 years old and 45.8% are between 18 and 50 years old. The male-tofemale ratio is 5:1. All patients were administered volatile anesthetics, and one patient received succinylcholine.

The overall mortality among the 48 MH patients was 41.6%. With the increasing use of dantrolene over the years, a decreasing trend in patient mortality was observed.

Genetic sequencing of 22 patients disclosed 19 MH mutations, consisting of 17 variants in RYR1 and 2 in CACNA1S. Among of these, 4 newly discovered variants were detected in RYR1 gene (c.12587T>C, c.5194G>A, c.10670T>C, and c.5011_5015delinsAC) and 2 in CACNA1S gene (c.3853G>T, c.4392T>A).

Conclusion: This study establishes the first MH clinical database in China, enabling the analysis of epidemiological, clinical manifestations, and outcomes of MH in China. Integration of clinical and genetic data provides high-quality evidence for optimizing MH perioperative management.

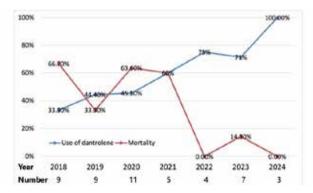

Fig 1. Association betwen dantrolene use and mortality from 2018 to 2024.

The impact of a restrictive oxygen strategy versus a liberal oxygen strategy on health-related quality of life after trauma - a follow-up study on the TRAUMOX2 trial

F. Dinesen¹, T. Arleth¹, V. Siersma², M. van Vledder³, W. Hautz⁴, J. Steinmetz^{1,5}

¹Rigshospitalet, Copenhagen University Hospital, Department of Anaesthesiology, Centre of Head and Orthopaedics, Copenhagen, Denmark, 2University of Copenhagen, The Research Unit for General Practice and Section of General Practice, Department of Public Health, Copenhagen, Denmark, 3Erasmus MC, University Medical Center Rotterdam, Trauma Research Unit, Department of Surgery, Rotterdam, Netherlands, 4Inselspital, Bern University Hospital, University of Bern, Department of Emergency Medicine, Bern, Switzerland, 5Danish Air Ambulance, Aarhus, Denmark

Background and Goal of Study: Liberal supplemental oxygen is recommended in the acute treatment of severely injured trauma patients, but guidelines lack recommendations on an upper limit and duration of the treatment. The evidence on the use of supplemental oxygen for trauma patients is limited and certainty of evidence is low to very low. The international, multicentre, controlled trial, TRAUMOX2, randomised adult trauma patients to receive either a restrictive oxygen strategy or a liberal oxygen

strategy for the first eight hours after injury and assessed 30day mortality and major respiratory complications within 30 days

This study aimed to assess health-related quality of life of TRAU-MOX2 participants at six and 12 months after trauma. We hypothesised that the restrictive oxygen group would have a better selfrated health by 12-month follow-up.

Materials and Methods: A total of 1508 participants completed the TRAUMOX2 trial and were eligible to participate in this followup study. Participants were contacted by telephone at six and 12 months after trauma. Health-related quality of life was assessed with the EQ-5D-5L questionnaire. This covers five domains: mobility, self-care, usual activities, pain or discomfort, and anxiety or depression.

Further, the questionnaire assesses the participants' self-rated overall health evaluated with the EQ-VAS ranging from 0 (the worst imaginable health) to 100 (the best imaginable health). The last participant was contacted for follow-up in October 2024.

The primary outcome was EQ-5D VAS score at 12 months after trauma and the primary analysis was an intention-to-treat analysis. The EQ-5D VAS scores were compared between the two groups using multivariable linear regression adjusted for the stratification variables site of inclusion and endotracheal intubation status at randomisation. Results were reported as mean difference with corresponding 95% CIs.

Results and Discussion: Results will be available at the time of presentation.

Conclusion: This study will provide evidence on the long-term effects of a restrictive oxygen strategy versus a liberal oxygen strategy for the first eight hours after trauma on health-related quality of life.

24AP01-6

Continuous electrocardiograph and plethysmography dataset for the prognostic prediction in critically ill patients

H. Lim¹, L. Lim¹, H.-C. Lee¹

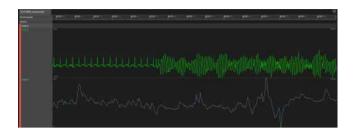

¹Seoul National University, Department of Anaesthesiolgy and Pain Medicine, Jongno-gu, Korea, Republic of

Background and Goal of Study: Continuous 3-lead ECG is essential for cardiac monitoring in the ICU, while PPG offers portability for tracking cardiac features. Advances in machine learning have facilitated arrhythmia and outcome prediction but are constrained by lack of high-quality clinical datasets.

This study aims to address this gap by creating a comprehensive dataset of continuous ECG and PPG waveforms with precise cardiac arrest event labeling.

Materials and Methods: This study was approved by the Institutional Review Board and Data Review Board with international release after confirming proper anonymization. Patients admitted to the surgical and medical ICUs at Seoul National University Hospital (SNUH) between Oct 2019 and Dec 2023 with ICU stays over 48 hours were included.

The dataset includes a CSV file with patient demographics and outcomes(cardiac arrest, mortality, discharge), and waveforms of lead II ECG and PPG. Waveforms span 48 hours before and 1 hour after the event time. Clinical outcomes were extensively reviewed, with only the first event recorded. Waveforms were collected using patient monitors, stored using VitalRecorder, and saved and provided as vital file (Figure 1). Clinical data were categorized, and vital file timestamps were anonymized relative to the event time, standardized as 2100-01-01 00:00.

Results and Discussion: 4,737 continuous ECG and 3,832 corresponding PPG waveforms were included. Among these, 378 cases (8.0%) resulted in death, and cardiac arrest occurred in 77 cases (1.6%). The median age was 65 [55-75] years with 60.0% being male. The median ICU stay duration was 70.0 [36.9-149.0] hours.

Conclusion(s): We have developed a novel dataset of continuous ECG and PPG waveforms with precise cardiac arrest event labeling. This dataset addresses the limitations of existing cardiac waveform resources and offers significant potential for advancing prognostic algorithms and wearable technologies for critically ill patients.

Acknowledgements: This dataset is freely available via the National Strategic Technology Research Institute(https://nstri.net) platform of SNUH for users who consent to the data use agree-

Prehospital triage of pediatric emergencies treated by helicopter emergency medical services

E. Tsuchiva¹. O. Rosenkrantz¹. T.M. Hansen². J.A.K. Petersen³, J. Steinmetz¹ ¹Copenhagen University Hospital, Department of Anesthesia, Center of Head and Orthopedics, Copenhagen, Denmark, 2Danish Air Ambulance, Steering Group, Aarhus, Denmark, 3Aarhus University, Department of Clinical Medicine, Aarhus, Denmark

Background and Study Goal: Helicopter Emergency Medical Services (HEMS) are part of Emergency Medical Services in many countries. In Denmark, HEMS are staffed by anesthesiologists trained in prehospital emergency medicine and mainly respond to severe trauma and urgent emergencies. Upon assessment, HEMS clinicians triage patients to tertiary or local hospital emergency departments (EDs), prioritizing critically ill or injured patients for tertiary EDs.

We aimed to evaluate the impact of HEMS triage decisions for pediatric patients by comparing 30-day mortality in those triaged to tertiary versus local EDs, hypothesizing higher mortality and more critically ill patients in the tertiary ED group.

Materials and Methods: We conducted a registry-based cohort study including patients aged <18 years treated or examined by a Danish HEMS crew between September 1, 2019, and August 31, 2024. We excluded interhospital transfers, patients without valid civil registry numbers, and those pronounced dead or treated/released at the scene.

The primary outcome was 30-day mortality. Secondary outcomes were National Advisory Committee on Aeronautics (NACA) scores, ICD-10 diagnoses, and prehospital interventions.

Results and Discussion: We identified 1.113 helicopter missions registered during this period. Of these, 836 patients were included in the analyses. 30-day mortality was significantly higher in the tertiary ED group with 32 patients (5.4%) compared to one patient in the local ED group (0.4%; Fisher's exact test, P<.001). The only local ED patient who died suffered cardiac arrest: the

HEMS clinician opted for ambulance transport to the nearest ED for a short critical procedure and likely treatment termination, prioritizing speed over a longer helicopter transfer. Patients triaged to tertiary EDs had higher NACA scores and underwent more prehospital interventions.

Among tertiary ED patients, the most common ICD-10 diagnosis group was Injuries and Poisoning, while for local ED patients, it was Other factors influencing health status. Pediatric triage may pose a challenge for HEMS clinicians.

However, our findings support our hypothesis, indicating that the most critically ill pediatric patients are generally identified correctly by HEMS clinicians and triaged to higher-level treatment

Conclusion: 30-day mortality was higher in patients triaged to tertiary EDs, possibly reflecting appropriate triage of critically ill or injured pediatric patients by HEMS clinicians.

24AP01-8

Corticosteroid prophylaxis decreases the incidence of fat embolism syndrome in lower extremity fractures

M. Bajraktari¹, L. Fezollari², B. Arapi³, R. Domi⁴ ¹University of Medicine, Faculty of Technical Medical Sciences, Tirana, Albania, ²University Trauma Hospital, Department of Orthopedics and Traumatology, Tirana, Albania, ³Hygeia Hospital, Department of Anaesthesia Intensive Care, Tirana, Albania, 4University of Medicine, Department of Anaesthesia Intensive Care, Tirana, Albania

Background and Goal of Study: Fat embolism syndrome (FES) is a relatively infrequent, yet potentially life-threatening complication associated with long bone fractures [1], exhibiting an incidence of approximately 2-5% [2,3].

This study investigates the utilization of corticosteroids as a prophylactic measure to reduce the occurrence of FES in such cases.

Materials and Methods: A retrospective, single-center study was conducted at the Trauma University Hospital in Tirana, Albania, spanning from January 2011 to January 2012. The study encompassed a cohort of 232 patients diagnosed with fractures of the lower extremities. The primary goal was to evaluate the prophylactic role of corticosteroids, specifically methylprednisolone at a dosage of 10mg/kg, in the development of fat embolism syndrome (FES). Patients were dichotomized into two groups: Group 1, consisting of 116 patients administered corticosteroid prophylaxis, and Group 2, encompassing 116 patients without corticosteroid prophylaxis for FES.

Results and Discussion: Within Group 1, the incidence of FES was recorded at 2.58%, with an absence of severe respiratory manifestations. In contrast, Group 2 exhibited an FES incidence of 11.20%, out of which 6.03% necessitated intensive care unit (ICU) respiratory support. The prevalence of FES was significantly lower in Group 1, subjected to corticosteroid prophylaxis. in comparison to Group 2, where no such prophylaxis was administered (p < 0.05). Group 2 patients also displayed heightened instances of pulmonary complications.

Conclusion(s): The administration of corticosteroid prophylaxis in cases of lower extremity fractures was correlated with a notable reduction in FES incidence. Furthermore, this intervention demonstrated its merit by effectively attenuating pulmonary complications associated with FES.

Anaesthetic challenges in a patient with penetrating cervical trauma: a multidisciplinary success

A. Sousa¹, M. Coimbra¹, M. Pereira¹ ¹Coimbra Local Health Unit, Anaesthesiology Department, Coimbra, Portugal

Background: Penetrating cervical trauma presents significant challenges due to the complex anatomy and high risk of injury to vital structures. A multidisciplinary and well-coordinated approach is essential for achieving optimal patient outcomes.

Case report: A 54-year-old male sustained a cervical impalement injury following a 2-meter fall. On arrival at the emergency department, he had a patent airway, cervical subcutaneous emphysema, and was hemodynamically stable with no active bleeding. CT imaging (fig. 1) revealed the metallic object's trajectory: entry at the cricoid cartilage level, descending between the trachea and the common carotid artery.

In the operating room, general anesthesia was induced with careful hemodynamic management and standard monitoring, complemented by cerebral oximetry (NIRS). The airway was secured using videolaryngoscopy, with an otolaryngologist (ENT) specialist on standby for potential surgical airway management.

Esophagogastroduodenoscopy excluded esophageal perforation. Angiography was performed, and an intra-aortic balloon was placed ready for inflation if required, prior to cervicotomy and foreign body removal. Considering the risk of postoperative airway compromise from cervical edema and hematoma, the patient remained intubated for 24 hours.

Discussion: The successful management of this case highlights the critical importance of interprofessional teamwork, thorough planning, and anticipation of potential complications. Coordination among anaesthesiology, general surgery, vascular surgery, ENT, and gastroenterology was key. The strategy prioritized the prevention of respiratory compromise and injury to vital structures, demonstrating the value of a multidisciplinary approach.

Fig. 1

References:

Hyub Huh et al. Anesthetic management of penetrating neck injury patient with embedded knife - A case report. Korean J Anesthesiol. 2012;62(2):172-174.

Learning points: Comprehensive planning, interprofessional collaboration, and the anticipation of complications are pivotal in managing penetrating cervical trauma. The use of a multidisciplinary approach ensures enhanced patient safety and outcomes.

24AP01-10

Anesthesiology and critical care on warships: **Experience in the Spanish Navy (1999-2025)**

S. Gil-Díaz¹, R. Navarro-Suay², V. Fernández-Grande¹, D. Valerian-Pintea², R. García-Cañas³, E. López-Soberón⁴ ¹Hospital Central de la Defensa Gómez Ulla, Anesthesiology and Critical Care, Madrid, Spain, ²Alcala/Academia Central de la Defensa, Escuela Militar de Sanidad, Madrid, Spain, 3 Hospital Central de la Defensa Gómez Ulla, Trauma Service, Madrid, Spain, 4Hospital Central de la Defensa Gómez Ulla, Cardiology, Madrid, Spain

Background and Goal of Study: Medical care in naval environment is based on a stepped treatment that goes from level 1 (physician, nurse and paramedic on-board) to level 4 (hospital in national territory). The major surgical capacity on board is from level 2. Spanish naval medicine has participated in humanitarian support, armed conflicts, fight against piracy and training cruises in the last quarter of century.

The objective of this study is to analyze type anesthesia performed on board Spanish Navy warships by military anesthesiologists in the last 25 years (1999-2024).

Materials and Methods: Retrospective and descriptive study about anesthesiological support performed in Spanish navy warships with Role 2 capacity from 1999 to 2024. The dichotomous variables are included: general anesthesia and regional anesthesia, and the following polytomous variables: name of the ship, international operation, type of injury or illness that generated the need for anesthesia, type of regional anesthesia (intradural, epidural, peripheral nerve - interscalene, axillary, median, femoral, popliteus). To obtain this information, the final mission reports and related scientific publications are analyzed and semi-structured interviews are conducted with anesthesiologists who were on board during the operations that are the subject of this study. The confidentiality of the data obtained is maintained, preserving the information on a computer with an access code. Authorization is obtained from the HCDGU ethics committee (67/18 amendment 1).

Results and Discussion: During the study period, a total of 100 anesthetic techniques have been performed on Spanish navy warships. 72 have been general anesthesia, while the remaining 28 have been regional anesthesia (15 intradural, 6 epidural, 7 brachial plexus blocks). 41 techniques were carried out in humanitarian support (hurricane, tsunami or earthquakes), 36 in the Iraq war, 18 in the fight against piracy and 5 on training cruises. One patient suffered aspiration during anesthesia induction.

Conclusion(s): General and regional anesthesia has been carried out on Spanish Navy ships in humanitarian missions, naval deployments in combat zones, anti-piracy navigations and training cruises.

A comparative study of two chest compression methods using a manneguin in infant cardiopulmonary resuscitation: the two-finger method versus the thumb-index finger method

K. Mizuno¹

¹Fukuoka Children's Hospital, Center for Perioperative Services and Critical Care, Fukuoka, Japan

Background and Goal of Study: Chest compressions using the two-finger method, currently considered the standard for infant CPR by a single rescuer, tend to be weak and tiring. Therefore, the two-finger and thumb-index finger methods were compared to determine whether the latter could become the new standard. Materials and Methods: This prospective crossover comparative study evaluated the effectiveness of two infant CPR chest compression methods - the standard two-finger method and the thumb-index finger method developed by Zeynalov et al. - using a Resusci Baby QCPR® manikin. Nurses without physical limitations participated, excluding pregnant women. Each subject performed 5 CPR cycles (30 compressions:2 ventilations) for 2 minutes per method, synchronized to a 112 bpm metronome, with an 8-second pause for artificial respiration. Compression depth, position, tempo, release, and uninterrupted compression time were analyzed. A Visual Analog Scale questionnaire assessed ease, fatigue, effectiveness, and preference. Statistical analysis used paired t-tests (p<0.05).

Results and Discussion: A total of 27 subjects, all female, were included in the study. While both methods showed similar scores for compression rate, position, and interruption time, the thumbindex finger method demonstrated significantly greater compression depth (42.2 \pm 1.7 mm vs. 40.0 \pm 2.5 mm) and depth score (95.1% vs. 77.2%, p<0.01). However, the two-finger method had a higher pressure release score (p<0.05). The thumb-index finger method was preferred by participants, who found it less tiring, easier to use, and more effective. Limitations include a short observation period, mannequin-based simulation, and unfamiliarity with the thumb-index finger method, which may have affected the release scores. Longer studies and additional training may further validate these findings.

Figure. Standard "Two-Finger Method" and the "Thumb-Index Finger Method".

Conclusion(s): The thumb-index finger method for single-rescuer infant CPR offers better compression depth and causes less fatigue than the two-finger method, suggesting its potential to become the standard chest compression technique.

Zeynalov BF, et al. J Med Dent Sci 2011;58:15-22

24AP01-12 Blast Grenade explosion in hand: an anesthesiology approach beyond pain control

B.D. Gomes¹, C. Alves Carneiro¹, M. Dantas da Silva Lima¹, T. Sampaio de Lacerda¹, C.R. Miranda¹, J. Perdigão Cerqueira¹ 1hospital geral de nova iguaçu, anesthesiology, Nova Iguaçu, Brazil

Background: Anesthesia role should be redefined, specially regarding the benefits of regional blockade. The brachial plexus block not only aids in pain management but can improve healing and modulates the inflammatory response to trauma. Employing a perineural catheter prolongs the positive effects during the recovery of devitalized tissues following high-intensity trauma.

Case Report: 44 year old male, p1, victim of a grenade explosion in his right hand during work. He arrived in the OR alert but in hypovolemic shock. General anesthesia and a brachial plexus block approach were initiated. The surgical team initially proposed amputation of the hole hand. Due to the patient's youth and economically active, they decided to amputate 4th and 5th limbs, opting for surgical reconstruction of 1st, 2nd, and 3rd digits preserving pinch movement.

At the end, a perineural catheter was placed in the infraclavicular region. The anesthesiology team conducted follow-ups, monitoring capillary refill time, healing and pain management. Infusions of a local anesthetic and corticosteroid were administered through the catheter g12, alongside 2g of IV ascorbic acid daily. Seven days post trauma the catheter was removed and he was discharged. Five months later he maintain skin integrity, sensitivity and complete mobility of the remaining fingers, with pincer movement.

Discussion: Microvascular changes induced by the anesthetic block enhanced tissue oxygenation, increased local temperature, improved nutrient supply, accelerated healing, optimized motor rehabilitation, reduced opioid consumption and shorter hospital stay.

Reference: British Journal of Anaesthesia 106 (6): 887–95 (2011) Advance Access publication 6 April 201.doi:10.1093/bja/aer085

Learning points: regional anesthesia reducing inflammatory response; regional anesthesia regaining motor function; pain control management

Metronome use enhances the maintenance of a target compression pace in a manikin model of cardiopulmonary resuscitation - new directions

F. Solti¹, K.P. Frugoli Rodrigues¹, L. Gatti Fonseca¹, M.E. Rosa Cerqueira¹, N. Pereira Colombo Farias Ramos¹, M. Balbino1

¹Centro Univessitário São Camilo, Medicine, São Paulo, Brazil

Background and Goal of Study: Our university group has been exploring the influence of a metronome on the quality of chest compressions in the educational environment. Using the device could significantly enhance the effectiveness of CPR training, potentially leading to improved patient outcomes in real-life emergencies.

Materials and Methods: We used a manikin model and collected data from medical students during CPR classes. After a thorough one-hour training, the students were randomly assigned to two groups: no metronome (NM) and metronome at 110 (M110). Each student performed three cycles of 30 compressions, alternating with a second student and then returning to the first student, completing nine cycles.

The authors meticulously recorded the frequency and depth of the compressions using LLEAP® simulation software and analyzed the data with the image processing program Image-J®).

Results and Discussion: Our investigation encompassed 13,230 compressions from 441 cycles involving 98 students. One hundred forty-four cycles (32.65%) had means out of the recommended range (100-120), with fewer cases in M110 (p=0.009).

Most out-of-range cycles were above 120 CPM. Survival analysis showed a difference between the groups across time, considering the failure criteria if surpassing 120 CPM (p=0.026, Figure 1).

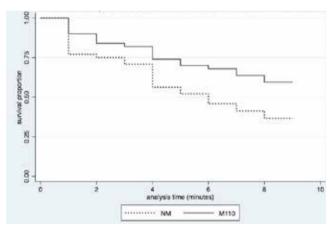

Figure 1. Kaplan-Meier survival estimates for CR> 120 CPM.

The students who repeated the three cycles did not decrease the depth compressions using or not the metronome in the last three cycles (p=0.06). Adopting the CPR board under the manikin increased the overall mean depth compared to another study in the previous semester, in the same conditions, from 37.17 ± 7.77 to 40.54 ± 7.2 , p=0.0009.

Conclusion(s): Our study's results have substantial implications for using metronomes in CPR training. The overall compression depth was below the recommendations for an emergency setting, but the instrument's frequency is a reliable quide to keep students within the correct rate range. Using a CPR board effectively increases the compression depths.

Not every confusional syndrome is a delirium: beware of the dangerous simulator, the stroke

B. García Iniesta¹, A. Plaza Saura¹, M. Cano Castellote¹, A.I. Mateos Hernández¹, C.M. López López¹, R. González Celdrán¹ ¹Hospital General Universitario Reina Sofía, Anestesiología y Reanimación, Murcia, Spain

Background: Endovascular treatment of thoracic aortic aneurysm (TEVAR) has revolutionized the management of this pathology by offering a less invasive alternative to open surgery. However, this procedure is not free of complications, among which ischemic stroke represents one of the most serious and might be confused with delirium.

Case Report: A 75-year-old man was admitted to the surgical ICU after endovascular placement of a fenestrated endoprosthesis in the aortic arch and dissecting stent in the descending aorta as treatment for descending aortic aneurysm.

The procedure lasted 8 hours. Upon arrival, the patient presented significant agitation that prevented neurological examination, reauiring neuroleptics.

After the agitation improved, we examined the patient, drawing attention to a left oculocephalic deviation and mild dysarthria, so we activated the ICTUS code. CT was performed showing established ischemic infarction of the left PICA, not susceptible to revascularization, so antiplatelet therapy was started.

Three days later the patient started with weakness in MMII, and MRI was performed, leading to the diagnosis of spinal ischemia.

Discussion: Acute confusional syndrome is a very common entity in elderly post-surgical patients. However, it is important to perform a differential diagnosis with other possible causes of cognitive impairment, especially in the context of surgeries that can release thrombi into the cerebral circulation, as in this case.

The incidence of stroke after TEVAR is 2.7% and in the case of our patient it probably occurred during surgery. Therefore, not only is the neurological examination important when waking up, but also the monitoring of cerebral oximetry and BIS during the procedure, which in this case was not performed.

Another complication of this surgery is spinal cord ischemia, with an incidence of 2.2%, which our patient also developed.

Reference:

Buth J et al Neurologic complications associated with endovascular repair of thoracic aortic pathology. EUROSTAR Registry. J VascSurg. 2007Dec;46(6):1103-1111.

Learning Points: Not all postoperative agitation is acute confusional syndrome. It is important to perform a good neurological examination of our patients, always keeping in mind the complications inherent to each type of surgery.

In surgeries that can release thrombi into the CNS, cerebral oximetry and BIS should be monitored, since although they are not diagnostic monitors, they can warn us that something is not right.

Optimal prehospital blood pressure thresholds in patients with severe traumatic brain injury – A BRAIN-PROTECT study

F.J. Mansvelder¹, S. Bossers¹, L. Schwarte¹, S. Loer¹, P. Schober¹

¹Amsterdam University Medical Centre AUMC, Anesthesiology, Amsterdam, Netherlands

Background and Goal of Study: Severe traumatic brain injury (TBI) is a leading cause of mortality and morbidity among young adults. In the prehospital setting a primary treatment focus is the prevention of secondary brain injury. A key component of this management is maintaining an appropriate cerebral perfusion pressure (CPP), and hence, systemic blood pressure.

However, the optimal blood pressure threshold remains a topic of ongoing debate. Current guidelines recommend a minimum systolic blood pressure (SBP) of 110 mmHg, based on level III evidence. For patients aged 49 to 70 years, the recommended minimum SBP is 100 mmHg. We aimed to identify the blood pressure threshold that is associated with the lowest mortality

Materials and Methods: The BRAIN-PROTECT study is an observational multicentre study that included patients with severe traumatic brain injury, treated by Dutch Helicopter Emergency Medical Services between February 2012 and December 2017. Patients were followed for one year after inclusion.

Blood pressure measurements were recorded at multiple time points during prehospital treatment. The association between blood pressure and 30-day mortality was analysed using multivariable logistic regression.

Results and Discussion: A total of 1,814 patients were included in the analysis. A U-shaped relationship was observed between systolic blood pressure (SBP) and the probability of 30-day mortality (p<0.001). The lowest mortality probability occurred in patients with an SBP between 110 mmHg and 140 mmHg, with increased mortality observed at both lower and higher SBP values.

When categorizing the lowest recorded prehospital SBP, patients with an SBP \leq 90 mmHg had an odds ratio (OR) of 2.22 [95% CI: 1.85–2.65] for mortality compared to the reference category (110–150 mmHg). For those with an SBP of 90–110 mmHg, the OR was 1.07 [95% CI: 0.92–1.24], while patients with an SBP >150 mmHg had an OR of 1.90 [95% CI: 1.60–2.25] compared to the reference category.

Subgroup analysis of patients with isolated traumatic brain injury (TBI) showed an increased OR of 3.78 [95% CI: 2.67–5.32] for those with an SBP \leq 90 mmHg and an OR of 2.23 [95% CI: 1.78–2.79] for those with an SBP >150 mmHg.

Conclusion(s): In this observational cohort of patients with suspected severe TBI it shows that an SBP <90 mmHg and >150 mmHg is associated with increased mortality in both multi-trauma and isolated neurotrauma.

The optimal SBP range appears to be 110–150 mmHg, emphasizing the importance of targeted blood pressure management in severe TBI.

24AP02-4

Prehospital prevalence of severe hypotension in TBI patients

<u>A. Macaite</u>¹, L.S. Scholl², J. Schwietring³, S. Rehberg¹, K.-C. Thies¹, A. Hoyer⁴

¹Bielefeld University, Medical School and University Medical Center OWL, Protestant Hospital of the Bethel Foundation, Department of Anesthesiology, Intensive Care, Emergency Medicine, Transfusion Medicine and Pain Therapy, Bielefeld, Germany, ²University Hospital Münster, Gerhard-Domagk-Institute of Pathology, Münster, Germany, ³ADAC Luftrettung gGmbH, ADAC Luftrettung gGmbH, München, Germany, ⁴Bielefeld University, Biostatistics and Medical Biometry, Medical School OWL, Bielefeld, Germany

Background and Goal of Study: Hypotension (systolic BP < 90 mmHg) is an independent predictor of poor outcomes in traumatic brain injury (TBI). Effective prehospital management of hypotension is critical to reducing secondary brain injury.

This study quantifies the prevalence of severe hypotension in TBI patients in the prehospital environment using BP on hospital arrival as a surrogate for prehospital hypotension and identifies high-risk groups to guide future research into targeted prevention and treatment strategies.

Materials and Methods: This retrospective analysis used data from the ADAC-Luftrettung electronic mission logs (2017–2021), including 22,028 TBI patients. Injury severity was classified in line with the German Trauma Registry into isolated TBI, multiple injuries, and polytrauma. TBI severity was categorized by Glasgow Coma Scale (GCS) into mild (GCS 13–15), moderate (GCS 9–12), and severe (GCS 3–8). Statistical analyses assessed correlations between hypotension prevalence, TBI severity, and injury patterns.

Results and Discussion: Among severe TBI patients, hypotension on hospital arrival was observed in 6.9% of isolated TBI, 5.0% of those with multiple injuries, and 18.5% of polytrauma cases. Moderate TBI patients showed hypotension rates of 1.5% (isolated), 1.4% (multiple injuries), and 6.8% (polytrauma). For mild TBI, hypotension prevalence was 0.4% (isolated), 0.3% (multiple injuries), and 3.1% (polytrauma). A significant positive correlation was found between TBI severity and hypotension prevalence (Spearman Rank ρ = 1, ρ = 0.0). Polytrauma was consistently associated with higher rates of hypotension across all TBI severities (Table 1).

	Isolated	TBI &	TBI &
	TBI	Multiple Injuries	Polytrauma
Severe TBI (GCS 3-8); N	1290	821	2160
BP<90mmHg on hospital arrival; N (%)	89 (6.9%)	41 (5.0%)	400 (18.5%)
Moderate TBI (GCS 9-12); N	652	564	704
BP<90mmHg on hospital arrival; N (%)	10 (1.5%)	8 (1.4%)	48 (6.8%)
Mild TBI (GCS13-15); N	4388	8563	2886
BP<90mmHg on hospital arrival; N (%)	19 (0.4%)	33 (0.3%)	89 (3.1%)

Table 1.

Conclusion(s): This study identifies severe TBI patients with polytrauma as the highest-risk group for prehospital hypotension, emphasizing the need for aggressive prehospital blood pressure management, including vasopressor administration and prehospital blood transfusions. Future research should focus on tailored strategies for high-risk groups to reduce hypotension and improve outcomes.

Cardiac arrest due to massive carbon dioxide embolism during laparoscopic surgery: a case

IA. Chen1, T.C. Chiu1, J.L. Wang1, T.R. Yang1, M.H. Hsieh1, C.Y. Lu1

¹Chi Mei Medical Center, Department of Anesthesiology, Tainan, Taiwan

Background: Clinical presentation of carbon dioxide (CO_a) embolism ranges from asymptomatic to cardiovascular collapse or even death. Clinically evident CO₂ gas embolism is rare. Transesophageal echocardiogram (TEE) is the most sensitive method for diagnosis of massive gas embolism.

Case Report: A 73-year-old woman with history of left renal invasive urothelial carcinoma with left renal vein tumor thrombus. The induction of anesthesia was smooth. An arterial line and a central venous catheter was placed.

About 75 minutes into the procedure, during surgical approach to the renal vessels and kidney, accidental tear in the inferior vena cava (IVC) was reported. Massive bleeding occurred, prompting urgent blood transfusion. The surgeon attempted laparoscopic repair and hemostasis of the torn IVC.

However, she developed significant bradycardia and hypotension. Systolic arterial pressure decreased from 140 to 40 mmHg. Sudden decrease in EtCO₂ and cardiac arrest were found. She was quickly repositioned to Trendelenburg position and cardiopulmonary resuscitation was initiated. Emergent TEE showed air bubbles in all four chambers. Massive CO, embolism was diag-

Forty minutes post-arrest, V-A ECMO was initiated due to persistent PEA. Emergent laparotomy was performed to actively control bleeding. Operation using an open approach and the IVC defect was repaired by cardiovascular surgeon.

Discussion: Clinical presentation of CO₂ embolism ranges from asymptomatic to neurologic injury, cardiovascular collapse or even death, which is dependent on the rate and volume of CO₂ entrapment and the patient's condition.

In our case, the etiology of bubbles might be entering the vessel via the tear on IVC. In such situations, immediate notification to the surgical team is vital for patient safety.

Reference:

Kim et al. Cardiac arrest associated with carbon dioxide gas embolism during laparoscopic surgery for colorectal cancer and liver metastasis - A case report. Korean J Anesthesiol. (2012)

Learning points: Our case highlights the critical importance of prompt diagnosis and treatment in the event of a massive carbon dioxide embolism during laparoscopic surgery.

24AP02-6

An atypical case of acute liver failure caused by hypovolemic shock

A. Vivaldo 1, G.L. Bruno1, M. Albore1, B. Cochis2, G. Carlidi1, A. Della Selva¹

¹Ospedale Pietro e Michele Ferrero, Struttura complessa Anestesia e Rianimazione, Verduno, Italy, 2University of Turin, Department of Surgical Sciences, Turin, Italy

Background: We present the case of a 26-year-old woman who was conducted to the hospital with severe hyperpyrexia and acute altered mental status. She had a pre-existing psychiatric disorder and intellectual disability, on chronic psychotropic medication. From an initial condition of hypovolemic shock probably caused by heat stroke or neuroleptic malignant syndrome, her condition rapidly progressed to fulminant liver failure, necessitating an urgent hepatic transplantation. This conditions are infrequently and difficult to diagnose but can still be associated with serious consequences.

Case Report: Before urgent hospital admission, the patient was in good health on regular follow-up and well-controlled on medications. During outdoor activities in the summer, she acutely developed altered behavior that rapidly progressed to coma, accompanied by marked hyperpyrexia and cardiovascular instability.

Upon admission, she required invasive mechanical ventilation and vasopressors. Initial investigations revealed acute kidney injury, elevated AST/ALT, myoglobin, troponin, and CK, with negative inflammatory markers and toxicology screen.

A persistent coma was initially associated with a non-ST-elevation myocardial infarction and a positive fecal test for toxigenic Clostridium Difficile, which was treated with antibiotics. On the second day of admission, she developed acute liver failure, leading to urgent liver transplant with a successful outcome.

Discussion: The differential diagnosis included neuroleptic malignant syndrome or heat stroke, possibly exacerbated by a toxigenic Clostridium Difficile infection. The absence of frank muscle rigidity and moderately elevated CK levels seemed to favor heat stroke, but differentiating between these two conditions is challenging due to their rare prevalence, overlapping clinical presentations and the lack of specific diagnostic tests.

Management is similar for both conditions. Initial severity scores (SOFA 13, SAPS II 80, APACHE II 26) predicted a high mortality rate. Evidence suggests that ischemic hepatitis is a common consequence of hypovolemic shock, particularly in young, healthy patients with limited treatments if the condition does not respond to supportive care.

Conclusions: This case highlights the diagnostic challenges posed by rare clinical conditions that lack specific diagnostic tests or treatments. Early consultation with a specialized center allowed for timely liver transplantation and patient survival.

Intubation setting and mortality in trauma patients undergoing hemorrhage control surgery: a propensity score-matched analysis

T. Talmy^{1,2,3}, I. Radomislensky⁴, I. Brzezinski Sinai¹, E. Katorza⁴, G. Twig⁵, S. Gendler⁶, Israel Trauma Group ¹Tel-Aviv Sourasky Medical Center, Division of Anesthesia, Intensive Care & Pain Management, Tel Aviv, Israel, 2Israel Defense Forces, Medical Corps, Ramat Gan, Israel, ³The Hebrew University of Jerusalem, Department of Military Medicine, Faculty of Medicine, Jerusalem, Israel, 4The Gertner Institute for Epidemiology and Health Policy Research, Israel National Center for Trauma & Emergency Medicine Research, Ramat Gan, Israel, 5Sheba Medical Center at Tel Hashomer, Institute of Endocrinology, Ramat Gan. Israel. 6Rabin Medical Center (Beilinson Campus). Department of Surgery, Petah Tikva, Israel

Background and Goal of Study: Endotracheal intubation is essential for airway management in trauma patients but may cause hemodynamic instability and delay resuscitation. Recent studies suggest emergency department (ED) intubation may be linked with higher mortality compared to operating room (OR) intubation in trauma patients. However, it is unclear if these findings apply to broader trauma populations, including civilian and military patients.

This study uses a nationwide trauma registry to assess the association between ED intubation and in-hospital mortality in major trauma patients.

Materials and Methods: Registry-based analysis of the Israeli National Trauma Registry evaluating major trauma patients (Injury Severity Score [ISS] ≥ 16) requiring hemorrhage control surgery within an hour of admission between 2016-2023. ED intubation was the primary exposure. Multivariable logistic regression and propensity score matching adjusted for confounders, including injury severity, vital signs, penetrating injury, and blood product administration.

Results and Discussion: The study included 975 patients, 470 (48.2%) of whom were intubated in the ED. ED-intubated patients had significantly higher ISS and a higher proportion of profound shock than OR-intubated pateitns. In-hospital mortality was higher among patients intubated in the ED (22.6%) compared with OR intubation (8.5%). Unadjusted logistic regression showed ED intubation was associated with higher odds of in-hospital mortality (OR: 3.13, 95% CI: 2.15-4.62).

After adjusting for confounders, the association became nonsignificant and persisted across sensitivity analyses. Propensity score matching resulted in 1:1 matching of 271 patients per group. balancing characteristics such as ISS, shock, Glasgow Coma Scale, and penetrating injuries.

After matching, mortality rates were similar (12.5% ED vs. 12.2% OR), and logistic regression did not demonstrate a significant association between ED intubation and mortality (OR: 0.97, 95% CI: 0.58-1.61). ED intubation was linked to a two-fold increase in ICU admission odds in adjusted and matched analyses.

Conclusion(s): ED intubation was not significantly associated with increased in-hospital mortality after controlling for injury severity and shock.

These findings suggest ED intubation, while more frequent in severely injured patients, has an unclear independent impact on mortality in trauma patients undergoing urgent surgery, warranting further prospective research.

Virtual Reality (VR) based CPR algorithm model as educational and training tool for medical and allied health professions students

S. Kropveld^{1,2}, O. Wacht², A. Shoham², E. Brotfain¹, D. Margulis¹, M. Pugachov¹

¹Soroka Medical Center, Ben-Gurion University of the Negev, Division of Anesthesia and Critical Care, Beer-Sheva, Israel, ²Ben-Gurion University of the Negev. Department of Public Health, Faculty of Health Sciences. Beer Sheva. Israel

Background and Goal of Study: The use of immersive technologies for medical education, which place students in a virtual environment whereby they can perform practical procedures as well as interact with a variety of simulated clinical scenarios. In medical education, the three main types of technology used to construct these simulated environments are: virtual reality (VR), augmented reality (AR) and mixed reality (MR).

The present study prospectively analyzed the feasibility and usefulness of a virtual reality (VR) platform for BLS (Basic Life Support) CPR algorithm training during studies of 1st year academic students in a variety of medical professions.

Materials and Methods: This study is prospective and observational. Overall, 279 1st year students (medical, emergency medicine-paramedics, physiotherapy and nurses students) were included in the study. Of them, 140 students were included in control (Group 1, students who learned the standard educational protocol of BLS CPR including hands on training); and 139 students in study (Group 2, Students who learned the standard educational protocol of BLS CPR with hands on experience and additionally experience a VR-based platform learning of the BLS CPR algorithm model) of the present study. VR platform for present study was built and integrated by UAB Cloyd IXR company.

Results and Discussion: We demonstrated that the percentage of final OSCE score trended higher in the study group (Group 2, VR-based platform) in all medical specialties. There was significantly high OSCE score grades for the nursing (p<0.023) and physiotherapy (p< 0.024) students populations compared to the control group (Group 1).

Moreover, in present study we shared questionnaire regarding the learning experience on VR-based platform of CPR BLS. All students populations reported better comfortability, safety and understanding CPR BLS algorithm using VR-based platform.

Conclusion(s): Our study demonstrated a potential usefulness of VR -based platform in CPR BLS algorithm learning experience. We suggesting it is a safe, simple and effective practice for medical education.

Acidemia augments lactate level elevations in the prediction of survival but not the neurological outcome of cardiac arrest patients

A.-I. Ganea^{1,2}, D.A. Duse¹, P. Horn¹, M. Kelm^{1,3}, C. Jung¹, R. Erkens¹

¹Heinrich-Heine University, Department of Cardiology, Pneumology, and Vascular Medicine, Duesseldorf, Germany, ²University of Cologne, Department of Anesthesiology and Operative Intensive Care Medicine. Köln, Germany, 3Heinrich-Heine University, Cardiovascular Research Institute Düsseldorf (CARID), Düsseldorf, Germany

Background and Goal of Study: Acidemia is independently associated with higher mortality in several shock types. Therefore, we analyzed the additive value of pH decrease on top of serum lactate levels in predicting mortality and neurological development of cardiac arrest (CA) patients following cardiopulmonary resuscitation (CPR).

Materials and Methods: The predictive power of initial pH and lactate levels was retrospectively analyzed in non-traumatic CA patients admitted to a high-volume center in Germany (University Clinic Duesseldorf). The association between these biomarkers and 30-day mortality was assessed using receiver operating characteristic (ROC) curves. Patients were stratified by the Youden Index for lactate levels and the clinically established pH threshold 7.2. 30-day mortality was analyzed between the four stratified groups.

An independent association between pH and survival was established using Cox regression analyses with adjustments for several CPR-related variables, including lactate. Preliminary findings were validated in the eICU database, which comprises data from over 2000 patients across multiple intensive care units in the United States of America.

Results and Discussion: Initial lactate and pH levels showed high accuracy in predicting 30-day mortality (area-under-curve of 0.83 and 0.75, respectively, p<0.0001). Patients with pH levels ≤ 7.2 had significantly higher mortality in each lactate stratification group. The hazard ratios for pH ranged between 0.1 and 0.3 and remained significant after adjusting for lactate, age, CPR duration, and type of cardiac arrest.

When applying individual thresholds from this analysis to patients in the eICU database, a pH ≤ 7.2 accurately distinguished groups at higher mortality risk in each analyzed lactate group.

Multiple logistic regression showed an HR of 0.14 (p<0.0001) for each pH unit after lactate, age, and initial creatinine level adjustment. No significant association was observed between initial pH levels and neurological outcomes. Correlation analyses showed only a mild relationship between lactate and pH levels in both analyzed collectives.

Conclusion(s): pH levels augment the predictive capacity of lactate, with values of pH ≤ 7.2 independently indicating higher mortality in cardiac arrest patients, regardless of lactate levels. pH does not accurately predict neurological outcomes in CPR survivors.

24AP03-1

Association between COVID-19 vaccination and mechanical ventilation in critically ill COVID-19 pneumonia patients

M.N. Mokhtar¹, W.S.F. Lau¹, J.S.M. Ooi¹, I. Azaharuddin¹, F.H. Abdullah¹, I. Khalid¹

¹Universiti Kebangsaan Malaysia, Department of Anaesthesiology & Intensive Care, Faculty of Medicine, Kuala Lumpur, Malaysia

Background and Goal of Study: In Malaysia, COVID-19 vaccination was introduced following WHO guidelines on 24 February 2021. This study aimed to examine the relationship between COVID-19 vaccination status and the need for invasive mechanical ventilation in critically ill patients with COVID-19 pneumonia. Additionally, the study sought to evaluate co-morbidities and demographic factors among these patients and assess the severity of organ dysfunction at intensive care unit (ICU) admission using the Sequential Organ Failure Assessment (SOFA) score.

Materials and Methods: This was a retrospective, single-center study conducted at Hospital Kuala Lumpur, Malaysia involving patients with COVID-19 pneumonia admitted to the ICU between July 1, 2021, and February 28, 2022. Data collection included demographic characteristics, comorbidities, vaccination status (complete vs. incomplete), and clinical parameters such as SOFA scores and PaO2/FiO2 ratios. Logistic regression analysis was utilized to identify factors associated with the requirement for invasive mechanical ventilation.

Results and Discussion: Among 340 patients with COVID-19 pneumonia admitted to the ICU, 42.6% required invasive mechanical ventilation. Incomplete vaccination status significantly increased the likelihood of requiring mechanical ventilation (Adjusted Odds Ratio [AOR] 2.09, 95% CI: 1.115-3.946, p=0.002). Higher SOFA scores (AOR 1.653, 95% CI: 1.457-1.853, p<0.001) and moderate PaO2/FiO2 ratios (AOR 0.302, 95% CI: 0.115-0.790, p=0.015) were also linked to increased ventilation needs. The complete vaccination group exhibited reduced mechanical ventilation duration and lower mortality compared to the incomplete vaccination group, reinforcing the protective role of full vac-

Conclusion(s): COVID-19 vaccination was significantly associated with improved outcomes in critically ill patients, particularly by decreasing the necessity for invasive mechanical ventilation and reducing ICU mortality.

These findings highlight the importance of complete vaccination in mitigating severe COVID-19 outcomes, emphasizing vaccination as a critical component in managing high-risk patient populations.

24AP03-2

Use of ECMO-CPR in in-hospital cardiac arrest secondary to anaphylactic shock: a case report

<u>E. Lacoba</u>¹, A. Carramiñana¹, P. Masgoret¹, J. Vallverdú¹, M. Suñé¹, B. Tena Blanco¹

¹Hospital Clínic of Barcelona, Department of Anaesthesia, Pain Management and Critical Care, Barcelona, Spain

Background: Extracorporeal Membrane Oxygenation for Cardiopulmonary Resuscitation (E-CPR) is a life-saving technique for cardiac arrest (CA) patients unresponsive to conventional CPR. While E-CPR extends the window for addressing reversible CA causes, its benefits, optimal patient selection criteria, and procedural timing remain unclear.

Case report: We present a 66-year-old woman with a history of NSAID allergy, obesity, smoking, and essential tremor treated with propranolol. She was scheduled for a right tumorectomy under general anesthesia due to a breast intraductal papilloma.

Ten minutes after surgery began, the patient developed severe bronchospasm, hypoxemia, and bradycardia unresponsive to atropine or adrenaline. Advanced life support (ALS) was initiated, revealing pulseless electrical activity (PEA) as the initial rhythm. Intra-arrest transoesophageal echocardiography showed no right ventricular dilation or cardiac tamponade signs.

After 15 minutes of ALS, PEA persisted, prompting E-CPR protocol activation. Ultrasound-guided right femoro-femoral veno-arterial cannulation (23Fr-17Fr) was performed. ECMO support was initiated 38 minutes after tresucitation onset, achieving pulsatility with proper aortic valve opening and maintaining adequate peripheral perfusion pressure.

A normal pulmonary CT angiography ruled out pulmonary embolism. Elevated acute tryptase (211 ng/mL) suggested refractory anaphylactic shock, later confirmed by the allergology department.

The patient improved in the ICU, achieving successful ECMO weaning after 7 days. She was discharged 40 days later with a good neurological outcome (Cerebral Performance Category ICPCI 2).

Discussion: Survival rates for in-hospital cardiac arrest (IHCA) at discharge range from 15–25%, with 60–80% achieving favorable neurological outcomes (CPC 1–2). ECMO during IHCA is associated with a 37.9% survival rate and favorable CPC in up to 84.4% of cases.

Specialized and multidisciplinary teams are critical to facilitate decisions and minimize "low-flow time". In this case, E-CPR likely prevented worse neurological outcomes.

Reference:

Abrams, D., MacLaren, G., Lorusso, R. et al. *Extracorporeal* cardiopulmonary resuscitation in adults: evidence and implications. Intensive Care Med 48, 1–15 (2022).

Learning points: ECMO reduced low-flow time, likely improving neurological outcomes. Further research is needed to define E-CPR indications, timing, and cost-effectiveness compared to conventional CPR.

24AP03-3

ECMO as a life-saving intervention in acute respiratory failure refractory to conventional therapies

B. Buntasheska¹, B. Andonovska², M. Mojsova Mijovska³, A. Gavrilovska Brzanov⁴, <u>M. Jovanovski-Srceva</u>⁵, A. Krsteska⁶

¹St.Kiril i Metodij, Anesthesia and intensive care, Skopje, North Macedonia, The Republic of, ²St.Kiril i Metodij, Anesthesiology and intensive care, Skopje, North Macedonia, The Republic of, ³Universiti Goce Delcev, Anesthesiology and intensive care, Shtip, North Macedonia, The Republic of, ⁴St.Kiril I Metodij, Anesthesiology and intensive care, Skopje, North Macedonia, The Republic of, ⁵St.Kiril and Metodij, Anesthesiology and intensive care, Skopje, North Macedonia, The Republic of, ⁵General Hospital Ohrid, Anesthesiology and intensive care, Ohrid, North Macedonia, The Republic of

Background: This case underscores crutial role of veno-arterial extracorporeal membrane oxygenation (VA-ECMO) as a life-saving intervention in patients with severe respiratory insufficiency unresponsive to conventional therapies.

Case Report:18-years-old patient polytrauma patient sustained critical injuries, including hemopneumothorax and severe respiratory failure, following a motor vehicle accident. He underwent multiple computed tomography (CT) scans, including one prior to admission and several during hospitalization, alongside mechanical ventilation.

Despite comprehensive supportive measures – mechanical ventilation, sedation, and multidisciplinary care – the patient's respiratory function and gas exchange deteriorated progressively. The clinical course was complicated by significant blood loss, with no evident bleeding source identified on CT imaging.

Multiple bronchoscopy procedures were performed, ultimately localizing the bleeding source, which necessitated surgical intervention

The patient underwent a right bilobectomy to control the hemorrhage. However, despite these efforts, the patient's respiratory condition continued to decline. VA-ECMO was initiated as a last-resort therapy, leading to stabilization and eventual full recovery of respiratory function.

Following successful decannulation, the patient was transferred back to the intensive care unit (ICU) for ongoing management.

Discussion:This case illustrates the complexity of managing polytrauma patients with multifactorial challenges, including respiratory failure, surgical complications, and hemodynamic instability. It highlights the necessity of advanced interventions such as ECMO and extensive surgical management.

The successful outcome was attributed to regular imaging, targeted diagnostic procedures, and a collaborative, multidisciplinary approach.

24AP03-4

Enhancing CPR safety with BIS monitoring and VA ECMO in perioperative cardiac arrest: a case report

S. Machetti¹, R. Navarro Pérez¹, V. Alfaro¹, P. Buendia¹, J. Ripolles-Melchor², L. Sante-Serna² ¹Hospital Clinico San Carlos, Anaesthesia, Madrid, Spain, ²Universidad Complutense Madrid/Hospital Clinico San Carlos, Anaesthesia, Madrid, Spain

Background: During cardiopulmonary resuscitation (CPR), optimizing cerebral perfusion and minimizing neurological injury are critical. The bispectral index (BIS) offers real-time feedback on cortical activity and sedation depth, providing a unique tool to guide CPR guality.

This report describes a perioperative cardiac arrest during ambulatory platelet-rich plasma (PRP) injection combined with hip arthrocentesis, managed with VA ECMO and BIS monitoring to enhance safety and outcomes.

Case Report: A 60-year-old male smoker with emphysema underwent PRP injection combined with hip arthrocentesis under general anesthesia. Forty minutes into the procedure, following the PRP injection, the patient developed hypotension, hypoxemia, and cardiac arrest with pulseless electrical activity. Despite 20 minutes of high-quality advanced cardiac life support (ACLS), return of spontaneous circulation was not achieved.

VA ECMO was initiated to address the refractory arrest, with fat embolism syndrome suspected as the underlying cause. BIS monitoring, used throughout the resuscitation, showed not suppressed cortical activity (BIS values >20). Real-time BIS feedback guided CPR quality, ensuring cerebral perfusion and supporting sedation adjustments during ECMO initiation. With ECMO support, hemodynamic stability was restored. The patient was successfully weaned from ECMO after 48 hours, with intact neurological function, and fat embolism syndrome was confirmed.

Discussion: This case highlights the potential of BIS monitoring to enhance CPR safety by optimizing cerebral perfusion and guiding resuscitation quality. BIS-guided interventions during VA ECMO initiation ensured optimal neurological recovery conditions. Integrating BIS into advanced resuscitation protocols could significantly improve outcomes, particularly in perioperative settings.

References:

1. Seder D B, et al. Feasibility of bispectral index monitoring to guide early post-resuscitation cardiac arrest triage.

Resuscitation. 2014; 85(8):1030-6

Learning Points: Combining VA ECMO and BIS monitoring enhances CPR safety by prioritizing cerebral protection and optimizing resuscitation. This approach may serve as a model for improving outcomes in complex resuscitation scenarios and warrants further exploration (1).

24AP03-5

Relevance of reversible causes of out-of-hospital cardiac arrest (REBECCA)

J.M. Lintschinger^{1,2}, S. Ulbing¹, L. Reischmann¹, T. Hamp³, M. Krammel^{3,4}, C. Hafner^{1,2}

¹Medical University of Vienna, Department of Anaesthesia, Intensive Care Medicine and Pain Medicine, Division of General Anaesthesia and Intensive Care Medicine. Vienna, Austria, ²Ludwig Boltzmann Gesellschaft, Ludwig Boltzmann Institute Digital Health and Patient Safety. Vienna, Austria, 3City of Vienna, Emergency Medical Service Vienna, Vienna, Austria, ⁴PULS, Austrian Cardiac Arrest Awareness Association, Vienna, Austria

Background and Goal of Study: Early identification of reversible causes of out-of-hospital cardiac arrest (OHCA) is crucial for effective treatment. Portable diagnostic tools, including prehospital ultrasound, toxicological screening, and blood gas analysis, play a key role in facilitating timely and accurate diagnosis.

This study aims to assess the prevalence of reversible causes of OHCA.

Materials and Methods: This prospective single-center study was conducted in the Vienna metropolitan area. Patients were included if they experienced an OHCA and if prehospital ultrasound, blood gas analysis, and toxicological screening could be integrated into the advanced life support algorithm.

Exclusion criteria included age under 18 years, suspected pregnancy, and delays in treatment or transport due to study enrolment.

Results and Discussion: From April 2023 to August 2024, data were collected on 81 patients with complete diagnostic information. In 30 cases (37.0%), resuscitation was terminated in the prehospital setting, while 51 patients (63.0%) were transported to hospital. 43 (84.3%) of the transported patients achieved a sustained prehospital return of spontaneous circulation.

A reversible cause of cardiac arrest was identified in 42 cases (51.9%; Fig. 1), although in 11 of these cases (26.2%) resuscitation was terminated prehospital.

Notably, in 15 of all cases, the findings of the extended approach in identifying reversible causes of OHCA led to a change in therapy (n=9, 11.1%) or influenced the choice of destination hospital (n=6, 7.4%).

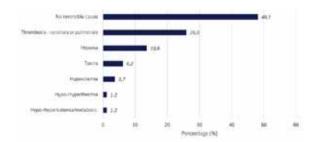

Fig 1. Reversible causes of out-of-hospital cardiac arrest.

Conclusion: These preliminary data suggest that a potentially reversible cause of OHCA can be identified in more than half of cases. However, completing a comprehensive diagnostic workup to identify the underlying cause remains a significant challenge. Acknowledgements: We thank Luca Dronigi, Sybille Behrens, Angelika De Abreu Santos, Martina Hermann, Guenter Gmeiner, Christoph Reisinger, and Daniel Grassmann for their support in helping us carry out this study.

Persistent inflammation, immunosuppression, and catabolism syndrome: New murine sepsis model

S. Kwak¹

¹Chonnam National University Medical School & Hospital, Anesthesiology & Pain Medicine, Gwangju, Korea, Republic of

Background and Goal of Study: Sepsis, defined as dysregulation of immune and inflammatory responses to infection, can develop refractory shock and multiple organ failure (MOF) leading to early in-hospital death or persistent inflammation, immunosuppression, and catabolism syndrome (PICS) leading to extended recovery periods and multiple complications. The recent development of programs that support earlier diagnosis and intervention with best-practices for sepsis should increase the portions of PICS. However, these processes of develop to PICS from sepsis are not well-understood.

Materials and Methods: In this study, we utilized cecal ligation and puncture (CLP) method in mice for three steps sepsis models involving SIRS and CARS (CLP only), MOF (lipopolysaccharide (LPS) + CLP), and PICS (LPS + CLP + Antibiotic) models. We examined mortality, the levels of pro- and anti-inflammatory cytokine, mitogen-activated protein kinases (MAPKs), nuclear factor kappa b (NF-κB) expression in lung and immune cell involving neutrophils, T cells, and myeloid derived suppressor cells (MDSCs) recruitment in serum.

Results and Discussion: Mortality were 100% (MOF), 60% (PICS), 20% (SIRS/CARS), and 0% (SHAM). We found that mice develop MOF at day 5 post-CLP surgeries, and pro-inflammatory cytokines were elevated from days 5–10. In the contrast, anti-inflammatory cytokines express highly level after 24hr from surgery, and continued to significantly increase from days 5 to 10 in PICS.

Furthermore, the recruitment of MDSCs were significantly augmented over time; whereas neutrophils recruitment and T cells functions were elevated at day 5 and decreased at day 10 post-CLP surgeries.

We also observed an increase of the mortality of PICS model, approximately 60% of mice had died after 14 days.

Conclusion(s): Our results contribute to characterization of three sepsis phases, which may support the diagnosis and treatment of sepsis in the future.

24AP03-7

The REBECCA interactive checklist to determine reversible causes during out-of-hospital cardiac arrest

A. Stoiber¹, M. Hermann¹², J.M. Lintschinger¹², S. Ulbing¹², T. Hamp³, C. Hafner¹²
¹Medical University of Vienna, Department of Anaesthesia, Intensive Care Medicine and Pain Medicine, Division of General Anaesthesia and Intensive Care Medicine, Vienna, Austria, ²Ludwig Boltzmann Gesellschaft, Ludwig Boltzmann Institute Digital Health and Patient Safety, Vienna, Austria, ³City of Vienna, Emergency Medical Service Vienna, Vienna. Austria

Background and Goal of Study: In patients suffering from outof-hospital cardiac arrest (OHCA), detection and treatment of reversible causes, besides adequate cardiopulmonary resuscitation (CPR) and defibrillation improves patients' survival. Team leading on scene can be demanding due to several circumstances and thus be associated with an increased cognitive load.

The aim of this study was to design a checklist to determine the reversible causes during OHCA.

Materials and Methods: We designed an interactive mobile checklist for reversible causes of OHCA (Fig.1) within a focus group of ten emergency physicians at the Medical University of Vienna. Furthermore, 20 emergency physicians analysed the usability of the checklist through questionnaires.

Results and Discussion: Of all participants, 70% were specialists with a median time working on the emergency response vehicle of 2.0 (1.0-4.3) years. Most participants were confident about their level of experience with OHCA and yet still, 85% of participants found the checklist to be helpful. The majority preferred the digital checklist over a paper-based and liked the fact that it was linked to the point-of-care ultrasound (POCUS) application.

Many participants appreciated the colour-coding, but stated against adding an acoustic alarm in case when a reversible cause is detected. Although there was no significant need for further details on most causes, a small majority favoured more information on intoxication and electrolyte disorders.

Fig.1 The REBECCA checklist.

Conclusion: Our study showed that the majority, regardless of their training level, found the REBECCA checklist helpful, while there was almost no need for further detailed information on the reversible causes in particular. This underlines the importance of reducing cognitive load by preparing clear instructions that allow

to stay focused. The wish for more information on relatively rare reversible causes may reflect their often-versatile presentation, making diagnosis even harder.

Acknowledgements: We gratefully thank all participants as well as A. Schmid, A. De Abreu Santos, D. Grassmann, M. Krammel, and A. Stria for their invaluable contribution.

Clinical cases of veno-venous extracorporeal membrane oxygenation in patients with refractory status asthmaticus

A. Shakhova¹, A. Dushkin², V. Chernyshev¹, E. Filimonova¹, D. Pavlov¹, G. Arbolishvili³

152 Clinical Hospital, Intensive Care Unit #7, Moscow, Russian Federation, 252 Clinical Hospital, Project Office, Moscow, Russian Federation, 352 Clinical Hospital, Administration, Moscow, Russian Federation

Background: This study presents a clinical evaluation of venovenous extracorporeal membrane oxygenation(VV-ECMO) in patients with refractory status asthmaticus (RSA) complicated by unresponsive to conventional respiratory support and protectivemode mechanical ventilation(MV) requiring.

A retrospective analysis was conducted on 4 patients who underwent VV-ECMO for RSA. Each clinical case explored different approaches to respiratory support.

Case Report: The cohort included 4 females aged 22 to 37 years. All cases were complicated by severe respiratory failure (RF) necessitating endotracheal intubation and MV with non-protective parameters. Despite the medical therapy the patient's conditions didn't improve and experienced complications from elevated airway pressure including subcutaneous emphysema, pneumothorax and pneumomediastinum - complications contraindicated the continuation of high-pressure MV. We used VV-ECMO as therapy to correct RF and reduce risk of complications worsening when MV and medical treatment didn't correct it.

Early initiation of VV-ECMO improved gas exchange parameters and prevented the RF progression in all cases. The patients were successfully weaned off ECMO and discharged in satisfactory condition.

Discussion: Advances in bronchial asthma treatment have reduced mortality to 6,5-10,3%. The application of VV-ECMO minimized the risk of ventilator-induced lung injury by enabling lungprotective MV settings and facilitates accelerated respiratory recovery with a reported survival rate of approximately 85 %1. The research Zakrashek JK et al. (2022) highlights that VV-ECMO reduces mortality, without affecting the duration of hospitalisation2. References:

Extracorporeal Membrane Oxygenation for Refractory Asthma Exacerbations With Respiratory Failure.Chest.2023 Jan;163(1):38-51.doi:10.1016/j. chest.2022.09.029.Epub 2022 Sep 30.PMID: 36191634;PMCID: PMC10354700.

Learning points: The findings underscore the potential, clinical relevance of VV-ECMO as an escalated intervention in severe asthma exacerbations with respiratory failure and complications connected with high airway pressure.

24AP03-9

Optimizing flow-controlled ventilation: impact of I:E ratios and oxygen concentration in a porcine model of total airway obstruction

T. Karlsson¹, J. Gustavsson², K. Wellfelt², M. Günther² ¹Karolinska Institutet, Dept of Clinical Science and Education, Section of Perioperative Medicine and Intensive Care, South General Hospital, Stockholm, Sweden, ²Karolinska Institutet, Experimental Traumatology, Department of Neuroscience, Stockholm, Sweden

Background and Goal of Study: Airway obstruction is a medical emergency requiring immediate intervention in the pre-hospital settings. When the insertion of a larger bore tube over a bougie catheter is hindered by obstruction, flow-controlled ventilation (FCV) combined with expiratory ventilation assistance (EVA) may offer an alternative solution.

This method employs an inspiratory-to-expiratory (I:E) ratio of 1:1 with continuous bidirectional flow, necessitating a high-pressure gas source, typically 100% oxygen, However, oxygen supplies may be limited or pose safety risks in austere pre-hospital or military environments.

Additionally, alterations in the I:E ratio can influence intratracheal pressures and hemodynamics.

We hypothesized that arterial oxygenation with 21% oxygen would vary between different I:E ratios and, secondarily, that FCV/EVA would remain feasible in terms of PaO₂, PaCO₂, oxygen delivery (DO₂), consumption and extraction rates, intratracheal pressures, and hemodynamic stability.

Materials and Methods: In this randomised cross-over trial, FCV/ EVA with different I:E ratios and fraction of inspired oxygen were compared in total airway obstruction during 15 minutes of ventilation. Male swine (n=6), mean weight 56.6 (2.1) kg, were anaesthetised, muscle relaxed and desaturated <80%.

A bougie catheter, sealed in a connector, was inserted into the endotracheal tube and FCV/EVA was initiated in an obstructed porcine airway model.

Results and Discussion: In I:E 1:1 vs 1:2 with 21% oxygen, mean difference (MD) of SaO₂ was 33.8% (95% CI: 16.3-51.4, p=0.002) and PaO₂ was 4.7 kPa (95% CI: 1.3-8.1, p=0.01), at five minutes from desaturation. PaCO2 was more efficient in 1:1 than 1:1 with a pause and 1:2. PaCO₂ remained <5 kPa with small variability in 1:1 with 21% oxygen. MD was -1.3 kPa (95% CI: -2.0-(-)0.6, p=0.002), in 1:1 vs 1:2 with 21%, at five minutes.

Indexed DO_a increased significantly in 1:1 with 21%. Intratracheal minimal pressures in I:E 1:2 were severely negative and significantly different from 1:1 with 21% oxygen (p<0.0001). Hemodynamics remained unchanged.

Conclusion(s): I:E ratio of 1:1 was feasible and superior to 1:2 in terms of SaO₂, PaO₂ and PaCO₂ with 21% oxygen. DO₂ remained above critical thresholds, and SaO2 levels were adequate throughout the intervention. This approach may offer a viable alternative in a totally obstructed airway in resource-limited or austere settings where higher oxygen concentrations are unavailable.

Nitric oxide supplementation during cardiac arrest induces inflammation and apoptosis in rat hearts

B.D.A.G.F. El Sady¹, G. Luciani², A. Ahmed³, A. Shaker⁴, A.b. Salama²

¹Great Western Hospital, NHS Foundation Trust, Anaesthesia, Swindon, United Kingdom, ²University of Verona, Surgery, Verona, Italy, ³Basingstoke and North Hampshire Hospital, Emergency, Basingstoke, United Kingdom, ⁴National Research Centre, Physiology, Cairo, Egypt

Background and Goal of Study: Neuroprotection during cardiac arrest and cardiac and aortic arch surgeries has garnered significant attention, with various protocols developed to optimize neurological outcomes. Among these, nitric oxide (NO) supplementation via extracorporeal membrane oxygenation (ECMO) has shown promise in influencing neurological outcomes during cardiac surgeries. However, its direct effects on the myocardium remain underexplored.

This study investigates the molecular and physiological impacts of NO supplementation on the heart during cardiac arrest.

Materials and Methods: Male Sprague Dawley rats (n=20, 450–550 g) were anesthetized, cooled to a core temperature of 19 \pm 1°C, and subjected to 30 minutes of hypothermic cardiac arrest. Subsequently, the rats were rewarmed to a target temperature of 35°C over 60 minutes using extracorporeal life support either without (control group) or with NO supplementation (20 ppm, experimental group) using ECMO.

By the end of the experiment, hearts were harvested for analysis, including RNA sequencing, RT-PCR, and assessment of oxidative stress markers such as superoxide dismutase (SOD)malondial-dehyde (MDA).

Results and Discussion: RNA sequencing revealed that NO supplementation differentially regulated genes involved in lipid metabolism, oxidative phosphorylation, inflammatory signaling, proteasome formation, autophagy, calcium handling, smooth muscle relaxation, and apoptosis compared to the control group. RT-PCR confirmed these findings.

The experimental group exhibited a six-fold increase in inflammatory markers IL-1 and NF- $\kappa\beta$. Oxidative stress markers showed elevated MDA levels and reduced SOD activity in the NO-treated group, indicating increased oxidative stress. NO supplementation also led to apoptosis in the myocardium, evidenced by a 50% rise in TUNEL-positive nuclei compared to controls.

Notably, while the control group demonstrated elevated $\alpha 1$ and $\beta 1$ adrenergic receptor expression, NO supplementation normalized these levels but induced a three-fold increase in $\beta 2$ adrenergic receptor expression.

Conclusion(s): NO supplementation during cardiac arrest exacerbates oxidative stress, triggering a heightened inflammatory response and increased apoptosis in the myocardium.

These findings suggest that the adverse effects of NO may be mediated through oxidative stress pathways, warranting further investigation into its therapeutic application during cardiac surgeries.

24AP03-11

Transdiaphragmatic cardiac massage during laparotomy – quick access, greater success? A case report

A. Vieira¹, <u>J. Pais</u>¹, B. Gonçalves¹, A. Silva¹

¹Unidade Local de Saúde do Tâmega e Sousa, Anesthesiology, Penafiel, Portugal

Background: Cardiorespiratory arrest (CA) in the perioperative period is rare but can be fatal and it's usually quickly detected due to continuous monitoring. Internal cardiac massage (ICM) via thoracotomy was the standard treatment until the 1960s, but external chest compressions (ECC) are now the first-line approach. ICM should still be considered if spontaneous circulation is not restored. Transdiaphragmatic ICM may be a valuable alternative for CA during laparotomy.¹

Case Report: A 73-year-old male, ASA II, underwent an urgent total gastrectomy due to a perforated gastric neoplasm. On the 6th postoperative day, he developed shock. The emergency team suspected hemorrhagic shock and started untyped blood transfusion. Orotracheal intubation was performed, and the patient was taken for exploratory laparotomy.

During surgery, massive hemoperitoneum was identified, originating from a lesion in the gastroduodenal artery, which was promptly treated. The patient then experienced CA with pulseless electrical activity, and advanced life support (ALS) maneuvers were initiated.

Once the origin of the shock was controlled, opening the diaphragm was suggested for ICM, which led to full recovery after 4 cycles of ALS. The patient was transferred to the intensive care unit, with the possibility of extubation in the immediate postoperative period and a full recovery with preserved neurological function.

Discussion: Previous studies confirm better cardiac indices, coronary perfusion pressures, and higher rates of recovery of spontaneous circulation in patients undergoing ICM. Due to the increased cardiac output achieved with ICM, metabolic deterioration occurs more slowly, justifying longer resuscitation maneuvers to treat reversible causes. In patients with CA during laparotomy, the transdiaphragmatic approach provides quick, easy access with minimal additional trauma.

In our clinical case, rapid access to the heart by opening the diaphragm and pericardium allowed high-quality ALS maneuvers, resulting in complete recovery without neurological deficits.

References:

1. Schnüriger B, et al. Transdiaphragmatic resuscitative open cardiac massage: description of the technique and a first case-series of an alternative approach to the heart. World J Surg. 2014 Jul;38(7):1726-9

Learning points: In patients with CA during laparotomy, the transdiaphragmatic approach allows quick and easy access to the heart, with excellent ALS performance.

Prolonged successful VV ECMO in COVID-19 pandemic

E. Mangoubi¹, O. Yehorov¹, D. Kompaniets¹, K. Negem¹ ¹Carmel Medical Centre, Anesthesiology, Intensive Care and Pain Medicine, Haifa, Israel

Background: Patients with COVID-19 who require mechanical ventilation have a high mortality rate, and VV ECMO (veno-venous extracorporeal membrane oxygenation) may serve as a lifesaving intervention, especially for young patients with single-organ failure. According to the ELSO Registry, in-hospital mortality for COVID-19 patients on ECMO is 47%, with only 26% of patients successfully discharged to home or rehabilitation facilities.

Case Report: A 43-year-old male with a history of mild hypothyroidism and smoking was hospitalized 3 days after testing positive for COVID-19. By the 16th day, due to severe respiratory failure, he was placed on awake VV ECMO with spontaneous breathing. After three days, he was intubated, and ECMO support continued for 97 days (a total of 2,325 hours).

During this time, the patient experienced multiple episodes of massive bleeding, including nasopharyngeal, ECMO cannulation sites, and tracheostomy-related bleeding. He received 33.3 liters of red blood cells, 3.74 liters of platelets, 17.6 liters of fresh frozen plasma, and 5.25 liters of cryoprecipitate. His lowest platelet count was 19,000, and he tested negative for heparin-induced thrombocytopenia.

The patient also experienced a single prolonged CPR event during ECMO, although kidney function remained intact. After 119 days of hospitalization, he was transferred to an acute rehabilitation center. Several months later, he achieved full recovery and returned to his pre-COVID activity level.

Discussion: This case represents one of the longest documented instances of VV ECMO support in Israel for COVID-19-related ARDS. Despite prolonged ECMO duration, extensive blood product transfusions, and a prolonged CPR event, the patient's lung function was eventually restored, allowing him to fully recover. The case underscores the critical role that ECMO can play in COVID-19 patients with severe respiratory failure, even with prolonged complications.

References: https://www.elso.org/registry.aspx

Learning Points:

- VV ECMO can be an effective rescue therapy for patients with COVID-19-induced ARDS, especially in younger individuals with single-organ failure.
- Timely intervention with ECMO may help prevent multi-organ failure, and in some cases, allow full lung recovery.
- This case emphasizes the value of persistent support and comprehensive care in achieving favorable outcomes for critically ill COVID-19 patients.

Pain and Palliative Medicine

25AP01-1

Evolution of published randomised controlled trials on non-opioid analgesics for postoperative pain: a bibliometric study

B. Doleman¹, J. Lund¹, J. Williams¹
¹University of Nottingham, School of Medicine, Derby, United Kingdom

Background and Goal of Study: This study aimed to analyse the changes by year in the number of publications of randomised controlled trials (RCTs) on non-opioid analgesics for postoperative pain.

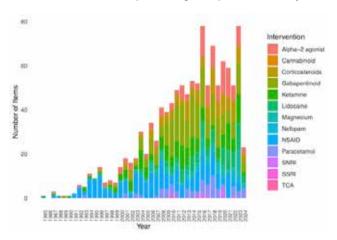

Materials and Methods: We conducted a systematic review in July 2024 of major electronic databases (MEDLINE, Embase and CENTRAL). We included RCTs with available full text, that administered a single non-opioid analgesic versus placebo either preor intra-operatively and assessed postoperative pain outcomes. We did not include studies which focussed on non-opioids to treat established postoperative pain.

We analysed the change in the number of publications using negative binomial regression. Effect estimates are presented as incident rate ratios (IRR) with 95% confidence intervals (CIs). All analyses were conducted in R statistical software.

Results and Discussion: We included 1149 RCTs. There has been a large increase in the number of publications since 1985, which may have stabilised over the last 15 years (Figure 1).

Beyond their introduction into clinical practice, there is no clear trend in the number of publications when considering the type of agent used (Figure 1).

The number of publications has increased by around 10% per year (IRR 1.10; 95% CI 1.08 to 1.11). There continues to be a large number of RCTs on non-opioid analgesics published each year.

Conclusion(s): There is an urgent need to appraise the large evidence base of RCTs of non-opioid analgesics in order to reduce the risk of potential research waste, provide new evidence of treatment efficacy and guide the conduct of future RCTs.

25AP01-2

The potential of modern non-opioid analgesics in the prevention and treatment of pain syndrome in decompressive-stabilizing spine surgeries

V. Khoronenko¹, <u>T. Lukonina</u>¹, G. Abuzarova², G. Alekseeva³

¹P. Herzen Moscow Research Institute of Oncology, Branch of the National Medical Research Center of Radiology, Anesthesiology and Intensive Care, Moscow, Russian Federation, ²P. Herzen Moscow Research Institute of Oncology, Branch of the National Medical Research Center of Radiology, Palliative Care Center for Cancer Patients, Moscow, Russian Federation, ³P. Herzen Moscow Research Institute of Oncology, Branch of the National Medical Research Center of Radiology, Administration, Moscow, Russian Federation

Background and Goal of Study: The study compared the effectiveness of intravenous NSAIDs (Ibuprofen) and a combination of NSAIDs (diclofenac + orphenadrine) with tramadol to optimize pain management in cancer patients with chronic pain syndrome (CPS) due to metastatic spinal lesions (MSL) during spinal surgeries.

Materials and Methods: A total of 87 patients (39 men and 48 women, M±SD 60.48±9.55 years) with CPS due to MSL were included. Patients were randomized based on the type of analgesia: in the control group (T, n=28), tramadol was used, while in the comparison groups (D, n=30), diclofenac and orphenadrine combination or ibuprofen (I, n=29) were administered i/v intraoperatively and for 2 days postoperatively. Pain intensity was assessed at rest and on exertion using a visual analog scale (VAS, mm) at the following time points: during extubation (1), during transfer in the intensive care unit (2), 1 hour (3) and 3 hours (4) postoperatively, at 21:00 on the day of surgery (5), and at 06:00 the next day (6). Statistics included non-parametric tests.

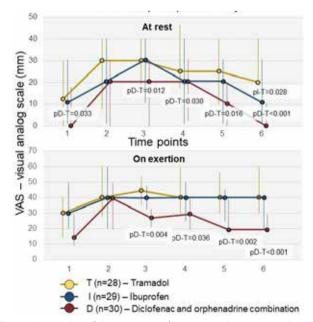

Figure. Dynamics of the intensity of post-op pain syndrome in groups at rest and on exertion in the 1st postoperative day.

Results and Discussion: It was shown that D was more effective than T at rest time points 1,3,4,5,6 (Me 0.00 vs. Me 12.5, p=0.033; Me 20.00 vs. Me 30.00, p=0.012; Me 20.00 vs. Me 25.00, p=0.030; Me 10.00 vs. Me 25.00, p=0.016; Me 0.00 vs. Me 20.00, p<0.001 respectively) while I had greater analgetic effect only at time point 6 (Me 10.00, p=0.028).

Similar results were obtained on exertion: D was more effective at time point 3.4.5.6 (M±SD 27.67±15.30 vs. M±SD 44.29±22.68. p=0.004; Me 20.00 vs. Me 40.00, p=0.036; Me 20.00 vs. Me 40.00, p=0.002; Me 20.00 vs. Me 40.00, p<0.001 respectively). Duration of analgesia (min) in D was longer than T or I (Me 450.00 vs. 97.50 or 120.00, p=0.019).

Opioid-sparing effect was in groups D and I; median daily dose of tramadol was 100.00, p<0.001 vs. 200.00, and the duration (day) of opioid therapy was significantly lower than in groups T (Me 5, Me 6 vs. Me 7; p< 0.001, p=0.017).

Conclusion: Pain management in patients with MSL using combined NSAIDs is more effective than with ibuprofen or tramadol. Future research with larger sample sizes is necessary to confirm these findings.

25AP01-3

Quantitative Sensory Testing (QST) in patients with high frequency and burst Spinal Cord Stimulation (SCS), follow-up

N. Ninidze1

¹Medical University of Vienna, Department of Anaesthesiology and Special Pain Therapy, Vienna, Austria

Background: SCS after implantation is rated as "successful" when it achieves ≥50% pain relief. Although in this population, burst or high-frequency stimulation was considered successful, several patients reported a change or a reduction in its effect, especially after switching to non-perceptible stimulation.

The primary aim of this study was to investigate the associations between initial SCS outcomes and long-term SCS pain

Methods: Monocentric.non-randomized.follow-up observation of routine, standardized therapeutic measurements in 32 patients with either low back pain, radiculopathy or with pseudo-radiculopathy, who received aSCS unit and who had been treated successfully with HF or burst stimulation for one to three years. QST was first performed with the SCS system switched on stimulating the painful area.

Afterwards, stimulation was paused for 24h. The residual effect should have been vanished after this lapse of time.

Results: All patients including 20 women 63% aged between 32-83 years completed the trial. Temperature sensitivity as well as pain perception were not significantly altered after paused stimulation: Cold Detection CDT; P=0.61, Warm Detection WDT; P=0.66, Cold Pain Threshold CPT; P=0.56, Heat Pain Threshold HPT; P=0.16. SCS stimulates afferent nerve fibres, flooding the $A\beta$ fibres with tactile input, thus activating the GATE neuron and alleviating pain by inhibiting the spinothalamic neuron.

Conversely, stopping the stimulation for only 24 hours quickly deactivates the pain inhibitory neurons.

This was demonstrated in our study by a significant pain sensitivity to pinprick and pressure and clear signs of allodynia. No significant difference was shown in wind-up and vibration swell.

Conclusions: Paused SCS implies that different peripheral fibre classes, induce pain sensitization whose spatial spread and secondary hyperalgesia result in increased sensitivity to pinprick. pressure, vibration, and touch.

Nociceptive alpha- δ and A-B afferents, which mediate pain sensitization, are deactivated by spinal cord stimulation in prolonged chronic pain, but are easily and rapidly reactivated when stimulation is turned off. C-fibres' homo- and heterotopic long-term pain potentiation can be assessed by temperature perception during

In contrast to the observed quick deactivation of pain inhibitory neurons after paused SCS C-fibres are not rapidly reactivated. We assume that different mechanisms are involved in this path-

25AP01-4 Pain management for emergency laparotomies

V. Vasikaran¹, C. Luximon¹, J. Illingworth¹ St Mary's Hospital, Paddington, Anaesthetics, London, United Kingdom

Background and Goal of Study: Emergency laparotomy is a common surgical procedure, which has significant associated morbidity and mortality. Poorly managed pain contributes to postoperative complications. However, research surrounding pain management for emergency laparotomies is limited, particularly compared to the abundance of literature on elective colorectal and other major surgical procedures. We performed a service evaluation to assess pain management after emergency laparotomy in a London hospital.

Materials and Methods: We reviewed data for emergency laparotomies performed in adults aged 18 years and above between March 2023 and March 2024. Patients were identified by searching the hospital database (Surginet) and additional clinical information gathered from individual patient records.

We collected data on commonly used pain management techniques including epidurals, spinals, rectus sheath catheters and patient-controlled analgesia (PCA) pumps. We recorded the number of patients who complained of moderate or severe pain on arrival to the Post Operative Recovery Unit (PACU) to assess the effectiveness of each analgesia technique.

Results and Discussion: A total of 59 patients were identified. Regional anaesthesia techniques were used for 75% of patients. PCAs were used commonly alongside a regional technique as part of pain management post-operatively. 56% of patients were transferred to PACU post-operatively while the remaining patients were admitted to the Intensive Care Unit (ICU).

Analgesic technique	Proportion of patients	Proportion of patients receiving a PCA	Proportion of patients reporting moderate or severe pain in PACU
Epidural	39%	39%	11%
Spinal	19%	82%	0%
Rectus Sheath Catheter	17%	70%	38%
No regional technique	25%	27%	33%

Currently a multi-modal approach is used to manage pain postoperatively in patients undergoing emergency laparotomies at St Mary's Hospital. A significant proportion of patients are admitted to ICU post-operatively and this may influence individual analgesia plans.

We found that neuraxial analgesia is particularly effective in managing early postoperative pain and was more effective than rectus sheath catheters in this patient cohort.

Conclusion: Based on our findings we would recommend that neuraxial techniques should be included in the analgesia plan of patients undergoing emergency laparotomies whenever possible. Rectus sheath catheters should be considered in cases where neuraxial analgesia is contraindicated.

25AP01-5

Pain management model for acute postoperative pain in adults: a network meta-analysis

L. Chen^{1,2}, X. Feng^{1,2}, R. Zhou^{1,2}, G. Chen^{1,2}, T. Zhu^{1,2} West China Hospital, Sichuan University, Department of Anesthesiology and National Clinical Research Center for Geriatrics, Chengdu, China, 2West China Hospital, Sichuan University, Laboratory of Anesthesia and Critical Care Medicine, National-Local Joint Engineering Research Center of Translational Medicine of Anesthesiology. Chengduchina, China

Background and Goal of Study: An optimal pain management model is essential for guiding postoperative care and monitoring. This study aimed to compare the efficacy of various pain management models for managing acute postoperative pain in adults. Materials and Methods: Databases in English (PubMed, Web of Science, Embase, Cochrane Library) and Chinese (CNKI, WAN-FANG, SinoMed, Chinese Medical Ace Base) were systematically searched to identify randomized controlled trials (RCTs) that examined the efficacy of different postoperative pain management models. Two researchers independently conducted the search and screening, with discrepancies resolved by a third researcher. Data, including postoperative pain intensity measured by the Visual Analog Scale (VAS) or Numeric Rating Scale (NRS), were collected for network meta-analysis using STATA 18.

Results and Discussion: The network meta-analysis included 37 RCTs with a total of 5,815 postoperative adult patients. Results demonstrated that the acute pain service model (SMD = -0.79, 95% Cl: -1.39, -0.18), nurse-based anesthesiologist-supervised acute pain service model (SMD = -1.82, 95% CI: -2.37, -1.28), and multidisciplinary pain management team model (SMD = -1.32, 95% CI: -1.74, -0.89) were more effective than the traditional pain management model in reducing VAS scores 24 hours after surgery. When comparing the three models, the nurse-based anesthesiologist-supervised acute pain service model was more effective than the acute pain service model (SMD = -1.04, 95% CI: -1.60, -0.47) in reducing the maximum postoperative VAS score, with no significant difference observed between the nurse-based anesthesiologist-supervised model and the multidisciplinary team model (SMD = -0.51, 95% CI: -1.20, 0.18) in VAS scores 24 hours post-surgery. The SUCRA curve analysis indicated that the nursebased anesthesiologist-supervised acute pain service model was the optimal approach for managing postoperative pain.

Conclusion(s): The acute pain service model, nurse-based anesthesiologist-supervised acute pain service model, and multidisciplinary pain management team model were all more effective than the traditional pain management model. Among these, the nursebased anesthesiologist-supervised acute pain service model was identified as the optimal strategy for postoperative pain management.

25AP01-6

Pain after adenotonsillectomy in pediatric patients: is it adequately controlled?

G. Montenero¹, G. Sfregola¹, A. Ragone¹, M. Ciuffreda², C. Piangatelli², D. Galante¹

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, ²Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Postoperative pain management in pediatric patients undergoing adenotonsillectomy is a significant clinical concern. Adequate pain control is essential for recovery, reducing the risk of complications, and improving overall patient satisfaction.

This study evaluates the effectiveness of various pain management strategies in 100 children who underwent adenotonsillec-

Materials and Methods: A survey was conducted in 10 hospital anesthesia departments on 100 pediatric patients (ages 4-12 years) undergoing adenotonsillectomy. Pain management protocols included preoperative, intraoperative, and postoperative interventions with a combination of opioid and non-opioid analgesics, as well as regional anesthesia in select cases.

The primary outcome measure was the reduction in postoperative pain, assessed using the Wong-Baker FACES Pain Rating Scale at 6, 12, and 24 hours post-surgery.

Secondary outcomes included incidence of postoperative nausea and vomiting (PONV) and the need for additional analgesics. Results and Discussion: At 6 hours postoperatively, 72% of patients reported mild or no pain, while 18% experienced moderate pain, and 10% had severe pain. By 24 hours, the proportion of patients with mild or no pain increased to 85%. The use of a combination of acetaminophen, ibuprofen, and local anesthetic infiltration significantly reduced pain levels compared to opioidbased regimens.

The incidence of PONV was low (7%) and was significantly lower in patients who received multimodal analgesia. The need for additional analgesics was minimal in most patients.

Conclusion(s): Multimodal analgesia, including non-opioid medications and local anesthesia, is highly effective in managing postoperative pain in children undergoing adenotonsillectomy.

These strategies reduce the need for opioids, minimize side effects, and provide better pain control, facilitating a faster recovery. Future studies should explore the long-term effects of these strategies on pain outcomes and quality of life.

Music for pain relief: investigating music preferences for pain management across twenty countries

E.S. van der Valk Bouman¹, A.S. Becker¹, J. Schaap², J. Oude Groeniger³, M. Klimek⁴

¹Erasmus MC, Neuroscience, Rotterdam, Netherlands, ²Erasmus Universiteit, Arts and Culture Studies, Rotterdam, Netherlands, 3Erasmus MC, Public Health, Rotterdam, Netherlands, 4Erasmus MC, Anesthesiology, Rotterdam, Netherlands

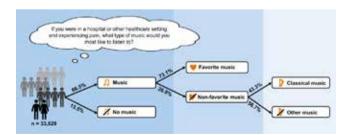

Background and Goal of Study: Music is increasingly used in healthcare to manage pain, anxiety, and stress. This study investigates 1) to what extent people across twenty countries are willing to listen to music for pain relief in healthcare settings, and 2) which music genres they choose, in light of their national context, background characteristics, and overall music preferences.

Additionally, we examine the universality of the 'Mozart effect,' which describes the belief that classical music is most effective in healthcare, despite evidence that favorite music, regardless of genre, is most effective.

Materials and Methods: We used data from the International Federation of the Phonographic Industry's international survey, which included one question from our research group: "If you were in a hospital or other healthcare setting and experiencing pain, what type of music would you most like to listen to?" Data were analyzed using logistic multilevel regression models to examine the influence of gender, age, income, and race-ethnicity on music preferences for pain relief.

Results and Discussion: The study surveyed 33,629 participants across 20 countries. The mean age was 38.4 years. Overall, 13.5% preferred no music when in pain. Most participants chose their favorite music genres for pain relief (63.5%). Females and older participants were more likely to choose non-favorite music. Income and ethnicity influenced preferences in a subgroup analysis of the USA and UK. Pop music was the most chosen genre, followed by classical and mellow music.

Conclusions: A large majority (86.5%) of the global population is willing to listen to music when experiencing pain in healthcare settings (see Figure).

Participants predominantly chose their favorite music, with classical music being the most common choice when selecting a genre not aligned with their overall music preference. This supports the 'Mozart effect,' the belief that classical music is particularly effective for pain relief.

Differences between national populations and social groups highlight the need for a culturally sensitive and personalized approach to using music as medicine in healthcare settings.

25AP01-8

Perceptions of music listening for pain management: a mixed-methods study

A.S. Becker¹, E.S. Van der Valk Bouman¹, J. Schaap², R. Cats¹, M. Berghman², M. Klimek³ ¹Erasmus Medical Center, Neuroscience, Rotterdam, Netherlands, ²Erasmus University, Department of Arts and Culture Studies, Rotterdam, Netherlands, 3Erasmus Medical Center, Anesthesiology, Rotterdam, Netherlands

Background and Goal of Study: Integrating music into pain management is a promising nonpharmacological approach to improve patient outcomes, but its implementation remains challenging. Studies have shown that music can alleviate pain and reduce anxiety. Despite the evidence, implementing music in clinical practice faces barriers such as lack of knowledge and poor communication. Additionally, the subjective experience of music listening in the context of pain is not well-studied.

This study explores healthy volunteers' perceptions of music for pain management, focusing on their attitudes, implementation strategies, and subjective experiences.

Materials and Methods: This mixed-method study included a quantitative survey (n=169) and qualitative interviews (n=20). It is a follow-up to a randomized trial on music genres' influence on pain tolerance, conducted six months after the initial experiment, where participants received music listening advice. The protocol (ETH2324-0398) has been approved by the ESHCC Research Ethics Review Committee of Erasmus University Rotterdam.

The survey was distributed via Qualtrics software (Version 2020©. Qualtrics, Provo, UT). Quantitative data were analyzed with SPSS (IBM Corp., Chicago, USA) version 28.0. Interviews were semistructured and analysed following a thematic analysis.

Results and Discussion: Participants showed a high willingness to use music in healthcare, particularly for so-called emotional pain. Individual attitudes varied regarding type of music, situation and pain. Barriers included not remembering the option to listen to music and social sensitivity. Consequently, the optimal situation for music in healthcare is shown in the Figure 1.

A proactive approach by healthcare professionals was emphasised and nearly all interview participants emphasized the importance of having control and autonomy. Interestingly, the "wrong" type of music or the "wrong" situation were considered as nonbeneficial or even harmful.

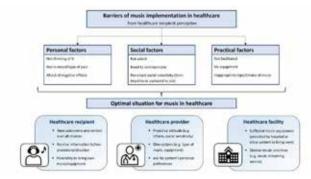

Figure 1.

Conclusions: Awareness of individual needs and potential negative emerged as crucial factors. To effectively implement music in healthcare, a proactive and personalized approach is required.

25AP01-9

Management of spastic paraplegia with intrathecal alcohol injection: a case report

S.I. Mociu^{1,2}, A. Moldovan¹, P. Mihalache¹, A. Atudorei¹, R. Buiuca¹, N. Ciufu^{1,2}

¹Ovidius Clinical Hospital, Anesthesia, Ovidiu, Romania, ²Ovidius University Of Constanta, Faculty of Medicine, Constanta, Romania

Background: Spastic paraplegia can significantly impair the quality of life in patients with spinal cord lesions due to trauma. Traditional management strategies often fall short in providing adequate relief. This case report explores the use of intrathecal alcohol injection as a novel approach to convert spastic muscle contractions and pain to a flaccid state in a patient with a spinal cord lesion.

Case Report: We present a 62-year-old male patient with a spinal cord lesion at the T12 level resulting from a traumatic injury. The patient suffered from continuous involuntary muscle contractions and pain in the lower limbs, severely impacting his daily comfort and overall well-being. In an effort to alleviate spasticity, a therapeutic intervention using intrathecal pure alcohol injection was performed.

Discussion: The intrathecal injection of pure alcohol effectively targeted the spasticity associated with the spinal cord lesion, leading to a successful transition from spastic paraplegia to a flaccid state. This intervention not only provided substantial pain relief but also improved the patient's comfort.

The case underscores the potential of intrathecal alcohol injection as a viable option for pain management and spasticity reduction in patients with spinal cord injuries.

References:

- 1. Tzeng, R. C., & Lee, H. J. (2018). Efficacy of Intrathecal Alcohol Injection for Spasticity in SCI Patients. Spinal Cord, 56(9), 825-832.
- 2. Karlsson, A. K., et al. (2019). Pain Management in Spinal Cord Injury: New Perspectives and Therapies. Pain Physician, 22(2), E123-E130.

Learning Points:

- Intrathecal pure alcohol injection can be effective in managing spastic paraplegia associated with spinal cord lesions.
- This approach provides an alternative for patients unresponsive to conventional therapies.
- Further research is warranted to explore the long-term effects and safety of this technique.

25AP01-10

Neurolytic transverse abdominal plane block with alcohol for severe abdominal pain resulting from abdominal wall metastasis: a case report

J. Jung¹, D.H. Kim¹, S. Cho¹

¹Daegu Catholic University Hospital, Anesthesiology and Pain Medicine, Daegu, Korea, Republic of

Background: The concentration and dose of alcohol used in transverse abdominis plane (TAP) neurolysis have been reported to vary from case to case (67% 12 ml, 77% 13 ml, 60% 25 ml, 33% 15 ml).

Case Report: A 67-year-old woman diagnosed with a gall bladder tumor accompanying metastasis to the liver, ovary, and abdominal wall visited the pain medicine outpatient clinic. She complained of aching pain in the right flank, with a VAS score 8. A CT imaging 3 weeks prior showed 4.2 cm RLQ anterior abdominal wall metastasis.

Ultrasound-guided right TAP block was performed twice at 7-day intervals using a mixed solution of 0.75% ropivacaine 10 ml and 2% mepivacaine 10 ml. Immediately after the TAP block, the patient reported that the pain disappeared, but the pain returned 7 hours later.

Two days after the second TAP block, the patient visited the emergency room complaining of right flank and pelvic pain, nausea, and vomiting with a VAS score of 10. On the abdominal CT scan taken at the time, the abdominal wall mass size increased (6.3 cm), and the patient complained of severe nausea and vomiting due to the side effects of intravenously administered morphine and refused pain medication.

The next day, after pain relief was confirmed with a TAP block using 5 ml of 0.75% ropivacaine under ultrasound guidance, TAP neurolysis was performed using a mixed solution of 2.5 ml of 0.75% ropivacaine and 7.5 ml of 100% alcohol. The total alcohol concentration and volume used in TAP neurolysis were 50% and 15 ml, respectively. Immediately after TAP neurolysis, the patient reported complete relief of right flank pain and no complications. The patient died 6 weeks after TAP neurolysis receiving hospice care. For 6 weeks, the patient complained of pain around the umbilicus (VAS 2), right pelvic pain (VAS 4), and back pain (VAS 6), but no right flank pain.

Discussion: Following the neurolytic TAP block using 15 ml of 50% alcohol, the patient had significant pain relief lasting about 6 weeks until the patient passed away. In addition, TAP neurolysis has been affected by reducing opioid consumption.

Hung JC, Azam N, Puttanniah V, Malhotra V, Gulati A. Neurolytic Transversus Abdominal Plane Block with Alcohol for Long-Term Malignancy Related Pain Control. Pain Physician 2014; 17(6): F755-60.

Learning Points: What percentage of alcohol is appropriate for TAP neurolysis?

How much injection volume is needed for TAP neurolysis?

25AP01-11

Persistent abdominal pain after laparoscopic cholecystectomy - risk factors and lidocaine impact

M. Abreu Pires¹, C. Cavaleiro^{1,2}, H. Machado^{1,2} ¹Centro Hospitalar Universitário de Santo António. Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva Emergência e Urgência, Porto, Portugal, ²Instituto de Ciências Biomédicas Abel Salazar, Ensino Médico Pré-Graduado, Porto, Portugal

Background and Goal of Study: The incidence of persistent abdominal pain after laparoscopic cholecystectomy is estimated between 9% to 25%. Data concerning persistent abdominal pain after elective laparoscopic cholecystectomy (PAPELC) intensity and its neuropathic characteristics is scarce. Lidocaine is used on multimodal analgesia however intravenous lidocaine (IVL) benefit on PAPELC is not clarified. The authors pretend to determine PA-PELC prevalence and risk factors, characterize the intensity, and categorize as neuropathic pain. Intraoperative IVL impact was explored in the PAPELC population.

Materials and Methods: A cross-sectional study was performed in 2021 after institutional approval. Included patients subjected to elective laparoscopic cholecystectomy (ELC) under general anesthesia in 2018 were surveyed via telephone after informed consent. Demographics data, perioperative analgesia, acute pain control and PAPELC intensity and DN4 classification were analyzed. The Numeric Pain Scale Score (NPSS) in the first 48 hours was registered.

Results and Discussion: Included 93 (71%) participants and a 15.05% prevalence of PAPELC was observed. About 57.1% of PA-PELC patients reported moderate to severe pain (NPSS≥4) and 28.6% classified as neuropathic pain.

The potential risk factors for PAPELC observed were height (r=-0.287;p=0.005), pain during the first 48 hours (r=0.404;p<0.001) and its control (U=365;p<0.001), postoperative morphine administration (r=0.248;p=0.017) and postoperative complications (r=0.518;p<0.001).

Dexamethasone administration was PAPELC related (r=-0.205;p=0.048). IVL was used in 27 cases and the decrease of the PAPELC risk was observed on ≥2mg/kg/h dose (OR=0.73). The need for opioid rescue (r=-0.201;p=0.054) and intraoperative fentanyl (H-KW=11.22;p=0.004) was related to ≥2mg/kg/h IVL doses.

The IVL dose was negatively associated with postoperative paracetamol (r=-0.270;p=0.009) and NSAIDs (r=-0.217;p=0.037).

Conclusion(s): This is the first study on patients' outcome evaluation after ELC regarding PAPELC prevalence, intensity, and DN4 classification and the IVL role on PAPELC. The observed PAPELC prevalence is according to published data.

The authors found an increased percentage of NPSS≥4 in PA-PELC patients. The potential risk factors for PAPELC observed were acute postoperative pain and its control, rescue opioid administration, and postoperative complications. On adequate IVL dose, a reduction in PAPELC risk was identified.

25AP01-12

Effective pain management through cryoneurolysis: a case report of brachial plexus cryoablation in advanced breast cancer

S.I. Mociu^{1,2}, L. Mazilu^{1,2}, A. Caloian^{1,2}, E. Calin¹, M. Iliescu^{3,2}, N. Ciufu^{1,2}

¹Ovidius Clinical Hospital, Anesthesia, Ovidiu, Romania, ²Ovidius University Of Constanta, Faculty of Medicine, Constanta, Romania, ³Balneal and Rehabilitation Sanatorium, Techirghiol / Ovidius University of Constanta, Faculty of Medicine, Techirghiol, Romania

Background: Pain management in advanced cancer patients remains challenging, particularly when nerve structures are involved. This case report discusses the use of cryoneurolysis for alleviating severe brachial plexus pain due to metastatic breast cancer with the local invasion of the brachial plexus.

Case Report: We present a 53-year-old female patient diagnosed with end-stage breast cancer, exhibiting local invasion and metastasis affecting the left brachial plexus. The patient experienced debilitating pain and plegia, significantly impacting her quality of life. After exhausting conventional pain management strategies, we opted for brachial plexus cryoneurolysis as an intervention.

Discussion: The cryoneurolysis procedure was performed, providing targeted pain relief by interrupting nerve conduction. The patient achieved remarkable results, enjoying six months of complete pain relief. Upon recurrence of pain, cryoneurolysis was repeated, again yielding excellent results. This case highlights the effectiveness of motor nerve cryoablation in managing palliative pain in cancer patients, demonstrating that it can be a safe and reproducible procedure.

References:

- 1. Smith, J. A., & Jones, M. B. (2021). Advances in Palliative Pain Management. Journal of Pain Research, 15, 123-130.
- 2. Patel, R., et al. (2020). Role of Cryoanalgesia in Cancer Pain Management. Pain Medicine, 21(4), 733-740.

Learning Points:

- · Cryoneurolysis can provide significant relief for severe cancer pain associated with brachial plexus nerve involvement.
- It is a minimally invasive option that can be safely repeated when necessary.
- · Understanding its application can enhance palliative care strategies for cancer patients suffering from refractory pain.

25AP02-2

Update on the management of acute postoperative pain in the renal transplant patient

C. Docampo¹, F.V. Tomás Ríos¹, A. Tur Alonso¹,

B. García Rivas¹, P.M. Canales Lara¹, M.P. Argente Navarro¹ ¹Hospital Universitario y Politécnico La Fe, Anestesiología, Valencia, Spain

Background and Goal of Study: Currently we perform a multimodal analgesic treatment, with effective techniques and drugs (cost-effectiveness ratio) for acute postoperative pain in patients undergoing renal transplantation.

The effective treatment of acute postoperative pain, in addition to reducing costs, improves the quality of care, reduces secondary complications, in addition to the hospital stay and provides greater comfort for the patient during the postoperative period. In this type of intervention, pain can be considered moderate to severe, hence the need for follow-up and treatment by the ADU. Prior to this study, pain management was performed with iv morphine boluses on patient demand.

Materials and Methods: The study included 70 patients, six months from the start of the protocol, renal transplant recipients included in the period from the day of surgery to the first 48 hours post-surgery. The postoperative analgesic control protocol contemplates several branches of pain management, depending on whether the patient presents moderate pain (VAS 7-8), where a continuous infusion of: tramadol 300 mg + ondansetron 12 mg to be administered in 24 hours IV is started.

On the other hand, if the patient presents severe pain (VAS >8), we have four possible options, being (a): continuous infusion of morphine. Option (b) an incisional catheter: Ropivacaine 0.2% 5-7 ml/h. Option (c) epidural catheter: Ropivacaine 0.2% via epidural. Option (d) Tap block infiltration: Ropivacaine 0.5% 20-30 ml.

In addition to all of them, infiltration of the subaponeurotic fascia in the operating room.

Results and Discussion: Tramadol pump was used in 80% of cases. It was only necessary in 20% with VAS >8 treatment with the other four branches where none proved to be superior to the others.

In comparison, since the beginning of this protocol >75% of the patients presented pain < 5 compared to the previous treatment (morphine on demand to boluses if pain). Complications: 5-7% of PONV, and <1% paralytic ileus.

25AP02-3

Subcutaneously implanted epidural ports for management of severe cancer pain: two case reports

H. Oue¹, T. Hayashi¹, A. Koyama¹, S. Hayashi¹, K. Miyasaka¹, N. Fujita1

1St. Luke's International Hospital, Department of Anesthesia, Tokyo, Japan

Background: The number of cancer patients who wish to receive palliative care at home has been increasing in Japan. Managing severe cancer pain effectively while enabling discharge to home remains a challenge.

We present two cases where implantation of an epidural port provided effective pain control, allowing the patients to transition to home care.

Case Report 1: A 44-year-old woman presented with right-sided chest pain caused by meningeal carcinomatosis from lung cancer. Despite high-dose opioid therapy (up to 2000mg morphine daily), pain control was inadequate, and the patient experienced somnolence as a side effect. An epidural port was placed for epidural administration of morphine and ropivacaine, reducing morphine usage to 25-200mg per day. The patient was discharged to home two weeks later with effective pain management.

Case Report 2: A 55-year-old woman with ovarian cancer, lung metastases, and pelvic lymphadenopathy presented with severe left groin and abdominal pain (NRS 8/10). Initial systemic opioid therapy was insufficient. An epidural port was placed for continuous administration of local anesthetics and opioids, reducing her pain to NRS 0-1/10. She was discharged 10 days later with pain effectively controlled through the epidural system.

Discussion: The use of implanted epidural ports in these cases highlights their effectiveness in providing adequate pain control while reducing opioid load and side effects such as somnolence and sedation. Both patients transitioned to home care with improved quality of life. No implant-related infections were observed, demonstrating the safety and reliability of this technique. These cases emphasize the role of epidural analgesia in advanced cancer pain management and its potential to support home-based palliative care.

Conclusion: Implanted epidural ports can provide effective pain relief while minimizing opioid-related side effects, enabling hospital discharge and home-based care.

Reference:

1. Inoue D, Sakuyama T, Ichiba T, et al. [Usefulness of epidural catheter with the subcutaneous reservoir for cancer pain control in homecare service]. Gan To Kagaku Ryoho. 2011;38(Suppl 1):61-3.

Learning Points: Severe cancer pain in the home-based palliative care setting may be managed by epidural analgesia via an implanted epidural port, reducing systemic opioid requirements and minimizing side effects.

25AP02-4

Genome-wide expression profiling of the amygdala in neuropathic pain rats

W.H. Lee¹, E.H. Jin², H. Kim¹

¹Eulii Medical University, Anesthesiology and Pain Medicine, Daejeon, Korea, Republic of, 2Chungnam National University Medical School, Pharmacology, Daejeon, Korea, Republic of

Background and Goal of Study: Pain is an unpleasant sensory and emotional experience. The amygdala is known to play a crucial role in both nociceptive and emotional processing. Recent studies suggest that the right amygdala may have a more pronociceptive function, while the left amygdala appears to be less involved.

This study aimed to explore differential gene expression in the left and right amygdalae of neuropathic pain rats. Genome-wide expression profiling was performed to identify pain-related genes that are specifically expressed in the amygdala.

Materials and Methods: Amygdalae were obtained from three rat pain models (male Sprague-Dawley) at 3, 9, and 14 days postspinal nerve ligation (SNL), with pain confirmed by the von Frey test. Microarray analysis and quantitative qRT-PCR were used to identify differentially expressed genes in the amygdalae at each time point.

Additionally, we examined whether gene expression differed between the left and right amygdalae in the SNL model (n = 3 per time point). Experimental procedures were conducted in accordance with the animal care guidelines of the Korean Academy of Medical Science (Animal Ethics Committee of Chungnam National University Hospital: CNUH-014-A0005-1).

Results and Discussion: Tight ligation of the L5 spinal nerve induced allodynia in the left hind paw by day 3 post-ligation. Gene expression analysis revealed a significant increase in the expression of Npsr1 (Neuropeptide S receptor 1), Nr4a2 (Nuclear receptor subfamily 4, group A, member 2), Rgs18 (Regulator of G-protein signaling 18), and Satb2 (SATB homeobox 2) in the right amygdala on day 3 post-SNL.

On day 9, Adora2a (Adenosine A2a receptor) and Rgs9 (Regulator of G-protein signaling 9) were significantly upregulated in the right amygdala, and on day 14. Stoml3 (Stomatin-like 3) expression was significantly increased in the right amygdala compared to the left (p \leq 0.05, Table1).

Conclusion(s): These results suggest that the right amygdala may play a more prominent role than the left amygdala in the processing of neuropathic pain in rats.

25AP02-5 Patients with post-breast surgery chronic pain: a case series

F. Lemos¹, I. Nunes¹, D. Veiga¹, A. Regalado¹, A. Pimenta¹, C. Raposo¹

¹Unidade Local de Saúde de Santo António, Multidisciplinary Pain Unit, Anesthesiology Department, Porto, Portugal

Background: Chronic pain after breast surgery is a common condition, affecting patients' quality of life. Chronic shoulder pain can arise as a secondary complication, limiting arm mobility and daily activities. This case series describes four patients with chronic shoulder pain associated with breast cancer treatment and assesses different treatment approaches.

Methods: This case series includes four patients who developed chronic shoulder pain related with post-breast surgery chronic pain. DN4 questionnaire was used to identify neuropathic features of breast pain, and numeric rating score (NRS) were recorded before and after interventions for both breast and shoulder pain.

Therapeutic approaches included physiotherapy and ultrasoundguided corticosteroid injections for shoulder pain, and topical 8% capsaicin for breast neuropathic pain.

Results and Discussion: All patients were female. The average age of the patients was 49.5 years. Three of the four patients had an initial diagnosis of breast cancer, with an average time since diagnosis of 58.7 months ranging from 24 to 83 months. Time since breast surgery had an average of 50 months, with a range from 23 to 77 months. DN4 scores corroborated the neuropathic component of breast pain in 3 out of 4 patients, with a range of 4-7. Two patients were treated with topical capsaicin, with pain reduction >30%. In three patients was also performed ultrasoundguided corticosteroid injections, with >50% pain reduction.

Conclusion: This case series describes and evaluates the treatment of patients with chronic shoulder pain following breast surgery, emphasizing the importance of recognizing patients with post-surgical breast chronic pain, particularly those with neuropathic pain, as a high-risk group for developing chronic shoulder pain. Early identification and intervention in this population may help reduce long-term disability and improve quality of life.

25AP02-6

Bipolar pulsed radiofrequency as a light of hope in post-traumatic xiphodynia: a case report

A.C. Segundo¹, A. Castelo Branco¹, N. Carrillo-Alfonso¹, A. Lares1

¹Unidade Local de Saúde do Algarve, Serviço de Anestesiologia, Faro, Portugal

Background: Bipolar Pulsed Radiofrequency (BPRF) is a minimally invasive procedure used for pain management. Post-traumatic xiphodynia can be associated with severe dysfunction in daily activities, especially in young and active individuals. BPRF can be utilized in cases refractory to medical treatment.

Case report: We report the case of a 33-year-old male with a history of an electric motorcycle accident 5 years prior. Following the accident, he developed constant pain in the xiphoid process region, with progressively increasing intensity, exacerbated by exertion and superficial palpation. Trials with analgesics such as non-steroidal anti-inflammatory drugs, metamizole, paracetamol, pregabalin, and nutraceuticals were unsuccessful.

Relief was only achieved with combined tramadol 37,5 mg and paracetamol 325mg, which he used as needed due to excessive drowsiness.

On the numerical pain scale, he reported a maximum of 9 out of 10, a minimum of 4 out of 10, and an average of 7 out of 10. The Douleur Neuropathique 4 questionnaire was negative. Thoracic computed tomography showed no musculoskeletal abnormali-

In this context, a bipolar pulsed radiofrequency procedure was performed under ultrasound guidance at the intermediate zone of the xiphoid process (the most painful area), with needles placed transversely to the xiphoid process, delivering a total of 6 minutes of treatment, with posterior administration of dexamethasone 8 mg and ropivacaine 6 mg.

One month after the treatment, the patient reported no baseline pain, with few episodes of breakthrough pain, reaching a maximum of 5/10, with very sporadic use of as-needed medication.

Discussion: This case presents Bipolar Pulsed Radiofrequency as a possible treatment option for patients with post-traumatic xiphodynia, particularly those unresponsive to conventional pharmacological therapies.

To our knowledge, there are no similar cases described in the literature. Although the follow-up period is short, the results are promising and suggest a potential treatment pathway for refractory cases.

Further studies are needed to confirm these results.

Bajaj H, Drake D. Utility of Pulsed Radiofrequency Ablation in Xiphodynia. Pract Pain Manag. 2019;19(3).

Learning points:

- 1. BPRF offers a minimally invasive alternative for patients unresponsive to conventional pharmacological treatments.
- 2. BPRF can provide effective pain relief for patients with refractory post-traumatic xiphodynia.

25AP02-7

Efficacy and safety of meloxicam nanocrystal injection for postoperative analgesia in adult patients undergoing laparoscopic surgery: a multicenter, randomized, double-blind, placebo-controlled phase III trial

M. Yang¹, M. Li¹, L. Yang¹, W. Su¹, J. Deng¹, R. Jiang¹ ¹Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Anesthesiology, Chengdu, China

Background and Goal of Study: Postoperative pain after laparoscopic surgery is a significant issue, delaying recovery and affecting quality of life. Despite various analgesic methods, more effective and safer options are needed. Meloxicam, a nonsteroidal anti-inflammatory drug (NSAID), has shown analgesic and anti-inflammatory effects. Meloxicam nanocrystal injection is expected to have improved pharmacokinetic properties and enhanced ef-

This study aimed to evaluate the efficacy and safety of meloxicam nanocrystal injection for postoperative analgesia in adult patients undergoing laparoscopic surgery.

Materials and Methods: This multicenter, randomized, doubleblind, placebo-controlled phase III trial included adult patients aged 18-65 scheduled for elective laparoscopic surgery under general anesthesia, with expected surgery duration <4 hours and a postoperative hospital stay ≥48 hours. Eligible patients had NRS pain scores ≥4 within 4 hours postoperatively.

Patients were randomized to receive either meloxicam nanocrystal injection (30 mg once daily for 2 days, intravenous) or placebo (1 mL normal saline once daily for 2 days, intravenous).

The primary endpoint was the time-weighted sum of pain intensity differences over 24 hours (SPID24).

Secondary endpoints included time-weighted total pain relief scores (TOTPAR). SPID at other intervals, time to first use of rescue analgesics, frequency of rescue analgesic use (0-24 and 24-48 hours), proportion of patients requiring rescue analgesics, total rescue analgesic use, and the patient's global assessment of analgesia (PGA) at 48 hours.

Results and Discussion: A total of 222 patients from 8 centers were randomized. The SPID24 in the meloxicam nanocrystal injection group was significantly better than the placebo group (P < 0.0001), meeting the primary endpoint.

Secondary efficacy endpoints showed significant improvements in the meloxicam group, demonstrating superior analgesic effects. In terms of safety, the incidence of adverse events (AEs) was lower in the treatment group compared to the placebo group. Most AEs were mild to moderate and resolved without intervention.

Conclusion(s): Meloxicam nanocrystal injection is effective for moderate to severe postoperative pain following laparoscopic surgery. It significantly reduces pain and the need for rescue analgesics, with good safety and tolerability.

25AP02-8

Enhanced vs. standard pain management of patients at risk for chronic post-surgical pain: a randomized controlled pilot trial

P. Sypniewska El Khoury¹, N. Silvestrini¹, F. Ennahdi¹, N. Elia^{1,2}, B. Rehberg-Klug^{1,2}

¹Geneva University Hospitals, Department of Anaesthesia, Geneva, Switzerland, 2University of Geneva, Faculty of Medicine, Geneva, Switzerland

Background and Goal of Study: Moderate to severe chronic postsurgical pain (CPSP) occurs in up to 12% of patients 6 months post-surgery, according to a large European cohort study. Some hospitals have implemented "transitional pain services" (TPS) to implement strategies to reduce the risk of transition from acute to CPSP. The impact of the TPS on the occurrence of CPSP remains to be demonstrated. In this pilot trial, we tested the feasibility of performing a trial answering this question.

Materials and Methods: We conducted a randomized, single center, open-label pilot clinical trial with as 1:1 allocation. Patients scheduled for spine, total knee replacement or thoracic surgeries (with a stratification 2:2:1), aged 18 years old or more, speaking and reading French, were included. Patients filled in baseline questionnaires assessing psychological risk factors and preexisting chronic pain.

After surgery, patients allocated to the TPS group were followed by the TPS team consisting of members of the acute and chronic pain teams working together. The TPS proposed individually targeted measures. Patients in the control group received usual care by a surgeon and/or general practitioner. Patients were followed for 6 months.

The primary outcome was the recruitment rate.

Secondary outcomes were retention rate, data completeness rate, and incidence of CPSP at 6 months. No statistical test was applied.

Results: 60 patients were randomized. Mean age was 65.1 (SD12.1), mean BMI was 28.4 (SD4.4), 29 were female, 54 had chronic pain before surgery and 21 patients had pain at surgery site. Mean VAS pain intensity before surgery was 6.2 (SD1.8). The mean recruitment rate was 10 patients per month.

Complete data from 50 patients could be analyzed at 6 months. Only 20 of 30 patients in the TPS group had a visit by the TPS team, and 5 patients were followed by the TPS team until 6 months. 23 of 50 patients with available data had chronic pain at 6 months after surgery, 18 of them chronic pain at the site of surgery, 5 presented increased pain intensity at 6 months.

Conclusion(s): This pilot study supports the feasibility of a larger randomized trial in terms of patient recruitment for the selected types of surgery.

However, an efficient TPS needs sufficient resources which were not available at the time of the study, resulting in a low rate of patients visited and followed-up. The endpoints to be examined should be clarified in a patient and public involvement perspective.

25AP02-9 **HSK21542** in patients with postoperative pain: one phase 3, multicentre, double-blind, randomized, controlled trials

X. Chen¹, T. Zhang¹, L. Han¹, S. Fan¹, S. Sun¹, Y. Wang¹ ¹Huazhong University of Science and Technology, Wuhan Union Hospital, Wuhan, China

Background and Goal of Study: HSK21542, a peripherally restricted kappa opioid receptor agonist, was evaluated for efficacy and safety in patients with postoperative pain following abdominal surgery. This was assessed in a phase 3, multicentre, randomized, double-blind, controlled trials (HSK21542-303) in China. Materials and Methods: HSK21542-303 was a three-arms study comparing HSK21542 1.0 µg/kg with tramadol 50 mg/dose and placebo. All treatments were administered intravenously.

The primary endpoint was the time-weighted summed pain intensity differences over 24 hours (SPID_{0-24h}).

Secondary endpoints included SPID_{0-12h}, use of rescue analgesics, and PID; proportion of patients with NRS ≤3; duration of analgesia; and postoperative satisfaction score with analgesia.

Results and Discussion: HSK21542-303 demonstrated superiority of HSK21542 over placebo (least squares [LS] mean [± standard error], -64.0 [2.25] vs -45.9 [2.25]; P<0.001) in terms of SPID while non-inferiority to tramadol (LS mean difference, -1.1; 95% confidence interval, -7.4 to 5.1; P<0.001) (Figure 1).

Patients who received HSK21542 experienced reduced requirements for rescue analgesics, longer mean duration of analgesic effect, lower PID, and higher satisfaction scores among patients and physicians compared with placebo.

Furthermore, HSK21542 had a comparable safety profile to placebo, inducing fewer gastrointestinal adverse events compared with tramadol. More than 30% improvement in SPID 0-24h with HSK21542 compared with placebo was observed in this study. This magnitude of improvement was consistent with other trials of novel analgesics such as VX-548 (NaV1.8 inhibitor), meloxicam (COX-2 inhibitor) and oliceridine (µ-receptor G-protein pathway modulator) that utilized SPID24 as efficacy endpoint in abdominoplasty and bunionectomy (1-3).

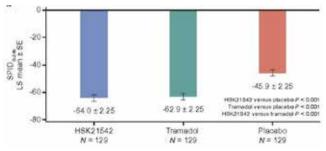

Figure 1. $SPID_{0-24h}$ after the post-operative administration of the first dose in HSK21542-303.

Conclusion(s): In conclusion, HSK21542 showed potent analgesic effect and was well tolerated in patients who underwent abdominal surgery and experienced postoperative pain.

25AP02-10

Intracanal radiofrequency for chronic neuropathic pain: Three case reports

C. Pallarés Fernández¹, J.M. Vázquez Ignacio¹,

R. Soler Martínez¹, L. Blasco Torres¹, J. Mañero Rey¹,

A. Sapes Barque¹

¹Consorci Corporació Sanitària Parc Taulí, Anesthesiology, Sabadell, Spain

Background: Chronic neuropathic pain is often refractory to conventional therapies, posing a significant clinical challenge. Intracanal radiofrequency (IRF) has emerged as a minimally invasive technique for modulating neural signal transmission.

This case series illustrates IRF's effectiveness in chronic sciatic pain, post-surgical neuropathic pain following tumor resection, and post-herpetic neuralgia, highlighting its value in conditions with limited therapeutic alternatives.

Case Report:

Case 1: A 54-year-old male with chronic sciatic pain due to pelvic fracture, unresponsive to pharmacological and infiltration therapies. After RFI pain intensity reduced by 60% in 1 month. Residual mixed pain persisted at 5 months, managed with tailored pharmacotherapy.

Case 2: A 39-year-old male with chronic neuropathic pain after sacral carcinoma resection and radiotherapy. Despite opioids and adjuvants, pain remained severe. IRF resulted in a 70% pain reduction, enabling opioid cessation and functional recovery.

Case 3: A 78-year-old female with post-herpetic neuralgia, unresponsive to gabapentinoids, opioids and topical therapies. IRF resulted in pain resolution within one month, along with functional and psychological improvement.

The IRF was performed with a Racz catheter inserted through a 16G Touhy needle, under radiological guidance, to the affected dorsal root ganglia. Sensory and motor tests were performed prior to pulsed radiofrequency at each level. Treatment parameters: 45V, 5Hz, 5 ms, 4-8 min. The neutral plate was placed in the gluteus in cases 1 and 3, and in the inguinal region in case 2.

Discussion: These cases underline IRF's clinical relevance as a viable option for refractory chronic pain, where conventional therapies fail. Its minimally invasive nature and sustained outcomes support broader application in similar contexts.

Further studies are warranted to validate its long-term efficacy and safety.

Reference:

García García L, López de la Torre I, Sánchez Fernández G, et al. Tratamiento del dolor neuropático crónico mediante radiofrecuencia intracanal. Revista de la Sociedad Española del Dolor. 2017;24(6):386-394. doi:10.20986/resed.2017.3611/2017.

Learning points: IRF is effective and safe for managing chronic neuropathic pain of diverse origins and it offers significant functional improvement in patients with refractory conditions. There's a need for individualized and multidisciplinary pain management strategies.

25AP02-12

The effectiveness of informed consent using a spine model in patients undergoing lumbar epidural steroid injection: a prospective randomized study

B. Gülsen Erol¹, G.E. Ozgencil¹, H.A. Ünal¹
¹Ankara Universty, Anesthesiology, Ankara, Turkey

Aim: Informed consent is a critical process in medical care that ensures patients are fully informed about procedures or treatments, allowing them to make educated decisions regarding their health. This process is not only ethically and legally required but also helps set realistic expectations, reduce patient anxiety, and improve satisfaction. Visual aids can enhance understanding by helping patients grasp medical concepts and reduce misunderstandings. Low back pain is a common complaint, and lumbar disc herniation is frequently associated with this condition.

For patients who do not require surgery but still need pain management, minimally invasive procedures like lumbar epidural steroid injections are often performed. Informed consent is essential before these procedures.

This study aims to assess the effectiveness of informed consent obtained with a spinal model for patients undergoing lumbar epidural steroid injections.

Materials and Methods: From December 2023 to May 2024, 163 patients who underwent lumbar epidural steroid injections at Ankara University Department of Algology were included. The patients were randomly assigned to two groups: a control group receiving standard verbal and written informed consent, and a study group where the procedure was explained using a visual spine model.

The study assessed the level of understanding of the informed consent, patient satisfaction (using a Likert scale), and anxiety and depression scores before the procedure (using the patient anxiety and depression scale).

Results: The study group demonstrated a significantly higher level of understanding of the informed consent (p<0.001) compared to the control group.

Additionally, the anxiety and depression scores of the study group were significantly lower (p<0.001).

Conclusions: Enhancing the informed consent process with visual materials, such as a spinal model, can improve patients' understanding, reduce pre-procedural anxiety, and increase satisfaction by aligning expectations.

This study found that using a spinal model during informed consent for lumbar epidural steroid injections significantly improved patient understanding and reduced anxiety levels.

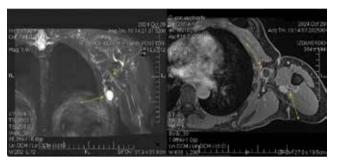

25AP03-1

Complex regional pain syndrome-related to axillary seroma and breast Mondor's disease after Mastectomy & Sentinel Lymph Node Dissection

A. Valente Rivero¹, C. Ramírez Paesano², <u>E.G. Rivero Novoa</u>², L. Cao López², C. Rodiera Clarens², M.J. Jimenez Andújar²

¹Universitat de Barcelona, Hospital Clínic de Barcelona, Barcelona, Spain, ²Teknon Medical Center Quironsalud, Servei Central d'Anestesia (Anestalia), Barcelona, Spain

Background: Post-mastectomy pain syndrome (PMPS) is frequent. However, complex regional pain syndrome(CRPS) is rare when total mastectomy (TM) with sentinel lymph node dissection (SLND) is performed(1).CRPS due to entrapment of the intercostalbrachial nerve (ICBn) by a seroma is presented.

Case Report: A 45-y.o woman underwent bilateral TM for intraductal cancer and left axillary SLND. One month later she developed severe neuropathic pain, allodynia, hyperalgesia, trophic skin changes, and left arm/hand edema. Memantine, pregabalin, lidocaine patches, and physical therapy were started. She developed a recurrent axillary seroma that compressed the brachial plexus(BP), and ICBn entrapment due to breast Mondor's disease (BMD). MRI-neurography showed inflammation of lower brachial plexus. Stellate ganglion blocks, paravertebral block, various seroma drainages and administration of steroids into the pseudocapsule, provided significant analgesia. US-guidance application of platelet-rich plasma (PRP)around the BP produced a 60% clinical improvement and remission of allodynia in 15 days.

Discussion: PMPS is common (30-60%); however, CRPS is rare after TM&SLND. The persistence of a seroma can damage the BP.BMD may increase pain and the risk of CRPS(1,2).PRP may be an option for neural regenerative treatment(3).

References:

Graham L.E et al. Rheumatol Int. 2002;21(4):165-6. Monib S, et al. Cureus. 2021. PMID: 33758712. Papanikolaou A. et al.J.Clin. Med. 2022, 11, 5062,

Learning points: CRPS requires early treatment. Anti-neuropathic medications, sympathetic blocks, PRP and multidisciplinary care can improve outcomes.

25AP03-2

Reducing dietary branched-chain amino acids intake alleviates high-fat diet-induced pain sensitization and postoperative pain in male mice

N. Lian¹, F. Li², P. Lu²

¹West China Hospital of Sichuan University, Huaxi MR Research Center (HMRRC), Chengdu, China, 2West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China

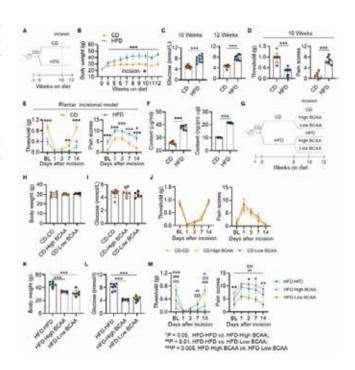

Background and Goal of Study: Pain is one of the main problems for modern society and medicine, being the most common symptom described by almost all patients. Dietary regimes affect pain alteration. This study aimed to elucidate the role of high-fat diet (HFD) on pain sensitivity and postoperative pain, and determine the potential effects of modulating branched-chain amino acids (BCAA) intake on pain phenotypes in preclinical studies.

Materials and Methods: Four-week-old male mice were fed a purified control diet (CD) or HFD for 10 weeks, followed by a hind paw incision. Four-week-old male mice were initially fed a CD or HFD for 8 weeks, then switched to the High or Low BCAA diet for another 4 weeks, and underwent a hind paw incision at 10 weeks of these diets. The BCAA content in homogenized DRG tissue or plasma samples were quantified with liquid chromatographytandem mass spectrometry. Pain behaviors were assessed.

Results and Discussion: Mice fed a HFD showed significant weight gain, starting at week 4 and lasting for 12 weeks, and elevated fasting blood glucose levels at 10 and 12 weeks (Fig A-C). HFD consumption induced pain sensitization and worsened postoperative pain (Fig D-E).

Consistent with previous study, in HFD mice, BCAA levels were significantly increased in plasma and L4-L5 DRGs (Fig F). Thus, we next questioned whether modulating BCAA intake would have effects on nociceptive and postoperative pain phenotypes (Fig **G**). In CD group, mice switching to High or Low BCAA diet displayed minor impacts on body weights, fasting blood glucose, and pain phenotypes (Fig H-J). In HFD mice, switching to High or Low BCAA diet benefited weight loss and fasting blood glucose (Fig K, L). High BCAA diet exacerbated hyperalgesia and postsurgical pain in high-fat feeding mice, whereas lowering dietary BCAA intake alleviated these pain effects (Fig M).

Conclusion(s): High BCAA intake has negative impacts on pain sensitivity and postoperative pain in high-fat feeding mice. Dietary BCAA restriction may be a novel non-pharmacological therapeutic to tackle pain sensitization and postoperative pain in individuals on a conventional high-fat diet.

25AP03-3

Alleviation effect of neuropathic pain by ZEB1 siRNA encapsulated PLGA nanoparticles in rat SNL model

J. Lee¹, Y.K. Ko¹, Y.H. Kim¹

¹Chungnam National University Hospital, Anesthesiology and Pain Medicine, Jung-gu, Korea, Republic of

Background and Goal of Study: Neuropathic pain is a debilitating chronic condition that arises from lesions or diseases affecting the somatosensory nervous system, and it is estimated to affect 7-10% of the global population. This condition has a significant impact on patients' quality of life. Recent studies have revealed the crucial role of the zinc finger E-box-binding homeobox 1 (ZEB1) gene in the development and regulation of neuropathic pain. The Methoxy polyethylene glycol (mPEG)-Poly (D,L-lactic-co-glycolic acid) (PLGA) nanoparticles may be able to cross the blood-brain barrier and reach astrocytes in brain tissue, with even greater delivery efficiency when the astrocyte-specific target ligand is attached to the surface of the nanoparticles.

Materials and Methods: Use spinal nerve ligation (SNL) model. Prior to the surgical procedure, rats were subjected to von Frey filament testing.

only those that met the predetermined baseline (≥10 g) were included.

An animal model of SNL-induced neuropathic pain was established by ligating L5 spinal nerves in rats.

Behavioral assessments were performed.

On post-surgery day 7, mPEG treated ZEB1 siRNA nanoparticles and mPEG treated scrambled siRNA nanoparticles were administered via an intrathecal injection.

Results and Discussion: In the group that received mPEG treated ZEB1 siRNA nanoparticles, mechanical hypersensitivity began to decrease as early as day 4 after injection, with the most noticeable difference observed at day 18 compared to the mPEG treated scrambled siRNA nanoparticle injected group.

c-Fos expression was significantly reduced in the group that received ZEB1 siRNA nanoparticles compared with that in the group that received scrambled siRNA nanoparticles.

Conclusion: A study involving rats with SNL demonstrated that intrathecal delivery of ZEB1 siRNA using mPEG treated PLGA nanoparticles led to a substantial decrease in pain symptoms compared to the control group. Moreover, c-Fos expression in neurons was significantly reduced in the dorsal horn.

These findings suggest that the inhibition of ZEB1 may be an effective strategy for managing neuropathic pain.

However, it is essential to further investigate the multiple factors that may contribute to the reduction in c-Fos expression in neurons.

25AP03-5

The use of intravenous clonidine in postoperative pain management: a scoping review

T. Mohr¹, E.A. Tsuchiya¹, B. Dybdal¹, J. Heiberg¹ ¹Centre of Head and Orthopaedics, Copenhagen University Hospital - Rigshospitalet, Department of Anaesthesia, Copenhagen, Denmark

Background and Goal of Study: Clonidine, an alpha-2 receptor agonist, has been explored as a potential analgesic in postoperative pain management, but its efficacy and safety profile remain unclear.

The aim of this scoping review is to present the evidence on the use of intravenous clonidine in postoperative pain management. Materials and Methods: This scoping review was conducted following the Preferred Reporting Items for Systematic Reviews and Meta-Analyses Extension for Scoping Reviews (PRISMA-ScR). We searched the following databases: The Cochrane Library (CENTRAL), Embase and MEDLINE for studies investigating the use of intravenous clonidine in postoperative pain management on any outcomes or comparators. The extracted data were synthesized descriptively, focusing on pain scores, supplemental analgesia, and adverse effects.

Results and Discussion: We included eight randomized controlled trials. Most patients were ASA I-II and underwent major elective surgery. The studies varied widely in clonidine dosage and timing and combination with other analgesics.

All included studies reported outcome data for pain and supplemental analgesia with high variability in their strategies of assessment. The data showed inconsistency in the efficacy of clonidine in reducing pain scores or the amount of supplemental analgesia. Reported adverse effects were grouped into hemodynamics, respiration, and others and also showed inconsistency across studies.

Only some studies found reductions in pain scores or supplemental analgesics, which were mostly transiently significant.

The heterogeneity in timing and dosage of clonidine administration, as well as varying combination of other analgesics across studies and varying assessment strategies of outcomes on pain scores, supplemental analgesics and adverse effects further complicate the interpretation of results across studies.

Intravenous clonidine may have only limited use as an analgesic but could be considered as part of multimodal pain strategies, particularly for patients with contraindications for other agents, patients suffering from "acute-on-chronic pain", or patients with chronic opioid use.

Conclusion(s): The amount of evidence on the use of intravenous clonidine in postoperative pain management was low. Findings are specific for major elective surgeries with no specific indications for use. The reported evidence shows little effect of clonidine on pain scores and supplemental analgesia.

25AP03-6

Efficacy and safety analysis of the use of Sublingual Sufentanil in the management of acute postoperative pain: an observational study

E. Cuellar Obispo¹, I. Fernandez Gonzalez¹, A. Martinez Marin¹, F. Santos Fernandez¹, J.I. Guadalix Torremocha¹, G. Perez Villarejo¹ ¹Hospital Regional Universitario de Malaga, Servicio de Anestesiologia, Reanimacion y Terapeutica del Dolor, Málaga, Spain

Background and Goal of Study: In recent years, the development of acute postoperative pain treatment has included an individualized approach to the patient, implementation of multimodal strategies and regional anesthesia techniques. At the Hospital Regional Universitario de Málaga, postoperative analgesia has had systematized protocols since 1993. However, it is still a challenge, since severe persistent postoperative pain affects between 2% and 10% of adults undergoing surgery.

The aim of this study is to analyze the real efficacy and safety profile of sublingual sufentanil 30ug (SST30) in clinical practice as a new analgesic alternative in the postoperative period.

Materials and Methods: Cross-sectional observational study. Survey conducted with 15 parameters to be measured to 28 anesthesiologists of the center, evaluating their experience to analyze the efficacy and safety of SST30 with one tablet per dispenser, between 12/2023 and 10/2024. A total of 21 anesthesiologists with experience with the drug were included, treating 235 patients in the postoperative period.

Results and Discussion: A 100% of respondents reported use in spine surgery, followed by 71.4% in thoracic surgery, 57.1% in major abdominal surgery and 52.4% in arthroplasty. A 23.8% and 71.4% reported immediate<5min and rapid<15min onset of action, respectively.

In terms of pain control, the most commonly reported parameter was "good: get mild pain" (81%), followed by "excellent: EVA 0" (19%). A 90.5% considered the usefulness in the analgesic therapeutic arsenal to be 'Essential or highly recommended'.

Side effects were infrequent (nausea and dizziness) and there were no cases of respiratory depression. It has been used in patients with comorbidities such as obesity, heart disease, respiratory, renal and hepatic insufficiency.

Inadequate control of severe pain is associated with delayed ambulation, higher rates of complications, longer postoperative stay and higher risk of developing chronic postoperative pain. SST30 shows clear advantages as a new alternative in the therapeutic arsenal, facilitating the individualization of treatment according to the needs of each patient.

Conclusion(s): Sublingual sufentanil 30 ug, due to its route of administration and pharmacokinetic profile, has proven to be an effective and safe opioid analgesic in the management of postoperative acute pain of moderate to severe intensity, being of special interest in procedures with difficult pain control.

Neuropsychiatric symptoms induced by intrathecal ziconotide: case reports

L. Mora Gomez¹, B. Perolada Beaus¹, M. Llobell Ruvira¹, J.L. Gómez Palonés¹, O. Aznar Millán¹, L. Edo Cebollada¹ ¹Hospital General de Castellón, Anestesiologia, Castellón, Spain

Background: Ziconotide is the only non-opioid analgesic approved by the FDA and EMA for the intrathecal treatment of refractory chronic pain. It blocks N-type calcium channels located in the dorsal horn of the spinal cord. The recommended initial dose is 0.5 to 1.2mcg/day, with weekly increases of 0.5 to 1.0 mcg/day up to a maximum of 19.2mcg/day. Neuropsychiatric symptoms are the most significant adverse effects, often necessitating dose reduction or discontinuation.

Case Report: A 52-year-old woman with a history of malignant pleural mesothelioma and mixed pain in the left T7-10 dermatomes. After implanting an intrathecal morphine pump, ziconotide was added at 1.31mcg/day and titrated to 7.5mcg/day over 11 months, improving pain. However, she developed confusion, auditory hallucinations and delusional persecution. Ziconotide was reduced by 20% and discontinued within 48 hours. Symptoms resolving after 72 hours.

A 68-year-old man with hypertension and severe traumatic brain injury causing cervical myelopathy and paraplegia. He experienced diffuse central neuropathic pain in the thorax and upper limbs. An intrathecal ziconotide pump (1.2mcg/day) was implanted, later combined with baclofen. Ziconotide was titrated over 22 months to 4.02mcg/day with pain relief, but led to somnolence and somatic delusions. Ziconotide was reduced by 25% over one week and then discontinued, resolving psychosis.

A 53-year-old woman with complex regional pain syndrome in the right arm after elbow surgery. An intrathecal morphine infusion pump combined with bupivacaine was implanted. Ziconotide was later introduced as a second adjuvant at 0.6mcg/day, titrated over one year to 6.3mcg/day. She developed auditory hallucinations, persecutory delusions and suicidal ideation. Symptoms subsided following antipsychotic therapy and gradual withdrawal (three weeks) of ziconotide.

Discussion: Intrathecal ziconotide effectively controls refractory chronic pain both as monotherapy and in combination but poses significant neuropsychiatric risks, even with recommended dose and titration. Patient profiles and neuropsychiatric presentations were heterogeneous. Many times, symptom resolution required drug discontinuation.

References:

DOI: 10.1016/j.heliyon.2024.e31105 DOI: 10.3389/fnmol.2024.141285

Learning points: Intrathecal ziconotide is a powerful analgesic but it is necessary to investigate new strategies that prevent and treat the neuropsychiatric symptoms.

25AP03-8

Multimodal management of postoperative pain control in Total Knee Replacement (TKR). Implementation of a protocol

I.A. Becerra¹, S. Heras¹, P. Heredia¹, M. Cormane¹, V. Blanco1

¹Hospital Virgen Macarena, Anestesiologia y Reanimacion, Sevilla, Spain

Background and Goal of Study: Managing postoperative Total Knee Replacement pain remains a major challenge, impacting both clinical recovery and patient satisfaction. TKR pain management protocols vary widely with no current consensus. These strategies aim to optimize pain control while minimizing side effects. They incorporate a range of methods, including nerve blocks, non-opioid analgesics, opioids, and non-pharmacologic techniques such as physical therapy.

However, evidence regarding the efficacy and optimal combinations of these interventions varies widely across studies. The purpose of our study was to present our pain management model, and the preliminary results of its application.

Materials and Methods: The analgesic protocol included:

- 1. Ultrasound-guided Femoral nerve block (single injection): Ropivacaine 0.5%, 20ml plus Dexamethasone 4 mg.
- 2. Single Local Infiltration Analgesia(LIA) (Ropivacaine 0.2%. 80 ml plus Adrenaline administered after bone preparation and before definitive implantation: Inject 40 ml in the posterior capsule and after definitive implantation of the components: 20 ml in the knee extensor apparatus and 20 ml for surgical wound infiltration. The analgesia protocol in the recovery room and on the ward based on the visual analogue scale (VAS).

Mild to moderate pain: Dexketoprofen alternate with Paracetamol. VAS greater than 4: Morphine

Results and Discussion: FNB and LIA with oral medication provided effective analgesia for TKR surgery and reduced the amount of perioperative opioid administration without adverse effects. This analgesia provided improvement in the patient's comfort and satisfaction.

Conclusion(s): Perioperative pain management in patients undergoing TKR is important to improve patient satisfaction, and rehabilitation. Multimodal analgesia should be the best analgesic regimen for this patients.

Global, regional and national burden of migraine among children and adolescent, 1990-2021: evidence from the Global Burden of Disease **Study 2021**

M. Yan¹, G. Luo¹, Y. Yao¹, X. Tao¹ ¹The Second Affiliated Hospital of Zhejiang University School of Medicine, Anesthesiology, Hangzhou, China

Background and Goal of Study: The burden of migraine is increasing and has become the leading neurological cause of disability among children and adolescents aged 5-19. We aim to provide updated epidemiological evidence on the burden of migraine among children and adolescents to inform policy development and promote equitable healthcare management.

Materials and Methods: Using data from the Global Burden of Disease (GBD) Study 2021, we estimated the age-standardized incidence rate (ASIR), prevalence rate (ASPR), and disabilityadjusted life years (DALYs) rate (ASDR), with 95% uncertainty intervals. Stratifications were performed by age, sex, geographic region, sociodemographic index (SDI) quintiles, and nation.

Results and Discussion: In 2021, the global burden of migraine among children and adolescents was estimated at 6.64 million new cases compared to 1990, and a prevalence of 206 million cases (95% UI: 153-269 million). Over the past three decades, ASIR, ASPR, and ASDR for migraine have shown upward trends globally. Females exhibited higher ASIR, ASPR, and ASDR compared to males, although males demonstrated a steeper rate of increase. The highest ASPR and ASDR were observed in low- and middle-SDI countries, while ASIR was highest in high-SDI countries. The burden was particularly pronounced in tropical Latin America, with Brazil experiencing the greatest burden and presenting the largest potential for improvement. Countries with low SDI such as Haiti, Afghanistan, and Yemen, as well as high SDI countries like Belgium, Germany, and Norway, have been identified as having greater potential for improving migraine burden.

Conclusion(s): From 1990 to 2021, the incidence and prevalence of migraine among children and adolescents increased, with a particularly severe impact in low- and middle-SDI countries and tropical Latin America. Targeted public health policies are urgently needed to address these disparities, prioritize vulnerable populations, and advance healthcare equity globally.

25AP03-10

Inhibition of ZIP7 improves diabetic peripheral neuropathy by regulating oxidative stress

C. Wang¹, J. Li¹, Z. Song¹, M. Zhang¹, L. Zhang¹, Y. Yu¹ ¹Tianiin Medical University General Hospital, Aneasthesiology, Heping District, China

Background and Goal of Study: Diabetic peripheral neuropathy (DPN) is the most common complication of T2DM. However, the underlying molecular mechanisms of diabetic neuropathic pain are still poorly understood. In recent years, the role of ZIP7 (zinc transporter, Slc39a7) in insulin resistance and T2DM has received widespread attention. However, there have been no reports on whether ZIP7 is involved in diabetic peripheral neuropathy.

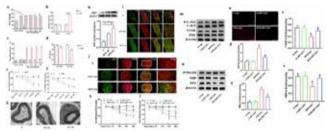

So, this study intends to explore the mechanism of ZIP7 on DPN, and provide new ideas for the treatment of clinical DPN.

Materials and Methods: A rat model of T2DM (DM group) was established by high-sugar and high-fat diet combined with intraperitoneal injection of STZ. Determine the model success. Rats in the DPN 14d and 21d group were randomly selected and sacrificed for ZIP7 and S100β IF staining, ZIP7 mRNA and protein expression. 4 weeks before STZ injection, ZIP7 adenovirus (DPN+ZIP7-AVV group) was injected in sciatic nerve, and the paw mechanical threshold (PWT) and thermal latency (PWL) were measured.

The myelin sheath structure of the sciatic nerve were observed and the expression of ERK, P-ERK, C-JUN, P-C-JUN, MPZ, MBP, and P75NGFR were measured.

Results and Discussion: The body weight was decreased, insulin sensitivity, fasting blood glucose of the DM group increased, and the sciatic nerve transmission rate slowed down, PWT and PWL of the DPN 21d decreased. The myelin sheath of sciatic nerve Schwann cells in DPN 28 group was observed to be loose and destroyed. ZIP7 and S100\beta co-localized in sciatic nerve, and ZIP7 expression increased at 21 days of DPN.

Compared with the DPN group, PWT increased and PWL prolonged in the DPN+ZIP7-AVV group, the sciatic nerve transmission rate was accelerated. And an increase of MBP and MPZ expression, a decrease of p-ERK, p-C-JUN expression, an increase in ROS and MDA production, and a decrease of T-AOC and GSH were observed in DPN+ZIP7-AVV group.

Conclusion(s): Inhibition of ZIP7 expression can improve DPN myelin damage by inhibiting Schwann cell dedifferentiation and mitigate the development of DPN by inhibiting mitochondrial oxidative stress.

Use of DiscoGel® for the treatment of lumbosciatica: case series

I. Moh Martínez¹, J.C. Callejas Rodelas², M.J. García Cebrián², A. Martín Arrabal², M.R. Pretel Lara², D. Díaz Pérez²

¹Hospital Universitario Clínico San Cecilio, Anestesiología y Reanimación, Granada, Spain, ²Hospital Universitario Clínico San Cecilio, Anestesiología, Granada, Spain

Background: Low back pain has an incidence in the general population between 60-90%, of which between 5-40% will radiate to a lower extremity, constituting the condition of sciatica. The causes of this are diverse, with intervertebral disc herniation being the most common etiology (85%) [1].

In the Spanish population, up to 40% of cases require invasive management or surgery.

Currently, DiscoGel® is presented as a non-invasive method for the treatment of symptomatic disc herniation that promises a high success rate.

Case Report: We present a series of cases from our unit in which DiscoGel® was used as a treatment for herniated disc. In all of them, maximum pharmacological treatment was reached and epidural infiltrations with corticoesteroids and local anesthetic were performed, without result.

Discussion: DiscoGel® shows a results rate that is considered very good or good for 91.4% of respondents.

For the effectiveness rate to be high, it is important to properly select the type of hernia on which to use DiscoGel®. The ideal case. it would be a contained hernia, small to medium in size, occupying less than half the diameter of the canal on MRI, with failure of conservative treatment for 4-6 weeks, combined with at least one corticosteroid infiltration [2] [3].

- 2. Bellini M, Romano DG, Leonini S, Grazzini I, Tabano C, Ferrara M, Piu P, Monti L, Cerase A. Percutaneous injection of radiopaque gelified ethanol for the treatment of lumbar and cervical intervertebral disk herniations: experience and clinical outcome in 80 patients. AJNR Am J Neuroradiol. 2015 Mar;36(3):600-5.
- 3. Volpentesta G, et al. Lumbar percutaneous intradiscal injection of radiopaque ethanol («Discogel») in patients with low back and radicular pain. J Pain Relief. 2014;3(145):2167-0846

Learning Points: 3 of the 4 patients treated in our case series had a VAS < or = 3; 3 months after the procedure, and were considered satisfied.

1 of the 4 treated patients had a VAS of 7 at 3 months. He was probably not well selected for the technique. He was the only one who needed subsequent surgery. It was carried without complications thanks to the fact Discogel does not alter the anatomy. A larger sample size, greater technical experience, and longer follow-up are necessary to continue studying the results in our unit.

25AP04-2

Comparison of analgesic efficacy of tramadol, petidine and morphine in the treatment of pain after elective thoracic surgery under the Erector Spina Plan (ESP) block: preliminary results

B.N. Gökdemir¹, S. Issı², F.İ. Yeşiler³, H. Şahintürk¹, M. Yavuz Çolak⁴, A. Torgay¹

¹Baskent University Faculty of Medicine, Anesthesiology and Reanimation, Ankara, Turkey, ²Baskent University Faculty of Medicine, Thoracic Surgery, Ankara, Turkey, ³Baskent University Faculty of Medicine, Intensive Care, Ankara, Turkey, 4Baskent University Faculty of Medicine, Biostatistics, Ankara, Turkey

Background and Goal of Study: Thoracotomy is commonly used but painful procedure in lung surgeries, with prevalence of postthoracotomy pain syndrome ranging from 33% to 91%. Postoperative pain can hinder effective coughing, leading to atelectasis, hypoxemia, and complications. Effective pain management reduces complications and accelerates recovery.

The aim of this study is to compare the analgesic efficacy of tramadol (T), pethidine (P), morphine (M) under ESP block and to monitor their effectiveness using the Analgesic Nociceptor Index (ANI).

Materials and Methods: A single-center, prospective, RCT was conducted between 10/2023-11/2024, involving 50 patients who underwent elective thoracic surgery. After obtaining informed consent, patients were randomly assigned to 3 opioid groups.

In OR, ASA monitoring was applied and ESP block was applied for pain management. Group T received 1 mg/kg loading dose followed by T-PCA. Group M received 0.1 mg/kg loading dose followed by M-PCA. Group P received 1 mg/kg loading dose followed by P-PCA. After ICU admission, ANI monitoring was applied, values were recorded for 48 h.

In the postoperative period, VAS, RASS, PONV, opioid consumption and need for additional analgesics/antiemetics were monitored. Extra analgesics- antiemetics were administered if VAS>4 or PONV >2. Side effects, such as respiratory depression, constipation were recorded.

Results and Discussion: There was no significant difference in intraoperative-postoperative hemodynamic parameters, VAS, PONV, ANI. Opioid consumptions, need for additional analgesic/ antiemetic were similar. A significant difference was found in the RASS (Richmond Agitation Sedation Scale) scores at 12 hours postoperatively (p=0.006).4/14 patients in group T had RASS -1(28.6%), while no patients in group P exhibited this state. For RASS 0, Group P and Group M showed similar results, but there was a significant difference when compared with Group T.

Specifically, 8/14 patients in Group T had RASS 0, while all 15 patients in Group P and 16/18 patients in Group M had RASS 0(88.9%). No significant differences in RASS 1-2 scores between 3 groups.

Conclusion(s): This study is the first to compare 3 opioid groups under ESP block in thoracic surgery. While ANI is more commonly used in intubated patients, there are few studies on its use in awake patients.

In this preliminary analysis, due to its correlation with nociception, ANI may serve as an early indicator for effective pain management before VAS scores increase.

Spatial metabolomics combined with 16S RNA sequencing revealed the effect of gut microbiota on different brain regions in rats with chronic pain-induced cognitive dysfunction

X. Xiaolin¹, B. Jiao¹, C. Yan¹, W. Liu¹, C. Chen¹ Sichuan University, Department of Anesthesiology, West China Hospital, Chengdu, China

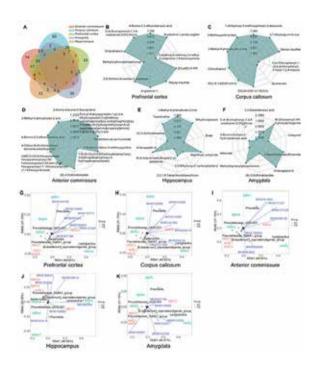

Background and Goal of Study: Under the long-term distress of chronic pain, some patients will have cognitive dysfunction. Gut microbiota was found to be involved in the development of neuropsychiatric disorders.

Materials and Methods: Rats were divided into experimental group with chronic constriction injury (CCI group) and control group (Sham group). Fecal samples were collected on day 21 for 16S RNA sequencing and fecal microbiota transplantation (FMT). The pseudo-sterile rats were transplanted with feces from the CCI and Sham groups, named FC and FS groups accordingly. After FMT, feces from both groups were collected for 16S RNA sequencing, and brain tissues were collected for spatial metabolomics. The metabolite were analyzed in prefrontal cortex, corpus callosum, anterior commissure, hippocampus, and amygdala.

Results and Discussion: 16S RNA sequencing results showed that compared with the Sham group, the structure of gut microbiota in the CCI group was changed. After FMT, rats in the FC group showed decreased pain threshold and impaired cognitive function compared with the FS group. 16S RNA sequencing results showed that there was a significant difference in the composition and structure of gut microbiota between the FS group and the FC group (Figure 1).

Spatial metabolomics showed that after FMT, the levels of metabolites in the prefrontal cortex, corpus callosum, anterior commissure, hippocampus, and amygdala in the FS group and FC group were significantly changed. Unexpectedly, the altered metabolites were different among the five brain region (Figure 2).

Conclusion(s): Gut microbiota was involved in the occurrence and development of chronic pain combined with cognitive dysfunction, and it has different effects on metabolites in different brain regions of the host.

Intraoperative continuous esmolol infusion for perioperative opioid and postoperative pain reduction: a systematic review of randomized controlled trials, meta-analysis and metaregression

E. Neto1, S. Abreu1, M. Sanches1, M.C. Florêncio1, V. Carvalho², F. Thyrso¹

¹Santa Casa de Misericordia de Santos, Anesthesia, Santos, Brazil, 2State University of Campinas, Department of Anesthesiology, Campinas, Brazil

Background and Goal of Study: This meta-analysis evaluated the perioperative analgesic efficacy of intraoperative continuous esmolol infusion (ICEI) compared to placebo in various surgical settings. Given the limitations of previous meta-analyses and the need for opioid alternatives, this study aimed to provide updated evidence.

Materials and Methods: PubMed, Embase, and Cochrane databases were systematically searched using terms related to esmolol. Primary outcomes were postoperative opioid consumption(POC), pain scores, and intraoperative morphine equivalent(ME) requirements. Meta-regression analysis explored correlations between patient ages, surgical complexity, and analgesic outcomes. Effect sizes were summarized as mean differences (MD) with 95% confidence intervals (CI). Statistical analyses were performed using R version 4.X.X

Results and Discussion: A broad search strategy found 641 records. Of the 32 studies screened, 18 RCTs were included, totaling 968 patients (ICEI n=485; control n=483). ICEI significantly reduced POC (MD = -3.07 mg; 95% CI -40.62 to -5.72; I² = 95.4%; p < 0.001) and intraoperative ME (MD = -21.97 mg; 95% CI -40.62 to -3.33; $I^2 = 99.5\%$; p < 0.001). Pain scores were also lower in the ICEI group (MD = -1.43: 95% CI -2.09 to -0.76: I^2 = 98.7%: p < 0.001). Meta-regression indicated a significant association between younger age and reduced POC (p < 0.0438) and between higher surgical complexity and intraoperative analgesic use (p < 0.0001).

Conclusion(s): Esmolol reduces opioid consumption and pain scores when comparated with placebo.

25AP04-5

Quadratus lumborum and piriformis muscle infiltration, a new approach for low back pain in pregnant patients: case reports

R. Pinto de Sá¹, R. Torres¹, D. Pereira¹ ¹ULS de Braga, Anesthesiology, Braga, Portugal

Background: Low back pain (LBP) is a common issue in pregnancy. Postural changes from abdominal and breast enlargement increase lumbar lordosis and paravertebral muscle tension. Weight gain also strains gluteal muscles and the piriformis, potencially compressing the sciatic nerve. This condition impacts physical, social, and economic well-being, with persistent pain in 10% of cases lasting up to 2 years. We report 2 cases of pregnant women with LBP refractory to non-invasive measures.

Case Report: Patient A. a 33-year-old, at 27 weeks' gestation. presented a 4-month history of LBP. The pain, rated 8/10, radiated from her left lower back pain to the left foot, unresponsive to physical therapy and opioid analgesics. Examination revealed tenderness over the left paravertebral trigger points without sacroiliac joint involvement.

Patient B, a 26-year-old obese woman, at 24 weeks' gestation, was admitted for refractory pain following treated renal colic. In this case, the LBP radiated from her right lower back pain to her posterior thigh and only partially improved with optimized medical

In both cases, following informed consent, an ultrasound-guided injection was performed, administering a combination of levobupivacaine and betamethasone into the quadratus lumborum and piriformis muscles.

Patient A reported significant improvement four hours after the procedure, with complete pain resolution by one month, maintaining pain relief until after delivery.

On patient B, the technique resulted in immediate pain relief, with her being discharged three days later, reporting complete resolution of pain.

Discussion: Chronic pain treatment during pregnancy can be challenging due to generalized concerns about analgesic drug use, putting pregnant women at risk of undertreatment. For instance, non-steroidal anti-inflammatory use after 28 weeks of gestation comprises risk of premature ductus arteriosus closure, while opioid use poses potential risks to fetal development and may lead to fetal opioid dependency. A multimodal management of LBP is recommended for optimizing outcomes in pregnant patients. In this case, we suggest an alternative strategyinvolving the targeted infiltration of local anesthetic and corticosteroid into the fascial planes compressing the sciatic nerve.

Learning points: We believe this approach has the potential to provide effective and lasting analgesia for pregnant patients with radicular pain while minimizing side effects.

25AP04-7

The effect of the music therapy model "The **Bonny Method of Guided Imagery and Music** (GIM)" in patients with rheumatoid arthritis and chronic pain. Results of a randomized controlled

G. Nika¹, A. Karakosta², N. Ntalarizou¹, M.P. Ntalouka¹, M. Bareka¹, E. Arnaoutoglou¹ ¹Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa University Hospital. Anaesthesiology, Larissa, Greece, ²Facutly of Medicine, University of Ioannina, Anaesthesiology and Postoperative Intensive Care, Ioannina, Greece

Background and Goal of Study: Current literature suggests that music therapy can alleviate chronic pain through a pleasurable aesthetic experience. We aimed to assess the effect of the music therapy model "The Bonny Method of Guided Imagery and Music (GIM)" on chronic pain in patients with rheumatoid arthritis (RA). Materials and Methods: This prospective randomized trial (NCT04380129) included adult patients with chronic pain due to RA, who were referred to our Outpatient Pain Clinic.

After informed consent, participants were randomized (electronically) either in music therapy-conversation sessions (GIM group) or in music listening only (control group). "Intervention" was defined as "a weekly session of listening to Helen Bonny's Caring program for 4 weeks".

At the beginning of the 1st session and 1 week after the 4th session the Wong-Baker Face Scale Pain Rating Scale (WBS) and the painDETECT questionnaire (PD-Q) were applied. WBS assesses pain with a simultaneous visual, numeric and functional analogue display. PD-Q is a screening tool for neuropathic pain (NP). According to power analysis 33 participants per group were required to improve pain more than 2 points on the WBS scale (probability of 90%).

To counteract for dropouts 37 participants per group were recruited. Linear regression models were used to investigate the statistical significance of the applied therapy on pain. Tests were two-tailed and statistical significance was established at 5% (p<0.05). Data were analyzed using Stata ™ (Version 10.1 MP, Stata Corporation, College Station, TX 77845, USA).

Results and Discussion: Seventy-four patients (37 per group) were included. Groups were homogenous concerning demographical characteristics. According to WBS baseline pain did not differ between GIM and control group (5.89 vs 6.24, p=0.488) before intervention.

However, based on PD-Q baseline NP score differ between GIM and control group (23 vs 26, p=0.033). At the end of intervention WBS was significantly lower in the GIM group compared to controls (-2.3, p<0.001). Moreover, at the end of intervention NP, according to PD-Q, was significantly lower (p<0.001) in the GIM

Conclusion(s): Based on the results of our study, it seems that "GIM" model of music therapy has the potential to lower the pain scores of patients suffering from RA.

25AP04-8

Effect of sphenopalatine ganglion blockage for postoperative pain control in tonsillectomies

C. Horiguchi¹, C. Horiguchi¹, M. Lopes², R. Silva¹, A. Bechara¹, T. Vasconcelos² ¹Rede Mater Dei de Saude, Anestesiologist, Belo Horizonte, Brazil, ²Rede Mater Dei de Saude, Otorhinolaryngologist, Belo Horizonte, Brazil

Background: Tonsillectomy is a highly prevalent surgical procedure in adults and children. For anesthesiologists and otolarvngologists, management of tonsillectomies postoperative (PO) pain has always been challenging. Many of these patients have sleep-disordered breathing or obstructive sleep apnea, making them particularly susceptible to respiratory depression. Requiring the use of opioids, the likelihood of laryngospasm and airway edema increases, which can intensify the respiratory depressive effects. The use of nonsteroidal anti-inflammatory drugs is still debated due to concerns about PO bleeding.

The objective of this report is to demonstrate a new alternative for PO pain control in tonsillectomies.

Case Report: A 32-year-old patient, ASA 3, body mass index 48 and severe sleep apnea submitted to tonsillectomie and sinusectomy. After the procedure, he developed an intense pain (9/10 in the VAS).

After obtaining his consent, we performed a bilateral sphenopalatine ganglion blockage (SPGB). SPGB was performed with 2 cotton swabs soaked into 1ml of Ropivacaine 0,75%. The patient reported important and immediate pain relief (5/10).

Two hours after he reported 1/10 pain and was able to eat a liquid diet normally. He was contacted the next seven days and reported no pain in home.

Discussion: Despite advances in anesthesiology and otolaryngology equipment and techniques, PO pain in tonsillectomy is still a persistent problem. SPGB has attracted the interest of practitioners treating a lot of pain for over a century. Sluder had described the first recorded instance of a remote dysfunction arrested by anesthetization of the SPG in 1903. In 1930 Byrd described observations that have accumulated in the literature on the SPG during the past twenty-five years.

Over the years, this simple and valuable technique has been ignored. When studying SPGB, trends show good results in endoscopic sinus surgeries. However, there is a lack of studies that correlate blockade with tonsillectomy surgery in adults.

The impact of language used prior to the insertion of intravenous cannula on patient experience

E. Edwards¹, J. Mitchell², G. McCreath³, D. Earlie⁴ ¹Kyle Academy, Science, Ayr, United Kingdom, ²University Hospital Ayr, Anaeshtesia, Ayr, United Kingdom, 3University Hospital Crosshouse, Anaesthesia and Intensive Care, Kilmarnock, United Kingdom, 4University Hospital Ayr, Emergency Department, Ayr, United Kingdom

Background and Goal of Study: The use of language can impact the patient experience of pain and discomfort. Nocebo language is a negative suggestion that can cause undesirable effects, such as pain or discomfort. A procedure that is often associated with the used of nocebo language is the insertion of an intravenous cannula, with phrases such as 'sharp scratch' commonly associated with this procedure1.

The nocebo effect is becoming more appreciated, and it is hoped that improved knowledge will have an impact on the use of language. An observational study involving patient questionnaires to see what patients recalled as the intravenous cannula was inserted, level of pain or discomfort they recalled was conducted. The actual words/phrases used were not recorded.

Materials and Methods: Thirteen patients who had a cannula consented to take part in a questionnaire. They were in different locations across the hospital including the Emergency Department (4 patients), Clinical Assessment Units (5) and Day Surgery Units (4).

Patients were asked if they recalled what was said before the cannula was inserted, and then to rate both pain and discomfort scores using a numerical and verbal rating. The data was analysed by pain and discomfort scores in relation to the type of lan-

Results and Discussion: The results were divided into three groups - one that used distraction or neutral techniques (3), a group using phrases with negative connotations (3) and a third group who reported they didn't recall what was said (7).

Pain scores for each group were similar, but discomfort comfort scores were lower in the nocebo group. Most interestingly, the patient who recalled being told that it wouldn't hurt did not report any pain or discomfort.

Conclusion(s): This study does not show significant difference in the interpretation of pain during the insertion of a cannula. The context of the situation may influence their cannulation experience as some patients had been unwell when the cannula was inserted.

Overall, most people did not perceive this procedure as painful, despite the language that they recalled being used however there are cases where patients have specific concerns such as needle phobia which should be considered.

The sphenopalatine ganglion block in the treatment of postdural puncture headache: serie of cases

C. Horiguchi¹, C. Horiguchi¹, R. Silva¹, P.C. Sales¹ ¹Rede Mater Dei de Saude, Anestesiologist, Belo Horizonte, Brazil

Background: Management of post-dural puncture headache (PDPH) has always been a challenge for anesthesiologists. Supportive therapy with symptomatic medications is the initial approach in patients with mild PDPH. Epidural blood patch (EBP) is the gold standard procedure when supportive therapy fails or in cases with severe manifestations. However, it is not a risk-free procedure. Sphenopalatine ganglion block (SPGB) has long been used to treat headaches of different etiologies, and has been suggested as an alternative for the treatment of PDPH.

Case Report: A serie of 52 cases that occurred in 16 months, at the same service in Belo Horizonte, Brazil, will be presented. Of the 52 blocks, 8 occured in patients with PDPH after inadvertent puncture of the dura mater in an epidural attempt. 1 patient underwent prophylactic block, after inadvertent puncture. 43 cases of PDPH occured after spinal anesthesia with a Quinck needle. Of the 8 post-epidural patients, 7 reported satisfactory improvement (decrease of at least 4 points on the pain visual scale). Of the 43 patients after spinal anesthesia, 40 reported a satisfactory improvement.

The patient who underwent prophylactic blockade intraoperatively, after inadvertent perforation, was followed up for 7 days and did not develop headaches or other complaints. 3 patients developed complications possibly associated with SPGB.

In one patient, despite the improvement of headache, there was worsening of diplopia and photophobia. In the other two patients in which SPGB was performed, it occurred an important improvement of pain, however, they evolved with seizures and cerebral venous thrombosis was diagnosed.

Discussion: Some authors state that this is a safe technique and reported successful cases. This treatment proved to be effective in improving headaches, but it does not affect its probable etiology. It may be associated with complications as liquoric hypotension, cerebral venous thrombosis and cranial nerve traction. Anesthesiologists consulted to perform SPGB must always be aware of differential diagnoses and possible variations in PDPH presentations.

Learning points: SPGB is a reliable alternative for treatment of CPPD.

25AP04-12

Determination of postoperative pain intensity in difficult laparoscopic cholecystectomy surgeries

D. Bayram¹, T. Umuroğlu², N. Atalan Özlen², Y. Masatlıoğlu², R. Abdullayev² ¹Sancaktepe Prof. Dr. İlhan Varank Teaching and Research Hospital, Anaesthesiology and Reanimation, İstanbul, Turkey, ²Marmara University, Anaesthesiology and Reanimation, İstanbul, Turkey

Background and Goal of Study: In current practice, laparoscopic cholecystectomy (LC) has become the preferred choice for the treatment of cholelithiasis due to its advantages such as postoperative patient comfort, rapid wound healing, early oral intake, low complication rates, and early discharge. While recommendations for postoperative analgesia following LC are clearly defined, there are no specific guidelines or studies in the literature regarding analgesia for difficult LC cases.

Our study aims to compare the postoperative pain levels between uncomplicated LC and difficult LC cases, and to identify the risk factors influencing postoperative pain.

Materials and Methods: Patients aged 18-80 years with ASA physical status I-II were included in our study. All patients received 4 mL of 0.5% bupivacaine injected into 5 mm trocar sites and 6 mL into 10 mm trocar sites before incision. Insufflation pressure for pneumoperitoneum was set at 10-12 mmHg.

After anesthesia induction, all patients received 8 mg dexamethasone. Thirty minutes before the end of surgery, 1 g paracetamol and 50 mg dexketoprofen were administered as postoperative analgesics. Laparoscopic difficulty was determined according to the Nassar classification.

Patients' NRS scores were evaluated at postoperative 1, 5, 10, 15, and 20 minutes, as well as at 2, 4, 6, 8, 12, 18, and 24 hours. Additionally, pain assessments were conducted using the short form McGill pain scale at 6 and 24 hours.

Results and Discussion: NRS-PACU values were 2.8 (2.4-4) for the easy LC group and 3 (2.35-4.05)

for the difficult LC group (p=0.491). NRS 24-hour follow-up values were 2.1 (1.7-2.6) for the easy LC group and 1.95 (1.3-2.32) for the difficult LC group (p=0.08). There was no significant difference observed in pain levels between the two groups.

Conclusion(s): Our study concluded that difficult LC surgery is not directly associated with higher pain intensity.

25AP05-1

Postoperative neuropathic pain after knee arthroplasty: The role of transitional pain medicine

T. Castanho Santos¹, T.G. Rocha Barros¹, F. Santos¹, L. Gonçalves¹, E. Ferreira¹ ¹Local Health Unit of the Leiria Region, Anesthesiology, Leiria, Portugal

Background: Neurological complications in surgery/anesthesia present challenges in postoperative recovery. Acute pain, specifically neuropathic pain, may persist after surgery, complicating recovery and potentially leading to chronic pain. Effective management prevents long-term disability and enhances outcomes.

Transitional Pain Medicine is key in bridging the gap between acute postoperative care and long-term pain management and reducing the risk for pain chronification.1

Case Report: Male, 70-year-old, ASA III, underwent right total knee arthroplasty under combined spinal-epidural anesthesia, with no complications. The patient remained stable during the intraoperative and immediate postoperative periods. He was discharged 3 days after surgery with adequate pain control.

At home, he developed severe neuropathic pain in the right lower limb (burning pain and cold dysesthesia), from the foot to the inguinal region (L1-S2 dermatomes).

He experienced allodynia and hypoesthesia on the lateral side of the knee, without motor or sphincter dysfunction or symptoms in the contralateral limb.

He was prescribed gabapentin, alpha-lipoic acid supplement, tapentadol, tramadol+paracetamol combination, duloxetine, and metamizole, and referred to the Transition Pain Clinic.

Electromyography revealed sensitive axonal polyneuropathy in both lower limbs. Lumbar CT showed degenerative changes not correlated with the symptoms.

The patient was followed for 7 months, gradually reduced pain medication, and initiated physical therapy. Neuropathic pain symptoms were resolved at discharge.

Discussion: This case highlights the importance of early intervention and specialized care in managing postoperative neuropathic pain.2

This comprehensive approach led to a favorable outcome, emphasizing the tole of Transition Pain Medicine in contemporary pain management.

Learning points: Transition Pain Medicine helps ensuring appropriate follow-up and preventing pain chronification, particularly in patients with risk factors.

25AP05-2

The effect of different background doses of oliceridine PCIA following bone tumor excision: a prospective double-blind randomized controlled trial

X. Lu1, G. Li1, Y. Gao1, W. Liu1, S. Liu1, Y. Guo1 ¹The Affiliated Cancer Hospital of Zhengzhou University & Henan Cancer Hospital, Department of Anesthesiology and Perioperative Medicine, Zhengzhou, China

Background and Goal of Study: Oliceridine, a novel G proteinbiased µ-opioid receptor agonist, is designed for managing acute moderate to severe pain in adults, aiming to offer safer analgesic

This study sought to compare the comprehensive effects of traditional opioid sufentanil and different background doses of oliceridine in patient-controlled intravenous analgesia (PCIA) following bone tumor resection, and to explore the appropriate analgesic regimen of oliceridine.

Materials and Methods: This prospective, randomized controlled trial enrolled 99 patients who underwent elective bone tumor resection under general anesthesia. Participants were randomly assigned into four groups. The control group (Group S) received sufentanil with a PCA dose of 0.04 µg/kg, a lockout interval of 15 minutes, and a background infusion rate of 0.04 µg/kg/h. The experimental group (Group O) received oliceridine with a PCA dose of 0.35 mg and a lockout interval of 6 minutes. Group O was further divided into three subgroups based on the background infusion rates: Group O1 (0 mg/h), Group O2 (0.2 mg/h), and Group O3 (0.4 mg/h). The primary outcome was the 48-hour postoperative activity NRS scores.

Secondary endpoints included resting NRS and Ramsay sedation scores, usage of analgesic pump, rescue situations, adverse events, and patient recovery indicators within 48 hours postop-

Results and Discussion: Significant differences were observed in the 48-h postoperative activity NRS scores among the four groups (P<0.05). Compared to Group O1, in the groups receiving background infusions, activity NRS scores were substantially reduced, with a notably diminished number of PCA compressions. Whereas, analgesic consumption in Group S and O3 was greater than in Group O1(P<0.001).

Compared to Group S, nausea and vomiting were less frequent in Groups O (P<0.05). Additionally, Group O2 demonstrated markedly higher postoperative satisfaction scores and superior recovery indicators than the other three groups (P<0.05).

No statistically significant differences were noted in resting NRS scores, the need for rescue analgesia, or the incidence of other opioid-related adverse events among the four groups (P>0.05).

Conclusion(s): Oliceridine can be safely and effectively utilized for postoperative analgesia in orthopedic patients, providing analgesic efficacy comparable to sufentanil, with a significantly reduced incidence of adverse effects.

A background infusion of 0.2 mg/h offers the optimal balance by reducing opioid consumption, minimizing opioid-related adverse effects, enhancing patient satisfaction, and promoting early postoperative recovery, while maintaining effective analgesia.

25AP05-3

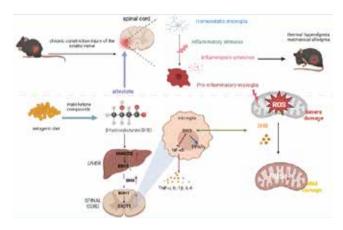

SIRT3 is required for the protective function of ketogenic diet on neural inflammation and neuropathic pain

R. Ding¹, H. Yuan¹

¹Changzheng Hospital, Second Affiliated Hospital of Naval Medical University, Department of Anesthesiology, Shanghai, China

Chronic neural inflammation is the key pathology of neuropathic pain. The ketogenic diet (KD) has been shown to reduce neural inflammation and hyperexcitability in Alzheimer's disease. However, the function and mechanism of KD in neuropathic pain remains unclear.

In this study, we first found that the KD production was decreased upon neuropathic pain induced by chronic constriction injury (CCI). Then we demonstrated that KD effectively alleviated CCI-induced thermal hyperalgesia and mechanical allodynia and relieved neuroinflammation by reducing microglia activation and pro-inflammatory cytokines. β-hydroxybutyrate (BHB), a major component of KD, reduced ROS production by enhancing mitochondrial membrane potential in microglia, thereby decreasing microglia-induced inflammatory responses. In vivo and in vitro experiments revealed that the expression of UCP2. SIRT3 and PGC-1α expression in the spinal dorsal horn was increased by KD. SIRT3-deficiency abolished the protective function of KD on neuropathic pain.

Additionally, SIRT3 deficiency decreased BHB production due to the reduced expression of ketone body synthases in the liver and ketone body-utilizing enzymes in the spinal dorsal horn. These findings suggest that SIRT3 is a promising therapeutic target for neuropathic pain, particularly in the context of a ketogenic diet, which may inspire novel therapeutic strategies.

Evaluation of a machine learning score based on electrocardiographic activities to predict pain during a virtual reality hypnosis session in healthy volunteers

D. Graff^{1,2}, C. Chauvin^{3,2}, F. Grosch⁴, C. Terzulli², M. Oppelt^{5,4}, N. Lang-Richter⁴ ¹Clinique Rhéna, Anesthesiology, Strasbourg, France, ²HypnoVR, R&D, Strasbourg, France, ³CHRU Strasbourg, Anesthesiology, Strasbourg, France. ⁴Fraunhofer Institute for Integrated Circuits IIS. Department Digital Health and Analytics, Erlangen, Germany, 5Friedrich-Alexander-University Erlangen Nuremberg, Machine Learning and Data Analytics Lab (MaD Lab), Department Artificial Intelligence in Biomedical Engineering, Erlangen, Germany

Background and Goal of Study: Clinical gold standard pain assessment is based on subjective methods (visual analogue or numerical scale (VAS)) in case of an awake, fully oriented patient. Automated pain detection from physiological data offers objective insights, especially for sedated patients to better standardize pain assessment. Research on machine learning for pain assessment shows promising results (1).

We choose Electrocardiographic (ECG) data to predict pain in awake, healthy adults during a virtual reality hypnosis (VRH) session (HypnoVR Biofeedback®), using heart rate and heart rate variability (HRV) features to assess sympathetic-parasympathetic balance (2,3).

This study aimed to evaluate a machine learning-based score using ECG activities to predict pain in awake adults.

Materials and Methods: We collected ECG data (BIOPAC or Faros®) from 98 subjects using a VRH during 3 experiments:

- 1, 20 acute heat stimulations and 10 temperature ramps.
- 2. Cold stimuli of increasing intensities.
- 3. Hot and cold stimuli.

We selected 51 subjects who reported a VAS > 3.5. We computed all features over 2-minute sliding windows, with pain stimuli as target variables within that window.

We extracted HR, and time- and frequency-based HRV components as features and trained five XGBoost classifiers. The mean predictive probability of the ensemble served as the pain indication (termed comfort score) where values <0.5 indicate pain.

The dataset was split subject-wise into train and evaluate sets, with 40 subjects for training and 11 for evaluation. We used 5-fold cross-validation within the training set. The test set was used for reporting the score to prevent data leakage.

Additionally, we acquired another set from 22 subjects using VRH during heat stimulation for testing the score.

Results and Discussion: For our balanced non-overlapping test set, we achieved an area under the receiver operating characteristic (AUROC) of 0.68. With a threshold set at 0.5, we detected 66% of records where VAS > 3.5 was induced. We used a VAS threshold of 3.5 to distinguish pain from no pain conditions, considering it before treatment and to try to detect low pain as a start of discomfort.

The additional evaluation set (54.5% women, mean age 28 ± 9.6 years, mean postgraduate education 3.5 ± 2 years) showed that the computed score was <0.5 during the stimulation period for 77% of pain intensity and 88% of pain unpleasantness cases.

Conclusion(s): In this cohort, the comfort score based on machine learning showed good discriminatory capacity for VAS>3.5 in healthy volunteers. Multimodal approaches for automatic pain estimation, especially in clinical settings, show significant improvements when the temporal aspects of the modalities is in-

However, there are limitations in the available public pain databases for optimally supporting deep machine learning model development, validation, and application as decision-support tools in real-life scenarios.

Further studies on patients are needed to validate the effectiveness of pain score based on ECG activities.

Exploring genetic contributions to chronic post-surgical pain: insights from GWAS

A.Y. Peres^{1,2}, R. Unger¹, E. Mangoubi³, M. Salmon-Divon⁴ ¹Bar Ilan University, Computational Biology, Ramat Gan, Israel, ²Rabin Medical Center, Anesthesia, Petah Tikva, Israel, 3Carmel Medical Center, Anesthesia, Haifa, Israel, ⁴Ariel University, Molecular Biology, Ari'el, Israel

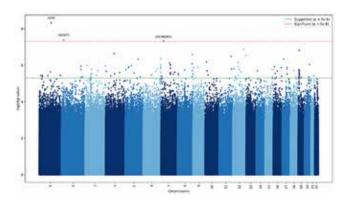

Background: Chronic post-surgical pain (CPSP) affects numerous patients, reducing their quality of life and increasing healthcare demands. While surgical and psychological factors are recognized as risks, the genetic basis in CPSP remains unclear.

This study investigates genetic variations associated with CPSP and aims to develop predictive models for personalized pain man-

Methods: We used the UK Biobank dataset, including genetic and clinical data from participants who underwent major surgeries. Cases were participants with chronic pain after surgery, while controls had similar surgeries but no chronic pain. Quality control ensured sex concordance, limited population substructure to White British participants, and excluded related individuals, Genome-wide association studies (GWAS) were conducted to identify genetic variants associated with CPSP. Clinical factors- age, sex, smoking, alcohol use, and depression history-were analyzed and stratified by group.

Results: Baseline characteristics are summarized in Table 1. Preliminary GWAS analysis identified several loci meeting suggestive (p<5×10-6) and genome-wide significance (p<5×10-8) thresholds, as shown in Figure 1. Three genes (ACP6, HS1BP3, and LOC402641) showed significant variant frequency differences between cases and controls suggesting their role in CPSP pathophysiology.

Feature	Category	Cases	%	Controls	%	P-value
Sex	Male	1,399	57.36	18,764	57.69	0.77
	Female	1,040	42.64	13,762	42.31

	No	816	33.45	10,690	32.86	
	Information					
Total		2,439		32,526		

Conclusion: Our findings demonstrate the potential of genetic data to predict CPSP risk. Understanding these variants may reveal mechanisms underlying chronic pain, particularly after trauma and surgery. Further research should focus on validating these results, developing polygenic risk scores, integrating phenotypic data, and testing models in diverse populations.

Acknowledgments: This research has been conducted using the UK Biobank Resource under Application Number 164591.

The effect of the use of NMDA antagonists on the reduction of postoperative pain

M. Stojanovic^{1,2}, P. Stevanović^{3,2}, S. Vučković^{4,2}, M. Đurić^{5,2}, I. Nenadić^{3,2}, S. Bojić^{5,2} ¹Institute for Cardiovascular Diseases Dedinje, Clinical Department for Anesthesiology and Intensive Therapy, Belgrade, Serbia, ²University of Belgrade, Medial Faculty, Belgrade, Serbia, 3Clinical Hospital Center Dr Dragiša Mišović Dedinie. Clinic for Anesthesiology and Intensive Therapy, Belgrade, Serbia, 4Clinical Center Serbia, Institute of Pharmacology, Belgrade, Serbia, ⁵Clinical Hospital Center Dr Dragiša Mišović, Clinic for Anesthesiology and Intensive Therapy, Belgrade, Serbia

Background and Goal of Study: Pain is a complex entity with a harmful effect on the whole organism. The aim of the study is to examine the impact of preemptive administration of a bolus dose of ketamine and continuous infusion of ketamine and a bolus dose of magnesium sulfate on reducing the intensity of postoperative pain after laparoscopic operations for colon tumors.

Materials and Methods: A prospective study was conducted in 60 patients undergoing elective laparoscopic tumor surgeries. Patients were classified into one of three groups using simple randomization: ketamine-magnesium group (KM), magnesiumketamine group (MK), control group (C).

After introduction to anesthesia, patients in the KM group first received an intravenous bolus dose of 0,5 mg/kg ketamine, and then a continuous infusion of 0,6 mg/kg/h until near the end of the operation, after the bolus dose of ketamine they received magnesium sulfate 20 mg/kg in i.v. infusion (5-10 minutes).

Group MK received magnesium sulfate 20 mg/kg in i.v. infusion (5-10 min) and then ketamine in bolus and i.v. infusion in the same doses and in the same way as the KM group.

Group C received an infusion of 0.9% NaCl instead of ketamine or magnesium solution. Pain was assessed by reading the VAS scale. A VAS above 4 was determined for the administration of the analgesic ketorolac 30 mg, if after an hour the VAS was still above 4, tramadol 100 mg was administered.

A comparison was made of the VAS score between the studied groups and the total consumption of tramadol and ketorolac 48 h after the surgery.

Results and Discussion: Group mean values of VAS differed (p <0,0005), there is a statistically significant influence of time. It was proven that the level of pain in the examined groups differed statistically (p = 0,0005), the lowest level of pain was in the KM group, slightly higher in the MK group and the highest in the C group.

The multivariate test of changes in VAS scores by examined groups showed a statistically significant difference between KM and C group (p <0,000), as well as between MK and C group (p <0,002).

Differences in the consumption of ketoprofen and tramadol showed high statistical significance (p < 0,002). The highest consumption was in the C group and the lowest in the KM group.

Conclusion(s): Preemptive administration of ketamine and magnesium sulfate reduces the intensity of pain upon awakening as well as the cumulative consumption of tramadol and ketoprofen.

25AP05-8 Adults' experiences of perioperative opioid use: a mixed-methods study

D. Aljohani^{1,2}, R. Adam¹, P. Forget^{3,4} ¹University of Aberdeen, Institute of Applied Health Sciences, Academic Primary Care Group, Aberdeen, United Kingdom, ²Prince Sultan Military College of Health Sciences, Department of Anesthesia Technology, Dhahran, Saudi Arabia, 3University of Aberdeen, Institute of Applied Health Sciences, Clinical Chair in Anaesthesia. Epidemiology Group, University of Aberdeen Honorary Consultant, NHS Grampian, Aberdeen, United Kingdom, ⁴Aberdeen Royal Infirmary, NHS Grampian, Department of Anaesthesia, Aberdeen, United Kingdom

Background: As clinical perioperative pain management recommendations evolve and focus on patient-centred approaches it becomes important to understand how adults perceive and experience opioid use. Our scoping review highlighted several perioperative factors influencing opioid use but also identified a gap in studies specific to European populations. We aim to explore adults' multifaceted experiences with perioperative pain management, particularly examining the biopsychosocial factors. This ongoing study is part of a European project Pain and Opioid After Surgery.

Methods: It utilises a sequential explanatory mixed-methods approach

Phase 1 A telephone survey is conducted 14 days after surgery employing the IPO-Q designed to evaluate various aspects of pain outcomes, the data are analysed using descriptive statistics to guide the subsequent phase

Phase 2 interviews are conducted 3 months postoperatively to understand perioperative experiences better. Interviews address topics: perceptions of postoperative pain, goals, SDM and communication with healthcare staff. The data is subjected to an inductive thematic analysis and deductively mapped to the Theoretical Domains Framework (TDF). Findings are integrated to produce a comprehensive synthesis.

Results in tables:

Phase 1 Findings	Value/Description
Total participants	114
Feelings of helplessness and anxiety postoperatively	>60% of participants reported feelings of helplessness and anxiety after surgery
Need for additional pain Rrlief	20% (n=23), with the majority being female (n=14)
Average age of participants	61 years (SD = 15.88)
Gender distribution	49% females (n=56), 51% males (n=58)
Mean worst pain score	6 (SD = 3; 95% CI: 5.5 to 6.5)
Mean satisfaction with postoperative pain management	8 (SD = 2; 95% CI: 7.8 to 8.7)
Preoperative chronic pain	46% (n=55) reported having chronic pain before surgery
Involvement in pain treatment decisions	75% (n=85) reported being involved in decisions about pain treatment
Involvement in decision-making (Elective Surgeries)	73% (n=77) of participants in elective surgeries were more involved in decisions about pain management
Statistical significance	A significant association between involvement in decision-making and satisfaction (p = 0.0)

Phase 2 Findings	Value/Description		
Number of interviews conducted	15		
Shared Decision-Making (SDM)	Many interviewees were unfamiliar with the concept of shared decision-making despite survey claims. This discrepancy raises questions about whether reported involvement truly reflects shared decision- making practices.		
Pain management perceptions	Most patients felt pain was adequately managed		
Concerns about opioid use	Concerns about opioid dependence and side effects (e.g., drowsiness, nausea) were commonly reported		
Factors influencing pain treatment experiences	Preoperative education, effective communication, and positive relationships with healthcare providers influenced pain management perceptions		

Conclusion: A deeper understanding of the psychological social and contextual factors influencing adults' experiences is anticipated through more thematic analysis to help develop strategies to optimise pain management, enhance satisfaction and promote more meaningful shared decision-making in clinical settings.

25AP05-9 Stellate ganglion block as a treatment for post-traumatic stress disorder: a case report

A. Masoodi^{1,2}, O. Reshetnik¹, Y. Ivashvna¹, D. Dziuba^{1,2} ¹Kyiv Regional Clinical Hospital, Anesthesiology, Intensive Care and ED, Kyiv, Ukraine, 2Shupyk National Healthcare University of Ukraine, Department of Anesthesiology and Intensive Care, Kyiv, Ukraine

Background: The reported incidence of posttraumatic stress disorder (PTSD) is increasing - in part, due to improved recognition, but also as a result of recent large-scale military and civilian traumatic events in the world as Russian invasion in Ukraine. Enduring a trauma and then having to relive it through nightmares, flashbacks, and anxiety attacks is a terrifying experience. In early October 2022, an international research group conducted a survey, according to which 25.9% of respondents from Ukraine had symptoms of "probable PTSD."

This case report demonstrate our successful treatment of acute symptoms of PTSD.

Case Report: A 36-year-old male was the victim of an military conflict (War) at Ukraine. He received mine-blast injury of the lower extremities.35 days he was on treatment at the hospital. He denied intensive physical pain but reported having sporadic attacks of nausea, shaking, loss of appetite and insomnia. 20 days post trauma patient complained symptoms and he was evaluated by psychologist.

The medications which was prescribed by psychologist were not providing much relief. He had experiencing insomnia and nightmares and noted that his presentation was tearful and marked by extreme anxiety and vigilance. Based on these complaints and medical history psychologist diagnosed PTSD.CAPS-5 Scale was equal to 42. Patient had received 2 interventions- Stellate ganglion block (SGB) at 0 and 2 weeks.

To determine whether paired SGB treatments at 0 and 2 weeks would result in improvement in mean CAPS-Scale for DSM-5 (CAPS-5) total symptom severity scores from baseline to 8 weeks should drop of 10 or more points.

Discussion: After the SGB, the patient experienced a major reduction in anxiety. Over the next week his improved allowing a significant reduction of antianxiety medications. Clinician Administered PTSD Scale (CAPS-5) level reduced.

References:

1. Rae Olmsted KL, Bartoszek M, Mulvaney S. Effect of Stellate Ganglion Block Treatment on Posttraumatic Stress Disorder Symptoms: A Randomized Clinical Trial. JAMA Psychiatry. 2020 Feb 1:77(2):130-138.2. Wang D. Image Guidance Technologies for Interventional Pain Procedures: Ultrasound, Fluoroscopy, and CT. Curr Pain Headache Rep. 2018 Jan 26;22(1):6.

Learning Points: Multiple CNS structures that are neuronally connected to the SNS appear to play a role in the onset and maintenance of PTSD. We report that selective blockade of the stellate ganglion relieved our patient's symptoms of PTSD.Further trials should be there.

25AP05-10

Swimming partially relieves chronic pain after thoracotomy via µ-opioid receptors in rats

A.-K. Chou^{1,2}, Y.-W. Chen³

¹China Medical University Hospital, Department of Anesthesiology, Taichung, Taiwan, 2China Medical University, School of Medicine, College of Medicine, TaichungTT, Taiwan, 3China Medical University, Department of Physical Therapy, College of Health Care, Taichung, Taiwan

Background and Goal of Study: The purpose of this experiment was to utilize swimming exercise for the treatment of chronic pain after thoracotomy and to investigate the mechanism of action, including cytokines in the intercostal nerve and the effect of naloxone.

Materials and Methods: The experiment was divided into, shamoperated group, sham-swimming group, thoracotomy group, and thoracotomy-swimming group. Sprague-Dawley rats were trained to swim in water at a temperature of 37°C, seven days per week for four weeks. Behavioral responses to pain were measured using von Frey and acetone tests on day 1 after exercise, day 28 after exercise, and the day after 28 days of exercise, compared to naloxone injections. Cytokine levels were analyzed in the intercostal nerves of the four groups.

Results and Discussion: Increased force threshold and decreased cold sensitivity (scratches/min) in thoracotomy-swimming rats from day 14 to day 28 after swimming training. Naloxone injection (1 mg/kg) partially suppressed force threshold and increased cold sensitivity in thoracotomy rats. Swimming exercise suppressed tumor necrosis factor-alpha and interleukin-6 overexpression in intercostal nerves after thoracotomy.

Conclusion(s): The results showed that swimming exercise improves mechanical and cold allodynia after thoracotomy, while naloxone injection partially inhibits the analgesic effect of swimming exercise. Swimming exercise can reduce chronic pain after thoracotomy, which may be related to the inhibition of pro-inflammatory cytokine overexpression in intercostal nerves and activation of mu opioid receptor.

High-dose intravenous zinc sulfate effectively reduced electric shock and needle prickling pain in patients with postherpetic neuralgia: a retrospective study

J.-Y. Chen^{1,2}, W.-C. Liu¹, L.-C. Wu³

¹Chi Mei Medical Center, Anesthesiology, Tainan, Taiwan, ²National Sun Yat-Sen University, School of Medicine, College of Medicine, Kaohsiung, Taiwan, 3Chi Mei Medical Center, Precision Medicine, Tainan, Taiwan

Background and Goal of Study: Postherpetic neuralgia (PHN) is characterized by various pain. Zinc deficiency leads to neuropathy due to loss of inhibition on NMDA receptors. Zinc deficiency is a risk factor for the development of PHN. We reported the successful treatment of PHN with high-dose intravenous zinc sulfate in two cases. Thus, intravenous zinc was often used to manage PHN in our pain clinic.

This retrospective study was aimed to investigate the associations between serum zinc status and pain characteristics was well as the analgesic efficacy of intravenous zinc in PHN.

Materials and Methods: PHN patients in our pain clinics underwent regular serum zinc assessments (normal range: 70-120 mcg/mL) starting in 2016. Patients routinely completed pain evaluation and answered the DN4 questionnaire. Patients were divided into two groups (serum zinc deficiency and sufficiency) using a cut-off of 70 mcg/mL. Demographic characteristics, zoster immunity, and the rate of each item in the DN4 were compared between the two groups.

Intravenous zinc (elemental zinc 5 mg/mL, 10 mL) was administered three times within two weeks following the first clinic visit. Pain scores and pain characteristics were assessed at the second clinic visit. Adult PHN Patients with serum zinc data and pain clinic visit ≥2 during the study period were selected form Hospital records.

Results and Discussion: 87 patients were selected. The distribution of serum zinc status was as follows: 35 patients had deficiency (<70 mcg/mL), 52 had sufficiency (70-120 mcg/mL), and none had excess (>120 mcg/mL). Proportions of the ten items in the DN4 questionnaire indicated that zinc-deficient patients experienced greater incidences of electric shock and needle prickling pain compared to zinc-sufficient patients (p = 0.037; 0.001).

A total of 150 mg of intravenous zinc effectively relieved electric shock and needle prickling pain in 65 PHN patients (74.7%) with a decrease in pain score of ≥2. Among the 22 non-responders, 16 patients had positive VZV IgM levels, indicating current or recent infection. Zinc supplementation effectively reduced neuropathic pain. However, patients with positive VZV IgM did not respond to zinc therapy.

Conclusion(s): Compared to PHN patients with serum zinc sufficiency, zinc-deficient patients had greater incidences of electric shock and needle prickling pain. Intravenous zinc effectively relieved pain in PHN. A well-designed prospective study using intravenous zinc is required to confirm these findings.

25AP05-12

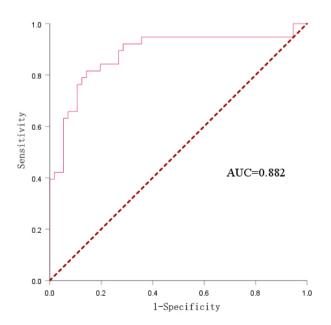

The association between preoperative pain threshold and the incidence of chronic postoperative pain in patients undergoing thoracoscopic pneumonectomy

F. Wang^{1,2}, Y. Zhu^{3,4}, F. Peng², T. Zhu¹, G. Chen¹ ¹West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China, 2Sichuan Provincial People's Hospital, University of Electronic Science and Technology of China, Department of Anesthesiology. Chengdu, China, 3State Key Laboratory of Complex Severe and Rare Diseases, Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Emergency Department, Beijing, China, 4Sichuan Clinical Research Center for Cancer, Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, Affiliated Cancer Hospital of University of Electronic Science and Technology of China, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: The early identification of patients at elevated risk for developing chronic postsurgical pain (CPSP) is crucial for mitigating the persistence of postoperative pain. This study aimed to investigate the potential of Pain Threshold (PT) as a predictive measure for identifying individuals at high risk of developing CPSP undergoing thoracoscopic pneumonectomy.

Materials and Methods: One hundred patients of both sexes, aged 18-75 yr, with body mass index of 18-35 kg/m², of American Society of Anesthesiologists Physical Status classification I or II, scheduled for thoracoscopic pneumonectomy at West China Hospital of Sichuan University from December 2019 to February 2020, were selected. The pain threshold was measured using Pain Vision at 1 day before surgery. Telephone follow-up was implemented by a pain questionnaire to assess CPSP (numerical rating scale score ≥1) at 3 months after surgery.

Multivariate logistic regression was used to identify the risk factors for CPSP, and the receiver operating characteristic curve was used to evaluate the accuracy of preoperative pain threshold in predicting CPSP.

Results and Discussion: Ninety-four patients were finally enrolled, of which 38 cases (40%) developed CPSP. The results of multivariate logistic regression analysis showed that low preoperative pain threshold was an independent risk factor for CPSP (OR=0.899, 95% confidence interval 0.854-0.946, P<0.001). The area under the receiver operating characteristic curve was 0.882 (95% confidence interval 0.804-0.960), Youden Index was 0.673, the sensitivity was 0.816, and the specificity was 0.857.

Conclusion(s): Low preoperative pain threshold is an independent risk factor for CPSP, and preoperative pain threshold can predict the occurrence of CPSP in the patients undergoing thoracoscopic pneumonectomy.

False positives with standard error-based funnel plots for assessing small-study effects: a systematic review and case study in non-opioid analgesics

B. Doleman¹, C. Eve¹, J. Lund¹, J. Williams¹ ¹University of Nottingham, School of Medicine, Derby, United Kingdom

Background and Goal of Study: Funnel plots are used in the assessment for small-study effects in meta-analyses. Concerns have emerged over the use of standard error-based assessments due to the risks of type I errors, especially in pain meta-analyses¹.

Materials and Methods: We performed a systematic review of studies assessing sample size versus standard error-based funnel plots and publication bias tests. Results are reported narratively. We applied the method to the outcome of morphine consumption for alpha-2 agonists to demonstrate the issue using a funnel plot and Egger's regression test. All analyses were conducted in R.

Results and Discussion: We included 16 studies. Overall, there were concerns over excessive type I errors with outcomes expressed as standardised mean differences, odds ratios and proportions. For morphine consumption data, there were also excessive type I errors for mean difference outcomes where efficacy is predicted by baseline risk (control group morphine consumption). When evaluating morphine consumption for alpha-2 agonists, funnel plot asymmetry was observed with a P=0.004 when using standard errors. Therefore, we are uncertain whether this result represents evidence of publication bias or a type I error.

Conclusion(s): Standard error-based funnel plots may lead to type I errors with a number of different effect estimates relevant to acute pain trials. We suggest alternative Y axis specifications such as sample size-based plots and tests.

References:

1. Doleman B, Freeman SC, Lund JN, Williams JP, Sutton AJ. Funnel plots may show asymmetry in the absence of publication bias with continuous outcomes dependent on baseline risk: presentation of a new publication bias test. Research Synthesis Methods 2020; 11(4): 522-34.

25AP06-4

Pain neuroscience education on disease severity and cognitive function in patients with fibromyalgia: preliminary findings of a randomized controlled trial

P.-S. Tsai¹, Y.-A. Lu¹, Y.-H. Yeh¹, C.-J. Huang² ¹Taipei Medical University, School of Nursing, College of Nursing, Taipei, Taiwan, ²Taipei Medical University, Department of Anaesthesiology, School of Medicine, College of Medicine, Taipei, Taiwan

Background and Goal of Study: The study firstly aimed to determine the effectiveness of a nurse-led Pain Neuroscience Education (PNE) program designed by a multidisciplinary team, compared with an active control group on disease severity and cognitive performance in patients with fibromyalgia.

Secondly, we explored PNE-induced changes to the brain waves in patients with fibromyalgia.

Materials and Methods: This randomized controlled trial enrolled participants who met the 2016 American College of Rheumatology diagnostic criteria for fibromyalgia. Eligible participants were randomly assigned to a 6-week PNE group and a self-management education group of equal duration.

Fibromyalgia severity was assessed using the Fibromyalgia Impact Questionnaire-Revised (FIQR). Sustained attention was determined by Psychomotor Vigilance Test (PVT). Brain waves were assessed using quantitative electroencephalography (QEEG).

Resting-state EEG measurements with eyes closed were taken for 10 min using the BrainMaster Discovery 24 EEG device (Brainmaster Technologies, Inc., Bedford, OH, USA) and five minutes of artifact-free EEG were used in this study.

All measurements were taken at baseline and after the 6-week PNE program. Preliminary analyses of between-group differences were estimated by calculating Cohen's d for effect size.

Results and Discussion: Preliminary data from 7 participants were analyzed. Differences in PVT mean reaction time and lapses between participants with high disease severity (n =3) and those with moderate severity (n = 4) showed large effect sizes (Cohen's d = 0.99 and 1.09, respectively). A large pretest-to-posttest effect (Cohen's d = 1.85) in reductions of FIQR was observed for the PNE group.

Large effect sizes were demonstrated for increases in alpha and gamma brain waves after 6 weeks of PNE (Cohen's d = 0.84 and 0.85, respectively).

Conclusion(s): Fibromyalgia severity was associated with impaired sustained attention. PNE shows promising effects for improving disease severity and cognitions.

Acknowledgements: This study was supported partly by the grant (grant No.: NSTC 112-2314-B-038-143-MY3) from the National Science and Technology Council, Taiwan.

25AP06-5

Chemical ablation of genicular nerves with 95% ethanol for pain relief and quality of life in patients with knee osteoarthritis: a prospective, double-blinded, randomized, controlled trial

M. Reysner¹, T. Reysner¹, G. Kowalski¹, M. Grochowicka¹, A. Mularski², K. Wieczorowska-Tobis¹ ¹Poznan University of Medical Sciences, Palliative Care, Poznan, Poland, ²University of Zielona Góra, Department of Forensic Medicine. Institute of Medical Sciences Collegium Medicum, Poznan, Poland

Background and Goal of Study: Knee osteoarthritis (gonarthrosis) can cause significant pain, particularly in elderly patients who may not achieve adequate relief with NSAIDs, paracetamol, or coanalgesics.

This study aimed to evaluate the efficacy of ultrasound-guided chemical ablation of genicular nerves using 95% ethanol in reducing pain and opioid consumption and improving quality of life in this population.

Materials and Methods: This single-center, randomized, controlled, double-blind, non-inferiority study was conducted at the Pain Treatment Clinic, Transfiguration of Jesus Clinical Hospital, Poznan University of Medical Sciences. One hundred patients aged 65-92 years with advanced gonarthrosis (K-L grade 3 or 4) and pain scores (NRS >3) unresponsive to standard treatments were randomized into two equal groups: the neurolysis group (n=50), receiving ultrasound-guided ablation of genicular nerves with 4 x 0.5 ml of 95% ethanol, and the sham group (n=50). Pain scores were assessed as the primary outcome at 7 and 30 days, 3 and 6 months post-procedure. Secondary outcomes included quality of life scores (EQ-5D-5L), opioid consumption, and incidence of neurological complications.

Results and Discussion: The neurolysis group showed significantly reduced NRS pain scores and total opioid consumption compared to the sham group at all time points (p<0.0001). Quality of life scores on the EQ-5D-5L were also higher in the neurolysis group across all measured intervals. Notably, no neurological deficits were observed in either group at any time point, underscoring the safety of this procedure in elderly patients with gonarthrosis.

	Control group (n=50)	Neurolysis (n=50)	p-value
NRS – 7 days after procedure	6.70 (0.89)	3.00 (0.78)	<0.0001
NRS – 30 days after procedure	6.58 (0.78)	2.74 (0.69)	<0.0001
NRS – 3 months after procedure	6.44 (1.03)	2.90 (0.76)	<0.0001
NRS – 6 months after procedure	6.84 (1.00)	3.1 (0.74)	< 0.0001

		Control group (n=50)	Neurolysis (n=50)	p-value
	7 days after procedure	31.90 (18.58)	3.15 (5.27)	<0.0001
Total Opioid	30 days after procedure	31.60 (18.73)	2.70 (5.20)	<0.0001
Consumption	3 months after procedure	32.05 (18.40)	3.00 (5.46	< 0.0001
(miligrams of oral morphine per day)	6 months after procedure	33.70 (20.15)	3.30 (5.70)	<0.0001

Conclusion(s): Ultrasound-guided chemical ablation of genicular nerves with 95% ethanol offers a safe, effective approach to managing severe pain in knee osteoarthritis, reducing pain and opioid use, and enhancing quality of life without causing neurological deficits.

25AP06-6

Dorsal root ganglion stimulation for the treatment of chronic pelvic pain - serie cases

L.A.d. Farias¹, P.d.S. Campos¹, R.H. Cristo¹, F.C. Gaspar², G.J.R.d. Oliveira3, J.L.d. Campos4

¹Vera Cruz Hospital, Anesthesiology, Campinas, Brazil, ²Vera Cruz Hospital, Pain, Campinas, Brazil, ³Vera Cruz Hospital, Chief Executive Officer Anesthesia Care Group, Campinas, Brazil, 4Vera Cruz Hospital, Chief Executive Officer Adora Clinic - Pain Institute, Campinas, Brazil

Background: Chronic Pelvic Pain (CPP) is a heterogeneous neuropathic condition that has historically been difficult to treat. The DRG stimulator (DRGS) allows for more precise localization than the conventional spinal cord stimulators.

This case series aims to report clinical information from patients treated with DRGS, aiming to expand evidence favorable to the use of this device in the treatment of CPP of different etiologies, refractory to conventional treatments.

Case Report: This case series describes five patients with severe CPP who did not respond to a variety of pharmacological and interventional treatments. All five patients underwent successful implantation of the DRGS.

MEMS, 66 years old, with pain in the perineum and pubis radiating to the soles of the feet, after radiotherapy for uterine cancer. JNS, 27 years old, reported colicky hypogastric pain associated with interstitial cystitis and endometriosis.

JBS, 48 years old, with a history of Peyronie's disease and excruciating penile pain.

AMSF, 37 years old, with endometriosis and pain in the infraumbilical abdominal wall and vagina.

PARZ, 44 years old, with pain in the urethra and pelvic abdomen after natural delivery with forceps.

Following treatment, all these patients experienced significant pain relief, as well as reduced opioid consumption and experienced significant improvements in quality of life and continue to report sustained pain relief with high satisfaction and functional improvement.

Discussion: The CPP developed by these patients had different etiologies, with involvement of different nerve roots according to clinical evaluation. It was decided to implant the DRGS in an individualized and targeted manner based on the clinical information of each patient. This result is opposite to the case series reported by Hunter¹ who suggested a single electrode configuration in L1-S2 despite treating CPP of different locations.

Reference:

Hunter, CW; Yang, A. Dorsal Root Galglion Stimulation for Chronic Pelvic Pain: A Case Series and Technical Report on a Novel Lead Configuration. Neuromodulation: Technology at the Neural Interface, 2018; 22: 87-95.

Learning Points: Our case series demonstrates that the DRGS can be a reproducible and effective therapeutic option for controlling CPP refractory.

However, larger comparative studies are needed to establish future standards for DRGS in managing CPP. We advocate for individualized implantation, considering the patient's symptoms.

25AP06-7 Complex pain scale for combat injuries (CPSCI)

O. Aivardzhi¹, D. Dziuba²

¹Communal Enterprise "Dnipropetrovsk Regional Clinical Hospital named after I.I. Mechnikov" of the Dnipropetrovsk Regional Council, Department of Anesthesiology for the Provision of Emergency Medical Care with Polytrauma Intensive Care Beds, Dnipro, Ukraine, 2National University of Health Protection of Ukraine named after P.L. Shupyka, Department of Anesthesiology and Intensive Care, Kyiv. Ukraine

Background and Goal of Study: Now, the problem of assessing the intensity of pain syndrome and analgesia in combat wounds is very important and occupies a central place both in our country and around the world. There are many different pain scales. But the existing scales for determining the level of pain syndrome in the wounded need to be developed and improved. Therefore, the aim of our study was to create a new scale for the assessment of pain in wounds.

Materials and Methods: During the full-scale Russian-Ukrainian war a study was conducted, which included 80 wounded people aged 18 to 60 with combat mine-explosive injuries received during the last day. Patients are divided into 2 groups of 40 people each - group 1 and group 2.

In group 1, a numerical pain assessment scale was used to assess the pain syndrome of conscious patients, and for patients with impaired consciousness or under sedation, a pain assessment scale during emergency medical care was used.

In group 2, we additionally used Complex pain scale for combat injuries. For the wounded in a state of hemorrhagic or traumatic shock, a correction factor of + 4 points is introduced.

Points	0	1	2
Indicators			
Heart rate, beats/min	55 – 85	85 – 110	110 and more
Mean arterial pressure, mm Hg	70 - 110	110 - 120	120 – 130 and more
Level of glucose in blood plasma, mmol/l	3,5 – 5,5	5,5 - 10	10 and more
Moisture of the skin	Dry skin	Moist skin	Very moist skin
The nature and extent of damage to tissues and organs	Minor gunshot shrapnel blind wounds	Significant damage to 1 organ or limb	Significant damage to several limbs or limbs and organs
Anamnesis of analgesia	Regional analgesia and/ or neuraxial analgesia and/or NSAIDs and/or acetaminophen and/or opiates and/or ketamine	NSAIDs and/or acetaminophen	Without analgesia

Table.

Interpretation: 0 - without pain; 1 - 4 points - mild pain, 5 - 8 points moderate pain, 9 - 12 severe pain, 13 - 16 unbearable pain.

Results and Discussion: We found that the patients of group 2 had more stable hemodynamics and glucose levels during the anesthesia stage and during wound dressing or at the traumatic moment of the operation. The level of pain syndrome according to the numerical pain assessment scale on the 2nd and 3rd day of stay in ICU was lower in group 2. The time of stay in ICU was also shorter in patients of group 2.

Conclusion(s): In this way, the provided scale allows to evaluate and objectify the manifestations of pain syndrome in injuries and provides an opportunity for a more qualitative and personalized approach to analgesia for each patient. However, the question of adequate assessment of pain in injuries remains open and requires further research and study.

25AP06-8

Astrocytes specifically enhance the SST interneurons-dependent synaptic transmission in VTA to induce depression in a mouse model of chronic neuropathic pain

C. Zhou¹, M. Ou¹, Y. Chen¹ ¹West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: Approximately 50%-85% of the chronic pain patients experience depression. Ventral tegmental area (VTA) GABAergic neurons play a crucial role in regulating emotions, and mainly classified into somatostatin (SST) and parvalbumin (PV) expressing neurons.1

Inward rectifying potassium channel 4.1 (Kir4.1) is an important potassium channel mainly expressed in astrocytes. Kir4.1 in lateral habenula (LHb) is upregulated in lipopolysaccharide (LPS)induced depression; and Lys05 (an inhibitor of Kir4.1) reversed the depression-like phenotype.2-3

However, it is unclear that how Kir4.1 change in chronic pain-induced depression.

Materials and Methods: Chronic constriction injury (CCI) model was used to induce chronic pain in mice, and depressive behaviors and effects of Lys05 were tested. The adeno-associated virus (AAV) was designed to knockdown or overexpress Kir4.1 in VTA astrocytes. Patch-clamp recording was applied to explore the effects of Kir4.1 on the excitability of VTA neurons. Specific activation of VTA GABASST or VTA GABAPV neurons by optogenetics was used to explore the role of neuronal subtypes.

Results and Discussion: Expression of Kir4.1 was decreased in VTA in the CCI-induced depression mice. Lys05 reversed the depressive behaviors induced by LPS; but produced no treatment to the depressive behaviors by chronic pain. The mice became depression after knockdown of Kir4.1 in VTA astrocytes.

Correspondingly, overexpress of Kir4.1 in VTA astrocytes reversed the depressive behaviors by chronic pain. Knocking down Kir4.1 in VTA astrocytes decreased excitability of dopaminergic neurons. Specifically inhibiting VTA GABASST neurons, but not GABAPV neurons, significantly rescued the depressive behaviors in the VTA Kir4.1 knockdown and/or chronic pain mice.

Conclusions: The expressions of Kir4.1 in VTA astrocytes are decreased by chronic pain, which activates GABASST neurons and inhibits dopaminergic neurons, then leads depressive behaviors. References:

25AP06-9

To compare the opioid sparing effects of combination of dexamethasone, paracetamol and ketorolac vs paracetamol, ketorolac in patients undergoing total laparoscopic hysterectomy: a prospective double blind randomized controlled trial

I. Nene¹, P. Lalwani¹, V. Rewari¹, R.K. Pandey², P. Khanna¹,

¹All India Institute of Medical Sciences, New Delhi. Anesthesiology, Critical Care and Pain Medicine, Delhi. India, ²All India Institute of Medical Sciences, New Delhi, Anesthesiology, Delhi, India

Background and Goal of Study: Postoperative pain management is essential especially after total laparoscopic hysterectomy (TLH). In recent years, there has been a concerted effort to explore opioid-sparing strategies that minimizing associated side effects.

This study hypothesizes that adding preemptive dexamethasone to paracetamol and ketorolac will reduce opioid consumption compared to paracetamol and ketorolac alone in women undergoing elective TLH.

Materials and Methods: This double-blind, randomized controlled trial at AIIMS, New Delhi, included 100 ASA I/II patients undergoing elective laparoscopic hysterectomy. Patients were randomized using STATA software with concealed allocation via opaque envelopes into two groups

Group C (Control): 10 mL saline pre-surgery, followed by IV ketorolac (30 mg) and paracetamol (1 g).

Group D (Study): Dexamethasone (0.2 mg/kg) pre-surgery, followed by IV ketorolac (30 mg) and paracetamol (1 g).

Postoperative Pain Management: Patient controlled analgesia pump with 20µg fentanyl boluses and a 15-minute lockout interval. Primary outcome: Total fentanyl use in 24 hours.

Secondary outcomes: VAS pain scores, postoperative nausea and vomiting (PONV), blood glucose, and wound healing.

Statistical Analysis: Data were analyzed using STATA 15.0. Descriptive statistics and Student's t-test or Wilcoxon signed-rank test were used, with p < 0.05 considered significant.

Results and Discussion: A total of 100 patients undergoing elective laparoscopic hysterectomy were analyzed. Demographic parameters, including age, BMI, and ASA grade, were comparable between groups. Fentanyl consumption in the first 24 hours was significantly higher in Group C (231.72 ± 84.07 μg) than Group D $(138 \pm 48.7 \,\mu\text{g})$ (p < 0.0001). Pain scores on the 0-100 VAS scale showed significant differences at all time points between groups (p < 0.05). PONV scores differed at 15 and 30 minutes (p < 0.05). A transient rise in blood glucose occurred in Group D at 16 hours (122 g/dl vs 115 g/dl in Group C, p = 0.013). Wound healing was similar in both groups.

Conclusion(s): In patients undergoing total laparoscopic hysterectomy, a multimodal analgesia regimen with dexamethasone, paracetamol, and ketorolac reduced 24-hour opioid use, improved pain scores, and minimized immediate postoperative nausea and vomiting. No safety concerns, including hyperglycemia or delayed wound healing, were found with perioperative dexamethasone use.

25AP06-10 Walking towards post-surgical comfort

N. de Luis Cabezón¹, D. Ly-Liu¹, M. Uribarri-López¹, C. Miguel-Martínez¹, V. Crespo-Asensio², A. Renedo-Fernández¹ ¹Basurto University Hospital, Anaesthesia and Intensive Care, Bilbao, Spain, 2Basurto University Hospital, Acute Postoperative Pain Unit Nursing, Bilbao, Spain

Background and Goal of Study: Since the creation of our acute pain unit at our Hospital in 2013, we have been improving patient satisfaction in terms of postoperative acute pain control, working for the goal of optimizing postoperative patient comfort. For our health system, a pain assessment every 24 hrs for postoperative patients is a quality standard. However, we believe that a VAS assessment per nursing shift is necessary, since a single assessment in 24 hrs is insufficient for optimal pain control.

For this reason, we decided to take a series of measures in 2024, with the aim of raising awareness among healthcare personnel, both surgeons and nurses, of the importance of optimal pain control, due to the significant morbidity of poor pain control in the postoperative period.

Thus, the goal of this study is to check if these implementations improve postoperative patient comfort.

Materials and Methods: The measures we implemented were:1-Continuing education programs for nurses and doctors. 2- Clinical guide and management of acute postoperative pain for nursing. 3- "Bottom up" monitor in post-surgical hospitalization wards. This is a pain monitoring system, which identifies the VAS records with different colors as a pain traffic light, visualizing the intensity of the pain that patients present. White color indicates first pending pain record, green represents VAS 0-2, yellow indicates a VAS 3-5, and red VAS 6-10.

In addition, it has flashing visual alarms that indicate when it is necessary to record the VAS again, 4- Increased number of VAS assessment instead of once every 24 hrs using "bottom up" monitorization.

Results and Discussion: In 2023, 11,379 patients were registered, 92.04% had at least one VAS assessment every 24 hrs recorded, and 8.76% had a record per shift. In contrast, results in 2024 were 97.24% for only one register every 24 hrs and 53.10% per shift. With the new implementations in 2024, 7,259 patients were recorded (from January 1st to September 30th).

Among them 6,628 (91.3%) were monitored with "bottom up" and 631 (8.7) were not monitored. With these new implementations, patient satisfaction increased up to 98.9% in relation to pain con-

Conclusion(s): We consider that the measures implemented are generating a positive impact on the management of acute postoperative pain in our hospital, since the recording of 1 VAS assessment every nursing shift has increased patient satisfaction up to 98.9% in relation to pain control.

25AP06-11

Enhancing traumatic neuropathic pain control following spinal cord injury with regional anesthesia

C. Alves¹, L. Faria¹, P. Gonçalves¹, S. Nogueira¹ ¹Unidade Local de Saúde São João, Anesthesiology, Porto, Portugal

Background: Neuropathic pain (NP) is highly prevalent in patients following traumatic spinal cord injuries (TSCI). Management typically relies on pharmacological strategies; however achieving effective control remains challenging¹.

The use of regional anesthesia (RA) in patients with preexisting neurological conditions poses unique challenges due to concerns about exacerbating deficits or causing new complications. These risks necessitate careful evaluation and individualized planning.

Case Report: A 25-year-old man, ASA I, was admitted to the Intensive Care Unit (ICU) following a vehicle accident. He presented with multiple trauma, including vertebro-medullary trauma with a C7 'teardrop' fracture and dislocation of C6 with spinal cord (SC) involvement. Urgent surgical correction and stabilization were performed. During hospitalization, he developed severe NP along the C6-C7 pathway on the left side.

Cervical MRI revealed SC contusion at C6-C7, associated with SC edema and apparent narrowing of the left neural foramen.

Despite the early implementation of multimodal analgesia, including Paracetamol, Gabapentin, Tapentadol, Duloxetine, Baclofen, Ketorolac and Dexamethasone, the patient continued to report severe pain, rating it 9/10 on the Numeric Rating Scale (NRS). Given the insufficient pain control, the placement of a perineural catheter was proposed.

An infraclavicular brachial plexus block was selected and performed under ultrasound and neurostimulator guidance, considering the patient's ongoing need for a cervical collar.

Pain control improved with ropiyacaine 0.2%, 7 mL every 4 hours. reducing the NRS score to 4/10.0n the twentieth day, he was transferred from the ICU to his local hospital for ongoing care.

Discussion: NP is a challenging complication following TSCI.Neurological compromise may increase the risk of additional injury with RA, potentially due to the 'double-crush phenomenon' or the heightened vulnerability of partially demyelinated nerves to local anesthetics2.

Voltage-gated sodium channel alterations in NP make local anesthetics and RA a promising tool for pain control3.

25AP06-12

Preoperative administration of duloxetine does not affect long-term functional recovery after surgery, but it may help reduce immediate postoperative pain

H. Yoshinuma¹, H. Matsui², K. Ichikawa³, Y. Kato³, K. Ueda¹ ¹Kameda Medical Center, Department of Anesthesiology, Chiba, Japan, ²The University of Tokyo,, Department of Clinical Epidemiology and Health Economics, School of Public Health, Tokyo, Japan, ³Kameda Medical Center, Department of Sports Medicine, Chiba, Japan

Background and goal of study: Duloxetine has been shown to reduce postoperative pain and the need for opioids when administered preoperatively in spinal and laparoscopic surgeries. However, its use in multimodal analgesia for high tibial osteotomy has not been studied, and its effectiveness remains unclear.

In this study, we examined the effects of preoperatively administered duloxetine on postoperative long-term functional recovery, as well as its impact on postoperative pain.

Materials and methods: This prospective randomized controlled trial compared the efficacy of duloxetine in knee surgery. From November 2020 to May 2022, 129 patients undergoing elective high tibial osteotomy under general anesthesia with femoral nerve block were enrolled (UMIN000043795).

Patients were randomly assigned to receive duloxetine (intervention) or not (control). Duloxetine administration started one month before surgery, with an initial dose of 20 mg, increased to 60 mg by two weeks pre-surgery, and maintained for two weeks post-operatively.

The primary outcome was the KOOS (Knee Injury and Osteoarthritis Outcome Score) six months after surgery.

Secondary outcomes included NRS (Numeric Rating Scale) scores for pain on days 1, 3, 5, and 7 after surgery and the number of analgesics used within 24 and 48 hours post-surgery.

Statistical analysis used chi-squared tests for categorical variables and t-tests for continuous variables (R, version 3.4.1), with p < 0.05 considered significant.

Results and discussion: Of the 129 enrolled patients, 105 met the inclusion criteria. 47 patients were in the duloxetine group. Twenty-four patients were excluded, 14 of whom could not take duloxetine as per the protocol.

The KOOS total score six months post-surgery was 70.12 in the intervention group and 72.85 in the control group, with no significant difference (p = 0.274).

The NRS score on the first day after surgery was 3.40 in the control group and 2.45 in the intervention group (p = 0.50).

However, the number of times analgesics were used within 24 hours was significantly different: 1.76 times in the control group and 1.02 times in the intervention group (p = 0.018).

Conclusion(s): While preoperative duloxetine does not impact long-term postoperative functional recovery, it may be effective for perioperative pain relief. However, many cases had difficulty continuing with the medication, and tolerability of the drug remains an issue.

25AP06-13

Navigating complex anesthesia: a case of multi-drug allergies and safe pain managment

A. Ghanem¹, <u>C. Thombare¹</u>, M.A. Omar¹, M. Elsheikh¹ ¹Kuwaite Sharjah Hospital, EHS, Anesthesia Department, Sharjah, United Arab Emirates

Background: Managing elderly patients with complex surgical and anesthesia histories presents unique challenge, particularly when the patient has a history of anesthetic complications such as repeated cardiac arrests

Case Report: A 74 old lady with a history of three episodes of cardiac arrest under anesthesia, She had undergone nine spine surgeries between 1990 and 1993 following a traumatic spinal injury, along with other procedures such as a hysterectomy and appendectomy.

The first cardiac arrest occurred during a hysterectomy, and the second and third during spinal surgeries. All surgeries were performed under general anesthesia, and except for the cardiac arrest episodes, they were otherwise uneventful.

The patient reported known allergies to short-acting local anesthetics, morphine, paracetamol, and penicillin. No other significant comorbiditieswere noted. Given her history of cardiac arrest, the anesthesia team selected medications with the least potential for allergic reactions and better hemodynamic stability.

General anesthesia with inhalational Sevoflurane and oxygen was planned, using a Laryngeal Mask Airway (LMA) withspontaneous ventilation to avoid neuromuscular blockers, as they are the most common agents in anesthesia to cause allergic reactions.Intraoperative pain management included ketamine and dexmedetomidine infusions.

The procedure was stable, and extubation was smooth. However, the post-procedural Dex-Ket infusion did not provide adequate pain control. A sciatic popliteal nerve block was then performed with an intradermal test dose of local anesthetic (0.125% Bupivacaine) to rule out hypersensitivity reactions.

The procedure was uneventful, with stable vital signs and no adverse reactions. Tramadol was added to the postoperative plan as needed for pain control.

Discussion: Anesthetizing a patient with a history of hypersensitivity reactions to multiple drugs including anesthetic agents present significant challenge, epidemiology data suggest that young females are more susceptible to hypersensitivity reactions, including anaphylaxis, in our case a history of cardiac arrest due to suspected anaphylaxis during previous surgeries was raisedIn Australia, the incidence of anaphylaxis is estimated to be between 1 in 10,000 and 1 in 20,000(Sally Ann Ryder, 2004) [2]. The clinical presentation of anaphylaxis and anaphylactoid reactions is similar, but the underlying mechanisms differ.

Metabolic Disease and Obesity

26AP01-1

Hyperacetylation increases myocardial ischemia-reperfusion injury sensitization by mediating Mitochondrial supercomplex assembly in T2DM

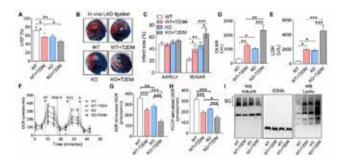

Y. Deng¹, W. Yang¹, Q. He¹, J. Yang², C. Jiang¹, T. Li¹ ¹Sichuan University, Anesthesiology, Chengdu, China, ²Sichuan University, Laboratory of Mitochondria and Metabolism, Chengdu, China

Background and Goal of Study: Epidemiological investigations have shown that type 2 diabetes mellitus (T2DM) remarkably enhances the sensitization of myocardial ischemia reperfusion (I/R) injury. Mitochondrial hyperacetylation is closely related to Sirt3, a mitochondrial NAD*-dependent deacetylase. In T2DM patients, Sirt3 is downregulated.

This study aimed to explore the mechanism by which Sirt3 increases myocardial susceptibility to I/R injury under T2DM.

Materials and Methods: Mice were subjected to a high fat diet (HFD) for 8 weeks, with intraperitoneal STZ injection in the fourth week to induce T2DM. Left anterior descending coronary artery ligation was performed to induce I/R injury in vivo. Cardiac function was evaluated using echocardiography, while levels of LDH and CK-MB were measured via a chemistry analyzer. Mitochondrial function was assessed using a seahorse XF24 analyzer. Mitochondrial supercomplex (SC) assembly and acetylation levels were examined through blue native gel electrophoresis of mitochondrial proteins.

Results and Discussion: Cardiac ultrasound showed a decreased left ventricular ejection fraction in T2DM mice compared with control mice after I/R injury (Fig.1 A). Consistent with the decreased cardiac function, the infract size of T2DM heart and plasma levels of the LDH and CK-MB were increased (Fig.1 B-E). Mechanistically, we found that ADP-stimulated and FCCP-stimulated respiration was decreased in mitochondria of T2DM mice hearts (Fig.1 F-H). Additionally, a decreased expression of Ndusf4 and an increased acetylation level was observed on mitochondrial SC (Fig.1 I). Moreover, Sirt3 knock out (KO) induced mitochondrial hyperacetylation, which aggravated cardiac function, increased infract size and the levels of LDH and CK-MB under T2DM mice after I/R injury (Fig.1 A-E). With a higher mitochondrial acetylation, KO reduced mitochondrial function and mitochondrial SC assembly in the T2DM hearts (Fig.1 F-I).

Conclusion(s): Our data suggest that myocardial I/R injury sensitization in T2DM may be due to Sirt3 deficiency induced mitochondrial SC hyperacetylation, which may downregulate mitochondrial SC assembly and respiratory efficiency.

26AP01-2

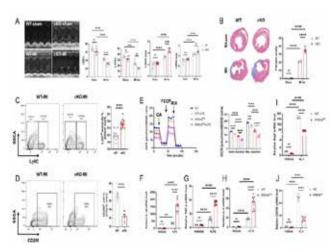

Defective branched-chain amino acids metabolism exacerbates myocardial infarction injury by affecting the phenotype and function of macrophages

W. Yang¹, Y. Deng¹, C. Jiang¹, T. Li¹ ¹West China Hospital, Sichuan University, Anesthesiology, Chengdu, China

Background and Goal of Study: Macrophages play a central role in tissue injury and repair post myocardial infarction (MI), undergoing a transition from proinflammatory to reparative phenotyp e to aid tissue healing. Branched-chain amino acids (BCAAs), including leucine, isoleucine and valine, whose aberrant accumulation was related to pathological ventricular remodeling post MI. Here, we investigate the role of BCAAs in macrophages phenotypic transition and MI process.

Materials and Methods: Wild-type (WT) and macrophage-specific PPM1K knockout (cKO) mice, with defective BCAAs catabolism, were received left anterior descending coronary artery ligation for four weeks to establish MI model. Echocardiography was used to assess cardiac function. We used Masson staining to evaluate myocardial fibrosis. Flow cytometry, Seahorse analyzer and qPCR were conducted to evaluate the phenotype and functions of macrophages in Raw264.7.

Results and Discussion: Macrophage-specific PPM1K deletion worsened cardiac contractile function and promoted tissue fibrosis, as evidenced by lower LVEF%, larger left interior diameter (Figure 1A) and increased infarct size (Figure 1B). Furthermore, the proportions of mononuclear macrophages were increased post MI in both peripheral blood and heart of cKO mice, especially Ly6Chi macrophages while CD206+ macrophages decreased in heart (Figure 1C and 1D), suggesting that cKO mice were still dominated by inflammatory macrophages post MI. Consistently, PPM1K deletion in Raw264.7 decreased the mitochondrial respiration of macrophages (Figure 1E) and promoted inflammatory cytokines (e.g IL-1\beta, IL-6 and TNF-a) gene expression (Figure 1F-H), but downregulated the markers of reparative-macrophages gene expression, such as CD206 and Arg1 (Figure 1I and 1J) in vitro. Taken together, the results showed that PPM1K deficiency promoted inflammatory response and impaired reparative functions of macrophages.

Conclusion(s): Our findings showed that defective BCAAs metabolism of macrophages promoted inflammatory response of macrophages and inhibited macrophages transit to reparative phenotype, might leading to excessive inflammation and adverse remodeling post MI.

26AP01-3

Ultrasound-guided external oblique intercostal plane nerve block for bariatric surgeries: a superior block for the morbidly obese? A case study

R. Zeng¹, C.H. Chan¹, C.H. Lim², J. Sim¹ ¹Singapore General Hospital, Department of Anaesthesiology, Singapore, Singapore, ²Singapore General Hospital, Department of General Surgery, Singapore, Singapore

Background: Optimisation of postoperative pain for bariatric surgeries can be challenging due to comorbidities such as obstructive sleep apnoea (OSA). Obese patients also report increased pain severity and interference (1).

The use of opioids may lead to respiratory depression and increased risk of postoperative nausea and vomiting in an at-risk group. Enhanced recovery guidelines in bariatric surgery show a decrease in opioid requirements with regional techniques (2).

We aim to describe and discuss the advantages of external oblique intercostal(EOI) block as part of a multimodal analgesic approach for bariatric surgeries.

Case Report: This case details the anaesthetic management of a 45-year-old female (BMI 64.7) with diagnosed severe OSA and obesity hypoventilation syndrome who underwent laparoscopic sleeve gastrectomy with ultrasound-guided bilateral EOI blocks (total 50ml 0.2% ropivacaine) after induction. In total, she received 200mcg of intravenous fentanyl. Postoperatively, sheexpressed "no pain" and maintained saturations without her usual BiPAP. No further opioids were required. She was discharged well the next day.

Discussion: The EOI block is a novel fascial plane block that provides analgesia to the anterolateral upper abdominal wall via the lateral and anterior cutaneous branches of the T6/7 to T10/11 intercostal nerves. The EOI block is easily performed in a supine position after induction. There is currently no published study comparing EOI with other regional blocks providing analgesia in similar dermatomes, e.g. the erector spinae plane or quadratus lumborum (3). These require targeting of significantly deeper structures that are challenging in obese patients.

References:

- 1. Basem JI, White RS, Chen SA, et al. The effect of obesity on pain severity and pain interference. Pain Manag2021; 11: 571-81 2. Ruiz-Tovar J. Enhanced Recovery After Surgery (ERAS) in Bariatric Surgery. Nova Science Publishers; 2021.
- 3. White, L., & Ji, A. (2022). External oblique intercostal plane block for upper abdominal surgery: use in obese patients. British journal of anaesthesia 128(5), e295-297.

Learning Points: This case highlights the success and efficacy of the novel EOI block in a high risk morbidly obese patient and describes its advantages. It is practical, allows for opioid-lite analgesiawith excellent pain scores and mitigates postoperative complications in obese patients. Further high-quality studies should be performed to strength current evidence.

26AP01-4

Long-term outcomes of Roux-en-Y gastric bypass on weight loss and obesity-related medical comorbidities: a retrospective, observational study in a Portuguese tertiary center

M. Abreu Pires¹, M. Guimaraes Adams¹, C. Cavaleiro¹, H. Machado¹

¹Centro Hospitalar Universitário de Santo António, Unidade Local de Santo António. Servico de Anestesiologia, Clinica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal

Background and Goal of Study: Obesity is a complex multifactorial disease characterized by excessive accumulation of fat predisposing individuals to develop metabolic related comorbidities. However, the lack of strong evidence regarding long-term outcomes of weight loss following bariatric surgery in the Portuguese population justifies further investigation.

Our goal was to evaluate percentage of weight loss and reduction of body mass index (BMI) over 5-12 years in patients who underwent Roux-en-Y gastric bypass (RYGB) and to describe the impact of weight loss on obesity related comorbidities.

Materials and Methods: An observational retrospective and longitudinal cohort study was conducted evaluating weight loss and obesity related comorbidity remission on patients who underwent primary bariatric surgery (RYGB) between 2011 and 2018. A cohort of 303 patients was obtained. Institutional Ethical Board approved the study, waiving informed consent. Quantitative data were presented as mean and standard deviation, while categorical variables were expressed as absolute and relative frequen-

In our analysis, we employed IBM SPSS Statistics (Version 29) to perform both bivariate analyses using logistic and linear regression techniques. A p-value of <0.05 and a 95% confidence interval was considered statistically significant, without adjustments for multiplicity.

Results and Discussion: The patient population included in the study was predominantly female (84.5%), mean age of 45 years and mean BMI of 35.4 Kg/m2 at the time of surgery. The majority of patients were classified as ASA-PS III (52.5%). After surgery, the average weight lost at minimum weight was 41.4kg (36% of initial body weight). The analysis of long term weight loss revealed a % weight loss of 27,7% over the entire study period, with a similar percentage of BMI decrease (28.6%).

In this study, 18% of patients had significant weight regain at the ≥2 year follow-up mark according to the >10kg from nadir definition, with this value increasing to 38% by the ≥5 year follow-up stage.

Despite the weight regain observed, it should be noted that the patients' BMI in 2020 and 2023 are close to what is defined as normal (24.6 in 2020 and 25.3 in 2024), underscoring the effectiveness of bariatric surgery in achieving weight loss.

Significant remission rates of obesity-related comorbidities were recorded: 73.9% for obstructive sleep apnea (OSAS), 67.7% for type 2 diabetes, 62.5% for high blood pressure (HBP) and 55.8% for dyslipidemia.

Conclusion(s): The authors validate the Roux-en-Y gastric bypass (RYGB) in obese patients as an effective surgery in terms of weight reduction up to 12 years of follow-up. Long-term BMI values close to those of non-overweight individuals were observed.

Anaesthetic management of emergency bilateral femur surgical fixation in a patient with newly diagnosed large adrenal incidentaloma – a case report

C. Lee1, J.Y. Wee1

¹Tan Tock Seng Hospital, Anaesthesiology, Singapore, Singapore

Background: Adrenal incidentalomas have become increasingly common in patients undergoing computed tomography (CT) scans. Anaesthesia may be required in some of these patients who present for emergency surgery, without adequate time for further evaluation and optimization.

Case Report: A 68 year-old woman with hypertensive urgency presented following an accident with lower limb open fractures. A 7.2x4.1x4.7cm right adrenal mass was incidentally noted on the trauma CT.

The patient had symptoms suggestive of phaeochromocytoma, but emergency surgeries were required, leaving insufficient time for definitive work-up and adequate alpha-blockade. Preemptive treatment for phaeochromocytoma was commenced peri-operatively.

External fixation was performed under general anaesthesia, with initiation of Phentolamine infusion peri-operatively on day 2 of admission. Alpha-blockade with Phenoxybenzamine was then started.

Definitive fixation was performed on day 6 of admission. Opioidsparing techniques to prevent phaeochromocytoma crisis were employed. The patient eventually underwent laparoscopic adrenalectomy, with histology proven adrenal cortical adenoma.

Discussion: This case presents a clinical dilemma: an emergency surgical condition requiring intervention versus the risk of a pheochromocytoma crisis without adequate alpha blockade. There is a paucity of data on how to manage such patients.

This highlights the anaesthetic considerations, such as avoidance of triggers, fluid and electrolyte management, and the management of peri-operative blood pressure changes.

References:

Lee JM, Kim MK, Ko SH, et al. Clinical Guidelines for the Management of Adrenal Incidentaloma. *Endocrinol Metab.* 2017;32(2):200-218.

Hariskov, Stefan; Schumann, Roman. Intraoperative management of patients with incidental catecholamine producing tumors: A literature review and analysis. Journal of Anaesthesiology Clinical Pharmacology 29(1):p 41-46, Jan–Mar 2013.

Learning Points: Clinical studies have shown that cortisol-secreting adenomas are more prevalent than phaeochromocytomas. With the increasing rates of adrenal incidentalomas, preemptive management for phaeochromocytoma before surgery should be considered in patients with adrenal incidentalomas and hypertensive urgency to avoid precipitating a crisis.

26AP01-7

Perioperative considerations for adult patients with pyruvate dehydrogenase complex deficiency

E.S. Kang¹, R. Karanofsky², D. Hickey³, D. Buhas⁴, S.S. Yang^{3,5,6}

¹McGill University Health Center, Anesthesia, Montreal, Canada, ²Jewish General Hospital, Dentistry, Montreal, Canada, ³Jewish General Hospital, Anesthesia, Montreal, Canada, ⁴McGill University Health Center, Human Genetics, Montreal, Canada, ⁵Jewish General Hospital, Lady Davis Research Institute, Montreal, Canada, ⁶Jewish General Hospital, Division of Critical Care, Montreal, Canada

Background: Pyruvate dehydrogenase complex deficiency (PDCD) is a rare mitochondrial disorder with significant anesthetic considerations.¹

Clinical manifestations include intellectual delay, neuromuscular diseases and severe metabolic acidosis. Due to associated high childhood mortality, it is often considered a pediatric disease, however, many patients survive into adulthood. This case report describes a successful case of anesthesia provided for an adult with PDCD.

Case Report: A 35-year-old man presented for wisdom teeth extraction. The patient is known for E1-alpha subunit related deficiency. His symptoms include developmental delay, hypotonia, spasticity, seizure disorder and scoliosis. A peripheral intravenous (IV) access was obtained pre-op with parental presence.

Anesthesia was provided using TIVA with rocuronium, avoiding potential triggers of malignant hyperthermia (MH) and lactic acidosis. Standard monitors were used with EEG-monitoring. Nasal intubation was successful with videolaryngoscopy without difficulty. Venous blood gas did not show signs of lactic acidosis.

The patient remained hemodynamically stable throughout the procedure and emergence, with successful reversal with sugammadex. The post-anesthesia recovery was uneventful.

Discussion: We present a unique case of providing anesthesia for an adult patient with PDCD. There is a paucity of information on perioperative management of PDCD, especially in adults with only one additional case report.²

Feared complications with PDCD are MH, propofol infusion syndrome (PIS) and lactic acidosis. Our case shows that the use of propofol for TIVA with rocuronium can be a safe option for adult PDCD patients undergoing a short procedure under general anesthesia.

- 1. Ganetzky R, McCormick EM, Falk MJ. Primary Pyruvate Dehydrogenase Complex Deficiency Overview. 2021 Jun 17. In: Adam MP, Feldman J, Mirzaa GM, et al., editors. GeneReviews® [Internet]. Seattle (WA): University of Washington, Seattle; 1993-2024.
- 2. Piñero-Merino M, García-Aroca M, Alvarez Avello JM. Management of a patient with pyruvate dehydrogenase deficiency. *Minerva anestesiologica*. 2023;89:227-229.

Learning points:

- Consider parental presence for pre-operative IV placement
- · Propofol is likely safe for short procedures with low risk of PIS
- Rocuronium appears safe with no evidence of prolonged effect and successful reversal with sugammadex
- Suggest placement of large IV or arterial line to monitor lactate in high risk cases.

Targeting brown adipose tissue thermogenesis by astrocytic acetate mitigates diet-induced obesity in mice

Q. He1, Y. Deng1, X.-s. Tang1, T. Li1 ¹West China Hospital, Sichuan University, Department of Anesthesiology, National Clinical Research Center for Geriatrics, Chengdu, China

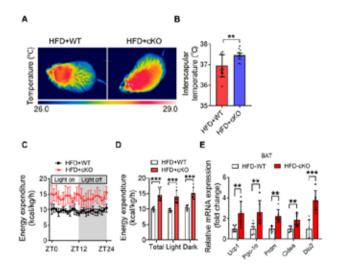

Objective: Obesity is a deteriorating global health concern. Accumulating studies highlight the significance of gut microbiota, such as acetate, in the emergence of various metabolic processes. As the specific energy substrate, whether acetate in astrocytes is required for the regulation of energy balance in obesity remains

The study is to explore the potential mechanism of astrocytic acetate in the metabolic regulation of obese mice.

Methods: Using a mouse model of high-fat diets (HFDs) for 12 weeks, we induced diet-induced obesity, which is common in humans. Body mass was measured. Plasma concentrations of total cholesterol (TC) and triglycerides (TG) were measured to profile the metabolic change. Interscapular brown adipose tissue (BAT) temperature was determined with an infrared thermal camera. Energy expenditure was measured using an indirect respiration calorimetry system. mRNA expression of thermogenic genes in BAT was calculated with RT-PCR.

Results and Discussion: Through astrocyte-specific Acss1 deletion to elevate acetate levels, we observed mitigated metabolic impairments in HFD mice. Compared with the HFD-WT mice, HFD-cKO mice showed significantly less body weight gain, which was associated with reduced total fat mass but unchanged lean mass (Fig. 1A-C).

Plasma TC and TG levels were significantly reduced in HFD-cKO mice, compared with HFD-WT mice (Fig. 1 D-E). Moreover, HFDcKO mice showed a significantly higher interscapular BAT temperature than HFD-WT mice (Fig. 2A-B). The energy expenditure and mRNA expression of thermogenic genes in BAT were significantly increased in HFD-cKO mice (Fig. 2C-E).

In the study, we found that high levels of acetate in astrocytes are required for the thermogenesis in BAT, thus protecting mice against dietary obesity.

Conclusion: Our findings provide evidence that astrocytic acetate is required to combat obesity.

Aortic valve replacement in a patient with Alkaptonuria: a case report

D. Maliamanis¹, A. Paschalis², A. Athanasiou², E. Evangelakis²

¹Nicosia General Hospital, Anaesthesia for Heart, Lung, Vascular Surgery, Strovolos, Cyprus, 2Nicosia General Hospital, Cardiac Surgery, Strovolos, Cyprus

Background: Alkaptonuria (AKU) is a rare inherited metabolic disorder, less frequent than 1 in 250 000 births, caused by Homogentisate 1,2-dioxygenase enzyme deficiency, which converts homogentisic acid (HGA) in the catabolic pathway of tyrosine.

Thus, HGA accumulates in connective tissues, producing ochronosis (colored pigment) and arthritis. Commonly, patients suffer also from valvular heart disease, restrictive lung disease and renal complications.

Case Report: A 62-year-old known alkaptonuric patient, after a syncope, was diagnosed with severe aortic stenosis (peak/ mean PG 80/54 mmHg, AVA 0,7 cm²) and was referred for surgical aortic valve replacement. His LVEF was normal, he had COPD, hypertension, low back pain, and allergy to aspirin, been also smoker for 45 years.

Airway examination revealed Mallampati I, no restrictions in neck movements, thyromental distance 8 cm and mouth opening > 5cm. His lab tests were normal, and he was classified as NYHA II, ASA III patient, having EuroSCORE II <1 %. During surgery, a 21 mm Inspiris Resilia aortic valve was implanted, total duration of cardiopulmonary bypass (CPB) was 90 min, and aorta clamped time was 75 min.

Weaning from CPB was uncomplicated and patient was extubated in the ICU some hours later. Postoperative transthoracic echo showed normal functioning bioprosthetic valve and patient was discharged from hospital a week later.

Discussion: AKU is a rare disorder that can cause pigment deposition in heart valves and progressive valve dysfunction. Arthritis and ochronosis could make perioperative management of these patients challenging.

3. Hiroyoshi et al. Aortic Valve Replacement for Aortic Stenosis Caused by Alkaptonuria. The Annals of Thoracic Surgery, Vol 95, Iss 3, 1076-1079

Learning points: Following guidelines for general population can apply for patients with AKU undergoing heart surgery.

26AP02-2

Combined multi-omics analysis identifies the mitochondrial metabolism mechanisms underlying sarcopenia

Z. Xinrong¹, T. Li¹

¹West China Hospital of Sichuan University, Department of Anesthesiology, Laboratory of Mitochondrial Metabolism and Perioperative Medicine, Chengdu, China

Background and Goal of Study: Sarcopenia is a progressive geriatric syndrome of skeletal muscle dysfunction with complex etiology and currently lacks pharmacological treatment.

This study will explore the molecular characteristics and energy metabolism changes of sarcopenia from the perspectives of mitochondrial energy metabolism and multi-omics, identify key pathogenic genes, and provide new targets for the prevention and treatment of sarcopenia.

Materials and Methods: A cohort of 60 age- and sex-matched elderly individuals was selected from West China Hospital, Sichuan University, based on the Asian Working Group for Sarcopenia (AWGS) criteria. Participants were divided into three groups: Healthy Aged (HA), Possible Sarcopenia (PS), and Sarcopenia (S), with 20 individuals per group.

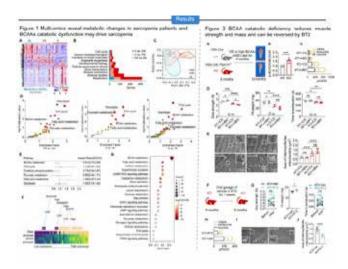

Transcriptome and metabolome analyses were conducted to compare differences among the three groups. Machine learning models and KEGG enrichment analysis were utilized to clearly distinguish key genes that differentiate sarcopenic from non-sarcopenic populations.

Concurrently, a mouse model with skeletal muscle-specific *Ppm1k* knockout (KO) was established to observe differences in skeletal muscle function and mitochondria, and mass spectrometry analysis was employed to detect the content of branched-chain amino acids (BCAAs) (Figure 1).

Figure 1. Overview of the experimental design workflow.

Results and Discussion: Multi-omics reveal metabolic changes in sarcopenia patients and BCAAs catabolic dysfunction may drive sarcopenia. BCAA catabolic deficiency impairs skeletal muscle function and can be reversed by BT2 in mouse.

Conclusion(s):

- 1. Sarcopenia patients' skeletal muscles exhibit energy metabolism disorders and mitochondrial dysfunction.
- 2. Multi-omics analysis reveals that impaired BCAA catabolism is involved in the development of sarcopenia.
- 3. Medications that promote BCAA metabolism can improve sarcopenia.

A mitochondrial depletion syndrome case – which anesthetic plan might be safer?

G.L.R. Freitas Pinto¹, M.I. Silva Carvalho¹, D. Pinho¹ ¹Unidade Local de Saúde Gaia e Espinho, Department of Anesthesiology, Vila Nova de Gaia, Portugal

Background: Mitochondrial depletion syndrome (MDS) is a rare genetic disorder characterized by reduced mitochondrial DNA content, resulting in multisystem dysfunction. All general anesthetics pose risks by disrupting mitochondrial bioenergetics. Anesthetic management is challenging due to potential neuromuscular, respiratory, and cardiovascular complications¹. No anesthetic plan is proven safer than others. We describe the strategy used for a plastic surgery patient.

Case Report: An 18-year-old male with MDS presented for elective mentoplasty due to chin hypertrophy and asymmetry. Preoperative evaluation revealed multisystem involvement but stable cardiorespiratory function. Airway assessment was remarkable for facial asymmetry. Informed consent was obtained. Anesthesia induction included a 1 mcg/kg dexmedetomidine bolus over 10 minutes, a TCI of remifentanil, ketamine, propofol, and rocuronium (20 mg). Nasotracheal intubation was performed with GlideScope videolaryngoscopy. Remifentanil and dexmedetomidine infusions and a low MAC of desflurane were used for maintenance. Multimodal analgesia included paracetamol (1 g), metamizol (1 g), and ketorolac (30 mg). Postoperative care prioritized monitoring for metabolic or neuromuscular complications, none of which occurred.

Discussion: General anesthetics disrupt mitochondrial bioenergetics and pose risk for metabolic stress and neuromuscular compromise in MDS patients. Both volatile anesthetics and propofol infusion should be minimized or avoided. Succinylcholine is contraindicated due to risks of hyperkalemia and myotonia, while nondepolarizing neuromuscular blockers must be cautiously dosed due to variability in effects2. We describe a case where dexmedetomidine and short duration agents were used successfully and safely. Multimodal analgesia minimized opioid use, reducing respiratory depression, and enhancing recovery. This case highlights the importance of individualized anesthetic plans for rare disorders with systemic impact.

References:

- 1. Mancuso M et al. Mitochondrial DNA depletion syndromes: a review. Neurology. 2021.
- 2. Dimmock D et al. Anesthetic considerations in mitochondrial diseases. Anesth Analg. 2019.

Learning points: And individualized plan is essential for MDS patients. Avoidance of volatile anesthetics and succinylcholine is key. The safety of dexmedetomidine in MDS patients should be further explored. Multimodal analgesia and tailored anesthetic approaches improve safety and recovery.

26AP02-4

Heart failure and obesity: the bariatric surgery dilemma

I. Diéguez Porto¹, Á. Barranco de Santiago¹, J. Vidal¹, A. Ibarzabal², G. Martinez-Pallí¹, E. Rivas¹ ¹Hospital Clínic de Barcelona, Anaesthesia and Intensive Care, Barcelona, Spain, ²Hospital Clínic de Barcelona, General Surgery, Barcelona, Spain

Background and Goal of Study: In patients with obesity and chronic heart failure (CHF), weight loss improves functional capacity. Overall bariatric surgery (BS) is considered an effective and safe treatment. However, there is not clear evidence on patients with severe CHF. We aim to assess the incidence of postoperative complications (PPC) in patients with severe obesity and CHF having BS.

Materials and Methods: Single-center observational retrospective study in patients with body mass index (BMI)>35 kg/m² and CHF with systolic disfunction defined as left ventricular ejection fraction (LVEF)<50% having BS. We recorded demographic and clinical data and perioperative complications, as well as weight loss, functional capacity and LVEF 1-year after BS. The primary outcome was the incidence of PPC graded by Clavien-Dindo scale and comprehensive complication index (CCI). The secondary, length of hospital stay (LOS), and weight loss, LVEF and functional capacity 1-year after BS.

Results and Discussion: 80 patients were included in the analysis, 38 with CHF and 42 in control group. There were not differences in demographic and clinical characteristics (Table 1). Moreover, the overall incidence of postoperative complications and the CCI were not different between groups. Notwithstanding, CHF patients had higher rate of minor complications (Clavien-Dindo grades 1&2) and slightly longer LOS (4 ± 5 vs 3 ± 1 days) than control patients (p<0.05, each).

One year after, BS was effective with 27% reduction in BMI. CHF patients showed a 17% improvement in LVEF, and in 10 (25%) of those patients LVEF increase over 50%. Alongside, CHF patients ameliorated functional capacity with a 79% reduction in NYHA III, and a 50% decrease of MET<4.

Conclusion: BS is effective in patients with CHF with LVEF<50%. Although these patients have higher incidence of minor complications and slightly longer LOS, they showed a significant improvement in both LVEF, and functional capacity. These patients will benefit from having the BS in a high-volume center involving a multidisciplinary team to minimize complications.

Postoperative pain management with opioid free intravenous pump infusion after sleeve gastrectomy - a case series

S. Karathanasi¹, A. Theodorou-Kanakari¹, E. Iordanidi¹, E.-A. Milou¹, S. Georgoudi¹, P. Kouki¹ General State Hospital of Nikaia - Piraeus "St. Panteleimon", Anaesthesiology, Athens, Greece

Background: Effective pain management of morbidly obese patients after laparoscopic sleeve gastrectomy can be of great challenge for anaesthesiologists.

Case Report: We present two cases of bariatric patients who underwent laparoscopic sleeve gastrectomy. A 41-year-old female with a BMI of 48 kg/m² and an ASA physical status classification of II and a 40-year-old female with a BMI of 50 kg/m², also classified as ASA II.

Multimodal, opioid sparing, preemptive analgesia was provided. Magnesium sulphate (2,5gr), dexamethasone (8mg), dexketoprofen (50mg), fentanyl (100µg) and oxycodone (8mg) were given before skin incision.

Propofol and rocuronium were used for induction of anaesthesia and desflurane for maintenance. Intraoperative pain management included lidocaine (1mg/kg IBW/h) and esmolol infusion -according to sympathetic stimulation, along with remifentanil (50µg/ml) in low dose.

Intraoperative monitoring included ECG, SpO2, invasive BP, BIS and core body temperature. At the end of operation 1gr of paracetamol and 2mg of oxycodone was given in addition to wound infiltration with levobupivacaine 0.25%.

Postextubation an infusion pump of nonopioids was initiated (0,5ml/10kg IBW/h). It was a mixture of dexmedetomidine (100µg), lidocaine (1gr) and ketamine (100mg) in N/S (total volume 100ml) according to Mulier's protocol (Mulimix).

Additionally paracetamol (1gr) guid and ondansetron (4mg) bid were prescribed. Duration of infusion was approximately 55 hours while the patients were observed by the anaesthesia team guid. for possible side effects and pain management requirements. Patients were mobilized in the afternoon of the first postoperative day. No side effects were present, and no extra opioids were required, while VAS score remained below 3 during stay in PACU and throughout whole postoperative period.

Discussion: Use of Mulimix in these two morbidly obese patients proved to be an effective strategy in postoperative pain management. The need for opioids was eliminated and early mobilization was achieved. No side effects were recorded. A larger sample of patients should be recruited to solidify these results.

Baek SY et al. Opioid-free anesthesia with a mixture of dexmedetomidine, ketamine, and lidocaine in one syringe for surgery in obese patients. J Int Med Res. 2020 Oct 28;48(10) Learning points: Opioid free postoperative analgesia with use of Mulimix can be an effective and safe alternative after laparoscopic sleeve gastrectomy.

26AP02-7

Preliminary results of the PRINCESS trial: Preoperative intermittent fasting to reduce insulin resistance

A.Y. Stobbe^{1,2}, J.A. Polderman¹, S.E. Siegelaar², J. Hermanides¹, M.F. van Stijn¹, A.H. Hulst¹ ¹Amsterdam UMC, Anaesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Endocrinology, Amsterdam, Netherlands

Background and Goal of Study: Surgical procedures are known to induce a metabolic stress response, causing increased insulin resistance and hyperglycaemia, with associated postoperative complications. Nutritional strategies, such as time-restricted eating (TRE), have been suggested to improve insulin sensitivity after a short period of time. If proven, short-term preoperative TRE could compensate for the increased insulin resistance after surgery, reducing postoperative complications.

This study aimed to investigate whether two weeks of TRE reduced fasting state insulin resistance preoperatively compared to the control group.

Materials and Methods: The PRINCESS study is an open-label, single centre, randomised clinical trial in patients with no history of diabetes mellitus that underwent elective orthopaedic surgery. In the intervention TRE group, participants received instructions to eat during a self-chosen 8-hour period for 14 days preoperatively, with no restrictions on meal content. In the control group, no specific instructions were provided. At baseline, the day of surgery and the day after, fasting glucose, insulin and c-peptide blood values were measured and used to calculate the updated homeostatic model assessment of insulin resistance (HOMA2-IR). Food intake was assessed using diet journals. For this preliminary analysis we report insulin resistance at baseline and the day of surgery, presented as medians + IQR with between-group differences compared with Mann-Whitney-U tests.

Results and Discussion: Diet journals of the participants revealed self-reported compliance with the instructed 8-hour period for eating in the TRE group. The results of this analysis (60% of intended sample size) showed normal, not significantly different HOMA2-IR values at baseline for the control group 1.29 (0.77-1.46) and the TRE group 1.07 (0.82-1.33), p=0.66. Interestingly, in the TRE group, HOMA2-IR increased at the preoperative measurements, 1.54 (0.89-1.77), a change of 0.25 (0.02-0.30). However, in the control group this increase in HOMA2-IR was also present: 1.39 (0.79-1.64), a change of 0.06 (-0.07-0.40).

Conclusion(s): This analysis showed an increase of insulin resistance instead of an expected decrease after a two-week period of TRE. The diet journals will be analysed for the final results and might provide valuable insight in the meal contents in both groups.

26AP02-8

Inguinal white adipose tissue-derived mtDNA exacerbates myocardial fibrosis post-ischemia under obesity

J. Yang¹, Y. Deng², T. Li²

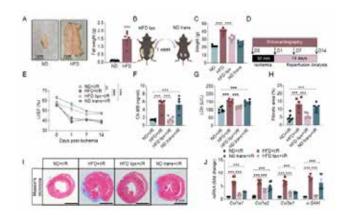

¹Sichuan University, Laboratory of Mitochondria and Metabolism, Chengdu, China, 2Sichuan University, Department of Anesthesiology, Chengdu, China

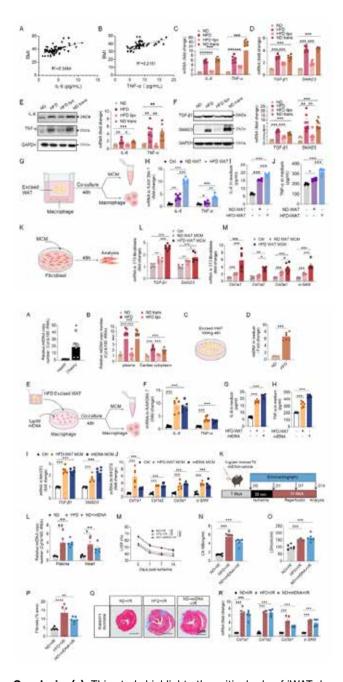

Background and Goal of Study: Obesity is associated with worsened outcomes following myocardial ischemia-reperfusion (I/R) injury. Inguinal white adipose tissue (iWAT) may play a role in cardiac damage, but the underlying mechanism remains not fully understood.

The aim of this study is to explore the role of iWAT in myocardial fibrosis following I/R injury in obesity.

Materials and Methods: A high-fat diet for 12 weeks was used to induce an obesity model. Myocardial I/R injury was created by ligating the left anterior descending coronary artery for 30 min followed by 14 days of reperfusion. Obese mice underwent iWAT removal surgery prior to the I/R procedure. Myocardial fibrosis was evaluated via Masson's trichrome staining, mtDNA levels were quantified via quantitative q-PCR.

Results and Discussion: Compared with control conditions, HFDinduced obesity led to more severe myocardial fibrosis following I/R injury, which could be alleviated by the removal of iWAT. Mechanistically, iWAT in obese mice promoted mtDNA release, which increased levels of IL-6 and TNF- α in hearts and plasma, and activated the TGF-β/SMAD3 signaling pathway.

Conclusion(s): This study highlights the critical role of iWAT-de-and activates the TGF- β /SMAD3 signaling pathway and exacerbates myocardial fibrosis in obese mice after I/R injury.

Perioperative management of massive splenomegaly in myelofibrosis: a case report

M. Ramirez Manotas¹, J.F. Villa Manrique², N. Staes¹, A. Owolabi¹, C. Ledet³

¹MD Anderson Cancer Center, Anesthesiology, Houston, United States, ²Universidad CES, Anesthesiology, Medellin, Colombia, ³MD Anderson Cancer Center, Surgical Oncology, Houston, United States

Background: Massive splenomegaly (MS) is defined as a spleen weighing over 1000 grams, crossing the midline, or reaching the iliac crest. This report outlines the perioperative management of a patient with MS undergoing an urgent splenectomy.

Case description: A 43-year-old male, with a history of myelofibrosis, presented with abdominal pain, early satiety, and shortness of breath. His lab results revealed a white blood count of 106 x 10^9/L, platelets of 20 x 10^9/L, and hemoglobin of 7 g/dL. CT imaging confirmed massive splenomegaly (Figure 1), while PET-CT excluded pulmonary embolism.

The patient was admitted to the ICU for respiratory failure which was managed on high-flow nasal cannula. Since medical treatment for splenomegaly was ineffective, the patient underwent splenic embolization followed by open splenectomy. Intraoperative management included rapid sequence induction due to aspiration risk from gastrointestinal compression. A central venous catheter, radial arterial line, and large-bore intravenous lines were placed.

Perioperatively, the patient received several transfusions of red blood cells and platelets to maintain hemoglobin >8 g/dL and platelets >20 x 10^9/LT. The procedure was uneventful, and his cytopenias resolved immediately after splenectomy. Resected spleen measured 12 x 23 x 40 cm and weighted 3.8kg.

Discussion: This case highlights the need for urgent surgical intervention for myelofibrosis-related MS unresponsive to medical management.²

Perioperative planning must include careful assessment of coagulopathy, anemia and thrombocytopenia. Massive transfusion protocol and invasive monitoring was essential.

Conclusion: MS in myelofibrosis requires individualized perioperative management to address bleeding risks, coagulopathy, and thromboembolic concerns, optimizing surgical outcomes and patient recovery.

Learning points: MS presents significant challenges due to bleeding risks and associated coagulopathy. The enlarged spleen can sequester up to 20 times more red blood cells than a normal spleen, leading to severe cytopenias and necessitating intraoperative massive transfusions.

tomosis).

Goal Directed Pulse Pressure Variation (PPV) guided intraoperative fluid administration in oral oncosurgery with free flap reconstruction - a retrospective case series analysis

I. Chowdhury¹, S. Aswin Raj¹, P. Sharma², P. Goyal³

¹Max Superspeciality Hospital, Max Institute of Cancer Care, Oncoanesthesia, Delhi, India, ²Max Superspeciality Hospital, Max Institute of Cancer Care, Plastic Surgery, Delhi, India, ³Rajiv Gadhi Cancer linstitute & Research Centre, Oncoanesthesia, Delhi, India

Background: Goal Directed Fuid Therapy (GDFT) based on minimally invasive dynamic monitoring is used for fluid optimization. Present retrospective observational study focuses on analyzing impact of Pulse Pressure Variation (PPV) based GDFT on blood Lactate, pH and free flap sugar levels as markers of tissue perfusion and flap health which has not been adequately reported in literature for oral oncosurgery with free flap (FF) reconstruction. Primary goal: Total Fluid Administered Intraoperatively, Blood Lactate, pH,Blood Sugar vs Flap Sugar (Post Microvascular Anas-

Secondary: Intraoperative Haemodynamics, Urine Output.

Objective: Flap viability at end of surgery.

Materials and Methods: Retrospective observation of anesthesia record from August 2023 to August 2024. Data collected-Demography, Free FlapType, Surgical Duration, Blood Loss, Fluid Transfused, Urine Output, PPV, Haemodynamics, Blood Lactate, pH, Blood Sugar, Flap Sugar.

Result: 28 oral malignancy patients met inclusion criteria. Age 55.36±11.08 years, ASA II,III. FreeFlap types ALT-17, RAFF-3, FFF-6. LD-1. DIEP-1. Surgical Duration 7.34±1.03hrs. PPV was maintained<13% with stable haemodynamics (Table1).

Total fluid transfused (4071.43 ± 37.32) Blood lactate ranged from 1.49 to 1.14 with significant P value between 1&3 (Table2). Blood pH was 7.37 to 7.38. Difference between flap sugar (149.93 ± 34.82) and blood sugar (144.43 ± 37.32) was minimal. All free flaps were healthy as per color, texture, pin prick at end of surgery.

	Baseline	10 min	60 min	120 min	180 min	240 min	300 min	360 min
PPV%	13.61	11.64	9.18	9.46	8.50	8.43	8.32	8.04
	±2.87	±2.78	±2.47	±2.35	±2.36	±2.38	±2.45	±2.56

HR,	79.39	78.36	75.50	75.00	74.14	73.89	74.21	73.86
bpm	±11.90	±10.76	±9.10	±9.76	±7.27	±8.11	±8.73	±7.77

Table 1: Intraoperative PPV and Haemodynamic Parameters

	After induction (1)	Middle of surgery (2)	Prior to end of surgery (3)	P value (1 vs 2)	P value (1 vs 3)	P value (2 vs 3)
Lactate, mmol/L	1.49 ± 0.63	1.22 ± 0.27	1.14 ± 0.28	0.025	0.004°	0.104
рН	7.37 ± 0.05	7.38 ± 0.06	7.38 ± 0.03	0.685	0.792	0.786

Table 2: Intraoperative Biomarkers values at different timepoints

Discussion: Our patients received GDFT based on PPV maintained below 13% as per departmental protocol which resulted in fluid transfused <5000ml, sufficient urine output. Tissue perfusion biomarkers were within normal range without signs of free flap vascular compromise.

Conclusion: This retrospective pilot case series highlights assessment of blood lactate, pH, free flap sugar under PPV based fluid therapy aiming for successful free flap in oral oncosurgery.

27AP01-3 Case report: management of a patient with port catheter line separation
