M. Ulug¹, C.M. Ozden¹, H. Zengin¹, V. Yildirim¹ ¹Ankara Gülhane Training and Research Hospital, Anaesthesiolgy and Reanimation, Ankara, Turkey

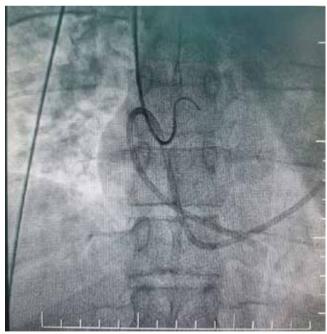

Background: Port catheter placement is frequently applied in oncology patients. However they have their own risks and complications. In this case report, we present the symptoms and management of a patient who had port catheter line separation.

Case report: A 24-year-old female patient diagnosed with ovarian sarcoma 2 years ago had a port catheter placed in an outer center clinic. After the catheter was used for 3 days, fluids from the port were not advancing and there was pain in the entry area. The patient had symptoms of dyspnea, pain when breathing and tachypnea about a year but no cause was established. The patient was than referred to us for a check of her port catheter. Scopy was performed and the catheter was seen, seperated from the entry level and advanced into the heart chambers, between right atrium and right ventricle (Figure 1).

The Cardiology Clinic was contacted and angiography was planned, the foreign body was removed with transjugular snaring under sedation (Figure 2). The removed object was made of polyurethane (PU). The patient refused any furher vascular intervention and was discharged from the hospital.

Discussion: Port catheters remain functional long-term with proper maintenance and quality materials, offering patient comfort and rarely causing complications like line rupture. The catheter dislodge was likely due to prolonged inactivity and its less flexible PU material, prone to breakage (1).

Reference:

1. Alzahrani K, Lejeune J, Lakhal W, Polyurethane versus silicone port a cath: What's going on at removal? J Pediatr Surg. 2018 Jul;53(7):1417-1419. doi: 10.1016/j.jpedsurg.2017.06.025. PMID: 28689888

Learning points: We have been using silicone catheters in our clinic for years and recommend regular checks for port catheters, preferably made of silicone for better flexibility and resistance to breakage.

Severe hypoglycemia in a non-diabetic patient with chronic subdural hematoma: Unmasking Doege-Potter syndrome

A.M. Vora¹, S. Beulens¹, D. Van Raemdonck^{2,3}, S. Rex^{1,4}, L. Al Tmimi^{1,4}

¹University Hospitals Leuven, Department of Anaesthesiology, Leuven, Belgium, ²University Hospitals Leuven, Department of Thoracic Surgery, Leuven, Belgium, ³KU Leuven, Department of Chronic Diseases and Metabolism, Leuven, Belgium, ⁴KU Leuven, Department of Cardiovascular Sciences, Leuven, Belgium

Background: Chronic subdural hematoma (cSDH) is a common neurosurgical condition. However, its association with severe hypoglycemia in non-diabetic patients is infrequent. Doege-Potter syndrome (DPS) is a rare paraneoplastic syndrome causing persistent hypoglycemia due to solitary fibrous tumors (SFTs) secreting prohormone insulin-like growth factor 2 (IGF-II) (1). We report a case of a patient who presented with a cSDH and severe hypoglycemia, eventually linked to undiagnosed DPS.

Case report: An 85 year old female on dual antiplatelet therapy for recent coronary stent placement presented with headaches following a recent fall. A CT imaging revealed cSDH with mass effect, necessitating burr hole evacuation after decline of consciousness and a seizure.

Severe intraoperative hypoglycemia (21 mg/dL) was detected and treated with IV glucose boluses. Persistent postoperative hypoglycemia prompted further investigation. The patient reported systemic symptoms, including fevers, night sweats, dizziness, and 7 kg weight loss over a short period. Laboratory tests showed low serum insulin (<2.8 pmol/L) and C-peptide (0.01 nmol/L), excluding endogenous hyperinsulinism.

Elevated IGF-II (538 ng/mL) and suppressed IGF-I (<25 µg/L) confirmed non-islet cell tumor hypoglycemia. PET-CT identified a large hypermetabolic mass in the right lung, which was highly suspicious for malignancy.

A few days later, thoracotomy was performed for complete excision of a 1533 g encapsulated pleural mass. On histopathology, the diagnosis of SFT was confirmed. Hypoglycemia resolved postoperatively, confirming DPS as the underlying cause.

Discussion: This case emphasizes the diagnostic difficulties in identifying DPS, particularly when overshadowed by conditions such as cSDH. Previous case studies have demonstrated the link between DPS and recurrent hypoglycemia¹, but the presentation in a neurosurgical context is novel. Severe hypoglycemia can lead to seizures, delayed recovery, or permanent neurological deficits (1). Prompt recognition and tumor resection are essential to resolve hypoglycemia, prevent adverse effects, and improve outcomes.

References:

1. Ahluwalia N, et al. Doege-Potter Syndrome. Ann R Coll Surg Engl. 2015 Oct;97(7):e105-7.

Learning points: Severe hypoglycemia in non-diabetic patients with cSDH warrants investigation and may indicate other serious conditions such as DPS. Recognizing the underlying cause and prompt management are essential for optimal patient outcomes.

The role of perioperative 80% FiO₂ in oncological recurrence and mortality: a 3-year follow-up study in colorectal cancer surgery

M. Sadurni Sarda¹, H. Rosinés², J. Vidal³, P. Rivera⁴, S. Sánchez¹, L. Castelltort¹

¹Hospital del Mar, Anaesthesiology, Barcelona, Spain, ²Universitat Pompeu Fabra, Anaesthesiology, Barcelona, Spain, ³Hospital del Mar, Oncology, Barcelona, Spain, ⁴Hospital Reina Sofia, Anaesthesiology, Murcia, Spain

Background: There is controversy regarding the use of perioperative high inspired oxygen fraction (FiO2>80%) to reduce the incidence of surgical site infections. Some authors have suggested that it could increase oncological recurrence and mortality!

The goal of this study was to assess whether perioperative 80% FiO2 increases oncological recurrence and mortality compared to standard therapy.

Materials and Methods: After approval by the ethics committee, we conducted a 3-year follow-up study of patients included in the previous TropO2 study².

This was a randomized controlled trial comparing the incidence of acute myocardial injury in elective colorectal surgery with the use of perioperative 40% FiO2 (control group) or 80% FiO2 (hyperoxia group).

We included only the oncological patients and recorded demographic data (sex, age, BMI, ASA status), intraoperative data (type and duration of surgery), and oncological data (tumor stage and postoperative adjuvant therapy).

Three years after surgery, we recorded the occurrence of oncological recurrence and mortality by reviewing hospital medical records or contacting patients if necessary.

Statistical analysis: t-test to compare means and chi-square test (\square^2) to compare proportions.

Results: We included only the oncological patients from the primary study (281 patients out of 403). Of these, 134 were assigned to the Control Group and 147 to the Hyperoxia Group.

There were no statistical differences in demographic, intraoperative, or oncological data.

After 3 years, we found a 19% incidence of oncological recurrence in the Hyperoxia Group versus 15% in the Control Group, but this difference was not statistically significant (p=0.36).

The 3-year mortality in the Hyperoxia Group was 15.6%, while in the Control Group it was 17.1%. This difference was also not statistically significant (p=0.73).

Conclusion: Although we observed a non-significant trend towards increased oncological recurrence in the Hyperoxia Group, mortality was not higher in this group compared to the Control Group.

Larger studies with more patients are needed to clarify this hypothesis.

Lidocaine enhanced antitumour efficacy and prevented hyperalgesia of intraperitoneal-suffusion chemotherapy in mice bearing metastatic gastric cancer

P. Gao¹, W. Zhang¹ Sichuan University, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: Local anesthetics are increasingly used in cancer surgery, drawing attention to their potential antitumor effects. This suggests combining them with antitumor drugs to relieve chemotherapy pain and improve efficacy. However, there is limited pre-clinical evidence, which hinders their clinical use.

This study examines intraperitoneal chemotherapy for gastric cancer to assess the effectiveness of a lidocaine (LIDO)/paclitaxel (PTX) combination.

Materials and Methods: We first used human gastric cancer cells to investigate the antitumor activity and related mechanisms of the LIDO/PTX combination *in vitro*. Then we used mice with intraperitoneal drug suffusion to evaluate the efficacy of LIDO to prevent paclitaxel-induced hyperalgesia and related mechanisms. Lastly, in tumor-bearing nude mice we evaluated the synergistic antitumor activity and pain-relieving effect of the LIDO/PTX combination.

Results and Discussion: The LIDO/PTX combination exhibited synergistic antitumor activity by inducing apoptosis, inhibiting migration and invasion of gastric cancer cells. In animal models, the LIDO/PTX combination effectively inhibited growth and peritoneal metastasis of cancer.

Average survival time of the LIDO/PTX group was much longer than saline control (P < 0.001, 95% CI 15.64-29.96), PTX group (P < 0.001, 95% CI 13.44-27.76) and LIDO group (P < 0.001, 95% CI 8.643-22.96). Meanwhile, hyperalgesia caused by paclitaxel was effectively inhibited by the anesthetic and anti-inflammatory effect of LIDO.

Conclusion(s): Through intraperitoneal administration, lidocaine could effectively enhance antitumor efficacy and prevent chemotherapy-induced hyperalgesia. Conventional intraperitoneal perfusion chemotherapy could be strengthened by using lidocaine as a dual-functional adjuvant.

Impact of enhanced recovery after surgery pathways on 5-year outcomes following elective colorectal surgery: insights from the POWER study

J. Ripollés Melchor¹, A. Zorrilla-Vaca², A. León Bretscher³, A. Abad-Motos⁴, E. Sáez-Ruiz¹, A. abad-Gurumeta¹¹Infanta Leonor University Hospital, Aneshesia, Madrid, Spain, ²Brigham and Women's Hospital, Anesthesia, Boston, Massachusetts, United States, ³Infanta Leonor University Hospital, Surgery, Madrid, Spain, ⁴Donosti University Hospital, Anesthesia, San Sebastian, Spain

Background and Goal of Study: Enhanced Recovery After Surgery (ERAS) pathways aim to optimize perioperative care in colorectal surgery, improving short-term outcomes. However, their impact on long-term outcomes, such as cancer recurrence and overall survival, remains unclear.

This study evaluates 5-year outcomes of patients undergoing elective colorectal surgery within the Postoperative Outcomes Within Enhanced Recovery After Surgery Protocol (POWER) Study.

Materials and Methods: This observational, multicenter study included 901 patients undergoing elective colorectal surgery, divided into ERAS (n=540) and non-ERAS (n=361) groups. A retrospective 5-year follow-up was conducted to assess cancer recurrence and overall survival. Additional data collected included demographic characteristics, ERAS compliance rates, and length of hospital stay. Kaplan-Meier survival curves and log-rank tests compared outcomes between groups, while multivariable regression analyses adjusted for confounders.

Results and Discussion: Baseline characteristics were similar between groups, with a median age of 68 years [IQR: 59-77] and 66.8% male patients. ERAS patients demonstrated higher compliance with perioperative protocols (median 72.7% vs. 54.5%,

p<0.01) and shorter hospital stays (median 6 vs. 8 days, p<0.01). Cancer recurrence rates over five years were not significantly different between groups (HR 0.91, 95% CI 0.68-1.22, p=0.53). Overall survival was also comparable (HR 1.14, 95% CI 0.88-1.49, p=0.32). ERAS pathways improve short-term recovery in elective colorectal surgery, including shorter hospital stays and higher compliance with perioperative protocols. However, no significant differences were observed in cancer recurrence or overall survival over five years.

Conclusion(s): These findings suggest that ERAS pathways optimize perioperative recovery without influencing long-term oncological outcomes. Further research is needed to explore strategies for enhancing long-term benefits in this patient population. References:

Fig.2-Haemodynamic monitor,BIS,screen

Discussion:TLV with SLET is associated with higher oxygenation during thoracoscopic phase of MIE than OLV using DLT/Bronchial Blocker¹. The hemodynamic changes related to artificial capnothorax (pneumothorax, surgical emphysema) are exaggerated in presence of PPM in these cardiac compromised patients which has to be avoided by SVV guided fluid therapy, controlled insufflation pressure upto 8mmHg and serial ABG for pH/PaCO₂/PaO₂/Lactate/Na¹/K¹/Ca¹²

References:

1. Cai L, Li Y et al. Better preoperative outcome in thoracoscopicesophagectomy with two lung ventilation in semi-prone position. *J Thorac Dis* 2017;9:117-22

Learning points:Literature search could not guide regarding anesthetic management of patient with PPM undergoing robotic thoracic surgery. Our case focuses on successful intraoperative anesthetic management of such a patient using SLET with artificial capnothorax, meticulous haemodynamic and respiratory mechanics monitoring.

27AP01-10

Anesthesia management for pheochromocytoma but with a twist, literally

P. Pinto¹, <u>M. Maia¹</u>, F. Teixeira¹, M.A. Costa¹¹Instituto Português de Oncologia de Lisboa Francisco Gentil, Department of Anesthesiology, Lisboa, Portugal

Background: Situs inversus totalis is a rare congenital variant characterized by the transposition of abdominal and thoracic organs contralaterally to their anatomical position. It is mostly asymptomatic but can also occur with cardiovascular, respiratory or gastrointestinal malformations.

Pheochromocytoma is a catecholamine-producing neuroendocrine tumor originating in the adrenal medulla. The typical presentation includes hypertension, headaches and palpitations. More often it is diagnosed accidentally on imaging scans carried out for another reason. Given the high risk of perioperative cardovascular complications, hemodynamic stabilization is essential.

Case Report: We present the case of a 74-year-old woman with a history of *situs inversus totalis* and pheochromocytoma of the left adrenal gland.

The patient underwent a left adrenalectomy by laparotomy under combined general anesthesia (intrathecal morphine and total intravenous general anesthesia), after adrenergic blockade started 5 months before the surgery in collaboration with an endocrinologist.

Due to the suspected invasion of the liver parenchyma and inferior vena cava, the collaboration of a hepatobiliary surgeon from another hospital was requested and the blood bank was contacted in advance.

The intraoperative period was marked by tensional lability, requiring boluses of phentolamine and labetalol, followed by phentolamine infusion until the tumor was excised and then noradrenaline infusion (max 0.33mcg/kg/min).

The post-operative period took place in an intensive care unit where vasopressor support was suspended 24 hours after surgery and was uneventful.

Discussion: The combination of these rare pathologies, which in themselves are complex to manage perioperatively, creates an unusual and challenging scenario for anesthesiologists, rarely described in the literature. Adequate management of cases as complex as this one can not be studied in controlled trials and are, therefore, dependent on case reports that describe successful outcomes like the one described above.

Reference:

Koç A., et al, Anaesthesia recommendations for Situs inversus totalis. Orphananesthesia. 2020;1–4.

Learning points: The combination of uncommon pathologies represents a challenge for the anesthesiologist, benefiting from timely preparation and a multidisciplinary team; Hemodynamic stabilization of a patient with pheochromocytoma is essential; The *situs inversus totalis* has an important impact on the anesthetic approach.

Irreversible electroporation for advanced tumors: An anesthesiologist's challenge!

S. Savarkar¹, E. Patwardhan¹

¹Tata memorial hospital, anaesthesia, critical care and pain, Mumbai, India

Background: Irreversible electroporation (IRE) is a promising technique for unresectable tumours which involves tumour ablation by delivering short pulses of extremely high voltage electrical current via electodes placed within tumour. It is essential to know the anaesthesia implications of IRE as it presents unique challenges to anaesthesiologist.

This is the case series of 3 percutaneous IRE cases in an Interventional radiology suite in a tertiary care oncosurgical centre.

Case Report: The first two cases of IRE were done in elderly patients with multiple comorbidities whereas the third patient was a 12 year old girl.

Second patient was a 68-year-old lady who was found to have left bundle branch block with low cardiac contractility. GA was administered to all three patients and neuromuscular monitoring was used to maintain deep muscle relaxation during ablation. Accusync device was used to deliver synchronized IRE pulses within the refractory period of heart.

Hypertension and tachycardia during electrical stimulation was managed by intermittent boluses of propofol, antihypertensives and fentanyl. Our patients experienced ventricular ectopics which were benign and short-lasting.

Discussion: Life threatening arrhythmias have been noted in literature when the tumours are in close proximity to heart. However, cardiac synchronization of current has shown to reduce its incidence. Apart from occasional ectopics and hypertension, our patients had an uneventful periprocedural course.

Majority of IRE procedures are done in radiology suite with CT guidance with limited space and resources. These factors present additional anaesthesia implications of anaesthesia in remote locations.

References:

K. Nielsen, H. J. Scheffer, J. M. Vieveen, A. A. J. M. van Tilborg, S. Meijer, C. van Kuijk, M. P. van den Tol, M. R. Meijerink, R. A. Bouwman, Anaesthetic management during open and percutaneous irreversible electroporation, *BJA: British Journal of Anaesthesia*, Volume 113, Issue 6, December 2014, Pages 985–992

Learning points: IRE is an attractive and safe option for surgically inoperable tumours. These patients aften cannot be completely optimized due to advanced disease or coexisting illnesses.

The procedure requires meticulous planning, a thorough understanding of the critical steps involved in IRE, and seamless coordination between the interventional radiologist, anesthesiologist, and bioelectric engineer to ensure its successful execution.

27AP01-12

Preoperative iron deficiency and outcomes in colorectal cancer surgery: preliminary results from the ID-COLO study

N. Mihalek^{1,2}, D. Radovanović^{1,2}, K. Krstić¹, N. Musulin¹, A. Tomas Petrović², G. Erdoes³

¹Oncology Institute of Vojvodina, Department for Anesthesiology with Reanimatology, Sremska Kamenica, Serbia, ²University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, ³Inselspital, University Hospital Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background and Goal of Study: Patients with colorectal cancer are highly susceptible to iron deficiency anaemia (IDA), a significant risk factor for perioperative complications, including increased in-hospital morbidity, delayed recovery and reduced quality of life. Latent iron deficiency (IDL), often unrecognised, may predispose patients without laboratory-confirmed anaemia to adverse perioperative outcomes.

The study aims to evaluate whether IDL increases perioperative morbidity risk and assess the diagnostic potential of red blood cell indices in identifying patients who might benefit from preoperative iron supplementation.

Materials and Methods: A prospective, observational cohort study (NCT06276140) was conducted, including patients undergoing radical colorectal cancer surgery. Participants were categorised into one of three groups based on preoperative laboratory analyses: IDA; IDL; and control group (CG) without iron deficiency and anaemia.

Overall morbidity during the hospital stay was assessed using the Comprehensive Complication Index (CCI), while recovery quality was evaluated on the first, second and fifth postoperative days using the 15-item Quality of Recovery scale (QoR-15). Red blood cell indices were derived from complete blood count parameters taken one day prior to surgery. Data analysis was conducted employing Student's t-test and ANOVA.

Results and Discussion: A total of 62 patients were included, with an IDA incidence of 29% and IDL incidence of 21%. Patients with IDA exhibited significantly higher CCI values (39.59±10.68 vs 29.17±12.75; p=0.009) and lower QoR-15 scores on the fifth postoperative day (109.11±20.45 vs 123.19±15.52; p=0.011) compared to the CG. No statistically significant differences in overall in-hospital morbidity or patient-reported recovery quality were observed when comparing IDL to IDA or CG.

While notable differences in red blood cell indices were evident between IDA and CG, RDW, Shine and Lal, and Ricerca indices showed statistically significant differences between IDA and IDL as well.

Conclusion(s): Although IDL was not associated with a higher risk of in-hospital morbidity or delayed recovery after colorectal cancer surgery, the small sample size may have limited statistical power. Red blood cell indices such as RDW, Shine and Lal, and Ricerca indices show promise as diagnostic tools for identifying patients who could benefit from preoperative iron supplementation, warranting further investigation.

Analgesia in radical mastectomy. Before and after erector spinalis plane block

<u>D. Peral</u>¹, E. Porcar Rodado², J. Lazaro Martínez¹, P. De Toro Pérez¹, P. De Mateo Garma¹, V. Mirayet Silvestre¹

¹Consorcio Hospitalario Provincial Castellon, Anesthesia, Castellon, Spain, ²Hospital La Plana, Intensive Care, Vilareal. Spain

Background and Goal of Study: In our hospital, analgesia for breast surgery has traditionally been performed using a combination of NSAIDs and morphine, obtaining acceptable results. However, the development of ultrasound-controlled regional blocks has brought about a major change in the management of these patients.

Specifically, the erector spinae block (ESP) has meant a significant change in the way of approaching this type of surgery, improving the anesthetic and analgesic quality.

Materials and Methods: We performed a retrospective analysis of 40 patients undergoing radical mastectomy.

The common procedure for both groups was:

- Premedication: Midazolam 2 mg, Ranitidine 50 mg, Dexamethasone 8 mg.
- Induction and maintenance: sevoflurane + fentanyl + rocuronium.
- Postoperative analgesia: Paracetamol 1 g alternating with Dexketoprofen.
- Rescues with Tramadol 100 mg and Dolantine 50 mg.

The difference between groups was that half of them received ESP at T4 level with 25 ml of 0.5% ropivacaine 20 minutes before the intervention.

We evaluated: hemodynamic stability during surgery, the dose of fentanyl administered, the need for analgesic rescues and the patient's level of comfort (scale 0-10) according to the nurses in the recovery room and the surgeon the day after the intervention. **Results and Discussion:** The ESP group showed greater hemodynamic stability, requiring a lower amount of intraoperative fentanyl and subsequent analgesic rescues. The comfort of the patients was similar in both groups of patients according to the assessment made by the nurses during the first 24 hours and by the surgeon the day after the intervention.

	IV analgesia (n=20)	ESP block (n=20)
Hemodinamic stability (n)	12	18
Lengh of surgery (min)	180	195
Intraoperative fentanyl (mcg)	400	300
Need for rescue in recovery room (n)	12	4
Need for rescue in hospital room (n)	10	4
Comfort according to nursing (0-10)	7	9
Comfort according to surgeon (0-10)	7	8

Conclusion(s): ESP block offers some advantanges in front of classic analgesia: less use of fentanyl with greater hemodynamic stability and less needing of rescue analgesia in the postoperative period.

These results, although not very valuable due to the number of patients, encourage our search for the optimization of analgesia in these patients.

Craniotomy and partial resection (Debulking) of a giant pretroclival meningioma with intraoperative continuous hemodialysis: a case report, anesthesiology and resuscitation. Sant Pau Hospital

L. Pardo¹, A. Bueno¹, M. De la Torre¹, S. Sabate¹ ¹Sant Pau Hospital, Anesthesiology, Barcelona, Spain

Background: This case highlights the management of a patient with chronic kidney disease (CKD) on intermittent hemodialysis (IHD) undergoing resection of a giant cerebellopontine angle (CPA) meningioma. Preoperative IHD was complemented with intraoperative continuous veno-venous hemodialysis using citrate anticoagulation to optimize homeostasis during this complex sur-

Case report: A 48-year-old male, ASA IV, with poorly controlled hypertension, chronic anemia, and undiagnosed CKD on IHD presented with decreased consciousness, leftward oculocephalic deviation, and mild right hemiparesis during an IHD session. MRI revealed a giant CPA meningioma with brainstem compression, infratentorial midline shift, right tonsillar herniation, and obstructive hydrocephalus, necessitating ventriculoperitoneal shunt placement.

Preoperative assessment showed cardiac comorbidities, including left ventricular hypertrophy, moderate aortic insufficiency, mitral valve disease, and pulmonary hypertension. Persistent fluid overload despite thrice-weekly IHD led to nephrology consultation and an increased frequency of dialysis. Considering the tumor's size, underlying conditions, and surgical complexity, intraoperative continuous hemodialysis with citrate was planned.

General anesthesia was administered, and the procedure lasted 8 hours. Intraoperative events included transient motor evoked potential loss, resolved with norepinephrine infusion, and a singleunit red blood cell transfusion for estimated blood loss of 500cc. Hemodialysis was uneventful.

Discussion: Meningiomas are typically benign but can compress critical structures. Surgical goals aim for maximal safe resection without compromising the quality of life. Intraoperative hemodialysis controlled intracranial hypertension, managed fluid balance, and minimized metabolic derangements, critical in a patient with significant renal and cardiac comorbidities.

Conclusions: The integration of intraoperative continuous hemodialysis represents a promising strategy for patients with CKD undergoing long-duration surgeries, particularly those with additional comorbidities.

Current gaps in guidelines for managing dialysis timing and intraoperative homeostasis underscore the need for further research into optimizing outcomes for this high-risk population.

31AP01-2

Intraoperative ischemic stroke: a case of complex etiology and remarkable neurological recovery following oncological surgery

A. Martínez Serrano¹, M. Cabellos Olivares¹, M.J. Puerta Ordóñez1, R. García Quiroga1, J.R. Rodríguez Fraile² ¹Hospital Universitario de Guadalajara, Anestesiología, Reanimación y Dolor, Guadalajara, Spain, 2 Hospital Universitario de Guadalajara, Jefe de Servicio Anestesiología, Reanimación y Dolor, Guadalajara, Spain

Background: Perioperative stroke is an uncommon complication, with an incidence of 0.1 to 0.8% (1) following non-cardiac and non-neurological surgeries. This case report describes an ischemic stroke of multifactorial etiology after a challenging oncological procedure.

Case report: A 62-year-old female with a history of hypertension, iron-deficiency anemia (preoperative hemoglobin level of 10 g/ dL), diabetes, and a transient ischemic attack (TIA) two months ago, underwent an elective radical hysterectomy and bilateral salpingo-oophorectomy for ovarian carcinoma.

The patient received general anesthesia combined with epidural analgesia. Intraoperative blood loss amounted to 1500 mL, requiring transfusion of three units of packed red blood cells (PRBCs), with a final hemoglobin level of 8.9 g/dL. Hemodynamic stability was maintained, although some episodes of hypotension occurred, which were effectively managed with vasopressors and fluid therapy. The total surgical time was five and a half hours. The patient was extubated in the operating room without complications.

In the immediate postoperative period, the patient exhibited somnolence, aphasia, and right-sided hemiparesis. A CT scan revealed multiple ischemic infarcts in both hemispheres, consistent with a perioperative stroke of multifactorial origin. Probable contributing factors included recent TIA, hypoperfusion, and a hypercoagulable state associated with cancer. Transthoracic echocardiography excluded a cardioembolic source.

Despite a severe initial presentation (NIHSS: 25), the patient had a surprisingly favorable recovery, with a final NIHSS score of 10. Discussion: This case underscores the role of multiple factors in the development of perioperative stroke. The literature indicates that prior TIA significantly increases the risk, particularly in patients undergoing surgery within six months of the event (1;2). The detection of postoperative stroke and the unexpectedly positive neurological outcome are noteworthy findings.

References:

1. Gelb AG, et al. Perioperative Stroke Following Noncardiac, Noncarotid, and Nonneurologic Surgery, UpToDate, 2024. 2. Benesch C, et al. Perioperative Neurological Evaluation and Management to Lower the Risk of Acute Stroke in Noncardiac, Nonneurological Surgery. Circulation. 2021.

Learning points:

- · Perioperative stroke has a multifactorial etiology and needs strict monitoring.
- Elective surgeries should be postponed for at least three months following a stroke.

Electromyogram (EMG) waves do not affect substantially BIS Vista™ monitoring parameters in terms of SEF95 and different frequency range bands

I. Rubio Baines¹, A. Martinez-Simon¹, L. Goñi Galindo¹, I. Folch Navarro¹, C. Castro Calderón¹, C. Honorato-Cia¹ ¹Clinica Universidad de Navarra, Anesthesia and Intensive Care, Pamplona, Spain

Background and Goal of Study: Depth of Anaesthesia (DOA) monitors might be affected by several factors (environment. patient status or drugs). It is said that neuromuscular blockers (NMB), lack of it and NMB antagonism alter DOA monitoring due to electromyogram (EMG) interferences. On the other hand, some studies suggest that EMG activity is thus necessary to reach high BIS Index values.

Our study aims to demonstrate that EMG does not alter significantly DOA (using BIS Vista™) measurements

Materials and Methods: In patients receiving NMB continuous infussion (Rocuronium bromide), we antagonized NMB administering 2 mg.kg-1 Sugammadex under stable anaesthetic concentrations once the surgical procedure was finished. Then, we compared BIS Vista™ measurements (including BIS Index, SEF95 and different frequency range electroencephalogram [EEG] waves) every 2 minutes from baseline to 6 minutes after Sugammadex administration. Afterwards, we designed a model adjusting SEF95 and EEG frequency bands by EMG.

Results and Discussion: We present our results in 2 ways, Model 1 is an unadjusted model showing raw data; Model 2 is adjusted for EMG. Table 1 shows our results compared to baseline in both models; neither of the p values derived from these coefficients lost statistically significancy, nor gained it.

Frequency			Time f	rom sugammad	ex administrat	ion (min)
band [Hz]			-2-0	0-2	2-4	4-6
05505	Model 1	β coefficient (95% CI)	Reference	0.09 (-0.15 to 0.32)	0.29 (0.05 to 0.52)	0.71 (0.47 to 0.94)
SEF95	Model 2	β coefficient (95% CI)	Reference	0.08 (-0.15 to 0.32)	0.29 (0.06 to 0.52)	0.74 (0.49 to 0.98)
Delta	Model 1	β coefficient (95% CI)	Reference	136 (-115 to 387)	-223 (-474 to 28)	-527 (-778 to -276)
[1,4 Hz]	Model 2	β coefficient (95% CI)	Reference	127 (-124 to 377)	-220 (-470 to 31)	-468 (-730 to -206)
Theta	Model 1	β coefficient (95% CI)	Reference	65 (-113 to 242)	65 (-113 to 242)	65 (-113 to 242)
[4, 8]	Model 2	β coefficient (95% CI)	Reference	63 (-114 to 241)	65 (-112 to 243)	-119 (-305 to 68)
Alpha	Model 1	β coefficient (95% CI)	Reference	-43 (-296 to 209)	-56 (-308 to 196)	-47 (-299 to 205)
[8, 14]	Model 2	β coefficient (95% CI)	Reference	-37 (-288 to 216)	-58 (-310 to 193)	-93 (-358 to 171)
Beta	Model 1	β coefficient (95% CI)	Reference	49 (-43 to 141)	93 (1 to 185)	208 (116 to 300)
[14, 35]	Model 2	β coefficient (95% CI)	Reference	50 (-42 to 142)	93 (1 to 185)	201 (104 to 298)

Conclusion(s): In reversing NMB, Sugammadex increases EMG activity. Adjusting BIS Vista™ derived results for EMG shows superposable data in both models. This finding might be interpreted as EMG does not affect substantially BIS Vista™ derived results in terms of SEF95 and different EEG frequency bands (delta, theta, alpha and beta).

Sugammadex administration under steady anaesthetic conditions decreases delta frequency range activity and increases beta frequency range activity in BIS Vista TM monitoring

C. Honorato Cia¹, A. Martinez Simon¹,

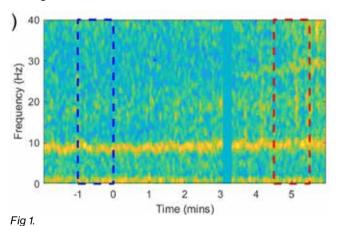

C. Garau Zaforteza¹, E. De Nalda Suarez-Barcena¹.

A. Casado Iglesias¹, I. Rubio Baines¹

¹Clinica Universidad de Navarra, Anaesthesiology and Intensive Care, Pamplona, Spain

Background and Goal of Study: Neromuscular blockers (NMB) and NMB reversal agents such as sugammadex are said to affect Depth of Anaesthesia (DoA) monitors due to electromyographic waves interferences. Several cases reported early arousal from anaesthesia after reversing NMB despite the fact that sugammadex does not cross blood-brain barrier (BBB).

Materials and Methods: We monitored DoA using BIS Vista™ in a patient receiving 2 mg.kg⁻¹ Sugammadex accordingly to Sugammadex information sheet⁷ under stable anaesthetic and haemodynamic conditions once the surgical procedure was finished. We then compared changes in frequency range bands after downloading BIS Vista™ data.

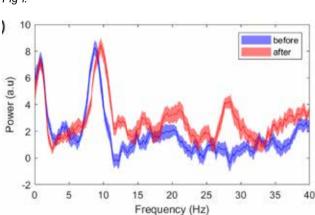

Fig 2.

Results and Discussion: When comparing both DSA and frequency range bands power baseline period (minute before sugammadex administration) and 4.5-5.5 min period after sugammadex administration, we observe an increase in frequency after sugammadex administration (Fig 1). We also observe a decrease in delta range frequency (0-4 Hz) and a beta range frequency (12-40 Hz) increase after sugammadex (Fig 2). These findings are compatible with a lighter anaesthesia stage or an anaesthesiaemergency pattern.

Conclusion(s): BNM reversal agents not crossing BBB, such as sugammadex, produce an increase in frontal EEG power frequency when comparing baseline measurements to 4.5 to 5.5 min after sugammadex in DSA. It also produces a decrease in delta frequency range (0-4 Hz) and an increase in beta frequency range (12-40 Hz) when comparing -1 to 0 and 4.5 to 5.5 periods. These findings are compatible with a lighter anaesthesia stage under steady anaesthetic conditions.

31AP01-5 Perioperative vision loss following spinal surgery: a case report

M. Rimaitis¹, B.R. Žaliūnas², D. Bilskienė¹, A. Macas¹ ¹Lithuanian University of Health Sciences, Department of Anesthesiology, Kaunas, Lithuania, ²Lithuanian University of Health Sciences, Medical Academy, Medical Faculty, Kaunas. Lithuania

Background: Perioperative vision loss (POVL) is a rare complication following non-ophthalmological surgery. Awareness of POVL and quality of evidence on prevention and management is limited.

Case report: A 72-year-old male with a history of coronary artery disease, hypertension, heart failure, dyslipidemia, and obesity, ASA class III, was admitted for lumbar laminectomy with fusion at L3-5 level. Surgery was performed in a prone position under general anesthesia.

The patient's eyes were carefully taped closed. The face was placed on a foam head cushion, MAP was maintained >65mmHg. The surgery lasted 4h, blood loss - 500 ml. The patient was transferred to the postanesthesia ward, alert and stable.

On postoperative day one, the patient complained of vision loss in his left eye, which had persisted since emergence from anesthesia. Fundoscopic exam showed retinal vasculopathy, sclerotic lesions, macular pallor and a cherry-red spot indicative of central retinal artery occlusion (CRAO). Cerebral CT angiography and MRI showed no specific changes. No treatment options were available due to delayed diagnosis.

Further postoperative course was normal, but unilateral vision loss was permanent. A review of older medical records revealed documented transient ischemic attack in the vertebrobasilar region, significant cerebrovascular atherosclerosis and bilateral retinal angiosclerosis.

Discussion: POVL incidence after spinal surgery is 0.09%, mostly attributed to ischemic optic neuropathy or CRAO. Prolonged surgery (>6h), high blood loss, eye compression, hypotension and elevated intraocular pressure are associated with POVL risk [1]. Our patient's history of vascular diseases and prone positioning may have contributed to the development of CRAO despite uneventful surgery.

Notably, initially the patient attributed impaired vision to the perception that the left eyelid was in a closed position and did not express any complaints. In the acute phase of CRAO, thrombolytic therapy and hyperbaric oxygen therapy may be attempted: however, an early recognition of this complication is crucial [2-3].

- 2. https://pubmed.ncbi.nlm.nih.gov/36639057/
- 3. https://pubmed.ncbi.nlm.nih.gov/34140653/

Learning points: Careful identification and information of patients at high POVL risk is necessary. Awareness of POVL risk may lead to better prevention, timely diagnosis, and treatment before the vision loss becomes irreversible.

31AP01-6

Associations between Spectral Edge Frequency (SEF-95) and oscillatory and aperiodic EEG dynamics during isoflurane anaesthesia

D. Hight¹, A. Lüthy², T. Dill^{3,4,5}, F. Lersch¹, J. Berger-Estilita⁵, H. Kaiser⁶ ¹University Hospital of Bern, Inselspital, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, ²Cantonal Hospital of Aarau, Clinic of Anaesthesiology, Aarau, Switzerland, 3Thun Hospital, Institute of Anaesthesiology, Thun, Switzerland, ⁴Air Glaciers, Lauterbrunnen Base, Heliport, Lauterbrunnen, Switzerland. ⁵University of Bern, Institute for Medical Education, Bern, Switzerland, 6Hirslanden Clinic Aarau, Center for Anaesthesiology and Intensive Care Medicine, Aarau, Switzerland

Background and Goal of Study: During isoflurane general anaesthesia, the electroencephalogram (EEG) is primarily constituted by strong aperiodic activity together with delta (0.5 - 4 Hz) and alpha (8 – 12 Hz) oscillations. The Spectral Edge Frequency (SEF) is the frequency under which 95% of the spectral power lies, and is often used to estimate a patient's brain state, within and between patients.

Although SEF is displayed on multiple commercial monitors, it is not known to what degree it correlates with the clear aperiodic, delta and alpha power shifts that occur during anaesthesia.

Materials and Methods: In 289 patients, taken from the first 300 patients of the EPOCAS study, we determined SEF and 6 key spectral parameters (spectral slope and intercept, peak delta power, peak and oscillatory alpha power, with peak alpha frequency) which were then used to calculate Pearson's correlation coefficients against SEF over time for the pre-bypass period.

Results and Discussion: The median population SEF value was 9.1 Hz. Median spectral parameters were: slope -0.90 dB/Hz; intercept 7.4 dB; delta power 23.1 dB; alpha (peak power) 13.3 dB, alpha (oscillatory) 13.3 dB; alpha frequency 8.8 Hz.

Figure 1 shows population histograms of Pearson's Correlations Coefficients for each spectral parameter against SEF. Vertical lines represent the median correlation coefficients.

Conclusions: Peak delta power and spectral (aperiodic) slope had the highest median correlation values with SEF, and are thus likely to be the strongest determinants of SEF. Peak alpha power, alpha frequency and spectral offset were less strongly correlated with SEF. Accurate simulations of clinical EEG (with realistic aperiodic, delta and alpha power changes in accord with our results) will be required to confirm the precise causal effect of each spectral parameter on SEF individually.

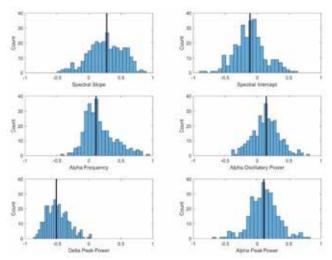

Figure 1: Population histograms of Pearson's Correlations Coefficients for each spectral parameter against SEF. Vertical lines represent the median correlation coefficients.

Age-dependent electroencephalographic pattern during remimazolam anaesthesia

Y. Song¹

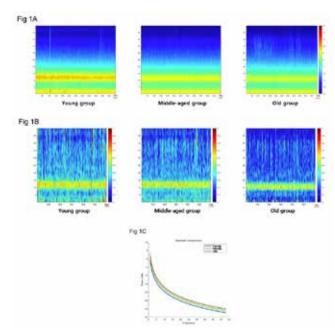

¹Yonsei University, Department of Anaesthesiology and Pain Medicine, Seoul, Korea, Republic of

Background and Goal of Study: Despite the potential of remimazolam as a safe and promising anaesthetic agent, the scarcity of electrophysiologic knowledge across different age groups limits its use in geriatric patients. While a recent study reported electroencephalographic (EEG) features during the peri-induction period in elderly patients, age-specific distinctions remain unexplored.

Materials and Methods: We analysed EEG data from 70 patients who received remimazolam as the primary anaesthetic. Patients were divided into three age groups: young (20-45 years), middleaged (45-65 years), and old (65 years and older) groups. Frontal electrode power spectrograms, inter-hemispheric coherence, and aperiodic offset and exponent values were assessed during anaesthetic maintenance prior to surgical incision. Linear regression was performed to examine age-related trends in computed EEG parameters, and group comparisons were conducted using ANOVA.

Results and Discussion: With increasing age, delta, alpha, and beta band power during remimazolam anaesthesia significantly decreased. Coherence in the delta, alpha, and beta bands also negatively correlated with age. Group comparisons revealed significantly lower alpha and beta oscillatory power in the old group compared to the young and middle-aged groups (Fig 1A).

The elderly group also exhibited significantly reduced delta, theta, alpha, and beta coherence compared to the young group (Fig 1B). Additionally, the aperiodic offset was significantly higher in the young group compared to the middle-aged and elderly groups (Fig 1C). Burst suppression was rare across all age groups.

Conclusion(s): EEG spectrograms, coherence analyses, and aperiodic measures revealed age-specific distinctive features during remimazolam anaesthesia. Leveraging unprocessed EEG with appropriate analytical approaches may enhance individualized anaesthetic management, particularly in geriatric patients, ensuring safer and more effective use of remimazolam.

31AP01-8

Steep Trendelenburg does not affect Bispectral Index measurements using BIS Vista™ monitor after 30 minutes of positioning

I. Rubio Baines¹, C. Honorato Cía¹, J.A. Fernández Molina¹, I. Garmendia Rufo¹, P. Martínez Martínez¹, A. Martínez Simón¹ ¹Clínica Universidad de Navarra, Anesthesia, Pamplona, Spain

Background and Goal of Study: Depth of Anaesthesia (DoA) monitors measurements can be affected by extreme positions 1,2 . Several surgical procedures, such as Robot-Assisted Radical Prostatectomy (RARP), require steep Trendelenburg position, thus DoA monitoring accuracy might be worsening over time 3. We aimed to compare BIS Vista ™ monitoring to EEG parameters over time in steep Trendelenburg.

Materials and Methods: We included 18 patients undergoing RARP and monitored them with BIS Vista [™] for 30 minutes after steep Trendelenburg positioning. We downloaded DoA monitorization data, and compared baseline BIS Index values to BIS Index values after 30 minutes in steep Trendelenburg. We consider baseline the moment just prior to steep Trendelenburg positioning

Results and Discussion: Contrary to what was reported by other authors, BIS Index remained stable in our study. We did not observe changes in BIS Index comparing baseline measurements to BIS Index values after 30 minutes in steep Trendelenburg positioning (Table 1). The main difference between the previous studies and ours is the monitoring time^{1,2}.

In other studies, authors monitored the first 15 minutes after anaesthetic induction (drug administration and haemodynamic

In our study, baseline register was made just prior to Trendelenburg positioning, which means that it's more than 15 minutes far from anaesthetic induction.

Parameter (Units)		Time since steep Trendelenburg positioning		
	rarameter	(Onits)	Basal (n=18) 30min (n=1	
	Left Hemis	phere, mean (SD)	44.5 (9.9)	43.1 (5.7)
BIS	Right Hemis	phere, mean (SD)	46.6 (13.3)	42.7 (4.9)
Index	p value	Left Hemisphere	Ref.	0.56
(compared to basal)	Right Hemisphere	Ref.	0.232	

Conclusion(s): BIS Index remains stable after 30 minutes in steep Trendelenburg when comparing to baseline measurements. Depth of Anaesthesia monitoring using BIS Vista ™ monitor seems to be an accurate parameter after 30 minutes in steep Trendelenburg position. Further investigations are required in this subject.

Impact of early moderate anemia on neurological outcome in neurocritically ill patients with mechanical ventilation

C. Garrido González1, N. Atencia-Urbaneja2, G. Laguna-Rivas², J. Vallverdú-Martinez², A. Jacas-Coma², L. Zattera²

¹Reina Sofía University Hospital, Anaesthesiology, Córdoba, Spain, ²Hospital Clinic, Anaesthesiology, Barcelona, Spain

Background and Goal of Study: Anemia is a frequent condition among neurocritical care patients and has been consistently associated with adverse clinical outcomes. Very low hemoglobin (Hb) levels can negatively affect neurological recovery and increase mortality, but the role of early anemia, as well as moderate anemia (Hb level <10 g/dL) in mechanically ventilated patients is not well studied.

In TBI patients, anemia has been independently linked to longterm unfavorable neurological outcomes and higher mortality. Evidence indicates that lower Hb levels at admission correlate with worse functional prognoses [1].

Similarly, in patients with ICH, anemia upon ICU admission is associated with limited functional recovery [2].

For SAH patients, anemia during ICU stays has been shown to increase neurological complications and lead to worse long-term outcomes [3].

The objective of the study is to define the role of early moderate anemia in unfavorable outcome in this subgroup of patients. We aimed to explore this association by evaluating the association between anemia and these outcomes in neurocritical ICU patients.

Our primary one was the Glasgow Outcome Scale Extended (GOSE) at six months post-admission. Secondary outcomes included mortality and length of hospital and ICU stay.

Materials and Methods: Retrospective analysis of a total of 158 neurocritical patients admitted to the Surgical ICU at Hospital Clinic of Barcelona between 2018 and 2023, who required invasive mechanical ventilation by the third day of admission.

A descriptive analysis was performed on the study variables: age, sex, comorbidities such as hypertension (HTN), diabetes mellitus (DM), dyslipidemia (DLP), chronic obstructive pulmonary disease (COPD), chronic kidney and liver disease; diagnosis; needing of surgery; laboratory data at 72 hours: hemoglobin, maximum dose of norepinephrine, C reactive protein, creatinine, leukocytes, platelets, temperature, minimum partial pressure of arterial oxygen, maximum partial pressure of arterial carbon dioxide; ICU and hospital length of stay; ICU and hospital mortality; and Glasgow Outcome Scale Extended (GOSE) at six months post-admission. Chi-square tests were used to evaluate associations between categorical variables, while Student's t-tests were applied for comparisons of continuous variables. Statistical significance was defined as p < 0.05.

Results and Discussion: A total of 158 patients were included in the study (mean age 54±17 years, 37% female). The patients were divided into two groups based on their Hb levels on the third day of admission. The moderate anemia group included those with Hb ≤10 g/dL, totaling 75 patients (48% of the sample), of whom 47% were women (p 0.02). It was observed an incidence of 48% HTN, 19% DM, 25% DLP, 9% COPD, 8% chronic kidney disease, 9% chronic renal disease. The diagnosis were 51% TBI, 24% SAH, and 25% ICH (p 0.016), needing 65% of them surgical procedures (p <0.001). The non-moderate anemia group, Hb >10 g/dL, included 83 patients (52% of the sample), 29% of whom were women. In terms of comorbidities, they presented 54% HTN, 10% DM, 22% DLP, 12% COPD, 6% chronic kidney disease, 6% chronic renal disease. In this case the diagnosis were 20% TBI, 40% SAH, 31% ICH; 31% of whom required surgical intervention. Moderate anemia was associated with longer hospital stay 37±32 days, versus 26±21 days in the non-moderate anemia group (p <0.001). The ICU length of stay was also longer in the moderate anemia group, 15±15 days compared to 12±8 days (p 0.097) (Image 1.A).

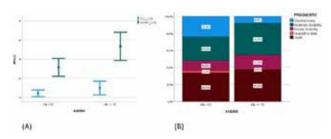

Image 1. (A) Difference in length of stay at hospital (p<0.001) and ICU (p 0.097). (B) Percentage of mortality and disability rate according to GOSE (p 0.04).

There were no differences in ICU (19%/21%, p 0.806) or hospital mortality (21%/25%, p 0.556). Six months after admission, these patients with moderate anemia showed a higher mortality rate (37%/34%) and a greater percentage of moderate (55%/45%) to severe disability (57%/44%) according to the Glasgow Outcome Scale Extended (GOSE). Additionally, the percentage of patients with complete recovery was significantly lower in the moderate anemia group (23%) compared to the non-moderate anemia group (77%) (p 0.04) (Image 1.B).

Conclusion(s): Early moderate anemia is associated with worse long-term outcomes, such as higher mortality and severe disabilities in neurocritical patients under mechanical ventilation. These findings suggest the importance of monitoring and properly managing anemia in these patients to improve functional outcomes and reduce long-term complications. However, further studies are needed to better define hemoglobin thresholds and the most effective transfusion strategies in this context.

EEG-based neuromonitoring in anaesthesia and preoperative identification of Parkinson's disease: limitations and potential pathways

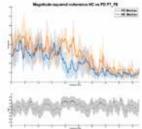

J. Dechent¹, S. Schwerin¹, G. Schneider¹, M. Kreuzer¹ ¹Klinik für Anästhesiologie und Intensivmedizin, Klinikum rechts der Isar, TUM Universitätsklinikum, School of Medicine and Health, Munich, Germany

Introduction: Patients with Parkinson's disease (PD) face increased perioperative risks. Up to 96% remain undiagnosed before age 50, making early identification crucial for optimizing anaesthesia and recovery care. [1] Preoperative electroencephalography (EEG) may be a biomarker, even when using the reduced frontal montage for anaesthesia neuromonitoring. However, processed indices used to assess anesthetic depth may obscure EEG signatures of PD.

Methods: Resting-state, eyes-open EEG data from an Open-Neuro dataset [2] were analyzed, including 15 PD patients and 16 healthy controls (HC). We focused on frontal electrodes (F3,F4, F7, F8). Absolute and relative power spectral densities (PSDs) were generated for $\delta,\,\theta,\,\alpha,\,\beta,\,\gamma$ bands. Processed parameters included spectral edge frequency (SEF), spectral entropy (SpEn), permutation entropy (PeEn), and the openibis index. [3] Magnitude-squared coherence (MSC) between frontal electrodes was also analyzed. All analyses were performed on individual channels and averaged for interhemispheric pairs. We used the Mann-Whitney-U-Test. Discriminatory ability was evaluated via AUROC. Results: Frontal PSD differences were modest. PD patients showed significantly higher relative [] power at F7 F8 (p=0.018), AUC: 0.63 [0.43-0.83]). No significant group differences in processed indices (SEF, SpEn, PeEn, openibis) were found: SEF (F3 F4 p 0.937, F7 F8 p=0.227), SpEn (F3 F4 p=0.464, F7 F8 p=0.858), PeEn (F3_F4 p=0.417, F7_F8 p=0.395), openibis (F3_F4 p=0.566, F7_F8 p=0.277). MSC analysis showed significantly increased coherence in the high [] range (20-29.9 Hz) for PD at F3_F4 (p=0.017, AUC: 0.75 [0.57-0.92] see Figure 1) and F7_F8 (p=0.034 AUC: 0.73 [0.53-0.90] see Figure 1).

Conclusions: Differentiating PD from HC using a reduced frontal montage is challenging. Conventional anesthesia monitoring parameters fail to detect pathological PD EEG signatures. MSC analysis could offer a promising future approach.

Cardiac tamponade, an unusual complication in subarachnoid hemorrhage

I. Merino¹

¹Hospital Universitario de Cruces, Anesthesiology, Barakaldo, Spain

Background: Traditionally, subarachnoid hemorrhage (SAH) causes a catecholamine storm, that leads to acute left ventricular systolic dysfunction. Cardiac tamponade is an infrequent complication in SAH.

Case Report: A 70 year-old woman, with a history of inflammatory ileitis, presented to emergency department, after severe headache and loss of consciousness. The initial Glasgow Coma Scale was 11. Computed tomography angiography (angioCT) revealed Fisher III SAH, due to 8 mm aneurysm in the left middle cerebral artery bifurcation. Successful embolisation was performed in the next hours.

Despite intended arterial hypertension and oral nimodipine for neuroprotection, on day 7 from diagnosis, the patient presented aphasia. Vasospasm was verified thanks to CT and 2 mg of focal intraarterial nimodipine were infused in both middle cerebral arteries (MCA). Vasospasm was diagnosed daily and treated angiographically.

On day+12 after SAH, hemodynamic instability begun, and increasing doses of norepinephrine were needed. Though maintaining mean blood pressure >80 mmHg, neurological clinical signs returned as mutism, and intraarterial nimodipine was again proceeded. At the end of nimodipine infusion, the need of high doses of catecholamine increased. There weren't changes in electrocardiogram. An echocardiography was performed, and revealed a cardiac tamponade. A pericardiocentesis relieved a 500 ml pericardic effusion with transudate characteristics. Despite of tamponade treatment, cardiogenic shock maintained. Moreover, cerebral angioCT concluded bilateral ischemic regions in both MCA areas. Unfortunately, patient died at day 26 after SAH.

Discussion: In a patient with previous systemic inflammation disease, SAH could act as a trigger of rare extracerebral complications (cardiac tamponade). Furthermore, this case reinforces the central role of the inflammation in the development of post-SAH complications, such as vasospasm.

Reference:

Miller BA, Turan N, Chau M, Pradilla G. Inflammation, vasospasm, and brain injury after subarachnoid hemorrhage. Biomed Res Int. 2014:2014:384342

Learning Points: Inflammatory response caused by SAH aggravates basal proinflammatory diseases, and in turn, those previous states worsen post-SAH neurological injuries.

In case of hemodynamic instability after SAH, echocardiography is a simple and non invasive diagnostic tool, in order to diagnose neurogenic cardiomyopathy or other causes, as cardiac tamponade.

31AP01-12

Assessing consciousness in acute central nervous system disorders: a study of four neurobehavioral scales

D. Zagorac¹, J. Tarcukovic², V. Sotosek² Sestre milosrdnice University Hospital Center, Department of Anesthesiology, Intensive Medicine and Pain Medicine, Zagreb, Croatia, 2 Clinical Hospital Center Rijeka, Department of Anesthesiology, Intensive Medicine and Pain Medicine, Rijeka, Croatia

Background and Goal of Study: Recovery following central nervous system (CNS) injuries typically involves distinct stages. marked by varying levels of consciousness. However, no universally accepted "gold standard" exists for quantitatively assessing disorders of consciousness, and a variety of neurological examinations and neurobehavioral scales are commonly employed in clinical practice.

This study aimed to evaluate the diagnostic sensitivity of four neurobehavioral scales in patients with CNS pathologies that included traumatic brain injury, hemorrhagic stroke, or ischemic stroke

Materials and Methods: The study analyzed 30 patients with CNS pathologies admitted to the Intensive Care Unit (ICU) at the Department of Anesthesiology and Intensive Care and the Department of Neurology, Clinical Hospital Center Rijeka. Data were collected over six months, excluding patients younger than 18 or older than 82 years. Each patient was assessed using four neurobehavioral scales - Glasgow Coma Scale (GCS), Full Outline of UnResponsiveness (FOUR), Glasgow Outcome Scale (GOS), and Coma Recovery Scale-Revised (CRS-R) – at three time points: upon admission, two days after discontinuation of analgosedation (first assessment), and 12 days post-analgosedation (second assessment). Statistical analysis was performed to assess the sensitivity of each scale over those three time points.

Results and Discussion: Statistical significance was observed in GCS scores between admission and the first assessment, specifically in the overall score, verbal response, and motor response. Similarly, FOUR scores showed significant differences between admission and both the first and second assessments, with notable changes in overall scores, motor response, brainstem reflexes, and breathing patterns. GOS and CRS-R scores did not demonstrate statistical significance.

The FOUR scale is considered superior to the GCS due to its ability to assess brainstem function as well as respiration. It also excludes verbal response, making it well-suited for use in intubated or tracheotomized patients. The scale demonstrates good reliability and is specifically designed for acute conditions.

Conclusion(s): In the acute phase following CNS injuries, the FOUR scale demonstrated superior sensitivity in detecting subtle changes in consciousness compared to GCS, GOS, and CRS-R. This highlights its potential as a valuable tool in the ICU for assessing consciousness levels in patients with CNS pathologies.

31AP02-1

Effects of remimazolam on the circadian rhythm mechanisms in mice

Y. Suzuki¹, R. Imai¹, T. Katoh², S. Mimuro¹, H. Makino³, Y. Nakajima1

¹Hamamatsu University School of Medicine, Anesthesiology and Intensive Care Medicine, Hamamatsu, Shizuoka, Japan, ²Yaizu City Hospital, Anesthesiology, Yaizu-shi, Shizuoka,, Japan, 3 Asahikawa Medical University, Anesthesiology and Critical Care Medicine, Asahikawa, Hokkaido, Japan

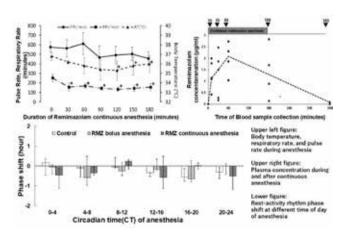

Background and Goal of Study: Central circadian clock in mammals is in suprachiasmatic nucleus (SCN), where Clock genes generate rhythm. Some anesthetics affect circadian rhythms, but the effects of remimazolam (RMZ) are unexplored. We examined the effects of RMZ on circadian rhythms of mice through a multidisciplinary approach.

Materials and Methods: Sudy was approved by the Animal Experimentation Ethics Committee. We used C57BL/6J mice.

Experiment 1: Anesthesia was performed by a single intraperitoneal (IP) injection of RMZ at 2 mg or by a IP injection followed by continuous infusion at 3 mg/h for 3 hours. Time to loss and recovery of the righting reflex, as well as body temperature(BT), respiratory rate(RR), and pulse rate(PR), were measured (n=52). Drug plasma concentrations were measured over time in separate animals (n=25).

Experiment 2: Rest-activity rhythm phase shifts and their variation by time of day of anesthesia(n=116) were examined, as well as clock genes expression using quantitative PCR (n=48).

Experiment 3: Cultured SCN from transgenic mice were exposed to RMZ, and clock gene expression rhythms were analyzed by luminometer (n=40). Kruskal-Wallis test, Mann-Whitney U test, and others were used for analysis (significance level P<0.05).

Results and Discussion: Time to loss of the righting reflex was 0.75 minutes (Median), and recovery was 11.9 minutes for single injection and 202 minutes for continuous infusion. BT dropped to 35.3°C, RR to 62%, and PR to 81% (upper left figure). Plasma concentration peaked at 2.08 µg/ml 1 hr after infusion began (upper right figure). Phase shift showed no difference between control group (-0.21 hr), single injection group (-0.04 hr), and continuous infusion group (-0.17 hr), with no fluctuation depending on the time of day of anesthesia (lower figure).

Expression of clock genes Period2, Bmal, Cryptochrome1, and Npas2 decreased to 76-90%. There was no marked change in bioluminescent circadian period of the SCN under exposure to RMZ at any concentrations.

Conclusion: RMZ suppressed the expression of clock genes, but there was no phase shift in behavioral rhythm. RMZ did not alter clock gene expression rhythm in SCN.

31AP02-2

The Association of Preoperative Glycemic Control as HbA1c Levels with Intraoperative **Burst Suppressions as a Potential Risk of Postoperative Delirium**

B. Caliskan¹, M. Gursac Celik¹ ¹University of Health Sciences Haseki Training and Research Hospital, Anesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Hyperglycemia's relationship with neurological abnormalities is not unexpected. Intraoperative monitoring with electroencephalography (EEG) enables observations such as burst suppressions related to possible central neuropathy and delirium.

So, this study searches for any relation between preoperative glycemic control as the cause of susceptibility to burst suppressions on EEG and postoperative delirium as a clinical consequence.

Materials and Methods: This retrospective analysis included 70 patients undergoing major arthroplasty under general anaesthesia and EEG monitoring within the last four months.

As part of the safe brain initiative, suppression time and rate (SR, ST) of processed EEG and postoperative delirium were recorded along with preoperative glucose and HbA1c levels of the diabetic patients.

Results and Discussion: There were no significant differences in burst suppressions or delirium in patients with diabetes, including insulin-dependent and non-dependent (Table 1).

There is no association between HbA1c levels; however, preoperative glucose levels were related to ST durations (Table 2).

		Diabetes (+) (n:42)	Diabetes (+) (n:28)	1.1	
		Mean:sd/n-% Median	Mean sd/n-% Median	Р	
Age		63.7 ± 9.6 66.5	66.4 ± 8.4 68.0	0.225 =	
Character	Female	25 59.5%	21 75,0%	0.181 X	
Gender	Male	17 40.5%	7 25.0%	0.181	
ASA Score 1	1	10 26.2%	0 0.0%	0.003 X	
	П	25 59.5%	23 82,1%	0.003	
	111	6 14.3%	5 17.9%		
Comorbidity	(-)	15 35.7%	3 10.7%	0.019 X

SR Max		6.8 ± 3.6 6.0	10.8 ± 6.9 9.5	0.136 =	

[&]quot;Mann-whitney u test / N Chi-square test (Fischer test)

Table 1.

		Preop Glucose	HbA1c
ST (sn)	r	0.526	0.110
	p	0.030	0.674
CD M	r	0.329	0.243
SR Max	p	0.197	0.347

Spearman Correlation

Table 2.

Regarding these preliminary findings, diabetes with high HbA1c levels could not significantly change susceptibility to burst suppressions and delirium. Despite the suggestion that preoperative diabetes is associated with postoperative delirium in older patients, the results could depend on prolonged exposure to high glucose levels rather than diabetes itself.

Conclusion(s): Our findings suggest that it is not diabetes, with high HbA1c levels, but rather preoperative hyperglycemia that could result in susceptibility to burst suppressions. This finding opens up avenues for future research, particularly in stress-induced hyperglycemia and its potential association with intraoperative burst suppression and postoperative delirium.

31AP02-3

Correction of post-induction hypotension during planned craniotomy for brain tumors

A. Kurbasov¹, A. Kulikov¹, A. Shmigelsky¹ ¹Burdenko National Medical Research Center of Neurosurgery, Department of Anesthesiology and Intensive Care, Moscow, Russian Federation

Background and Goal of Study: Arterial hypotension during anesthesia occurs in 5-99% of cases. About 1/3 cases of hypotension are post-induction arterial hypotension (PIH) - decrease in blood pressure in the period from induction of anesthesia to surgical incision. PIH is a common side effect of the general anesthesia, caused by a decrease of systemic vascular resistance[1]. Arterial hypotension during anesthesia associated with an increased risk of myocardial injury [2].

Perioperative myocardial injury after noncardiac surgery (PMI) is an asymptomatic complication of noncardiac interventions associated with increased postoperative mortality [3].

This nosology is poorly studied for patients with brain tumors. The use of vasopressors is an etiotropic method of correcting PIH. Arterial hypertension is a possible side effect of vasopressors, potentially dangerous in neurosurgery due to the risk of intracranial hemorrhage.

The goal of the study was to evaluate the effectiveness and safety of goal-directed prevention and correction of PIH for enhanced cardiac risk patients in elective surgery of brain tumors.

Materials and Methods: The analysis included 123 patients (aged 65 years and older or over 45 years old when assessed by RCRI ≥1) operated for brain tumors at Burdenko National Medical Research Center of Neurosurgery. Total intravenous anaesthesia (propofol + fentanil) was used in all cases.

Blood pressure was measured by a noninvasive interval method. PIH was defined as decrease in mean blood pressure <65 mmHg. In 92 patients, hemodynamic management in the perioperative period was carried out at the discretion of the anesthesiologist ("traditional approach" - group 1). Goal-directed prevention and correction of PAH was performed in 31 patients: withdrawal of antihypertensive drugs on the day of surgery (except beta-blockers), when systolic BP decrease <90 mmHg - infusion of crystalloids 5 ml/ kg, when mean BP a decrease <65 mmHg - simultaneous infusion of crystalloids 5 ml/ kg and norepinephrine at the starting dosage 0.03 µg/kg/min (group 2).

For PMI detection, patients underwent analysis of hs-sTpl concentration in blood serum and ECG recording before surgery, on the 1st and 2nd days after surgery.

PMI was defined as: elevated postoperative hs-cTnI concentration in blood serum with ≥1 hs-cTnl measurement above the 99th percentile of the URL (for initial normal hs-cTnl) or a change of hs-cTnl on 1 and/or 2 days after surgery by 20% or more (for initial abnormal hs-cTnI) without any ischemic changes in perioperative ECG. Perioperative hemodynamics, hs-cTnl concenstration in blood serum, and the incidence of PMI were compared between the groups.

Results and Discussion: The incidence of PIH was not differ significantly between the groups and was 45-52%. The dosages of propofol and fentanyl for induction and maintenance of anesthesia did not differ significantly between the groups.

The duration of PIH was significantly lower in group 2: ME 9 min (IQR 6-15) vs. ME 20 min (IQR 10-30), p=0.001. The frequency of norepinephrine use was significantly higher in group 2 (42% [n=13] vs. 11% [n=10].

None of the patients in group 2 had arterial hypertension (SBP >140 mmHg) in the post-induction period, in group 1 arterial hypertension was recorded in 2% (n=2) patients. PMI developed more often in patients of group 1: 17% (n=16) versus 6% (n=2).

Conclusion(s): The use of protocol for goal-directed correction of PIH does not reduce the risk of PIH development, but allows reducing PIH duration safely for the patient.

The use of protocol for goal-directed correction of PIH reduce the frequency of PMI for enhanced cardiac risk patients in elective surgery of brain tumors.

Pilot study to investigate the interrater agreement of intraoperative burst suppression identification

V. Zur¹, S. Letz¹, G. Schneider¹, J. Ostertag¹, M. Kreuzer¹,

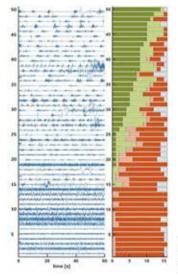

¹Klinikum rechts der Isar, Technische Universität München, Department of Anesthesiology and Intensive Care, München, Germany

Background and Goal of Study: Intraoperative neuromonitoring is crucial for evaluating anesthesia levels, as EEG patterns like Burst Suppression (BSupp) are linked to postoperative neurocognitive disorders, e.g. delirium. However, many commercial monitoring systems underestimate BSupp occurrence due to limitations in their algorithms.

Further, a standardized definition of BSupp is missing. Existing definitions from neurological expert societies cannot be directly applied to anesthetic-induced BSupp, as significant differences exist in underlying pathophysiological mechanisms. Additionally, factors such as patient age and anesthetic agents influence clinical characteristics and EEG frequency parameters.

Materials and Methods: To establish a consensus definition for anesthetic-induced BSupp, expert agreement is essential. This project aims to facilitate such consensus among anesthesiology experts. 50 representative 60 s EEG episodes containing definitive BSupp patterns (positive controls), intraoperative EEG without BSupp (negative controls), or patterns suggesting potential BSupp-like activity were used for expert assessment. A MATLAB tool was developed to enable 18 international experts to evaluate the dataset pseudonymously, revealing significant variability in the visual recognition of BSupp and highlighting the need for standardized classification standards.

Results and Discussion: The following graph shows the agreement of the visual EEG evaluation. While the scorers agreed upon the negative controls, the assessment of the (potential) BSupp episodes led to heterogeneous results for most of these episodes. This result highlights the lack of standard for BSupp definition and the need for a consensus to improve the (automated) BSupp detection. Such a consensus would also help to improve the reliability of processed BSupp parameters like suppression duration, amplitude, or the burst suppression ratio.

Conclusion: With these preliminary results of our study, we can visualize the discrepancy in BSupp assessment and highlight the need for a common BSupp definition as different assessments could influence study results.

31AP02-5

Electroconvulsive therapy in super-refractory status epilepticus: a case report

M. Medina¹, I.D. Pérez López¹, M. Islas Álvarez¹ ¹National Institute of Neurology and Neurosurgery, Neuroanesthesiology, Ciudad de Mexico, Mexico

Background: Super-refractory status epilepticus (SRSE) is a lifethreatening condition that lasts for more than 24 hours despite anesthetic treatment or recurs once treatment is withdrawn. It is associated with high mortality and significant neurological damage, posing a major clinical challenge.

Case Report: A 23-year-old female with autoimmune encephalitis developed SRSE after presenting with anxiety, motor impairments, and myoclonic seizures. Despite treatment with methylprednisolone, plasmapheresis, and cyclophosphamide, her condition remained refractory. Electroconvulsive therapy (ECT) was used as an additional therapeutic approach.

Discussion: The patient underwent multiple ECT sessions under controlled anesthesia in an intensive care unit. Although some ictal suppression was observed, full remission of seizures was not achieved. Neuroimaging and serological tests confirmed autoimmune encephalitis, and the patient eventually progressed to a persistent vegetative state with ongoing seizures and poor neurological prognosis. This highlights the complexity of SRSE and the limited effectiveness of available treatments, including ECT.

References:

- 4. Ochoa JG, Dougherty M, Papanastassiou A, Gidal B, Mohamed I, Vossler DG. Treatment of Super-Refractory Status Epilepticus: A Review. Epilepsy Curr. 2021 Nov 10;21(6):405-15. 5. Shorvon S, Ferlisi M. The outcome of therapies in refractory and super-refractory convulsive status epilepticus and recommendations for therapy. Brain. 2012 Aug 1;135(8):2314–28.

Learning points:

- SRSE is a critical and often refractory condition, particularly when associated with autoimmune encephalitis.
- ECT may offer short-term seizure suppression in SRSE but is not a guaranteed long-term solution.
- There is a need for further research to optimize treatment protocols for SRSE, especially in the context of autoimmunerelated cases.

31AP02-6

An unusual cerebral oximetry desaturation in carotid endarterectomy - the importance of clinical neurological monitoring: a case report

C. Viegas¹, C. Mateus¹, S. Neves¹ ¹Unidade Local de Saúde de Santo António, Anestesiologia, Porto, Portugal

Background: Protection of the brain from ischemic injury during carotid endarterectomy (CEA) is one of the main anesthetic goals. Regional anesthesia (RA) allows continuous neurologic assessment, widely considered the gold standard. Neuromonitoring with cerebral oximetry and processed electroencephalogram (pEEG) presents as alternatives.

Case Report: A 77 year-old woman, ASA IV, underwent a left CEA after a transient ischemic attack. Echo-doppler showed stenosis >70% in the left carotid artery (CA) and 50-70% in the right CA and CT angiography a right vertebral artery hypoplasia (VAH). Medical history included hypertension, heart failure NYHA 2 and long-term oxygen therapy after a recent hospitalization for viral pneumonia.

Surgery was performed under intermediate cervical plexus block, combined with dexmedetomidine infusion, and cerebral oxygen saturation (rSO2) and bilateral pEEG monitoring. After left CA clamping, a decrease of 20% in right rSO2 was observed, with dysarthria and decreased left motor response. Correct placement of electrodes was verified, head repositioned and blood pressure increased without changes. A carotid shunt was placed. with immediate increase of rSO2 and reversal of neurological deficits. At the end of the procedure, rSO2 was similar to baseline value, and the patient had no neurological deficits. Postoperative period was uneventful.

Discussion: An unusual contralateral rSO2 desaturation was observed after clamping (with simultaneous drop in right pEEG values), followed by neurological symptoms. An incomplete Circle of Willis has been associated with an increased risk of neurological events in patients undergoing CEA without shunting. However, despite a VAH, the patient's Circle of Willis was complete with no other documented intracranial stenosis interfering with collateral

Even though we cannot justify the drop in right rSO2, clinical signs and neuromonitoring changes agreed so the decision to perform a shunt was taken, with immediate increase in rSO2 levels and reversal of deficits.

Learning points: Under general anesthesia, detection of the neurological deficits associated with a simultaneous drop in right rSO2 would not be possible, risking a misinterpretation as an artifact. We emphasize the importance of a continuous neurologic assessment, highlighting the advantages provided by RA, particularly when continuous neurological monitoring is critical to ensure patient safety and outcomes.

31AP02-7

Reversible Posterior Encephalopathy Syndrome (PRES): A rare but reversible cause of seizures

M. Cano Castellote¹, A. Plaza Saura¹, B. Garcia Iniesta¹, A.I. Mateos Hernández¹, S. Ferrer Reverte¹, M. Escribano Jimenez¹

¹Hospital General Universitario Reina Sofia de Murcia, Anesthesiology and Intensive Care, Murcia, Spain

Background: Reversible Posterior Encephalopathy Syndrome (PRES) is a neurological condition characterized by clinical features such as headache, seizures, altered consciousness, and vision loss, along with radiological evidence of reversible structural changes in the parieto-temporo-occipital regions of the brain.

Case Report: A 55-year-old male with hypertension, type 2 diabetes, anxiety-depressive syndrome, and Crohn's disease was admitted to the ICU following multiple surgeries for perforations and obstructions related to Crohn's disease. He had a Bogotá bag for a wall defect and enterocutaneous fistula.

While he was hemodynamically stable, he experienced hypertensive spikes linked to agitation episodes and required mechanical ventilation via tracheostomy. During his ICU stay, the patient had

A brain CT scan was performed, which was normal. Neurology was consulted and decided against immediate intervention. Despite remaining conscious, the patient had difficulty controlling agitation and suffered two additional seizures.

A second CT scan revealed multiple hemorrhagic foci in the parieto-temporo-occipital regions, with the largest lesion measuring 2.5x3.1 cm, accompanied by adjacent brain edema.

This led to a diagnosis of PRES. The treatment plan included strict blood pressure control, seizure management with levetiracetam and lacosamide, and a brain MRI, which confirmed the diagnosis.

Discussion: The most widely accepted theory for the development of PRES suggests that a sudden increase in blood pressure exceeds the brain's autoregulatory capacity, leading to vasodilation, hyperperfusion, and endothelial damage with vasogenic edema. The clinical presentation is primarily neurological, ranging from confusion to stupor and seizures. Focal neurological deficits are rare. Initial assessment typically involves a brain CT, which may appear normal or show hypodensities in the temporal or posterior cortical-subcortical areas. A brain MRI is needed for a definitive diagnosis. With appropriate treatment, PRES is reversible, although neurological sequelae or even death if not managed in time can occur.

Learning points: In cases of unexplained neurological symptoms, it is crucial to perform imaging tests, keeping in mind that early stages of PRES may not show abnormal findings. Treatment consists of strict blood pressure control and active neurological monitoring. Early diagnosis is vital to initiate treatment during the reversible phase of PRES.

31AP02-8

Aneurysmal subarachnoid haemorrhage and ischemic stroke: case report

M. Fernandes¹, I. Bonito², T. Ferreira¹, V. Brito¹, S. Lança¹, A. Fernandes¹

¹Hospital Garcia de Orta, Serviço Medicina Intensiva, Almada, Portugal, ²Hospital de Nossa Senhora do Rosário - CHBM, Serviço Medicina Interna, Barreiro, Portugal

Background: Subarachnoid haemorrhage (SAH) is a neurovascular emergency. The spontaneous rupture of an intracranial aneurysm represents the majority of the cases. Cerebral vasospasm after SAH can lead to delayed cerebral ischemia increasing associated morbidity and mortality.

Case report: Male, 43-year-old, with no medical history, begins with vomits and headaches. Three days later as symptoms get worse, he comes to the emergency room. On physical examination, Glasgow coma scale (GCS) 10. Blood tests showed hyponatremia 122mg/dL.

Head computerized tomography (CT) with angiography showed SAH and a saccular aneurysm of the anterior communicating artery (ACA). Admitted to the intensive care unit and began nimodipine 60mg every 4 hours.

The day after admission he did Transcranial Doppler (TCD) with evidence of severe vasospasm in the right middle cerebral artery (MCA) and moderate in the left MCA, therefore, underwent digital subtraction angiography (DSA) with intraarterial verapamil injection and apparent resolution.

On the second day of hospitalization, he had neurosurgical intervention with aneurysm clipping. Over the next week, severe vasospasm was identified on daily TCD, so he did almost daily DSA. On the seventh day, he starts with left hemiparesis, head CT scan showed recent ischemic lesions in bilateral frontal, right temporal and parietal regions and underwent DSA.

On the ninth day, GCS of seven, he is intubated and ventilated. Intracranial pressure (ICP) monitoring is placed, initially ICP 64mmHg, lowering to 12-14mmHg with elevation of head of the bed and hyperosmolar agents.

DSA showed subocclusive thrombus of the right MCA, mechanical thrombectomy was performed, maintaining partial occlusion. During hospitalization, there was no evidence of atrial fibrillation as an embolic cause. The following day he developed refractory intracranial hypertension. Head CT scan shows a right malignant ischemic stroke, decompressive craniotomy is performed. Despite all the measures, there was clinical worsening with brain death.

Discussion: SAH remains a challenging and complex condition. This case represents a SAH complicated with an ischemic stroke. evidence of thrombus in the location of the severe vasospasm and distal to the site of the ACA aneurvsm.

Learning points: The pathophysiological mechanisms of aneurysmatic SAH are complex and not fully understood. Cerebral vasospasm is a common complication, which can lead to neurological deterioration.

31AP02-9

Early Quantitative Pupillometry Index (QPi) as a predictor of long term outcome in severe traumatic brain injury patients: a prospective observational study

B. Namdar¹, K. Goyal¹, M.P. Pandia¹, G.P. Rath¹ ¹All India Institute of Medical Sciences. Neuroanaesthesiology and Critical Care, Delhi India, India

Background & Goal of Study: Pupillary examination is integral to neurological examination & aids in decision-making and prognostication. Severe traumatic brain injury (sTBI) leads to raised intracranial pressure, which is the main factor altering pupillary reactivity.

In contrast to routine subjective pupillary examination, Automated pupillometry provides objective, quantitative and reproducible data of pupillary characteristics. Quantitative Pupillometry index (QPi) is a composite index of pupillary reactivity, with a score ranging from 0-5, provided by Automated pupillometer. We aimed to evaluate the association of early QPi and long term outcome (GOSE at 6 months) in adult sTBI patients.

Materials and Methods: This single centre, prospective, observational study was conducted after CTRI registration (CTRI/2023/03/050584) in 100 adult sTBI patients(GCS</=8) admitted to Neurocritical care unit within 48 hours of injury. After obtaining a valid consent, baseline demographic data of GCS on admission, mode of injury, hypoxia, hypotension, Marshall and Rotterdam CT score was obtained.

Automated pupillometry was performed at 0, 12, 24, 48, 72 hours and QPi was noted(0-5). Patients were followed up telephonically at 6 months to assess neurological outcome with extended Glassgow Outcome Scale (GOSE). We used logistic regression to assess the association between QPi and neurological outcome and mortality at 6 months.

Results & Discussion: Between December 2023 to September 2024, 100 sTBI patients were enrolled. The median age was 35 years, predominantly male, 89 (89%) patients, and RTA being the most common mode of injury- 84 (84%) patients. Median GCS at admission was 7 (4-8). Total of 980 QPi readings were obtained, 445 (45%) of which were abnormal (QPi<3).

Mean ICU and hospital stay was 9.8 (6.32) and 17.99 (14.50) days respectively. 6 months GOSE was assessed in 92 patients telephonically. 63 (68%) patients had a poor neurological outcome (GOSE</=4), of whom 35 (38%) died. The association of QPi with neurological outcome was adjusted for the effects of Age, GCS at admission, Marshall and Rotterdam CT scores. A single unit decrease in median QPi was associated with a poor neurological outcome (adjusted odds 1.80 [95% CI 1.04-3.11] p-value=0.03) and mortality (adjusted odds 4.15 [95% CI 1.50-11.49] p-value=0.006).

Conclusion: Automated Pupillometry derived QPI has statistical association with neurological prognosis and mortality in sTBI pa-

31AP02-10

Incidence, risk factors and outcomes in relation to seizures and epileptiform activity in neurocritically ill patients: a retrospective cohort study

A. Alandes Gallego¹, N. Atencia², E. Barbeta¹, G. Laguna¹, M.A. Perelló¹, L. Zattera¹ ¹Hospital Clinic de Barcelona, Department of Anesthesiology and Reanimation, Barcelona, Spain, ²University of Barcelona, Faculty of Medicine and Health Sciences, Barcelona, Spain

Background and Goal of Study: Epileptic seizures are commonly associated to acute brain injury (ABI), occurring in around 10% of these patients, and are related with poorer clinical outcomes. Accurate diagnosis of seizures in this context can be challenging, especially in patients undergoing sedation and mechanical ventilation.

Prophylactic use of antiepileptic drugs (AEDs) in this population is a common practice during the first days in ICU care. However, its role in improving clinical outcomes after an ABI remains un-

We aimed to describe the incidence of clinical and electrical seizures in our cohort of patients suffering from ABI, including subarachnoid haemorrhage (SAH), intracranial haemorrhage (ICH) and traumatic brain injury (TBI).

Our secondary objectives were to analyse the risk factors, longterm functional status and incidence of secondary epilepsy related to the occurrence of in-hospital seizures in this population.

Materials and Methods: A retrospective, single-center cohort analysis with ABI patients admitted in the Surgical ICU of a tertiary hospital between 01/01/2018 and 30/06/2023 was performed.

Patients aged ≥18 years with a diagnosis of SAH, ICH or TBI and a minimum of 72 hours of mechanical ventilation were included. Patients were stratified in two groups, based on whether they presented in-hospital seizures or not.

The incidence of secondary epilepsy and functional status with Extended Glasgow Outcome Scale (GOS-E) was compared between groups. Univariate and multivariate analysis were performed in order to explore variables possibly associated with seizure occurrence.

Results and Discussion: 159 patients were included. Seizures occurred in 25.2% of cases during in-hospital stay. Age >50 years (OR 3,35) and lack of prophylactic AEDs (OR 30,47) were independently associated with seizure occurrence in multivariate

None of the patients in the non-seizure group presented secondary epilepsy, whilst 19,4% of patients in the seizure group did. Patients in the non-seizure group presented overall better GOS-E scores, but the difference between groups was not statistically significant.

Conclusion(s): The incidence of in-hospital seizures in our cohort of patients with ABI was higher than previously reported in literature. Lack of prophylactic AEDs was the main factor associated with the occurrence of seizures. Further research is needed in order to determine the impact of AEDs and in-hospital seizures in long-term outcomes.

31AP02-11 Superficial spinal siderosis: is it worth taking

J.C. Santos¹, P.V. Salvador¹, E. Lima¹, A. Fonte¹ ¹ULS Entre o Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal

Background: Superficial Siderosis (SS) of the CNS is a rare disease. It originates from the deposition of hemosiderin in the subpial spaces of CNS and cranial nerves following chronic hemorrhages, usually clinically silent, in the subarachnoid space. It is also associated with dural ectasia due to defects or weaknesses in the dura mater, with CSF leakage. We present the clinical case of a woman with spinal involvement from SS, scheduled for surgical correction of a femur fracture.

Case Report: A 78-year-old woman, ASA III, followed in neurology due to spinal involvement from SS, was scheduled for surgical correction of a supracondylar femur fracture. Given the uncertainty about the optimal anesthetic approach and the potential risks of complications with a neuraxial approach, a decision was made to perform general anesthesia. After standard ASA monitoring, BIS and TOF, intravenous anesthetic induction was performed, followed by neuromuscular blockade and endotracheal intubation without complications. Maintenance was achieved with sevoflurane. The patient remained hemodynamically stable, with appropriate BIS values without suppression. During extubation, after reversal of neuromuscular blockade with sugammadex, monitored with TOF and adequate BIS, there was a prolongation in the ventilatory weaning process, with a delay in achieving autonomous and spontaneous ventilation. After progressive weaning, extubation was performed without complications or the need for ventilatory support in the PACU. The patient was discharged without postoperative complications

Discussion: Preferential involvement of SS at the spinal level was observed, associated with extensive dural ectasia. A neuraxial approach was avoided to prevent hemorrhagic complications and worsening of CSF leakage. General anesthesia proved to be effective, without complications. The difficulty in ventilatory weaning raised the hypothesis of respiratory muscle involvement. More documented clinical cases will be necessary to consolidate the anesthetic management.

Reference:

Weidauer, S., Neuhaus, E., & Hattingen, E. (2023). Cerebral Superficial Siderosis. Clinical neuroradiology Kumar, N. (2007). Superficial Siderosis. Archives of Neurology, 64

Learning points: In SS, neuraxial anaesthesia carries significant risks due to the potential for exacerbating CSF leaks or hematomas. General anaesthesia proved effective, as a safer approach. Further research is required to establish evidence-based guide-

31AP02-12

Conscious sedation and general anesthesia management in deep brain stimulation surgery for Parkinson's disease

A. Sezgi¹, E.Ş. Özdemir Sezgi², E. Arık³, M. Zengin³, D. Hökelek¹, J. Ergil³

¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Çankaya, Turkey, ²Beypazarı State Hospital, Anesthesiology and Reanimation, Çankaya, Turkey, ³University of Health Sciences, Ankara Etlik City Hospital, Anesthesiology and Reanimation, Çankaya, Turkey

Background: Deep brain stimulation (DBS) has become an effective treatment for Parkinson's disease (PD), with patient cooperation and consciousness during the procedure significantly enhancing its success (1). This case report presents our anesthetic management during DBS surgery for PD.

Case Report: A 50-year-old male patient, ASA II due to PD, was informed about the procedure and provided written consent. After routine ASA monitoring, 1 mcg/kg dexmedetomidine was administered intravenously for conscious sedation. A local anesthetic (LA) solution consisting of 36 mL of 0.5% bupivacaine and 4 mL of 0.05 mg/mL adrenaline was prepared for the scalp block. After sterilization, 5 mL of LA was administered to the greater occipital nerve, 3 mL to the lesser occipital nerve, 2.5 mL to the zygomaticotemporal nerve, 2.5 mL to the supraorbital nerve, and 2.5 mL to the auriculotemporal nerve bilaterally.

Fifteen minutes after the block, a stereotactic frame was placed. The patient was transported to CT for nucleus targeting. Anterior-posterior commissures coordinates were determined, and indirect coordinates were calculated using brain atlases. A burr hole was created, and bilateral electrodes were placed under neurological evaluation, with the patient maintaining a Ramsey sedation scale score of 3. Radiological confirmation was obtained with repeat CT.

The patient returned to the operating room for completing the electrode power source connections. General anesthesia was induced with 4 mg/kg thiopental and 0.6 mg/kg rocuronium, followed by intubation. The power source was implanted beneath the clavicle. Arterial blood pressure was maintained below 120/80 mmHg with nicardipine infusion. After 74 minutes of anesthesia, the patient was awakened with sugammadex and transferred to the ICU.

Discussion: DBS treatment for PD requires accurate mapping, patient cooperation, and pain-free procedures for success (2). Scalp block combined with awake craniotomy offers significant advantages, such as enabling intraoperative neurological assessment and reducing postoperative pain. This approach is optimal for such patients.

Dexmedetomidine-mediated modulation of brain oxygenation and neuromarkers' release during brain tumor surgery

A. Nikopoulou¹, E. Palaska¹, E. Chatsiou¹, T. Vyzantiadis², G. Tsaousi¹

¹Aristotle University of Thessaloniki, Anesthesiology and ICU, Thessaloniki, Greece, ²Aristotle University of Thessaloniki, Microbiology, Thessaloniki, Greece

Background and Goal of Study: Accumulating evidence supports that dexmedetomidine (DEX) exerts organ protective properties in several injury models including ischemia-reperfusion, inflammation, and traumatic brain injury. We aimed to investigate the impact of DEX on brain oxygenation and neuromarkers' release in patients subjected to craniotomy for tumor excision.

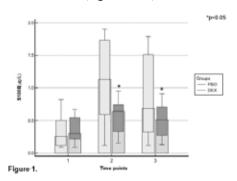

Materials and Methods: Prospective, double-blind randomized controlled trial enrolling 54 adult patients scheduled for elective craniotomy for tumor excision. A standard anesthesia protocol based on total intravenous anesthesia was applied to all cases. Patients were allocated into two groups:

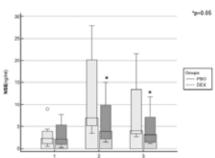

- 1. Group DEX received DEX 1µg/kg for 10 min (bolus) and thereafter 0.7µg/kg/h (civ) and;
- 2. Group PBO received N/S 0.9% at the same infusion dose.

Following jugular bulb catheterization blood samples were received at predefined time points: 5 min before intervention, 15, 30, 60, 120, 180, and 240 min after DEX infusion for jugular bulb oxygenation (SjO₂) registration. Blood samples were also obtained at baseline (1), 6, and 24 hours (2 & 3) after surgery completion for S-100B and NSE determination.

Results and Discussion: No differences were recorded regarding patients' demographic and intraoperative data. A relatively lower heart rate and a notably higher mean arterial pressure were registered following DEX infusion (p<0.05).

Moreover, DEX augmented SjO_2 at 10 and 30 min post-infusion (p<0.05) and attenuated the release of S-100B and NSE at 6 and 24 hours. Notably, the postoperative augmentation of both neuromarkers was rather trivial (Figures 1 & 2).

Conclusion(s): It seems that dexmedetomidine serves as an attractive anesthetic adjuvant during brain tumor surgery, on the basis that it can improve intraoperative brain oxygenation and attenuate perioperative brain injury.

31AP03-2

The use of density spectral array in anesthetic management of intraoperative epileptic activity in emergency neurosurgery: a case report

C. Dantas de Oliveira¹, P. Ribeiro Neto¹, I. Pestana¹, J. Barroso Moreira¹

¹Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Porto, Portugal

Background: Seizures affect 10% of the population and can result from brain injuries such as hemorrhagic strokes. Processed electroencephalography (pEEG) is widely used in the operating room (OR) to monitor anesthesia depth. The Bispectral Index (BIS) is a commonly used tool, recently complemented with density spectral array (DSA).

We report a case of intraoperative epileptic activity suggested by DSA during general anesthesia (GA).

Case Report: A 75-year-old woman with spontaneous intraparenchymal hematoma and intraventricular rupture presented with focal tonic-clonic seizures of the right hemibody, bradycardia and hypertension, treated with levetiracetam and proposed for external ventricular drainage (EVD) placement.

In the OR, repetitive right upper limb movements raised suspicion of seizure activity. After rapid-sequence induction with fentanyl, propofol, and rocuronium, GA was maintained with propofol.

Minutes later, DSA revealed bilaterally increased power evolving from low to high frequencies, consistent with epileptic activity unresponsive to propofol adjustments.

A midazolam bolus induced burst suppression and reduced discharges to <4 Hz. After EVD placement, the patient was transferred to the ICU. Postoperative EEG showed no epileptic activity. An unfavorable progression led to her death.

Discussion: Early treatment of prolonged seizures in severe neurological injury is crucial to prevent secondary damage. EEG, the gold standard for seizure diagnosis, is often unavailable in the OR. Neurologic examination is unreliable under GA and neuromuscular blockade.

DSA represents the frequencies and power of the EEG through time, being user friendlier to interpret EEG during GA. Seizures on DSA appear as increased power evolving from lower to higher frequencies.

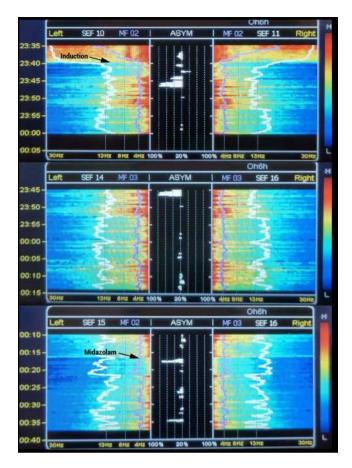

In this case, clinical context and DSA findings justified midazolam use, which partially suppressed epileptic activity.

Reference:

10.1016/j.seizure.2021.06.011

Learning Points: pEEG does not replace traditional EEG, but supports the anesthesiologist in real-time multimodal monitoring Multimodal monitoring should be interpreted in the clinical con-

DSA shows promise but needs more study.

31AP03-3

Anesthetic management of spinal tumor resection via sternotomy approach with intraoperative diagnosis of adrenergic storm

L. Canga¹, L. Pimenta¹, J. Mestres¹, I. Chateaubriand¹, G. Valarie¹, B. Miron¹

¹GAAP/Centro Universitário São Camilo, Anesthesiology, Sao Paulo, Brazil

Background: Paragangliomas (PGs) are rare extra-adrenal neuroendocrine tumors that share histological similarities with pheochromocytomas but differ in their location. Primary PGs of the central nervous system (CNS) are extremely rare, with an incidence of approximately 0.07 per 100,000 individuals (1).

This case report describes a patient who underwent spinal tumor resection at the T3 level, with no prior histological diagnosis, and developed an intraoperative adrenergic storm.

Case Report: A 44-year-old male with a medical history of asthma, hypertension, and prior abdominal tumor resection in childhood was scheduled for spinal tumor resection at the T3 level, associated with a vertebral fracture, accessed via sternotomy. The tumor's histological diagnosis was unknown before surgery. Upon admission, the patient was monitored with standard devices (including bispectral index), and his initial mean arterial pressure (MAP) was 152 mmHg. Anesthesia induction included 35 mcg of sufentanil, 150 mg of propofol, and 70 mg of rocuronium. Central venous access was achieved via the left axillary artery, and invasive blood pressure monitoring was placed in the right radial artery.

Initially, the patient remained stable. However, as tumor manipulation began, persistent hypertension was noted. Initially, inadequate analgesia was suspected, and 10 mcg of sufentanil was administered, but the hypertension worsened. Nitroprusside was given, but the patient's hemodynamic state deteriorated further, with episodes of hypertension (MAP 164 mmHg) alternating with severe hypotension (MAP 36 mmHg), requiring norepinephrine support.

Due to instability, surgery was terminated after 7 hours. The patient was transferred to the ICU, extubated 24 hours later, with stabilized blood pressure and no neurological deficits. Postoperative histological examination confirmed a paraganglioma.

Discussion: PGs can pose significant perioperative challenges due to catecholamine release. Early identification and management, including alpha-blockade, are critical to prevent adrenergic crises during surgery.

Learning Points:

- 1. Consider PG in Unexplained Hypertension
- 2. Prompt Pharmacological Intervention
- 3. Intraoperative adequate Monitoring and Management of the hemodynamics

31AP03-4

Anesthetic management of a patient with the rare CADASIL syndrome undergoing total hysterectomy

L. Canga¹, L. Vandoni Pimenta¹, K. Rosseto¹, C. Haddad Silveira¹, G. Badessa¹, B. Miron¹ GAAP-Centro Universitário São Camilo, Anesthesiology, Sao Paulo, Brazil

Background: CADASIL syndrome (Cerebral Autosomal Dominant Arteriopathy with Subcortical Infarcts and Leukoencephalopathy) is a rare, genetic condition characterized by alterations in the structure of blood vessels, leading to multiple small strokes and a clinical presentation of dementia. Around 500 families worldwide are affected, the majority of which are in Europe (1). In the present case, we highlight the anesthetic management of a patient undergoing a hysterectomy.

Case Report: A 99 kg, 169 cm woman with CADASIL syndrome and dyslipidemia underwent a total hysterectomy. Her medical history includes multiple strokes without sequelae. She was on daily medication, including aspirin and rosuvastatin.

The anesthesia was performed using spinal anesthesia combined

The spinal block was carried out with thoracolumbar at the L3-L4 interspace. A dose of 14 mg of heavy bupivacaine and 80 mcg of intrathecal morphine were administered.

Sedation was achieved with 5 mg of midazolam and 50 mcg of fentanyl, adjusted as necessary based on the Bispectral Index monitor. Intraoperative stability was maintained. infusion. In the recovery room, the patient was awake, with a Glasgow Coma Scale score of 15, and reported mild pain, which was controlled with 5 mg of IV morphine. The spinal block reached a T10 level, and the patient was transferred to the ICU in good condition.

Discussion: Due to the rarity of CADASIL syndrome, a cautious approach was taken. Sedation was chosen to allow the patient to maintain her own respiratory drive, thereby preserving normocapnia. BIS monitoring was utilized to detect any abnormalities early in its readings, whether in suppression rate, index, or electroencephalogram. Fortunately, throughout the procedure, the BIS remained stable without any changes.

Learning Points: The combination of spinal anesthesia and sedation was successful in the patient, providing adequate pain control and stable recovery. This case report contributes to clinical practice by offering evidence on anesthetic management in patients with this rare and under-reported syndrome, suggesting that this approach can be considered safe and effective in similar clinical scenarios.

Effect of vagus nerve denervation on hemodynamic autoregulation in increased intracranial pressure swine model using real-time recording system: pilot study

H. Seong¹, J.E. Cho¹, J.J. Park², S.Z. Yoon¹ ¹Anam Hospital, Korea University College of Medicine, Department of Anesthesiology and Pain Medicine, Seoul, Korea, Republic of, 2CHA Bundang Medical Center, CHA University School of Medicine, Department of Anesthesiology and Pain Medicine, Seongnam, Korea, Republic of

Background and Goal of Study: Cerebral autoregulation (CA) maintains constant cerebral blood flow despite arterial blood pressure (ABP) fluctuations, controlled by the autonomic nervous system (ANS). The vagus nerve, a key component of the parasympathetic branch of the ANS, plays an important role in CA. The effect of vagus nerve denervation on CA remains unclear; thus, this study seeks to examine its impact in a swine model of elevated ICP following bilateral vagus nerve denervation.

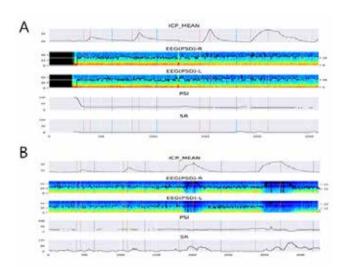

Materials and Methods: Eight male Yorkshire pigs (40.5 ± 0.76 kg, 11-12 weeks old) were divided into two groups (n=4/group): a control group and a vagotomized group, where the latter underwent bilateral cervical vagotomy prior to ICP elevation. ICP elevation was achieved by saline infusion into the lumbar subarachnoid space, progressively increasing ICP to 20, 30, 40, and 50 mmHg until a plateau was reached. Cerebral hemodynamics were monitored in real-time using data collection from ICP, EEG, and ECG, along with assessments of heart rate variability and electroencephalography.

Results and Discussion: During and after the lumbar subarachnoid space infusion, systolic, mean, and diastolic pressure were reported to be lower in the vagotomized group compared to the control group. The high frequency peak was also lower in the vagotomized group (Table). The EEG changes of the vagotomized group showed a decrease of δ wave power, attenuation of total power, and elevation of suppression ratio at ICP 40 mm Hg (Figure).

Conclusion(s): We propose that vagus nerve denervation may not offer a positive influence in the cerebral autoregulation.

	Control group	Vagotomized group	p-value
During lumbar subarachnoid space	infusion		
SBP	97.813 ± 10.816	81.615 ± 10.381	< 0.05
MAP	77.167 ± 10.773	62 ± 11.174	< 0.01
DBP	66.875 ± 10.726	52.263 ± 12.027	< 0.01
After lumbar subarachnoid space in	fusion.		
SBP	99.625 ± 10.809	82.385 ± 9.657	< 0.01
MAP	78.25 ± 10.328	62.538 ± 10.569	< 0.01
DBP	67.5 ± 10.239	52.692 ± 11.426	< 0.01

31AP03-6 Single-cell RNA sequencing reveals that Cebpb contributes to the surgery-induced cognitive impairment in mice

X. Huang¹, P. Cong¹, Y. Shi¹, L. Tian¹ ¹Tongji University, Shanghai Key Laboratory of Anesthesiology and Brain Functional Modulation, Shanghai, China

Background and Goal of Study: With the global trend of population ageing, the number of elderly patients undergoing surgery is steadily increasing. Postoperative cognitive dysfunction (POCD) is a prevalent complication among elderly patients during the perioperative period. This study explores anaesthesia-induced transcription factor changes at the single-cell level and investigates their molecular roles that mediate postoperative cognitive impairment in aged mice. These findings provide a foundation for targeted therapeutic strategies.

Materials and Methods: Single-cell RNA sequencing was performed on hippocampal tissues from 18-month-old mice subjected to anaesthesia and surgery. Data analysis and visualisation were primarily conducted using R. Additional interventions and validations included primary cell culture, animal modelling, behavioural assessments, in vivo calcium imaging, and other experiments.

Results and Discussion: Hippocampal cells from the control and surgery groups were annotated into nine major cell types. Differential gene expression, functional enrichment, and pseudotime analyses classified microglia into homeostatic (MG0), intermediately stressed (MG1), and pro-inflammatory (MG2) states, which are consistent with microglial cell type identification in the brains of elderly AD patients. Transcriptomic analyses identified significant upregulation of Cebpb across microglial states following surgery. Cebpb dose-dependently enhanced the transcriptional activity of the Unc93b1 promoter.

Upregulation of Cebpb was observed in primary microglial cells and BV2 cells stimulated with LPS, as well as in the hippocampus of surgery mice. Knockdown of Cebpb in the dorsal hippocampus of aged Cx3cr1CreER mice partially restored microglial homeostasis and downregulated mRNA levels of pro-inflammatory

Furthermore, both in vitro and in vivo experiments demonstrated that knocking down Cebpb in microglia alleviated inflammationinduced neuronal structural changes, restored Ca2+ signalling, and improved cognitive performance.

Conclusion(s): In summary, this study provides a comprehensive cellular-level molecular profile of the hippocampus following surgery in aged mice. It highlights the pivotal role of Cebpb in mediating POCD through the regulation of microglial activation states. Acknowledgements: This work was supported by the National

Natural Science Foundation of China and the Scientific Research Fund of Shanghai Fourth People's Hospital.

31AP03-8

The dynamic range of the EEG spectral slope between vigilant states decreases with age

C. Troyas¹, P.S. Garcia², G. Schneider¹, M. Kreuzer¹ ¹Technical University of Munich, School of Medicine, Department of Anesthesiology and Intensive Care Medicine, München, Germany, 2 Columbia University Irving Medical Center, Department of Anesthesiology, New York, **United States**

Background: Over the next decade, the aging population will lead to a rise in surgical procedures requiring general anaesthesia, often involving patients with increased brain vulnerability. Intraoperative electroencephalographic (EEG) monitoring enables the individualised administration of analgo-sedative medications. Age-related neurophysiological changes are known to impact EEG patterns.

We examined changes in EEG spectral slope across various states of vigilance during general anaesthesia across different age groups. The dynamic range of spectral slope observed in EEG recordings from distinct anaesthesia states provides insight into age-related neurophysiologic changes.

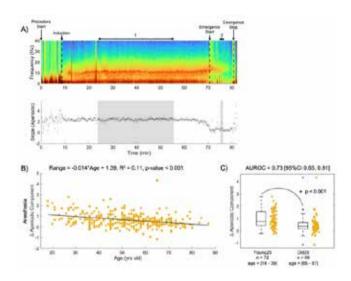

Methods: We retrospectively analysed 324 recordings of EEG during maintenance and emergence from anaesthesia (ages: 18-87 years old). Our analysis focused on the central 30-minute maintenance interval, and the central minute between emergence start and end (Fig. 1A).

For these intervals, we calculated power spectra and applied the "fitting oscillations & one over f" algorithm to obtain the EEG's aperiodic component (spectral slope). We determined the median dynamic range for each subject as the difference between the emergence and maintenance spectral slope.

Results and Discussion: The dynamic range of spectral slope during anaesthesia decreased linearly with age (Range=-0.014*age+1.39; R2=0.11) (Fig. 1B).

The youngest quartile of the subjects showed a significantly higher dynamic range than the oldest quartile. Age had a "very strong" effect on the dynamic range (Young25: 0.92[0.42, 1.35], Old25: 0.47[0.18, 0.66], p<0.001, AUC:0.72[0.64, 0.80]) (Fig. 1C).

Thus, the young brain expressed a larger dynamic range, i.e., a stronger change in EEG spectra between the more "awake" (anaesthesia maintenance) and more "sleepy" (emergence) state than the old brain.

Conclusion: Our findings revealed a reduced dynamic range between different vigilance states in older subjects during anaesthesia, indicating age-related alterations in brain dynamics. These insights have the potential to support the individualized monitoring and administration of anaesthetic agents across diverse age groups.

31AP03-9 Optic nerve sheath ultrasound during electroconvulsive therapy

İ. Aksoy¹, D. Lafli Tunay², M. Aksoy³ ¹Bursa City Hospital, Anesthesiology and Reanimation, Bursa, Turkey, ²Cukurova University, Anesthesiology and Reanimation, Adana, Turkey, 3Bursa City Hospital, Ophthalmology, Bursa, Turkey

Background and Goal of Study: Electroconvulsive therapy (ECT), which is applied by producing a seizure with an electrical current under general anesthesia, is an effective and reliable method in the treatment of most psychiatric diseases. Nevertheless, how the treatment affects neuronal mechanisms is controversial.

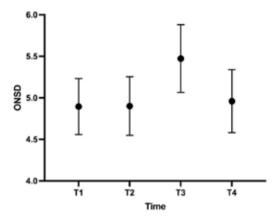

In this study, we aimed to evaluate the changes in cerebral physiology caused by ECT stimulus and induced seizure activity in real time by ultrasound-guided optic nerve sheath diameter measurement, which is a simple, non-invasive and inexpensive method.

Thus, the primary outcome of the study was to determine the change in ONSD value during the postictal period compared to baseline. Secondary objectives include identifying patient and ECT procedure-related factors affecting ONSD.

Materials and Methods: Thirty-nine patients were included in the study and ONSD measurements were performed on all patients four times: before and after anesthesia induction, after ECT (postictal), and during the recovery phase.

Age, weight, height, psychiatric diagnoses, medications and comorbidities, blood pressure and heart rate values, and motor seizure durations were recorded.

Results and Discussion: Postictal ONSD measurement was found to be statistically significantly higher than measurements in the pre-induction, post-induction and recovery periods (p<0.001) (mean values were 5.47 mm, 4.89 mm, 4.90 mm and 4.96 mm respectively) (Figure 1). The change in ONSD during ECT was significantly higher in patients with pre-existing hypertension than in those without hypertension (p=0.001). Additionally, increased blood pressure and increasing age were positively correlated with ONSD.

Conclusion(s): In patients with an indication for ECT and without an intracranial space-occupying lesion, ECT procedure may cause a transient increase in intracranial pressure (ICP). This change in ICP may be more pronounced in patients with a diagnosis of hypertension.

31AP03-10

Subcortical connectivity patterns during introduction of non-rapid eye movement sleep (NREMS) and isoflurane-induced loss of responsiveness are partly different in mice

M. Vadkertiova¹, L. Joyce¹, R. Nuttall¹, M. Kreuzer¹, G. Schneider¹, T. Fenzl¹ ¹School of Medicine, Technical University of Munich. Department of Anesthesiology & Intensive Care, Munich, Germany

Background: Anesthesia and NREMS may be seen as two distinct entities, although sharing physiological and behavioral similarities. As both processes are not fully understood, identifying common neuronal mechanisms may help optimizing anesthetic regimes. This study investigated functional neuronal connectivity between nuclei from the sleep/wake-promoting pathway (SWP) during wake/NREMS/wake transitions, and during isofluraneinduced (IA) loss (LOR) and recovery (ROR) of responsiveness. Similar neuronal activities in central nuclei of the SWP during these transitions may point towards an active role of the SWP in LOR and ROR.

Methods: Twelve male C57BL6/N mice were implanted with local field potential (LFP) electrodes in the ventrolateral preoptic nucleus (VLPO) and the locus coeruleus (LC) to monitor neuronal activity, as well as EEG electrodes to monitor sleep/wake behavior. Chronic recordings were performed simultaneously, including two baseline days and IA. Sleep/wake behavior was scored and all wake/NREMS/wake transitions were identified.

Functional connectivity between VLPO and LC during wake/ NREMS/wake, LOR and ROR were analyzed using coherence, inter site phase clustering (ISPC), and Granger casualty (GC) analyses. Significance was set at 95% (Wilcoxon signed rank test).

Results and Discussion: LFP data revealed increased coherence between VLPO and LC during NREMS and a decrease during wake. Coherence between the two nuclei decreased after LOR, compared to pre-LOR. During ROR, coherence did not change significantly. Analogous to coherence for wake/NREMS, ISPC between VLPO and LC showed an increase during NREMS and a decrease during wake. ISPC across LOR and ROR did not vary significantly. GC analysis between VLPO and LC during wake and NREMS revealed a bidirectional influence between VLPO and LC. VLPO activity granger caused LC activity during NREMS. At specific frequency bands, LC granger caused VLPO activity during wake and NREMS.

After LOR, the GC index from VLPO to LC increased partly. The study supports literature on functional VLPO/LC connectivity during wake/NREMS transitions, while the two nuclei seem to have at least a less prominent participation in LOR and ROR.

Conclusion: An active role of LC and VLPO in LOR and ROR remains unclear, based on the present results. At present we perform identical experiments together with a selective manipulation of the nuclei to gain a more detailed picture of neuronal dependencies during the transitions.

31AP03-11 Contrast-induced encephalopaty: a case report

M. Llobell¹, L. Mora Gómez¹, B. Perolada Beaus¹, O. Aznar Millán¹, L. Edo Cebollada¹ ¹Hospital General Universitario de Castellón, Anestesiología, Castellón, Spain

Background: Contrast-induced encephalopathy (CIE) is a rare neurological complication caused by direct neurotoxicity from the use of radiological contrast agents. The occurrence of this condition has been documented following both diagnostic procedures (e.g., CT scans) and therapeutic interventions (e.g., cardiac catheterization or cerebral angiography). The estimated incidence is low, around 0.3-2%, although it is believed to be increasing due to the more frequent use of radiological contrasts.

Case Report: We present the case of a 73-year-old woman with a history of hypertension, type II diabetes, dyslipidemia, and steatohepatitis, who underwent endovascular exclusion of an aneurysm in the left internal carotid artery. The procedure was performed under general anesthesia (TIVA) without incidents. Upon extubation, the patient exhibited difficulty connecting with her surroundings. Upon arrival at the ICU, she presented moderate psychomotor agitation, an unintelligible gaze, did not obey commands, and had mixed aphasia, receiving a GCS score of 9-10. A non-contrast CT scan showed blurring of the sulci predominantly in the left frontoparietal region, with asymmetry compared to the contralateral cerebral convexity, without signs of ischemia or hemorrhage. The patient was closely monitored, receiving fluid therapy and corticosteroids. Over the next 48 hours, she maintained the same clinical presentation, with newly developed right hemiparesis. At 72 hours, the patient showed progressive improvement and regained consciousness without motor focality, leading to her discharge from the unit with a diagnosis of CIE.

Discussion: The differential diagnosis of altered consciousness or neurological focality, which are the most common symptoms of CIE. is of great clinical interest. Since it is a diagnosis of exclusion. a high clinical suspicion is needed after ruling out more common complications such as stroke and posterior reversible encephalopathy syndrome.

Therefore, understanding the clinical features and diagnosis of this condition is particularly relevant. Even more importantly, knowledge of its evolution is crucial, as, unlike other conditions, it typically has a good prognosis with complete neurological recovery within 24-72 hours.

Reference:

DOI: 10.1016/j.nefro.2023.05.007

Learning Points: CIE is a rare neurological condition caused by the use of radiological contrast agents that should be suspected if altered consciousness is presented after its use.

31AP03-12

Alzheimer's disease polygenic risk scores applied to a surgical population

M. Thedim 1, J. Hu1, M. Maher1, J. Wiener-Kronish1, R. Saxena¹, S. Vacas¹

¹Massachusetts General Hospital, Department of Anesthesia, Critical Care and Pain Medicine, Boston, **United States**

Background and Goal of Study: Alzheimer's Disease (AD) polygenic risk scores (PRS) have emerged as valuable tools for predicting AD and identifying its preclinical stages. Previous research has demonstrated that surgery and anesthesia may accelerate cognitive dysfunction in individuals within the preclinical stages of AD. Early identification of patients at elevated risk for AD could facilitate the implementation of preventive measures and targeted treatment strategies, potentially altering the disease trajectory and improving perioperative cognitive outcomes.

This study assessed the feasibility and utility of applying AD-PRS to a surgical patient population within the Mass General Brigham (MGB) health system.

Materials and Methods: Data was obtained from the MGB Biobank, a repository of biospecimens and clinical data approved by the MGB Institutional Review Board. We included patients aged 40-89 years with current procedural codes for anesthesia and no documented AD diagnosis before surgery. AD-PRS derived from previous genome-wide association studies were applied to this cohort, and subsequently, a PRS-based phenome-wide analysis was conducted.

Results and Discussion: A total of 33,526 patients (median [IQR] age, 67 [19] years; 54% females) were identified. The distribution of AD-PRS within the cohort followed a normal distribution, with 3,352 patients presenting scores above the 90th percentile, Fig-

Our PRS-based phenome-wide analysis confirmed the genetic link between increased AD-PRS and its phenotypical expression, Figure 2.

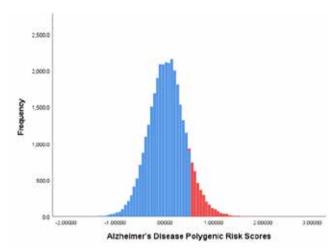

Figure 1.

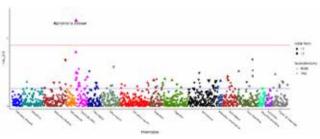

Figure 2.

Conclusion(s): The application of AD-PRS in surgical populations demonstrates potential for enhancing preoperative risk stratification. Identifying patients at increased genetic risk for AD may enable the development of targeted interventions aimed at increasing resilience against the cognitive challenges associated with surgery.

31AP04-1

Investigating the effect of age on the EEG's first-digit distribution during wakefulness and sevoflurane anaesthesia

S. Widmann¹, A. Prasad¹, G. Schneider¹, M. Kreuzer¹ ¹Technical University of Munich, Department of Anesthesiology and Intensive Care, Munich, Germany

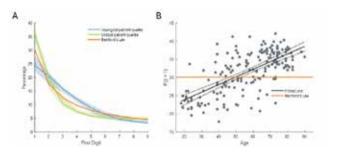

Background: Time-domain analyses, e.g. entropies, capture nonlinear information from EEG signals and reliably track consciousness levels. An alternative, yet less established, approach examines the first-digit distribution of EEG amplitudes, i.e., the probabilities of the leftmost non-zero digits. This is based on Benford's Law, which predicts a logarithmic distribution of leading digits 1-9. First-digit distributions of EEG signals differ between wakefulness and general anaesthesia while maintaining a Benford-like behaviour [1].

As age influences EEG patterns during general anaesthesia [2], we aimed to examine how age affects these distributions during different consciousness levels.

Methods: We retrospectively analyzed frontal EEG from 111 subjects aged 17-71 during resting wakefulness [3] and 180 patients aged 18-90 under sevoflurane anaesthesia without surgical stimulation [2]. 30 seconds of artefact-free, non-burst suppression EEG were used to derive first-digit distributions. Median absolute deviation (MAD) and sum of squared differences (SSD) were computed as effect sizes to compare distributions between age groups. Linear regression was used to examine age-related changes in the probability of specific digits.

Results: During wakefulness, first-digit distributions showed no significant differences between the youngest and oldest patient quartiles (MAD=0.0036, SSD=3.33), and linear regression revealed no age-related effects. During anaesthesia, however. MAD and SSD indicated differences between the age groups (MAD=0.0324, SSD=192.52; Fig. A).

The most pronounced deviation was in the probability of the digit '1', which increased significantly with age (P(d=1)=19.70+0.21*age, p<0.001, R²=0.45; Fig. B).

Conclusion: Our findings highlight the need to account for age when using first-digit distributions as an analytical tool in EEG research. Future research should investigate whether analysis of leading digits in the EEG can track unconsciousness in individual patients.

Intraoperative continuous non-invasive evaluation of cerebral compliance and correlation with early postoperative cognition status in elderly patients undergoing surgery in Trendelemburg position: an observational study

G. Tognini Saba1, V. Caldeira Quintão1, C. Marquez Simões¹, L.G. Villares da Costa¹, G.H. Frigieri Vilela², M.J. Carvalho Carmona¹ ¹University of São Paulo, Anesthesiology, São Paulo, Brazil, ²Brain4care, Scientific Director, São Carlos, Brazil

Background and Goal of Study: The Trendelenburg position can impair cerebral venous return, increasing intracranial pressure (ICP) and potentially contributing to postoperative cognitive dysfunction (POCD). As routine invasive monitoring of ICP intraoperatively is unfeasible, this study aimed to evaluate cerebral compliance as a non-invasive surrogate, its correlation with optic nerve sheath diameter ultrasound (ONSD), and its association with POCD in elderly patients.

Materials and Methods: After Institutional Ethics Committee approval, a prospective observational study was conducted on 48 male patients aged over 40 undergoing general anesthesia for laparoscopic or robotic prostatectomy in the head-down tilt position. In addition to hemodynamic and respiratory monitoring, processed EEG (SedLine®), optic nerve sheath diameter ultrasound, cerebral oximetry (O3®), and cerebral compliance (Brain4Care®) were measured throughout surgery. Brain4Care® assesses skull movement, with a P2/P1 ratio > 1.2 indicating increased ICP. Cognitive function was evaluated using the Montreal Cognitive Assessment (MoCA) pre- and postoperatively.

Data were analyzed using the t-test with Welch's correction and the Mann-Whitney test, with effect sizes calculated using Cohen's d and rank-biserial correlation. In addition, mixed-effects modes, accounting for variability between subjects and repeated measures were used to predict outcomes. Significance was set at P < 0.05.

Results and Discussion: The mean age of participants was 64.60 ± 8.67 years. Intraoperative P2/P1 ratios > 1.2 were observed in 39.5% of patients. Mixed-effects modeling identified significant predictors of cerebral compliance changes, including patient weight (OR 0.93, P < 0.001), surgery duration (OR 4.05, P = 0.03), mean arterial pressure (OR 1.04, P < 0.001), and heart rate (OR 1.03, P = 0.04). Age (OR 13.3, P < 0.001) and surgery duration (OR 1.32, P < 0.001) were significant predictors of postoperative cognitive impairment in the same model.

Conclusion(s): Trendelenburg positioning during prostatectomy in elderly patients was associated with reduced cerebral compliance, suggesting a transient rise in ICP. Non-invasive cerebral compliance monitoring may facilitate early detection and management of ICP increases, though further studies are required to confirm these findings.

31AP04-3

Delayed emergence from anesthesia after cranioplasty: a case report

K. Chen¹. C. Lu¹ ¹Chi Mei Medical Center, Department of Anesthesia, Tainan, Taiwan

Background: Cranioplasty is usually performed following decompressive craniectomy, which is aimed to alleviate cerebral swelling or herniation in traumatic brain injury. Primary reasons for cranioplasty are brain protection and cosmetic considerations, or to relieve the syndrome of trephine.

Case Report: This 67-year-old female with a history of right fronto-temporal intracranial hemorrhage(ICH) s/p craniotomy and cranioplasty in 2001, and recent traumatic brain injury(TBI) with right fronto-temporal large ICH s/p craniotomy, was admitted for scheduled cranioplasty. In OR, she was clear and oriented. Anesthesia induction was performed smoothly. Fentanyl was administered for intraoperative hypertension. Surgery lasted for 2 hours without complication. However, she had no response to painful stimuli, and constricted pupils were found. Naloxone was given to reverse opioid overdose. She was then extubated with eye opening to pain, acceptable neuromuscular reversal and intact gag reflexes. GCS score remained E2V1M3 at PACU. There was no electrolyte imbalance, hypoglycemia or hypercapnia. Clinical diagnosis was in favor of delayed emergence. To rule out emergent causes requiring surgical intervention, brain CT revealed right frontal epidural hematoma, 6.6mm. No acute ICH or brain swelling was noted. Further EEG revealed no epileptiform activity. She was discharged in her baseline cognitive function one week afterwards.

Discussion: Cranioplasty is considered a straightforward procedure; however, it carries the potential for unforeseen complica-

Although no specific cause for the prolonged altered consciousness was identified, the patient did exhibit impaired consciousness, which continued to significantly affect both patients and

We speculated that previous TBI with involvement to the prefrontal cortex was likely to play a role in delayed awareness.

Reference:

Edlow et al. Recovery from disorders of consciousness: mechanisms, prognosis and emerging therapies. Nat Rev Neurol 17, 135-156 (2021).

Learning points: Previous traumatic brain injury with involvement to the prefrontal cortex may lead to delayed emergence following cranioplasty.

31AP04-4

First steps to a novel method to quantify cerebral autoregulation efficacy continuous and real time

R.V. Immink¹, Y. Lam¹, D.P. Veelo¹, A.P. Vlaar², E. Kho¹ ¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Intensive Care, Amsterdam, Netherlands

Background and Goal of Study: Cerebral autoregulation (CA) efficacy can be quantified from the phase difference between blood pressure (BP) and middle cerebral artery flow velocity (MCAV) oscillations. When CA is present MCAV oscillations will lead BP oscillations (phase lead is positive) and when CA is absent both oscillations will parallel (i.e. phase lead tends to 0 degrees). Intra operatively, BP oscillations can be induced by intermittent positive pressure ventilation (IPPV).

Since it takes approximately 5 seconds for CA mechanisms to become operative, the BP oscillation frequency, needed to assess CA, has to be significantly slower that 0.2 Hz.

Our goal is to develop at tool to assess CA continuously intraoperatively.

Therefore, we ventilated patients with 8min-1 (0.125Hz) throughout a surgical procedure where longstanding deep hypotension is required. This enabled us to quantify CA every minute during the whole procedure.

We hypothesized that at normotension the phase lead is positive. towards 30 degrees, and at hypotension, defined as BP below the lower limit of the CA (LLCA), this phase lead will decrease towards 0 degrees, indicating impaired CA.

Materials and Methods: Continuous mean BP and the mean MCAV of 15 patients were monitored during surgery, with a ventilation rate of 0.125 Hz. The LLCA for each patient was assessed to determine the blood pressure where the CA is impaired (left to the LLCA), and intact (right to the LLCA).

Next, the phase lead was calculated every 60 s, based on 120 s of data. The derived phase leads corresponding to a BP below the LLCA, minus 10 mmHg, and above the LLCA, plus 10 mmHg, were averaged. Data are expressed as median (25th-75th percentile). Results and Discussion: Based on 15 patients, the median LLCA

was located at 56 (49 to 66) mmHg. Right from the LLCA, the median phase lead was 22 (15-28). Below the LLCA the phase lead was lower with 11 (5-15, p<0.01).

Conclusion: These preliminary results show that the CA can continuously be quantified, applying a ventilation frequency of 8min-1. Additional, a phase lead above 15 degrees might indicate a functioning CA, whereas a phase lead below it might indicate an impaired CA, but this should be assessed with more patients.

31AP04-6

The effect of intranasal dexmedetomidine on surgical field quality and hemodynamic stability in transnasal transsphenoidal pituitary surgery

E.-I. Tataki1, K. Manika1, I. Galonakis2, K. Barkas2, G. Gkantinas³, C. Balakera¹ General Hospital of Nikea-Piraeus, Anesthesiology, Athens, Greece, 2General Hospital of Nikea Piraeus, Neurosurgery, Athens, Greece, 3 Onassis Cardiac Surgery Center, Anesthesiology, Athens, Greece

Background and Goal of Study: Dexmedetomidine is an α 2adrenoreceptor agonist that provides sedation and sympatholysis, but also causes peripheral vasoconstriction. Intranasal dexmedetomidine has been explored for optimizing the surgical field in transsphenoidal pituitary surgery, though evidence is limited. This study compares the effects of adrenaline alone to a combination of adrenaline and dexmedetomidine, both applied locally to the nasal mucosa.

We hypothesize that the combination will improve surgical field conditions, particularly regarding mucosal bleeding, as well as reduce hemodynamic fluctuations.

Materials and Methods: We enrolled 24 participants, randomly assigned to two groups: Group C (control), receiving nasal preparation with one round of normal saline cotton strips and one round of adrenaline; and Group D, receiving one round of dexmedetomidine cotton strips and one round of adrenaline.

The primary endpoints were surgical field quality, assessed using Wormald's grading system at various stages (endoscope insertion, mucosal preparation, sphenoid bone drilling, tumor excision, and end of surgery), and hemodynamic stability, measured by mean arterial pressure (MAP) and heart rate (HR).

Secondary endpoints included the need for esmolol infusion to manage hypertension, tachycardia, or poor surgical field quality. Continuous data were analyzed using t-tests or Mann-Whitney U tests, and hemodynamic differences were assessed using repeated-measures ANOVA.

Results and Discussion: No significant differences in Wormald's scores were observed between the groups at any surgical stage. Hemodynamic parameters also showed no significant differences. The use of esmolol did not differ significantly between groups. These results may be due to the small sample size or the lack of additional benefit from combining dexmedetomidine with adrena-

Conclusion(s): Adding dexmedetomidine to adrenaline did not improve surgical field quality or hemodynamic stability in transnasal transsphenoidal pituitary surgery.

Nevertheless, larger randomized controlled trials are needed to confirm these findings.

Future studies comparing dexmedetomidine alone to adrenaline could provide further insight into its potential benefits. We also propose studying patients with acromegaly or Cushing's disease separately as the degree of bleeding may be exaggerated in these cases.

31AP04-7

Use of processed EEG in the ICU: enhancing real-time patient care and gaining insights into brain activity during sedation

I. Marcolino¹, M. Schreiber¹, D. Hight², J. Berger³ ¹Spital Limmattal, Institute of Anaesthesiology and Intensive Care, Schlieren, Switzerland, ²University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, ³University of Bern, Institute for Medical Education, Bern, Switzerland

Background: Processed electroencephalography (pEEG) has been used to assess the depth of anaesthesia in surgical settings. Its application has recently extended to the Intensive Care Unit (ICU) to monitor brain function in sedated patients. This case series explores retrospective EEG data to understand brain activity during sedation.

Case Report: This retrospective case series was conducted in three patients from a general ICU at Spital Limmattal (Schlieren, Switzerland). The dataset included pEEG records of ICU patients sedated with a protocol involving propofol, ketamine, and sufentanyl. Neuromuscular blocking drugs were not used. EEG recordings were visually analysed, focusing on delta (0.5-4 Hz) and extended alpha (7-12 Hz) frequency ranges. Visual analyses identified stable or cyclical alpha power and transition to low-beta (12-25 Hz) states. Only patients who had provided general consent for data use were included.

Discussion: Preliminary analyses revealed consistent sustained power in the delta frequency range during sedation. The alpha range displayed variability, with some patients showing alphadelta patterns similar to general anaesthesia, while others experienced intermittent alpha power loss reminiscent of natural sleep. Stable EEG patterns in the delta range and variations in the alpha and beta ranges highlight individual responses to sedation protocols.

Image:

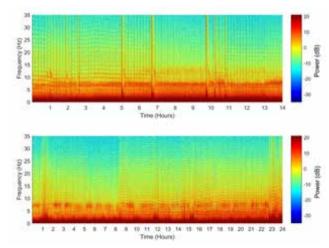

Image 1: Density Spectral Array (DSA) showing variations in alpha power during sedation. Above resembling general anesthesia and below resembling cyclical alpha power changes.

Learning Points: pEEG monitoring in the ICU offers valuable real-time data to optimise sedation management, enhancing outcomes beyond traditional clinical assessments. The ability to detect specific EEG patterns provides insight into sedation depth and patient variability.

Intraoperative neurophysiological monitoring: Prediction of motor deficits by transcranial motor evoked potentials in supratentorial oncological surgery

N. Faria¹, J. Leote², A. Pérez-Hick³, M. Silva⁴, J. Monteiro5, C. Casimiro4 ¹Hospital Garcia de Orta, Neurosurgery Techinician, Almada, Portugal, ²Hospital Garcia de Orta, Intensive Care, Almada, Portugal, 3Hospital CUF Teio, Anaesthesia. Lisboa, Portugal, 4Hospital Garcia de Orta, Neurosurgery, Almada, Portugal, 5Hospital de São José, Neurosurgery, Lisboa, Portugal

Introduction: Motor neurological morbidity associated with supratentorial brain oncology leads to a worse quality of life. For this reason, intraoperative motor evoked potentials (MEPs) and their stability during the surgical procedure promote surgical safety. However, transcranial electrical brain stimulation (TCMEPs) occurs in an undetermined area between the cerebral cortex and the internal capsule due to brain conductivity. Therefore, the relevance of isolated TcMEPs for predicting motor deficit in this type of procedure remains to be investigated.

Objective: To describe and correlate the presence of alarm criteria obtained in the TcMEPs and the presence of motor deficits 48 hours after supratentorial oncological surgery.

Methodology: A retrospective and observational study was carried out on a convenience population of patients who underwent craniotomy for supratentorial oncological pathology between July 2013 and

2023. The presence of alarm criteria in the TcMEPs was identified as follows: a peak-to-peak amplitude decrease of at least 50% in muscles contralateral to the craniotomy during the tumor resection period. Motor deficits at 48 hours were clinically assessed in comparison with preoperative deficits, using the Medical Research Council muscle strength scale. Anaesthetic induction was achieved using a bolus of muscle relaxant for intubation purposes and maintained with Target Controlled Infusion of propofol and remifentanil to maintain adequate hipnose (bis) and hemodinamic stability. A descriptive analysis of the sample and a correlation between the presence of alarm criteria and clinical motor deficit were performed.

Results: 211 patients were revised, 9 of whom were excluded due to insufficient records. The sample consisted of 202 patients with a median age of 55.5 years and an interquartile range of 22.25 years. TcMEPs warning signs occurred in 40 patients, of whom 25 (12% of the total) did not show new motor deficits in the immediate postoperative period. Patients with changes in TcMEPs showed a difference in the mean score of -1.12 (+/-1.5) on the muscle strength scale compared to the pre-surgical moment (vs0.28+/-0.79 in patients without changes in TCMEPs). The correlation between changes in TCMEPs and new motor deficits was moderate (rpb=-0.324.p<0.001).

Conclusion: Changes in TcMEPs during neurosurgical resection of supratentorial tumors correlate moderately with the presence of new motor deficits in the immediate postoperative period.

31AP04-9

Effects of positive end-expiratory pressure (PEEP) on cerebral arterial and venous flows in septic patients: Transcranial colour-Doppler ultrasound (TCCD) analysis

D. Vannini¹, M. Pillitteri¹, L. Vegnuti¹, B. Ferro¹ ¹Ospedali Riuniti di Livorno, Anestesia e Rianimazione, Livorno, Italy

Background and Goal of Study: Increased intrathoracic pressure can reduce cerebral venous outflow, leading to elevated intracranial pressure (ICP) with a reduction in cerebral perfusion. Monitoring these effects are of considerable interest. The primary goal of the study was to evaluate the impact of PEEP on the arterial and venous cerebral systems in septic mechanically ventilated(MV) patients.

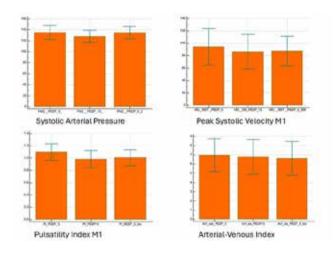

Materials and Methods: An observational case series was conducted on 12 septic MV patients; informed consent was obtained. We measured Driving Pressure (DP). Systolic Arterial Pressure (AP), velocity (PSV) in the cerebral middle cerebral artery (MCA) and Rosenthal vein (RV), Pulsatility Index (PI), and Arteriovenous Index (AVI). The AVI between MCA and RV is a parameter used to differentiate vasospasm from hyperperfusion, helping evaluate cerebral circulation. Measurements were taken at different levels of PEEP (P): 5 cmH2O, 15 cmH2O, and then returning to 5 cmH2O. The study adhered to the STROBE guidelines(1).

Results and Discussion: Results are shown in Table 1 and Figure 1. No significant variations were found in hemodynamic parameters, arterial and venous velocity, or the AVI index between the PEEP levels. This suggests that in septic patients with respiratory failure and hemodynamic stability, increasing PEEP to reduce DP does not appear to compromise cerebral circulation or cause intracranial congestion.

Conclusion: This study has limitations, including the small sample size and the lack of measurement of PaCO₂ variations. Future research could focus on evaluating patients with hemodynamic

The analysis of AVI is a simple and useful tool for monitoring signs of vascular congestion. TCCD allows for the rapid detection of venous circulation and is a suitable method for bedside monitoring of cerebral perfusion.

latrogenic stroke and intracranial hemorrhage: complications of intraauricular hyaluronic acid augmentation

Z.C. Su¹, Y.-Y. Chiang¹
¹China Medical University Hospital, Department of Anesthesiology, Taichung, Taiwan

Background: The rising popularity of hyaluronic acid injections for facial aesthetics, rhinoplasty, and intraauricular procedures has unfortunately been accompanied by an increase in the number of reported severe adverse events, including stroke caused by cerebral embolism and vision loss.

Case Report: This is a tragic case of a 36-year-old female who underwent bilateral grommet removal and bilateral hyaluronic acid injection tuboplasty. Patient developed left gaze palsy, left central facial palsy, and left limb paralysis after surgery.

Initial brain CT did not reveal any obvious problems like bleeding or a typical stroke. However, the lack of improvement prompted further investigation with an MRI, which revealed embolic ischemic stroke in the right internal carotid artery (ICA) territory, with evidence of hemorrhagic transformation.

Despite the initial diagnosis and treatment with aspirin, the patient's condition deteriorated rapidly. Emergent CT scan showing significant edema and hemorrhage in the right frontal-parietal lobe, leading to midline shift. A bilateral craniectomy was performed, along with a right temporal lobectomy to relieve pressure. An intracranial pressure (ICP) monitor and a Kocher's external ventricular drain (EVD) were also placed. Intraoperatively, the brain was noted to be swollen and under high pressure, accompanied by hypotension. Norepinephrine and vasopressin were administered throughout the procedure. Despite efforts, the ICP elevated at 88 mmHg. Tragically, the patient developed bilateral pupil dilation, a grim prognostic sign, and passed away two days later.

Discussion: This case highlights the potential for rare but serious complications associated with hyaluronic acid injections, even in seemingly low-risk procedures. While the exact mechanism of injury remains unclear, it is possible that the injection led to an embolic stroke, potentially due to accidental intra-arterial injection.

Reference:

1. Sito G, Manzoni V, Sommariva R. Vascular Complications after Facial Filler Injection: A Literature Review and Meta-analysis. *J Clin Aesthet Dermatol*. 2019;12(6):E65-E72.(2) Wang HC, Yu N, Wang X, et al. Cerebral Embolism as a Result of Facial Filler Injections: A Literature Review. *Aesthet Surg J*. 2022;42(3):NP162-NP175. doi:10.1093/asj/sjab193

Learning points: While hyaluronic acid injections are generally considered safe, there is a small chance of serious complications, including stroke.

31AP04-12

Predictive factors of extubation failure in brain injured patients: a clinical descriptive study

A. Erragh¹, <u>B. Salma</u>¹, C. Safia², A. Nsiri¹, R. AlHarrar², H. Sarah^{1,1}

¹CHU IBN Rochd, Anesthésie-Réanimation, Casablanca, Morocco, ²CHU IBN Rochd, Anesthésie Réanimation, Casablanca, Morocco

Background and Goal of Study: Acute brain injury is a common condition in the emergency department, often requiring intubation and mechanical ventilation to protect the airway. Extubation in brain-injured patients is a challenging process with a high failure rate, leading to delayed extubation, prolonged mechanical ventilation, and increased morbidity and mortality. The optimal timing for extubation remains a controversial issue with significant medical and economic implications.

This study aimed to identify predictive factors for extubation failure in brain-injured patients based on our local experience.

Materials and Methods: We conducted a prospective descriptive and analytical study of patients with acute brain injury requiring at least two days of mechanical ventilation.

The study was carried out in the surgical intensive care unit of the Anesthesiology and Intensive Care Department at Ibn Rochd Hospital, Casablanca, over a 54-month period from January 2019 to June 2023.

Results and Discussion: The study included 165 patients, with a mean age of 40 years and a male predominance (sex ratio 4.15). Traumatic brain injuries accounted for 78.2% of cases. Subarachnoid hemorrhage was the most common injury (39.4%), followed by epidural hematoma (34%) and subdural hematoma (23.6%). Most patients (91.5%) were intubated on the first day of hospitalization. The extubation failure rate was 31.5%. Predictive factors for failure included low Glasgow Coma Scale (GCS) scores at admission, bilateral mydriasis, the presence of intraventricular hemorrhage, subdural or epidural hematomas, delayed weaning, unresponsiveness to simple commands, GCS scores ≤10 before extubation, absence of protective airway reflexes, a facial VIS-AGE score <3, and a low CRS-R visual score.

Extubation failure significantly increased mechanical ventilation duration (15.65 vs. 6.93 days), ICU stay (23.27 vs. 11.77 days), ventilator-associated pneumonia (41.2% vs. 2%), and ICU mortality (88.9% vs. 11.1%), with all comparisons showing p<0.001.

Conclusion(s): This study demonstrates that a thorough neurological evaluation, including assessment of airway protective reflexes, consciousness levels (VISAGE and CRS-R scores), visual pursuit, and responsiveness to commands, can predict extubation success. Early identification of these factors can reduce delayed extubation and its associated complications.

31AP05-1

Effect of cerebral oxygenation on outcomes of patients with ruptured intracranial aneurysms undergoing endovascular embolization: a prospective observational study

K.R. Madhusudan Reddy¹, P. Giribabu¹, S. Venkat¹, D. Chakrabarti¹, H.R. Aravinda², R.P. Sangeetha¹ ¹National Institute of Mental Health and NeuroSciences (NIMHANS), Department of Neuroanaesthesia and Neurocritical Care, Bengaluru, India, 2 National Institute of Mental Health and NeuroSciences (NIMHANS). Department of Neuroimaging and Interventional Neuroradiology, Bengaluru, India

Background Goal of Study: Subarachnoid haemorrhage secondary to ruptured intracranial aneurysms compromise cerebral perfusion and oxygenation, threatening optimal cerebral function. This study explored the role of regional cerebral oxygenation monitoring in predicting outcomes in these patients.

Goal of Study: To detect and capture cerebral desaturation episodes during embolization of anterior circulatory aneurysms and its effect on incidence of vasospasm, duration of the hospital stay, morbidity and outcomes at discharge.

Materials and Methods: 52 adult patients scheduled for coiling of ruptured anterior circulation aneurysms were studied. Bilateral regional cerebral oxygen saturation (rScO2) was recorded in these patients using Near infrared spectroscopy(NIRS) sensors undergoing endovascular embolisation under general anaesthesia, rScO2 values were continuously monitored and recorded throughout the procedure at 10-minute intervals.

Data regarding the vital parameters and bilateral NIRS collected at every 10 minutes till the end of the procedure.

Cerebral desaturation episode (CDE) was defined as a drop in rScO2 by 20% from baseline.

patients were monitored with a 24-hour Glasgow Coma Scale (GCS) during hospital stay and a Glasgow Outcome Scale Extended (GOSE) scale at discharge.

	tpsilateral CDE		COE		GLOBAL Average CDE	
Outcome	Hegression spellident (95% CI)	p-varie	Forgression coefficient (95% CI)	p-veaue	Hogression coefficient (96% CII)	p-vonue
AGUITHUR VESOSORISM	-0.005 (-0.561.0.352)	0.722	(10.002.77.76)	E.001	27.86 (10.3,44.82)	0.002
Mean factor (SCS)	-0.199 [0.448,0.049)	0.313	-0.68 £ (.212, -0.180)	0.011 *	(12), 4(7)	0.011
DOSE was at Docharge	-0.495 (+1.211, (1.319)	9.251	-1.797. (A 508 -0.087)	*	-13 (-531 -00h	0.040
Length of hospital stay	5.511 (0.008, 6.965)	0.046 *	12,919 (5.965, 19.872)	<0.001 ★	12:52 (5:97,19.87)	+C, 001

Results and Discussion: Among the 52 recruited patients, ten patients had CDEs.

Among 10 patients CDE, 5 patients had ACOM aneurysm, and among the other 5 had MCA and ICA aneurysms.

Reasons for CDE in ACOM aneurysms were coil prolapse into ACA, Left ACA filling defect post coiling due to occlusion, catheter induced aneurysmal perforation, and during placement of first coil and the final coil.

Increased frequency of CDEs correlated with increased vasospasm, lower mean motor score, GOSE score at discharge and increased length of hospital stay.

Conclusion(s): The frequency of CDEs and the trend of decline in rScO2 from the baseline are predictive of an endangered hypoxic brain prone to secondary brain injuries, which guides the institution of prompt corrective measures.

31AP05-5

Comparing two baseline mean arterial pressure (MAP) reference values (admission vs. historical) with cerebral oximetry index (COx)-derived optimal mean arterial pressure (MAP opt) to determine the best baseline reference for intraoperative blood pressure management in neurosurgery

F. Pastrana-Marquez¹, G. Pujol-Fontrodona²,

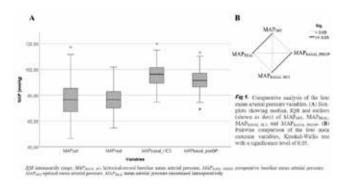

E. Pujol-Ayach², F.-J. Bellafont-Peralta², N. de Riva-Solla², E. Carrero²

¹University of Barcelona, Cirurgia i Especialitats Medicoquirúrgiques, Barcelona, Spain, 2Hospital Clinic Barcelona, University of Barcelona, Anaesthesiology, Barcelona, Spain

Background and Goal of Study: MAP fluctuations outside cerebral autoregulation (CA) range are frequent during surgery and linked to complications. COx-derived MAP opt supports individualized MAP management to preserve CA.

This study compared admission vs. historical MAP reference values with COx-derived MAP opt to identify the optimal baseline reference for neurosurgical procedures.

Materials and Methods: This retrospective study included adult patients who underwent elective brain and spinal surgeries between 2019 and 2023 at Hospital Clínic Barcelona. We reviewed the ABP electronic recordings within the Història Clínica Compartida de Catalunya (HC3) database for the two years preceding surgery and calculated the baseline mean arterial pressure (MAP $_{\mbox{\tiny BASELINE HC3}}$). This method was compared to an alternative approach based on the mean of three blood pressure measurements taken preoperatively (MAP_{BASELINE PREOP}). Differences between both methods, the COx-derived optimal mean arterial pressure (MAP OPT), (ICM+® software), and the real mean arterial pressure maintained during surgery (MAP_{REAL}) were assessed.

Results and Discussion: A total of 123 patients were included. $\mathsf{MAP}_{\mathsf{BASAL}\;\mathsf{HC3}}$ data were available for 86 patients (56%), of whom 34 (40%) had only one recording and 52 (60%) had two or more.

We found that the median (IQR) MAP $_{\rm BASAL_HC3}$ [96 mmHg (89-102)] and MAP_{BASAL PREOP} [91 mmHg (86-97)] were significantly higher than both MAP_{OPT} [77 mmHg (67-86)] and MAP_{REAL} [77 mmHg (70-83)] (p < 0.001, Kruskal-Wallis test). No significant differences were found between $MAP_{BASAL\ HC3}$ and $MAP_{BASAL\ PREOP}$ or between MAP and MAP The median (IQR) COx was 0.21 (0.09-0.28), and 97 patients (79%) had a mean COx <0.3 throughout the surgery. We were able to calculate NIRS-derived autoregulation parameters in 103 patients (84%).

Conclusion(s): Both baseline MAP values analyzed in this study. $\mathsf{MAP}_{\mathsf{BASAL}\;\mathsf{HC3}}$ and $\mathsf{MAP}_{\mathsf{BASAL}\;\mathsf{PREOP}}$ overestimated the $\mathsf{MAP}_{\mathsf{OPT}}$ Nevertheless, both clinical approaches to arterial blood pressure management in neurosurgical procedures ensured that real intraoperative pressures were optimal for maintaining CA.

31AP05-6

Impact of ultrasound-guided superficial cervical plexus block on early postoperative recovery in patients undergoing microvascular decompression

K.W. Shin1, Y.-J. Lim1

Seoul National University Hospital, Department of Anesthesiology and Pain Medicine, Seoul, Republic of Korea

Background and Goal of Study: Cervical plexus block (CPB) has been reported to provide postoperative analgesia and reduce postoperative nausea and vomiting (PONV) following various head and neck surgical procedures. Effective postoperative pain control and reduced PONV are important in improving postoperative quality of recovery (QoR).

This randomized clinical trial investigated the impact of superficial CPB on early postoperative QoR in patients undergoing microvascular decompression (MVD).

Materials and Methods: Patients undergoing MVD for trigeminal neuralgia and hemifacial spasm treatment were randomly assigned to receive superficial CPB (n = 30) or not (n = 30). Superficial CPB was conducted using 10cc of 0.5% ropivacaine under ultrasound guidance at the lower midpoint of sternocleidomastoid muscle prior to the start of surgery.

The primary outcome was the QoR-15K score on postoperative

Secondary outcomes included QoR-15K scores measured preoperatively and on postoperative day 3, postoperative pain scores, incidence of rescue analgesic requirements, PONV, and perioperative inflammatory cytokine levels.

Results and Discussion: The QoR-15K score on postoperative day 1 did not show a significant difference (94.5 [68.0-116.0] vs. 80.5 [51.5-100.8], p = 0.077) between the CPB and control groups and preoperative QoR-15K scores showed no significant time × group effect (p = 0.324). Postoperative pain scores and the incidence of rescue analgesic requirements did not differ between the two groups. The CPB group experienced reduced frequency and severity PONV at postoperative hours 6 and 12, and less frequent PONV on day 1. Perioperative inflammatory cytokine levels showed no significant differences between the two groups.

Conclusion(s): Ultrasound-guided superficial CPB was found to reduce the incidence and severity of PONV in patients undergoing MVD during the early postoperative period; however, it did not lead to an improvement in early postoperative QoR.

Antiepileptic drugs for de-novo seizures prevention after craniotomy: a systematic review and network meta-analysis of current evidence

G. Tsaousi¹, P. Tsistsopoulos², D. Mavridis³, A.B. Haidich⁴ ¹Aristotle University of Thessaloniki, Anesthesiology and ICU, Thessaloniki, Greece, 2 Aristotle University of Thessaloniki, 2nd Neurosurgery, Thessaloniki, Greece, ³University of Ioannina, Primary Education, Ioannina, Greece, ⁴Aristotle University of Thessaloniki, Hygiene-Medical Statistics, Thessaloniki, Greece

Background and Goal of Study: Epileptic seizures constitute a well-recognized clinical entity in patients harboring a brain tumor. We aimed to systematically evaluate the available clinical evidence concerning comparable efficacy and safety of currently used anti-epileptic drugs (AEDs) for early or late de novo seizures prophylaxis in patients undergoing elective craniotomy for brain tumor excision and synthesize this with a network meta-analysis (NMA).

Materials and Methods: Current literature was scrutinized to identify all randomized controlled trials (RCTs) relevant to the prophylactic use of AEDs in patients subjected to brain tumor excision. Total, early, or late post-craniotomy seizures constituted primary outcome measures, while mortality and treatment-related adverse effects served as secondary endpoints. A pairwise metaanalysis of head-to-head comparisons between drugs within trials to obtain 'direct' treatment effect estimates, while the inconsistency between direct estimates and NMA was investigated via node splitting. The quality of the retrieved RCTs was assessed by the RoB2 tool, while the quality of evidence was tabulated using the CINeMA software.

Results and Discussion: Twelve RCTs involving 10 interventions applied either preoperatively or postoperatively were retrieved. Seven RCTs were rated as having "some concerns" and the remaining as "high risk" of bias. Only levetiracetam reduced the incidence of total [OR 0.15; 95%Cl 0.03-0.73; P-score 0.90] and early [OR 0.08; 95%CI 0.02-0.43; P-score 0.90] postoperative seizures compared with phenytoin, valproate, placebo, or no-treatment. Eight studies reported the impact of prophylactic use of AEDS on late seizures and failed to show any significant effect versus placebo or no treatment.

With the single exception of carbamazepine [OR 2.68; 95%CI 1.16-6.22; P-score 0.08], none of the implemented AEDs affected mortality versus placebo. Phenytoin [OR 4.68; 95%Cl 1.43-15.27; P-score 0.29] presented a higher incidence of treatment-related AEs imposing drug discontinuation compared to other treatment regimens.

Conclusion(s): Our NMA indicates that, in seizure-naive individuals subjected to craniotomy, levetiracetam effectively prevents postoperative total and short-term seizure activity. Moreover, levetiracetam presents an enhanced safety profile, vet no statistical superiority over other AEDs, placebo, or no-treatment could be demonstrated.

31AP05-8

Patient state index (PSI) changes in children with global developmental delay (GDD) during magnetic resonance imaging (MRI) procedure under dexmedetomidine sedation

P. Pakal¹, R. Muthuchellappan², S. Bharadwaj², S Bharath², K Raghavendra³ ¹AIG Hospital, Neuroanaesthesia, Hyderabad, India, ²National Institute of Mental Health and NeuroSciences. Neuroanaesthesia and Neurocritical Care, Bengaluru, India, 3National Institute of Mental Health and NeuroSciences, Neurology, Bengaluru, India

Background and Goal of Study: Dexmedetomidine is used to sedate children requiring MRI. GDD children have exaggerated reactions to small environmental changes. Whether their sedation requirements differ from other children is not known. In this prospective observational study during MRI, PSI changes following dexmedetomidine infusion in GDD children was compared with non-GDD ones.

Materials and Methods: Children with and without GDD, aged 1-16 years, seizure-free in the last month, and requiring sedation for MRI were recruited after parental consent and institute ethics committee approval. A PSI sensor (SedLine monitor, Masimo) was applied to the forehead. Dexmedetomidine 1mcg/kg bolus was given over a 10 min period and continued as 1mcg/kg/hr infusion during MRI. PSI values (average of three recordings) along with RSA scale were noted before infusion, at 5 and 10 minutes of infusion, at return from MRI and every 5 minutes until RSA scale reached 4. Airway complications, movement episodes during shifting and scanning and rescue drugs requirements were noted. The sample size was calculated to be 37 in each group.

Results and Discussion: The PSI values significantly decreased at the end of dexmedetomidine bolus infusion, but no differences between the groups (Table 1).

	GDD group	Non-GDD group	P value
Boys: girls	18:21	26:17	
Age months (median (IQR))	48 (24-84)	60 (48-108)	0.033*
Weight kg (median (IQR))	12(10-18)	16.5(12-23)	0.013*
MRI duration min (median (IQR))	47(40-60)	60(42-70)	0.026*
Baseline RSA scale (>4) %	67	34	0.03*
Cumulative dexmedetomidine dose (mcg)	22(15-32)	32(24-39)	0.001*
PSI at baseline	95(93-96)	94 (92-95)	0.125
PSI at 5min of dexmedetomidine infusion	88(74-94)	87(80-91)	0.576
PSI at 10 min of dexmedetomidine infusion	73(36-86)	47(31-80)	0.119

Table 1.

Movement episodes were similar during shifting (33.3%: non-GDD vs 39.5%: GDD, p=0.56). During scanning, 8 children in the GDD group and 9 children in the control group moved once. The median recovery time (to achieve RSA 4) were similar in both the groups (5min: GDD vs 10 min: non-GDD, p=0.699). No airway complications happened in either of the groups. Changes in RSA and PSI correlated significantly (r=0.7, p<0.001).

Dexmedetomidine acts subcortically resulting in similar PSA values in children with and without GDD. Airway-related adverse events were not seen as dexmedetomidine maintains airway patency compared to other sedatives.

Conclusion(s): PSI changes following dexmedetomidine in GDD children were not different from their peers and hence, dose adjustments might be unnecessary. PSI correlated significantly with the RSA scale.

Opioid-free anesthesia for intracranial aneurysm clipping in opioid-dependent patient

I. Svanidze¹, L. Machitidze¹, T. Samadashvili¹, M. Khinikadze¹, G. Abashishvili², T. Svanidze¹ ¹Caucasus Medical Centre, Anesthesia and OR, Tbilisi, Georgia, 2Mmedi22, Anesthesia and OR, Tbilisi, Georgia

Background: Opioid-free anesthesia is gaining increasing popularity due to its advantages, in this case report we present an opioid-dependent patient whose surgery was performed without interrupting his anti-addiction therapy.

Case Report: The patient was a 52-year-old male with a history of hypertension and drug addiction (on methadone substitution therapy). The patient was admitted to the hospital due to a headache, selective angiography revealed an unruptured aneurysm of the right middle cerebral artery. Induction of anesthesia was performed with dexmedetomidine 1 µg/kg for 10 minutes followed by a loading dose of dexmedetomidine and propofol 2 mg/kg, followed by intubation.

Maintenance of anesthesia was with 0.7 MAC sevoflurane and 0.3/µg/kg/h dexmedetomidine. A unilateral scalp block with 0.5% ropivacaine was performed to anesthetize the surgical site.

The operation was performed without hemodynamic fluctuations. The depth of sedation was controlled by the BIS index (in the range of 35-45). The patient was extubated 30 minutes after surgery.

The immediate postoperative period was without any complications, patient was pain-free, without postoperative nausea and vomiting or episodes of hypertension. The patient did not receive any analgesics for the first 36 hours after the surgery and was discharged a few days later without complications.

Discussion: Pain management in patients undergoing opioid substitution therapy is guite challenging and can negatively impact their health, leading to higher rates of readmission, overdose, and relapse.

The primary reason for choosing dexmedetomidine in this context was to maintain relatively low blood pressure during and after surgery while achieving satisfactory anesthesia without relying on opioids. The surgery involved a regional block, and dexmedetomidine was particularly needed to manage pain associated with the dural incision. Anesthesia maintenance with low MAC (0.7) sevoflurane, allowed us to sedate the patient without increasing cerebral blood flow.

Learning Points: Postoperative pain and hypertension frequently occur after surgery, and elevated blood pressure can increase the risks of bleeding at the surgical site. Using opioid-free techniques can help reduce the chances of postoperative nausea and vomiting.

By adopting this approach, we lowered bleeding risks, improved patient satisfaction, and decreased the need for medications to manage hypertension and pain.

Incidence, predictors and sequelae of extubation failure among neurosurgical patients requiring intensive care: a prospective observational study

S. Rangaswamy Palaniswamy¹, R. Prasad¹, S. Kamath¹, D. Chakrabarti¹ ¹National Institute of Mental Health and Neurosciences, Neuroanesthesia and Neurocritical Care, Bangalore,

Background and Goal of Study: Extubation failure (EF) is an essential key performance indicator in the neurosurgical intensive care unit (NSICU). Its burden and influence on morbidity and mortality of neurosurgical patients remain to be elucidated in the context of Indian NSICUs. Hence, we aimed to evaluate the incidence, predictors and sequelae of EF among neurosurgical patients in our NSICU.

Materials and Methods: This prospective observational study was conducted from March 2023 to November 2024 after ethics approval at our tertiary care Neurosciences centre. We included all consenting neurosurgical patients admitted to the NSICU, excluding those with pre-existing tracheostomy and lack of consent.

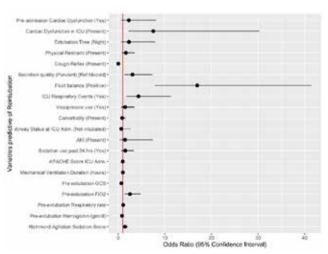

Image 1.

Sequelae	Effect	Effect (95% CL)	P-value
ICU_Tracheostomy	Odds Ratio	154.17 (55.26, 643.02)	<0.001
Post-extubation Pneumonia	Odds Ratio	73.13 (35.47, 171.67)	<0.001
In- Hospital Mortality	Odds Ratio	44.55 (12.92, 280.27)	<0.001
Length of hospital stay	Regression Coefficient	15.785 (10.98, 20.59)	<0.001
GCS at hospital discharge	Regression Coefficient	-2.552 (-2.97, -2.14)	< 0.001

Table 1: Seguelae of EF.

Results and Discussion: We screened 962 patients, of whom 396 were excluded as they did not undergo extubation (tracheostomised/died/discharged). The incidence of EF was 23.67% (134/566) among our recruited patients.

On univariate analysis, type of extubation, timing, restraint, cough/gag reflex, secretion quantity, fluid balance, ICU respiratory events, vasopressor and sedation use, cardiac dysfunction in ICU, pre-extubation FiO2, APACHE2 score, ventilation duration, GCS. RASS, haemoglobin and acute kidney injury were associated with EF.

On multivariate analysis, cardiac dysfunction in ICU (p = 0.001), positive fluid balance (p < 0.001), absent cough reflex (p < 0.001), respiratory events in ICU (p = 0.001), pre-extubation FiO2 (p = 0.003), pre-extubation haemoglobin (p = 0.035) and lighter sedation (p = 0.045) were predictors of EF (Image 1).

EF resulted in increased rates of tracheostomy, pneumonia, deaths, hospital stay and lower discharge GCS (Table 1).

Conclusion(s): The burden of EF is significant in the NSICU. Prediction using risk factors and timely restoration of modifiable variables are critical to prevent EF and its morbid and lethal sequelae.

31AP06-6

Efficacy of nalbuphine as an adjuvant to levobupivacaine scalp nerves block on postoperative analgesia in elective supratentorial craniotomy - a randomized double-blinded clinical trial

K. Yuwapattanowong¹, L. Tuchinda¹, S. Lerdsirisopon¹, S. Jatchavala¹, H. Hohma¹ ¹Faculty of Medicine, Chulalongkorn University, Anesthesiology, Bangkok, Thailand

Background and Goal of Study: The inadequate post-craniotomy pain can induce sympathetically mediated hypertension and tachycardia, which is related to morbidity and mortality. Scalp nerves block (SNB) has been shown to provide postoperative pain in early postoperative period. Nalbuphine was shown as an adjuvant to local anesthetics in various types of regional nerve blocks. The study was aimed to evaluate whether nalbuphine as an adjuvant to 0.25% levobupivacaine SNB can increase the duration of post craniotomy analgesia in elective supratentorial craniotomy.

Materials and Methods: The patients undergoing elective supratentorial craniotomy were prospectively, double-blinded randomized into two groups. After induction of anesthesia, SNB was done with 0.25% levobupiyacaine and 10 mg of nalbuphine in 1:200,000 adrenaline in the group NB, or with 0.25% levobupivacaine in 1:200,000 adrenaline in the group CB. The primary outcome was a postoperative opioid-free duration. The secondary outcomes were intraoperative mean arterial blood pressure (MAP), heart rate (HR), the total fentanyl consumptions, verbal numerical rating scale (NRS) and postoperative adverse events such as nausea, vomiting, and sedation during the first 24-hour. Post-operative analgesia was provided by patient-controlled analgesia (PCA) fentanyl. All data were collected for intention-to-treat

Results and Discussion: Sixty patients were recruited. The postoperative opioid-free duration was longer in group NB (360.03 \pm 114.93 mins) when compared to the group CB (342.4 \pm 109.12 mins) without statistical significance (p=0.545). Both intraoperative and the 24-hour postoperative fentanyl requirement were significantly lower in the group NB than the group CB (113.33 ± 50.07 mcg versus 136 \pm 34.65 mcg, p=0.047), (235.67 \pm 141 mcg versus 408.33 ± 211.62 mcg, p= 0.001) respectively. The averaged 24-hour NRS was significantly lower in the group NB (2.55 ± 1.95 versus 4.16 ± 1.8, p=0.002). MAP responses to pinning, incision and craniotomy compared with each patient at baseline was clinically greater in the group CB than the group NB. There was no difference in HR and the postoperative adverse events between

Conclusion(s): The addition of 10 mg of nalbuphine to 0.25% levobupivacaine for preoperative SNB did not prolong post-craniotomy opioid-free duration. However, nalbuphine can reduce intraoperative and 24-hour fentanyl consumption in elective supratentorial craniotomy patients.

31AP06-7

The potential of processed EEG monitoring systems in predicting postoperative cognitive disorders

E. Rieck¹, J. Ostertag¹, S. Widmann¹, G. Schneider¹, M. Kreuzer¹, S. Letz¹

¹Technical University Munich, Medicine, Munich, Germany

Background and Goal of Study: Postoperative neurocognitive disorders (PND), particularly postoperative delirium (POD), are a significant complication following surgery. It is especially prevalent among elderly patients, resulting in prolonged recovery and increased mortality [1].

This study aims to evaluate the efficacy of preoperative processed electroencephalogram (pEEG) indices to predict postoperative cognitive disorders.

Materials and Methods: 110 patients who underwent surgical intervention under general anesthesia were analyzed. Inclusion required intact preoperative EEG recordings (one minute eyesclosed and eyes-open) and cognitive assessments using the brief Confusion Assessment Method post-surgery. Processed EEG indices from three different systems (Bispectral Index (BIS), SEDLine Patient State Index (PSI), and Entropy Module's State Entropy (SE)) were analyzed. We used the Mann-Whitney U test for comparisons. Discriminatory ability was evaluated via Area Under the Curve.

Results and Discussion: Out of 80 patients (30 had to be excluded due to corrupted baseline data), 30 % showed signs of postoperative delirium. Analyses revealed significant differences in pEEG values between patients with and without delirium, particularly during the eyes-closed state. All monitor indices showed (significant but weak) predictive capability for postoperative cognitive deficits (BIS (p=0.04; AUC: 0.65 [0.51; 0.78]), PSI (p=0.05; AUC: 0.64 [0.51; 0.77]), SE (p=0.04; 0.64 [0.51; 0.76]) and RE (p=0.05: AUC:0.64 [0.51: 0.76], except BIS-SEF (p=0.09; AUC: 0.62 [0.49; 0.75].

Conclusion(s): This study highlights the potential of preoperative pEEG monitoring to identify patients at risk for postoperative delirium, particularly given the growing elderly surgical population. Results indicate that lower baseline values seem to correlate with increased risk for delirium. Its integration into preoperative assessments may enhance patient care and lower PND risks. Future work is essential to validate these findings across larger, diverse populations and to elucidate the mechanisms connecting pEEG patterns with postoperative cognitive outcomes.

Recurrent extubation failures in a patient with intracranial hemorrhage post surgery

W.X. Tan1, A.K.H. Tan1, P.K.C. Wong1 ¹Khoo Teck Puat Hospital, Anaesthesia, Singapore, Singapore

Background: Prolonged invasive ventilation is common post intracranial hemorrhage. Extubation is complex because both failure and delay increase morbidity and mortality1. Yet, there is no widely validated consensus regarding optimal timing and management. We describe a case of recurrent extubation failures in a patient with intracranial hemorrhage, to highlight key points of

Case Report: A 59 year old male presented with acute intracranial hemorrhage in the left cerebellar hemisphere measuring 3.9 x 2.7x 3.3 cm. He had a posterior fossa decompression, evacuation and insertion of external ventricular drain and was kept intubated. Post-operative scans showed a smaller residual hematoma. His GCS improved to E4VTM6, thus decision was made to extubate early after successful spontaneous breathing trials.

However extubation on post operative day (POD) 3 and 6 were unsuccessful as he went into profound bradycardia with asystole collapses, likely baroreceptor-mediated by the cerebellar hemorrhage affecting the medulla. Transvenous pacing wire was then placed for peri-extubation support. Extubation was also delayed until the edema has improved. Extubation was attempted again on POD19. However, he needed re-intubation due to Type 2 Respiratory Failure. Eventually, he was successfully extubated to BiPAP on POD22.

Of note, he required BiPAP throughout the day. He was diagnosed to have central sleep apnea superimposed on obstructive sleep apnea, attributed by his cerebellar hemorrhage. He was later discharged with nocturnal BiPAP.

Discussion: Stroke can cause cardiovascular autonomic dysfunction, causing cardiac arrhythmias. It may be prudent to delay extubation to mitigate the baroreceptor mediated effects. Mixed apneas can be prevalent post stroke, potentially manifesting as respiratory compromise before overt respiratory failure. Non-invasive ventilation should be considered for preventing post-extubation respiratory failure. References:

Reference:

1. Coplin WM, Pierson DJ, Cooley KD, et al. Implications of extubation delay in brain-injured patients meeting standard weaning criteria. Am J Respir Crit Care Med 2000;161:1530-6. 10.1164/ajrccm.161.5.9905102

Learning Points: Classical respiratory weaning parameters may not reliably predict extubation success in stroke patients. Understanding the cardiovascular and respiratory pathophysiology in stroke patients will help guide clinical management. Heightened vigilance should be exercised when extubating.

The role of neuromonitoring in catastrophic iatrogenic subarachnoid hemorrhage complication during mechanical thrombectomy

M. Santos¹, M. Marques¹, A. Martins Lopes¹, H. Pereira1 ¹Unidade Local de Saúde São João, Anesthesiology, Porto, Portugal

Background: Mechanical thrombectomy is an option to restore circulation in patients with basilar artery occlusion, which is a rare condition that affects the lower brainstem circulation, potentially leading to severe complications. Monitoring the depth of anesthesia and cerebral activity is particularly important, as it can provide real-time insights of cerebral function to guide clinical decisions (1).

Case Report: An 83-year-old woman, with chronic hypertension and dyslipidemia, was admitted to the angiography suite of a tertiary hospital for mechanical thrombectomy, due to a basilar artery stroke. At admission she was intubated, under mechanical ventilation, hypertensive, with new onset atrial fibrillation, and had mild anisocoria (right > left). The mechanical thrombectomy was performed under general intravenous anesthesia. Standard ASA monitoring, depth of anesthesia monitoring and cerebral oximetry were used.

After 90 min, an iatrogenic rupture of the basilar artery occurred during the thrombectomy, resulting in massive subarachnoid hemorrhage, simultaneously with a drop in BIS (from 45 to 0), an isoelectric EEG wave, and fixed mydriasis. Given the futility of attempts at hemostasis, care was shifted to comfort measures.

Discussion:In the setting of catastrophic cerebral hemorrhage, such as the basilar artery rupture, the BIS showed a dramatic decline in cortical electrical activity, correlating with the clinical progression toward brain death.

The sudden drop in BIS, the appearance of an isoelectric wave in the raw EEG and a flatlined spectrogram was consistent with the clinical picture of fixed mydriasis, loss of neurologic reflexes, and hemodynamic instability, reinforcing the diagnosis of irreversible brain injury.

Using BIS monitoring in this case made it possible to track brain activity in real time and offered clear data to guide the decision to focus on comfort care. This highlights how useful BIS can be in critical care and neurosurgery, especially for understanding the effects of severe neurological events.

Learning points: BIS is an important instrument used to assess the level of anesthesia and brain activity during the perioperative setting and in critical care context.

31AP07-3

Basal sleep differences correlate with anxious phenotypes in mice: establishing a valid animal model for post-anesthetic cognitive impairments

A. Altunkaya¹, A.E. Kreitmaier¹, C.I. Hedenig¹, M.V. Schmidt², G. Schneider¹, T. Fenzl¹ ¹TUM Universitätsklinikum Klinikum rechts der Isar. Department for Anesthesiology and Intensive Care Medicine, Munich, Germany, 2Max-Planck-Institute for Psychiatry, Neurobiology of Stress Resilience, Munich, Germany

Background and Goal of Study: Postoperative delirium (POD), ranging from mild cognitive impairments to chronic deficits or death, is relevant in up to 80% of patients after surgery under general anesthesia (GA). The systemic-mechanistic relationship between clinically relevant preoperative anxiety (POA) and POD, though frequently reported, remains largely unknown.

Identifying a preoperative-anxious phenotype and associated sleep impairments holds potential to establish predictive parameters for POD. These discoveries may further elucidate the neuronal mechanisms underlying these phenomena.

Materials and Methods: 50 C57BL/6N male mice (16 weeks old) were used. Chronic EEG and EMG recordings assessed basal sleep/wake behavior, followed by cued fear-conditioning (FC, 120s acc., 30s auditory stimulus (10kHz, 75dB/octave), 2s with 0.6mA foot-shock, repetition-rate=5) and fear retrieval after 24h

Anxiety phenotypes were classified into low anxiety (LA) and high anxiety (HA) groups using k-medoids clustering based on six freezing behavior measures obtained from FC and RET.

Results and Discussion: LA and HA mouse phenotypes were classified with a median silhouette score of 0.333. HA mice exhibited a unique sleep behavior at baseline before FC, including reduced REMS during light phase (p=0.004, AUC=0.742). decreased WAKE during dark phase (p=0.024, AUC=0.688), and shorter REMS bout lengths during dark phase (p=0.034, AUC=0.678).

Further, HA mice showed unique sleep spindle (SP) characteristics with shorter median SP duration (p=0.009, AUC=0.283) and lower normalized SP amplitude (p=0.018, AUC=0.303) during the dark phase.

Spectral analysis revealed that HA mice had reduced low-delta power (0.1-2.5Hz) during NREMS throughout 24h (AUC=0.730) and increased high-frequency power (15-30Hz) during REMS in both phases (AUC=0.281), compared to LA at baseline.

Our results showcase the classification of naive animals into LA and HA mice using only prognostic EEG parameters and establish an animal model for POA, based on their intrinsic predisposition to individual anxiety levels.

Conclusion(s): We are currently testing potential cognitive impairments in HA and LA animals after experimental GA exposure in the Water-Cross-Maze test, thereby extending our POA model to a POA/POD model.

This model will allow us to investigate GA-dependent physiological processes and morphological conditions systemically in vivo, that potentially lead to postoperative cognitive impairments.

Determinants of functional prognosis at 3-months in patients with acute ischemic stroke following successful mechanical thrombectomy under general anaesthesia

C.M. López Queijo1, B. Cardalda Serantes1, M. Méndez Palomanes¹, F. García González¹, K. Williams Cidre¹, L. Barreiro Varela¹ Santiago de Compostela, Anesthesiology and Intensive Care., Santiago de Compostela, Spain

Background and Goal of Study: Acute ischemic stroke (AIS) occurs due to an obstruction in cerebral blood flow. This leads to rapid loss functional brain tissue and neurological deficits. Mechanical thombectomy has become the treatment of choice. restoring blood flow effectively, particulary under general anaesthesia (GA), which improves reperfusion rates and functional outcomes. However, even after successful intervention, long-term functional outcomes vary significantly based on demographic, clinical and in-hospital factors.

This study analyses predictors of functional independence (modified Rankin Scale [mRS]) at three months following mechanical thrombectomy performed under GA.

Materials and Methods: A retrospective study was conducted at a tertiary hospital (University Hospital Complex of Santiago de Compostela) between January 2021 and March 2023. Adult patients with AIS who underwent endovascular treatment under GA, with anterior circulation involvement, a baseline mRS score ≤2 and a satisfactory angiographic outcome (TICI 2b-2c-3) were included. Patients were followed for three months post-procedure. A descriptive analysis was performed to evaluate the patients' characteristics and clinical factors. A binomial logistic regression model was developed to identify factors associated with an unfavourable functional outcome (mRS >2).

Results and Discussion: A total of 254 patients with AIS underwent endovascular treatment and were admitted to the intensive care unit (ICU) of our hospital. Of these, 74 patients were excluded for not meeting the inclusion criteria. Functional prognosis, assessed using the modified Rankin Scale (mRS) at three months, showed that 92 patients (49,5%) had an unfavourable functional outcome (mRS >2).

Factors associated with poor outcomes included advanced age (mean 81 years), hypertension (80, 4%) high NIHSS on admission (median 17), proximal vessel involvement (internal carotid artery and middle cerebral artery-M1, in-hospital infections (50% of cases) and prolonged mechanical ventilation (> 12h, p < 0.05).

Multivariate analysis identified advanced age (OR = 1.07, p < 0.001), high NIHSS on admission (OR = 1.09, p = 0.015) and inhospital infections (OR = 2.62, p = 0.012) as independent predictors of poor outcomes.

Conclusion(s): In patients with AIS treated with successful mechanical thrombectomy under GA, the most relevant predictors of unfavourable functional prognosis at three months (mRS >2) include advanced age, greater NIHSS and mRS scores at admission, proximal vessel involvement (ICA and MCA-M1), in-hospital infections and prolonged mechanical ventilation (>12h).

These findings highlight the importance of a thorough risk assessment and proactive measures to optimise perioperative management and improve long-term functional outcomes.

31AP07-8

"Sex-specific" influences after combined ASDH and hemorrhagic shock in a long-term, resuscitated porcine model

F. Münz^{1,2}, F. Zink¹, M. Feth^{1,3}, A. Hoffmann¹, M. Gröger¹, T. Merz^{1,2}

¹University Ulm, Institute for Anesthesiological Pathophysiology and Process Engineering, Ulm, Germany, ²University Hospital Ulm, Anesthesiology and Intensive Care Medicine, Ulm. Germany, 3German Armed Forces Hospital Ulm. Anesthesiology. Intensive Care Medicine. Emergency Medicine and Pain Therapy, Ulm, Germany

Background and Goal of Study: Outcome after polytrauma depends on the presence of traumatic brain injury (TBI) and hemorrhagic shock (HS). Equivocal data is available on the impact of sex. Therefore, we compared female and male swine undergoing combined acute subdural hematoma (ASDH) and HS.

Materials and Methods: Up to now, this prospective, randomized investigation comprised young adult (age 20-24 weeks) females (n=18) and non-castrated males (n=18) of comparable body weight. After induction of anesthesia, mechanical ventilation and neurosurgical instrumentation (bi-hemispheric multimodal monitoring for intracranial pressure, brain tissue temperature, O2 partial pressure, and microdialysis for glucose, lactate, pyruvate, glutamate), animals underwent combined ASDH (injection of 0.1 mL/ kg autologous blood into the subdural space) and HS (removal of 30% of the calculated blood volume while maintaining cerebral perfusion pressure (CPP)>55 mmHg).

At 2 hours of ASDH and HS, TBI-guided ICU care (maximum of 48 hours) was started (re-transfusion of shed blood, noradrenaline infusion to maintain CPP>70mmHg, and maintenance of normothermia).

Systemic and cerebral hemodynamics, gas exchange and metabolism were determined together with intermittent recording of a "Modified Veterinary Glasgow Coma Scale" (MGCS). Statistical evaluation was performed using non-parametric rank sum tests as appropriate.

Results and Discussion: Metabolism did not exhibit any significant inter-group differences at any time point, indicating the absence of pre-experimental differences between the groups and suggesting that the severity of the shock was comparable across all groups.

While the amount of removed blood volume during HS was comparable across the groups, the male animals tended to require more catecholamine support than the female animals. Survival did not significantly differ. The MGCS in females did not deteriorate between baseline and 48 hours of ICU care, whereas in males it decreased significantly.

Conclusion(s): Results from this long-term, resuscitated porcine model of ASDH and HS suggest that sex affects outcome after ASDH and HS.

i. Both sexes exhibited comparable survival times, however; ii. males had impaired neurological and motor function.

Research on the Role of Histone Deacetylase 2 (HDAC2) in sevoflurane-induced cognitive impairment in the hippocampus of aging model

M. Zhang^{1,2,3}, C. Yuan^{1,2}, X. Liang², C. OU¹, D. Wang³, Y. Zhanq^{1,2}

¹The Second Affiliated Hospital of Zunyi Medical University, Department of Anesthesiology, Zunyi, China, ²Zunyi Medical University, Key Laboratory of Anesthesia and Organ Protection of Ministry of Education (In Cultivation), Zunyi, China, 3Bijie Hospital of Zhejiang Provincial People's Hospital, Department of Anesthesiology, Bijie, China

Background: The global aging population has led to an increase in surgeries requiring anesthesia in elderly patients, with sevoflurane being a commonly used inhaled anesthetic in this demographic. Emerging evidence suggests that sevoflurane anesthesia may contribute to postoperative cognitive decline, especially in the elderly. Age-related alterations in synaptic plasticity-related proteins within the hippocampus are key contributors to this impairment. Histone deacetylases (HDACs), including HDAC2, are critical regulators of cognitive function through their influence on the expression of synaptic plasticity-related proteins. However, the specific role of HDAC2 in sevoflurane-induced cognitive dysfunction remains unclear.

Methods: Aging Model Development: Aging model mice were established by subcutaneous injection of D-galactose (120 mg/kg/ day) for 42 days. Spatial learning and memory were assessed using the Y-maze and Morris water maze, and hippocampal HDAC2 expression was measured via Western blot analysis. Aging model mice were further divided into five groups (n=12 each): aging model group, aging model + sevoflurane group, blank virus group, HDAC2 knockdown group, and HDAC2 knockdown + sevoflurane group. AAV-mediated HDAC2 knockdown was achieved via hippocampal microinjection.

Mice were exposed to carrier gas (1L/min O2 + 1L/min air) or 3.4% sevoflurane mixed with carrier gas for 4 hours daily over three consecutive days. Spatial learning and memory were evaluated using the same behavioral tests, and hippocampal protein levels (HDAC2, ac-H3K9, ac-H4K12, BDNF, and PSD95) were analyzed using Western blot.

Results: 1. HDAC2 knockdown in aging model mice significantly improved cognitive performance in both behavioral tests (P < 0.01), decreased hippocampal HDAC2 expression (P < 0.01), and increased levels of ac-H3K9, ac-H4K12, BDNF, and PSD95 (P < 0.01).

Following repeated sevoflurane exposure, HDAC2 knockdown mitigated cognitive impairments and associated protein changes compared to non-knockdown aging model mice (P < 0.01). However, no significant differences were observed in the magnitude of these changes between HDAC2 knockdown mice with and without sevoflurane exposure.

Conclusions: Hippocampal HDAC2 knockdown attenuates sevoflurane-induced cognitive dysfunction by modulating histone acetylation and synaptic plasticity-related proteins, suggesting that HDAC2 may underlie the increased vulnerability of aging brains to sevoflurane.

31AP07-10

Frontal alpha oscillations as a marker for anaesthesia quality - towards a systematic review with narrative synthesis

K. Ricci¹, D.P. Obert¹, P.S. García², J.W. Sleigh³, G. Schneider¹, M. Kreuzer¹ ¹Technical University of Munich, Department of Anesthesiology and Intensive Care, Munich, Germany, ²Columbia University, Department of Anesthesiology, New York, United States, 3Waikato Clinical School, University of Auckland, Department of Anaesthesiology, Hamilton, New Zealand

Background: There is a growing interest in alpha oscillatory activity during intraoperative EEG analysis, yet a lack of a unified approach has led to significant heterogeneity across studies. This systematic review aims to summarise the current literature and highlight the clinical relevance of frontal alpha and its associated correlates in the context of general anaesthesia.

Methods: We searched Ovid MEDLINE, Embase, Cochrane CEN-TRAL, and Web of Science from 1990 to October 2023. Inclusion criteria were human patients (age ≥18 years) undergoing any kind of surgery (except brain surgery) under general anaesthesia, with EEG monitoring frontal alpha activity. Studies using non-GABAergic hypnotics were excluded.

No restrictions concerning outcomes or observations were made. Independent reviewers screened titles, abstracts, and full texts against eligibility criteria and performed data extractions.

We used RoB 2 and ROBINS-I for risk of bias and GRADE for quality pilot assessments. We opted for a narrative synthesis instead of meta-analysing effect sizes due to the high heterogeneity of the included studies.

Results: Out of 1879 screened articles, 61 met eligibility criteria, while 52 are subject to further evaluation. Included studies were heterogenous, and methodological quality varied. Sample sizes ranged from 10 to 1002 patients, with female proportions from 0 to 100%, and widely varying age ranges. EEG monitoring techniques differed between studies, e.g. single or bipolar electrodes, EEG caps, etc. No uniform definition for alpha (Hz) was identified. The lowest reported limit for the alpha band was 6 Hz and the highest 17 Hz, with 8-12 Hz being the most reported range (n=19 studies).

Various EEG analysis methods were described. Changes in alpha activity were most linked to anaesthetic regimen (n=22), age (n=11), and postoperative neurocognitive outcome (n=7). Findings may evolve as further data are included.

Conclusion: Alpha dynamics are very complex, and various mechanisms are involved in the changes of alpha appearance, power, or patterns.

Understanding these mechanisms is crucial to avoid attributing importance to them, simply because significant confounding factors have been overlooked. With our ongoing analyses and preliminary findings, we can emphasise the high heterogeneity of approaches and results.

By highlighting these issues, we hope to contribute to more standardised approaches investigating anaesthetic-induced alpha oscillatory activity.

Cognitive, psycho-emotional and genetic testing patients with pathological tortuosity of the internal carotid arteries

O.V. Drakina^{1,2}, O.I. Zagorulko¹, A. Andropova², G.E. Shevtsova¹, N. Leyi², A. Ranatunga² ¹National Research Centre of Surgery, Pain Clinic, Moscow, Russian Federation, ²I.M. Sechenov First Moscow State Medical University (Sechenov University), Department of Operative Surgery and Topographic Anatomy of Sechenov University, Moscow, Russian Federation

Goal of Study: To identify surgical alternatives before treatment (neurological, cognitive, emotional and genetic testing), deficits in the postoperative periods (stroke, delirium, cognitive disorders) and to improve neurological and cognitive results of treatment in patients with Pathological tortuosity of the internal carotid arteries (PT ICA).

Materials and Methods: A total of 40 patients were analyzed and divided into 2 groups depending on the treatment tactics - surgical treatment (23) and conservative observation (17). The operation is most often aimed at immediate complete resection of the pathological fragment of the ICA. All patients underwent cognitive function testing (MOCa), the anxiety and depression testing (HADS), Delirium testing (RASS, CAM or ICDSC) and genetic testing.

Results and Discussion: The embolization was observed more often in patients with septal ICA PTs (21,7%). The Short-term, as well as the Long-term mental disorders were correlated with episodes of preoperative baseline presence of mild cognitive impairment, intraoperative microembolisation, episodes of decreased cerebral perfusion and postoperative delirium. Proven genetic syndrome - the Heritable connective tissue disorders (HCTD), including Marfan syndrome, was found in 7 cases (17.5%).

	Group 1 (23 patients)	Group 2 (17 patients)
Sex (M–F)	56,5% - 43,5%	11,8% - 88,2%
Side (R-L-Bilateral)	30,4%- 39,1% - 30,4%	11,8% - 0 - 88,2%
Septal stenosis	21,7%	0
Atherosclerotic	13,0%	23,5%
Cerebro-vascular insufficiency		
Asymptomatic	17,4%	17,6%
Discirculatory encephalopathy	65,2%	64,7%
Transitory ischemic attack	8,7%	5,9%
History of stroke	8,7%	11,8%

Conclusion: The intellectual sphere of patients depends on the competent management of the postoperative period in the intensive care unit. The main attention should be paid to the early detection of the patient's neurological impairment and diagnostic of delirium, including subsyndromal form.

We also came to the conclusion that in the presence of septal tortuosity, microembolization occurs in the territory of the ipsilateral Middle cerebral artery, which subsequently leads to multiple brain lesions. Identifying a genetic syndrome is important for prognostic purposes.

31AP07-12

Enhancing postoperative pain management in spine surgery: Intraoperative ketamine infusion and continuous erector spinae block

D. Katsaros¹, M. Pilakouta-Depaskouale¹, <u>S. Moutafidou</u>¹, A. Dimitropoulou¹, A. Dimakopoulou¹ ¹General Hospital of Athens "G. Gennimatas", Anaesthesiology, Athens, Greece

Background and Goal of Study: Effective postoperative pain control in spine surgery is crucial for patient recovery, reducing opioid consumption and minimizing complications. Many patients experience significant pain after spine procedures. This study investigates the combined use of intraoperative ketamine infusion and postoperative continuous erector spine block (ESP).

Materials and Methods: A prospective, observational study was conducted on adult patients undergoing elective spinal fusion of 3-5 levels. Exclusion criteria were the presence of dementia, malignancy and CNS infection. 53 patients were divided to two groups: group A received intraoperative ketamine infusion along-side continuous postoperative ESP block, while group B received standard multimodal analgesia as shown in Table 1.

	INDUCTION	MAINTENANCE	NERVE BLOCK	INTRA- OPERATIVE	POST- OPERATIVE
GROUP A (n=26)	TIVA-TCI (propofol- remifentanil), PSI target <30 fentanyl 100mcg IV, rocuronium 0,6mg/kg IV	TIVA-TCI (propofol- remifentanil), PSI target 30-40	Bilateral ESP block (20ml + 20ml ropivacaine 0,375%) at end of surgery and continuous post- op infusion (3ml/h ropivacaine 0,2%)	Paracetamol 2gr, ketamine 0,3mg/ kg bolus (10min IV infusion before incision) followed by 0,1mg/ kg/h infusion, morphine 0,05-0,1 mg/kg, Mg2SO4 2gr	Paracetamol 1grX3, ondansetron 4mgX2, PCA morphine regiment (1mg bolus, 10min lockout, 4mg hourly limit)
GROUP B (n=27)	TIVA-TCI (propofol- remifentanil), PSI target <30 fentanyl 100mcg IV, rocuronium 0,6mg/kg IV	TIVA-TCI (propofol- remifentanil), PSI target 30-40	-	Paracetamol 2gr, morphine 0,1-0,2 mg/kg, wound infiltration with ropivacaine 0,2%, Mg2SO4 2gr	Paracetamol 1grX3, ondansetron 4mgX2, PCA morphine regiment (1mg bolus, 10min lockout, 4mg hourly limit)

Table 1. Anesthetic techniques used.

Pain scores (NRS), opioid consumption, incidence of postoperative nausea and vomiting (PONV), and length of hospital stay were assessed at multiple time points postoperatively (0, 6, 12, 24, 48 hours).

Additionally, the incidence of complications such as catheter displacement, infection and neurologic determent were monitored. We gathered data from patient anesthesia forms and patient interview. We analyzed data with IBM SPSS software. T-test was used.

Results and Discussion: Group A experienced lower pain scores at 6, 12, 24 and 48 hours postoperatively compared to group B. Opioid consumption was reduced by an average of 40% in the ketamine-ESP block group. There was no significant difference in the incidence of PONV or length of hospital stay between the two groups. No complications related to the nerve block catheters or ketamine infusion were observed.

Post-operative pain levels						
	NRS MEAN at 0h	NRS MEAN at 6h	NRS MEAN at 12h	NRS MEAN at 24h	NRS MEAN at 48h	
GROUP A (n=26)	1	1	2	2	2	
GROUP B (n=27)	1	3	3	4	4	

Conclusion(s): The combination of intraoperative ketamine infusion and continuous postoperative ESP block appears to offer a promising approach for enhancing postoperative pain management in spine surgery. This regimen effectively reduces postoperative opioid use, provides sustained pain relief and is welltolerated, with minimal complications.

32AP01-1

Predictive factors for postoperative vasopressor use: a monocentric observational study

Z. El Hernoussi¹. A. Souadka². O. Ssouni¹. A. El Fassi¹. B. El Ahmadi¹, A. Ghannam¹ ¹Mohammed V University in Rabat, National Institute of Oncology Rabat - Anesthesia and Intensive Care Department, Rabat, Morocco, 2Mohammed V University in Rabat, National Institute of Oncology Rabat - Digestive Oncological Surgery Department, Rabat, Morocco

Background and Goal of Study: Postoperative hypotension is a common event after major non-cardiac surgery, often requiring intravenous vasopressor infusion. Postoperative hypotension could be a modifiable risk factor for postoperative complications. The aim was to determine the incidence and risk factors associated with the use of vasopressors postoperatively in digestive and gynecologic cancer surgery.

Materials and Methods: This was a prospective, descriptive, and analytical monocentric observational study conducted at the National Institute of Oncology (INO) - Mohamed Ben Abdellah Hospital, CHU Ibn Sina, Rabat. The studied event was defined as postoperative vasopressor infusion, which is the continuous intravenous infusion of a drug with a predominant vasoconstrictif effect. Patients receiving postoperative vasopressors were classified in the VASO group.

The primary endpoints were to determine the proportion of patients receiving vasopressors postoperatively, the incidence of organ dysfunctions, and to identify factors affecting care (patient, condition, surgery, and perioperative management) associated with postoperative vasopressor infusion.

Results and Discussion: A total of 90 patients were recruited for our cohort study. Comparative analysis of demographic and preoperative clinical data revealed no statistically significant difference between the control and VASO groups. Some variables showed a statistically significant difference between the two groups, for example : supra-mesocolic surgery vs. other types (p = 0.035); low systolic pressures during the perioperative period (p < 0.001); hemorrhage vs. resection surgery (p = 0.001).

Postoperative hypotension is a frequent complication after major non-cardiac surgery. It is often due to a combination of reduced preload (typically caused by relative hypovolemia, possibly from bleeding or fluid redistribution) or reduced afterload. Less commonly, there may be impaired cardiac contractility, we identified patient profiles at higher risk of postoperative hypotension, which may pave the way for randomized clinical trials to test specific interventions.

The incidence of postoperative vasopressor treatment has never been specifically described.

Conclusion(s): Our study was conducted to better understand the criteria and factors that influence the decision to administer vasopressors after surgery, particularly in maintaining normal blood pressure in patients with postoperative hypotension.

32AP01-2

Endothelial dysfunction as a predictor of perioperative myocardial injury: the use of flow-mediated dilation as a discriminative tool

F. Maldonado¹, R. González¹, M. Cáceres², C. Diaz¹, Fonis SA22I01446

¹Universidad de Chile, Anestesiología y Medicina Perioperatoria, Santiago, Chile, ²Universidad de Chile, Facultad de Medicina, Santiago, Chile

Background and Goal of Study: Perioperative myocardial injury (PMI) indicates myocardial damage and is associated with major adverse cardiovascular events (MACE). Endothelial dysfunction (ED) also correlates with MACE. Flow-mediated dilation (FMD) is a non-invasive method for assessing ED. If patients with ED are at higher risk of myocardial injury, FMD could identify those at risk of PMI. We aim to assess FMD's ability to predict PMI.

Materials and Methods: A nested analysis of the FONIS SA22I0146 project, a prospective observational study approved by the Ethics Committee of the Clinical Hospital of the University of Chile (Ref: OAIC 1316/22, NCT05778981). The study aims to define the incidence of myocardial injury in non-cardiac surgery and evaluate the predictive value of FMD. Here, we analyzed 100 patients undergoing intermediate- and high-risk elective surgery. High-sensitivity Troponin I (hs-Tnl, Ortho-Vitros, 99th percentile - 11 ng/mL) was measured preoperatively and at 24-, 48-, and 72-hours post-surgery. FMD was assessed preoperatively using brachial artery ultrasound, with images acquired at baseline and at 15, 30, 60, 90, and 120 seconds post-reperfusion, following a standardized 4-minute ischemic period. FMD was defined as the maximum dilation relative to baseline, while Delta FMD was the difference between maximum and minimum dilation. Thresholds of 10% and 15% were used for ED evaluation. PMI incidence was reported as a relative frequency. Daily hs-Tnl changes were analyzed, and the area under the curve (AUC, SD) of hs-Tnl concentration over time was compared between FMD thresholds (Student's t-test). ROC curves were constructed to assess the association between FMD and Delta FMD with PMI.

Results and Discussion: Hs-Tnl levels above 11 ng/mL were observed in 42% of patients, with 6% exceeding 60 ng/mL. No 30day mortality occurred. Using an Delta FMD threshold of 15%, differences in hs-Tnl concentrations over time were observed (AUC 21.76, SD 12.22 in the non-ED group vs. 30.71, SD 17.3 in the ED group, p=0.0014). ROC curves showed FMD had an AUC of 0.52 (95% CI: 0.40-0.64) for detecting elevations at 11 ng/mL and an AUC of 0.59 (95% CI: 0.36-0.83) for 60 ng/mL. Delta FMD had an AUC of 0.53 (95% CI: 0.41-0.65) at 11 ng/mL and 0.72 (95% CI: 0.55-0.88) at 60 ng/mL.

Conclusion(s): Flow-mediated dilation evaluation can predict the development of PMI. Endothelial function may guide risk stratification in patients undergoing non-cardiac surgery.

32AP01-3

Effects of cipepofol versus propofol on hemodynamics after induction in aortic stenosis patients: a randomized clinical trial

M. Yan¹, T. Ni¹, Y. Yao¹, Q. Gao¹ ¹The Second Affiliated Hospital of Zhejiang University School of Medicine, Anesthesiology, Hangzhou, China

Background and Goal of Study: Postinduction hemodynamic instability is a common complication in patients with severe aortic stenosis (AS). Cipepofol, a propofol analog, may reduce the incidence and severity of this instability.

The aim of this study was to assess whether cipepofol outperforms propofol in maintaining postinduction hemodynamic stability in patients with AS. We hypothesized that cipepofol would better mitigate the risk of postinduction hemodynamic instability compared to propofol.

Materials and Methods: A single-center, randomized controlled trial was conducted at the Second Affiliated Hospital of Zhejiang University School of Medicine, China, from June 29, 2023, to July 8, 2024. A total of 169 patients with AS scheduled for transcatheter aortic valve replacement (TAVR) were initially screened.

After exclusions, 124 patients were randomized in a 1:1 ratio to receive either cipepofol or propofol as anesthesia agents. Due to subsequent ineligibility, data from 122 patients (61 per group) were analyzed based on the intention-to-treat principle.

The primary outcome was the area under the curve (AUC) of the mean arterial pressure (MAP) difference from baseline within the first 15 minutes post-induction. The Wilcoxon rank-sum test was used to compare the AUC between the two groups.

Results and Discussion: Compared with the propofol group, the cipepofol group exhibited a significantly smaller AUC (median [IQR]: -8,505.0 [-12,402.8, -5,130.0] mm Hg·s vs. -13,189.0 [-17,006.7, -7,593.3] mm Hg·s; P < 0.001).

Moreover, compared with the propofol group, the cipepofol group demonstrated a significantly lower incidence of postinduction hypotension (PIH) (70.5% vs. 88.5%, P = 0.014) and required less norepinephrine during the first 15 minutes postinduction (median [IQR]: 6.0 μ g [0.0, 10.0] vs. 10.0 μ g [5.0, 20.0], P = 0.006). Subgroup analyses further confirmed that cipepofol provided better hemodynamic stability in high-risk patients.

These findings indicate that cipepofol offers superior hemodynamic stability during anesthesia induction in TAVR patients, with no compromise in anesthesia depth, as demonstrated by the similar BIS values between groups.

Conclusion(s): As an induction agent, cipepofol provides superior hemodynamic stability over propofol at comparable anesthesia depths for patients with AS. Cipepofol could therefore serve as alternative induction agent to propofol for patients with high cardiovascular risk.

32AP01-5

Diastolic dysfunction as a contraindication for robotic gynecologic surgery?

C. Fernandes Marques¹, M. Mariano Pereira¹, C. Salta¹, M.d.L. Castro1

¹Unidade de Saúde Local de São José, Área de Anestesiologia, Lisboa, Portugal

Background: Trendelenburg positioning and pneumoperitoneum during robotic-assisted laparoscopy induce physiological changes, including increased mean arterial pressure, peripheral vascular resistance, and myocardial oxygen consumption, reduced pulmonary functional capacity and enhanced pulmonary congestion.^{1,2} These changes pose significant risk for patients with cardiopulmonary pathology.

While robotic surgery lacks absolute contraindications^{1,2}, diastolic disfunction is not listed among relative cardiopulmonary contraindications.2

Case Report: A 73-year-old female with controlled hypertension was scheduled for robotic-assisted total hysterectomy and bilateral adnexectomy for endometrial cancer. Preoperative evaluations were normal, but the patient reported fatigue with a functional capacity of 3 METs.

Echocardiography revealed left atrial dilation without systolic dysfunction. After positioning and initiating pneumoperitoneum, the patient experienced sustained hypertension (maximum 290/217 mmHg) despite antihypertensive therapy, leading to procedure suspension.

Reversing positioning and pneumoperitoneum resulted in hypotension (54/43 mmHg), hypoxemia (SpO₂ 85%), and hypocapnia (EtCO₂ 21 mmHg), with pulmonary crackles and secretions.

Acute pulmonary edema was diagnosed and managed with vasopressors, diuretics and increased PEEP, restoring stability. Postoperative echocardiography revealed significant diastolic dysfunction.

Discussion: This case highlights hypertensive acute pulmonary edema in a patient with controlled hypertension and fatigue. Chronic hypertension and left atrial dilation, often overlooked, may predispose patients to diastolic dysfunction and heart failure. Symptoms like fatigue and reduced functional capacity (<4 METs) suggest latent cardiopulmonary pathology.

Detailed preoperative evaluation and risk stratification are critical, especially for hypertensive patients undergoing robotic-assisted laparoscopy.

- 2. Tameze Y, Low YH. Outpatient Robotic surgery: Considerations for the Anesthesiologist. Adv Anesth. 2022;40(1):15-32.

Learning Points: Robotic surgery introduces significant hemodynamic and ventilatory challenges. Chronic hypertension associated to left atrial dilation and fatigue may indicate underlying cardiopulmonary compromise, as diastolic dysfunction.

32AP01-6

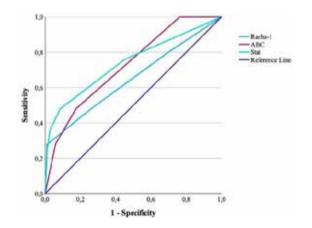

Comparison of risk scoring systems in pediatric patients undergoing congenital heart surgery

S. Kanbir¹, D. Sergin¹, N.S. Kocabas¹, A. Derbent¹ ¹Ege University Hospital, Anesthesiology and Reanimation, Izmir, Turkey

Background and Goal of Study: This study assessed the predictive accuracy of STAT, RACHS-1, and ABCS scoring systems for in-hospital mortality and clinical outcomes in pediatric congenital heart surgery to improve perioperative care (1,3).

Materials and Methods: A retrospective analysis of 321 pediatric patients treated at Ege University Medical Faculty (2018–2020) was conducted. Ethical approval was obtained. Demographic and surgical data, risk scores, and perioperative parameters like cardiopulmonary bypass (CPB) time and complications were analyzed using statistical methods including Mann-Whitney U tests. Kruskal-Wallis H tests, and ROC curve analyses.

Results and Discussions: Of the patients, 54.8% were female, and 45.2% male, with a median age of 24 months. Preoperative needs included ICU admission (6.5%) and mechanical ventilation (4%). Postoperatively, 80.1% required inotropic support, 20.2% had complications, and 7.8% mortality occurred. STAT scores showed strong correlations with mortality (p<0.05), while RA-CHS-1 effectively predicted outcomes in younger patients. ABCS scores provided insights into complexity but were less predictive for complications (1,2).

Conclusions: STAT, RACHS-1, and ABCS scoring systems are valuable tools for risk stratification in pediatric congenital heart surgery. Multidisciplinary planning and advanced predictive models can further optimize care and outcomes (3).

A rare case of transprosthetic cuff leakage after aortic valve replacement

Y. Nakajima¹, K. Kurooka¹, R. Sakuma¹, Y. Nakayama¹, M. Fuvuta1

¹Kindai University Faculty of Medicie, Anesthesiology and Critical Care, Osaka, Japan

Background: Peri- and trans-valvular leakage can occasionally occur following artificial valve replacement. Anesthesiologists must differentiate between various types of leakage and assess its severity during surgery, particularly through transesophageal echocardiography (TEE). In such cases, there is a possibility of atypical valve leakage.

Case report: A 78-year-old male presented with recurrent syncope over the past two months. Cardiac echocardiography revealed severe aortic stenosis, and the patient was scheduled for a bioprosthetic valve (PERIMOUNT Magna) aortic bioprosthetic valve. replacement. During weaning from cardiopulmonary bypass (CPB), transesophageal echocardiography (TEE) revealed a transvalvular leakage at the stent post, although the degree of leakage was mild.

Based on the findings, we diagnosed the leakage as transprosthetic cuff leakage (a form of non-peri, non-trans-valvular leakage), which resolved after the administration of protamine.

Discussion: Although recent advances in valve replacement techniques have been made, paravalvular leaks remain a life-threatening complication in patients with prosthetic heart valves. While these defects may sometimes have little clinical impact, they can worsen hemolysis or lead to heart failure due to regurgitation.

Therefore, it is vital to distinguish between different complications following prosthetic heart valve replacement.

Previous studies have pointed out possible causes of transprosthetic cuff leakage. The cuff, located between the metal stent and silicone ring, may become stretched at the commissure opposite to the others, resulting in transprosthetic leakage. We will address this topic in the presentation.

Reference:

1. Hiraoka A, et al. Transprosthetic Cuff Leakage of a Bovine Pericardial Aortic Bioprosthesis. Semin Thorac Cardiovasc Surg. 2019;31(4):773-779.

Learning points: Following artificial valve replacement, it is standard practice to assess perivalvular leakage and valve function immediately after cardiopulmonary bypass.

We should acknowledge that leakage, such as transprosthetic cuff leakage (a form of non-peri, non-trans-valvular leakage), may occur after cardiopulmonary bypass. It is essential to understand not only the potential causes of this leakage but also its implications for patient outcomes, including its resolution or persistence, and the overall prognosis.

32AP01-8

Spinal anesthesia versus general anesthesia for hip fracture surgery in elderly patients with moderate to severe aortic stenosis

T. Takahashi¹, N. Fujita¹, K. Miyasaka¹, S. Abe¹ 1St. Luke's International Hospital, Anesthesia, Tokyo, Japan

Background and Goal of Study: Anesthesia management for patients with severe cardiovascular complications, such as aortic stenosis, undergoing hip fracture surgery remains controversial. Historically, spinal anesthesia has been considered relatively contraindicated. However, recent studies suggest that spinal anesthesia may be safe and even beneficial for such high-risk patients.

This study investigates the impact of spinal versus general anesthesia on postoperative outcomes in patients with moderate to severe aortic stenosis undergoing hip fracture surgeries.

Materials and Methods: This single-center, IRB-approved retrospective study examined patients with moderate to severe aortic stenosis who underwent hip fracture surgery at St. Luke's International Hospital in Japan between January 2013 and December 2023.

Patients were divided into two groups based on the anesthesia method they received: spinal or general anesthesia. The primary outcome was 30-days mortality, and secondary outcomes included postoperative complications such as acute kidney injury, delirium, heart failure, aspiration pneumonia, and wound infection. We also investigated intraoperative hypotension, quantifying it in terms of vasopressor doses administered.

Results and Discussion: A total of 47 patients were included in the analysis, with 12 patients receiving spinal anesthesia and 35 patients receiving general anesthesia. There was only one death within 30days, with no statistically significant difference in mortality. There was no difference in incidence of postoperative complications such as acute kidney injury (OR 1.47: 95% CI, 0.33 to 6.65: P=0.62), delirium (OR 0.75; 95% Cl, 0.19 to 2.96; P= 0.68), and heart failure (OR 0.98; 95% CI, 0.86 to 11.2: P=0.99).

However, the spinal anesthesia group required smaller doses of intraoperative phenylephrine (0.58±0.63 versus 2.1±1.5 mg; P=0.001), suggesting a lower incidence of intraoperative hypotension.

Conclusion(s): The findings suggest that spinal anesthesia can be an option for patients with severe or moderate aortic stenosis undergoing hip fracture surgery. It appears to be a safe alternative to general anesthesia, with comparable mortality and complication rates in this high-risk population, and it may also contribute to hemodynamic stability.

32AP01-9

Changes in breathing maneuvers during preoxygenation impact myocardial function: a comparison of simulated and actual preoxygenation protocols

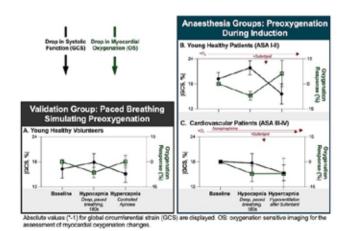

S. Keser¹, Y. Schwerzmann¹, B. Türler¹, T. Schweizer¹, D.P. Guensch^{1,2}, K. Fischer¹

¹University of Bern, Department of Anaesthesiology and Pain Medicine Inselspital Bern, Bern, Switzerland, ²University of Bern, Department of Diagnostic, Interventional and Paediatric Radiology, Bern, Switzerland

Background and Goal of Study: Variations in breathing, such as those during the preoxygenation phase of induction lead to fluctuations in blood gases, which may be a trigger of perioperative myocardial ischaemia. We performed a cardiovascular MRI study to investigate the impact of breathing patterns on the heart in both a simulated preoxygenation setting in the absence of other medications and during the preoxygenation phase of general anaesthesia.

Materials and Methods: In an MRI, a validation group of 32 awake controls performed paced deep breathing for 180s (hypocapnia) followed by controlled apnoea (hypercapnia). MRI images were quantified for changes in myocardial oxygenation (OS) and global circumferential strain (GCS) as a marker of systolic contractility. The same imaging was applied during preoxygenation in patients undergoing general anaesthesia in an MRI both without (ASA I-II, n=6) and with coronary artery disease (CAD, n=3). The hypocapnia timepoint was at 180s of paced breathing, while hypercapnia was defined when spontaneous breathing seized due to induction drugs.

Results and Discussion: In the validation group, paced breathing decreased oxygenation (OS) yet increased contractility (GCS), both normalizing with apnoea (Fig A). These findings were mirrored by the ASA I-II anaesthesia group (Fig B), OS dropped (-7.1±2.6%, p<0.01), and GCS (-19.2±1.5 to -21.9±1.7%, p<0.01) improved with paced breathing, while hypoventilation led to a return in OS (6.2±7.9%, p=0.11 vs baseline) and reduction in GCS (-15.1±2.0% p<0.01). In CAD patients hypocapnia reduced OS with no change in function (Fig C) in post-stenotic myocardium. However, in the hypercapnia phase both OS (-7.1±9.2%) and GCS (-18.1±0.3 to -15.3±1.9%), worsened in unison.

Conclusion(s): In healthy hearts, changes in breathing patterns during preoxygenation cause fluctuations in cardiac function but deoxygenation was not linked to systolic dysfunction. Yet, in CAD patients, this procedure led to coupled deoxygenation and systolic dysfunction indicating inducible ischemia. Understanding the role of changing blood gases on cardiac function may improve the safety of induction in vulnerable patients.

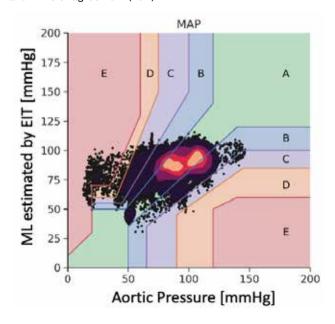

32AP01-10

Non-invasive beat-by-beat estimation of arterial blood pressures from electrical impedance tomography data processed by machine learning

F. Mueller-Graf¹, J.P. Thönes², S. Spors², A.R. Zitzmann¹, S.H. Boehm¹, D.A. Reuter¹ ¹University Medical Center Rostock, Department of Anesthesiology, Intensive Care Medicine and Pain Therapy, Rostock, Germany, ²University of Rostock, Institute of Communications Engineering, Rostock, Germany

Background and Goal of Study: Hypotension in perioperative and intensive care settings is a significant risk factor associated with complications thereby increasing perioperative mortality. Continuous blood pressure monitoring is essential, yet challenging due to the invasive nature of current methods. Non-invasive techniques like Electrical Impedance Tomography (EIT) have been explored, but face challenges in accurately and consistently estimating blood pressure.

Materials and Methods: This study utilized a machine learning (ML) approach to predict systolic (SAP), mean (MAP), and diastolic arterial pressures (DAP) from EIT raw voltage measurements in an animal model involving 9 pigs (approved by the governmental ethical board: LALLF, M-V, Germany; No: 7221.3-1-037/19). A convolutional neural network (CNN) was trained on a dataset of 75 298 heartbeats using raw EIT voltage data to estimate SAP, MAP, and DAP in individuals unknown to the algorithm. The Intraclass Correlation Coefficient (3,1) with absolute agreement (ICC) was calculated comparing reference blood pressure measurements and ML-derived estimates. Bland-Altman plots for repeated measurements were calculated with the respective mean bias and limits of agreement (LoA).

Results and Discussion: MAP estimated by the ML-Model and aortic reference pressure are presented in a color-coded scatter plot in Figure 1. The ML model demonstrated moderate correlation with invasive blood pressure (ICC for SAP of 0.530, for MAP of 0.563, and for DAP of 0.521). Bland-Altman analysis showed a low mean bias with wide limits of agreement, indicating room for future improvements (mean bias for SAP was 2.56 mmHg with LoA from -32.34 to 37.46 mmHg, for MAP 3.31 mmHg with LoA from -28.85 mmHa to 35.47 mmHa and for DAP 3.69 mmHa with LoA from -26.70 to 34.09 mmHg).

Conclusion(s): ML techniques show promising results in non-invasive blood pressure monitoring by EIT. Despite limitations in the sample size and in the experimental setup, this study illustrates the potential of integrating ML in EIT signal processing for realtime, non-invasive beat-by-beat blood pressure monitoring.

32AP01-12

Perioperative outcomes of tricuspid valve surgery in adults with Ebstein's anomaly

C. Bordes García¹, M. de Miguel¹, P. Galán¹, L. Villarino¹, M.S. Siliato², M. Ribas¹

¹Hospital Universitari Vall d'Hebron, Department of Anaesthesia and Intensive Care, Barcelona, Spain, ²Hospital Universitari Vall d'Hebron, Department of Cardiac Surgery, Barcelona, Spain

Background and Goal of Study: Tricuspid regurgitation (TR) is common in patients with Ebstein's anomaly (EA) who now frequently survive into late adulthood. Relatively little has been documented about the rate and manner of perioperative complications and early term patient outcomes. This study aims to review the perioperative outcomes of tricuspid valve surgery in adults with EA and severe TR.

Materials and Methods: A retrospectives cohort study was conducted on adult patients with EA and severe TR undergoing tricuspid valve surgery between January 1, 2012, and November 30, 2023, in a tertiary care university hospital. A comprehensive search of all relevant medical records was conducted, including hospital medical records and operation reports. Data collected included demographic variables, comorbidities, intraoperative and postoperative complications and mortality at 30 days and one year. Categorical variables are reported as frequencies and percentages (%) and continuous variables are summarised using mean and standard deviation. The Friedman test was used to compare pre- and postprocedural New York Heart Association (NYHA) functional class within patients.

Results and Discussion: Fourteen patients (9 women, 5 men) who underwent tricuspid valve replacement were recorded. The mean age at the time of surgery was 43.2±13.2 years. Preoperatively, 2 patients (14.3%) were NYHA Class I, 5 (35.7%) Class II and 7 patients (50%) Class III. In total, six patients (42.8%) had moderate or severe right ventricular dysfunction. The mean hospital stay was 14±5.3 days. Intraoperative complications occurred in 8 patients (57.1%). Also, eight patients (57.1%) had some episode of intraoperative hypotension.

Postoperative complications were noted in 9 patients (64.3%), with arrhythmias being most frequent, in 12 patients (85.7%). No perioperative, 30-day, or one-year mortality was. observed. Six patients improved their NYHA class at 30 days follow-up (p=0.058).

Conclusion(s): Tricuspid valve surgery in adults with EA showed excellent perioperative survival. However, the high incidence of intraoperative and postoperative complications highlights the need for careful perioperative management.

32AP02-1

HDC-Anaesthesia-Quality-Registry: a prospective observational study on patient-reported outcomes and quality of life after cardiac surgery and interventional procedures

M. Briefs¹, J. Fliegenschmidt¹, C. Middeke¹, A. Bergmann¹, N. Hulde¹, V. von Dossow¹

¹Heart- and Diabetescentre Northrhine-Westphalia, Institute for Anesthesiology and Pain Therapy, Bad Oeynhausen, Germany

Background, Goal of Study: Patient-reported outcomes (PRO) are increasingly recognized as key measures for evaluating treatment effectiveness and guiding patient-centered care in cardiac anaesthesia. Health-related quality of life (HR-QoL) is a valuable metric for assessing patient's physical and mental well-being following cardiac surgery or interventional procedures.

This study aims to identify key demographic and clinical factors influencing PRO, thereby improving future care strategies for these patients.

Materials/Methods: This prospective observational study involves patients treated at the Heart- and Diabetescentre NRW in 2023 who underwent cardiac surgery or interventional procedures with anaesthesiological support. During the premedication consultation, patients were informed about participation in the registry and consented to a two-stage, one-year follow-up study. The SF-12 questionnaire was used to assess the physical and mental components of HR-QoL. Initial analyses focused on the impact of age, gender and clinical variables, such as preoperative anemia, on the PRO of 956 patients.

Further variables, including ventilation duration, ICU stay, and involvement in OR-patronage programs will be analysed in the overall analysis of approximately 2.000 patients.

Results/Discussion: Preliminary results showed a high response rate of 89.51%, with 93.91% of the returned questionnaires fully completed. The mean physical component summary (PCS) was 43.14, well below the mean of 50, while the mean mental component summary (MCS) was close to average at 49.79.

Gender comparisons revealed that women scored lower in both PCS and MCS. Our analysis showed a decline in PCS with increasing age and decreasing preop. hemoglobin, while MCS remained stable across all age categories.

Additional influencing factors will be explored in the final analysis. The findings suggest significant differences in PRO, highlighting the need for personalized preoperative assessments and postoperative care, particularly for older, female and anemic patients. Future interventions should be critically evaluated not only for their life-extending potential but also for their ability to enhance HR-QoL

Conclusion: Incorporating PRO and HR-QoL into clinical decisions enables personalized strategies, especially for vulnerable groups such as older, female, and anemic patients. Targeted strategies to address these disparities may optimize the effectiveness of care in cardiac anaesthesia.

32AP02-2

Use of VA-ECMO with cardiotomy suction for patient blood management in thoracoabdominal open surgery: a single center experience

S.R. Jorge¹, C. Aparicio², A. Gonzalez², L. Carballo³, L. Muñoz¹, F. Manzano¹

¹Hospital Universitario Fundación Jimenez Diaz, Anesthesiology and Perioperative Medicine, Madrid, Spain, ²Hospital Universitario Fundación Jimenez Diaz, Angiology and Vascular Surgery, Madrid, Spain, 3Hospital Universitario Fundación Jimenez Diaz, Cardiovascular Surgery, Perfusionist Group, Madrid, Spain

Background: Thoracoabdominal aortic aneurysm open repair (TAAA-OR) is associated with 30-day mortality rates between 8 to 25%. One of the main characteristics of TAAA-OR is massive hemorrhages that entail transfusion of multiple blood components.

Furthermore, after development of endovascular techniques, open surgery has been selected for challenging cases like collagenopathy or failure endovascular technique. These surgeries have a high risk of bleeding and the association between transfusion and morbidity has been widely described [1].

Case Report: We present the first 4 cases performed in our center with veno-arterial extracorporeal membrane oxygenation (VA-ECMO) and cardiotomy reservoir suction. In order to save blood products, we use heparin ratio 1:1 for VA-ECMO maintaining systemic activated clotting time (ACT) up to 250 seconds. In the cardiotomy reservoir we add more heparin locally and measure ACT over 350 seconds (Figure 1).

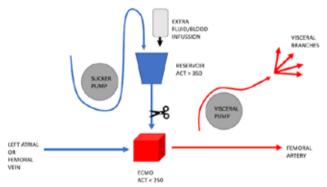

Figure 1.

This strategy has the advantage of avoiding the loss of fibrinogen, coagulation factors and platelets associated with the processed blood from a cell saver.

Discussion: Our intraoperative transfusion requirements were 9 red blood packed cell units in one patient and 8 in each of the other patients, 2 fresh frozen plasma units and 1 pooled platelet concentrate in each case. These data are far from usual requirements that are described on the literature [1].

The four patients were extubated between 12 and 72 hours postoperative. Although one of the patient dead by shock septic associated to bloodstream infection, the other three cases were discharge without transfusion related complications.

Reference:

1. S. Wang, C. Wang, Y. Gao, Y. Tian, J. Liu, Y. Wang, Risk factors of 30-day and long-term mortality and outcomes in open repair of thoracoabdominal aortic aneurysm, J. Cardiothorac. Surg. 19 (2024) 170. https://doi.org/10.1186/s13019-024-02666-2

Learning Points: The use of a cardiotomy suction and reservoir with a VA-ECMO may contribute to optimization of intraoperative patient blood management, limiting the incidence of coagulopathy during TAAA-OR.

32AP02-3

Takotsubo cardiomyopathy triggered by transcatheter mitral edge-to-edge repair (TEER): a rare case with atypical manifestations

J.-H. Chang¹, <u>H.-Y. Ou</u>¹, T.-C. Liu¹, K.-B. Chen¹, K.-W. Chen²

¹China Medical University Hospital (CMUH), Department of Anesthesiology, Taichung, Taiwan, ²China Medical University Hospital (CMUH), Division of Cardiology, Department of Internal Medicine, Taichung, Taiwan

Background: Takotsubo Cardiomyopathy (TCM) is often referred to as stress-induced cardiomyopathy or "broken-heart syndrome." This report describes an unusual case of TCM in a patient undergoing TEER.

Case Report: An 87-year-old female with severe mitral regurgitation, pulmonary hypertension, and chronic renal insufficiency underwent TEER with successful MitraClip placement, significantly reducing MR without immediate complications. Several hours later, she developed acute hypotension without chest pain, elevated myocardial enzymes, or ECG changes.

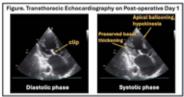

Echocardiography showed left ventricular (LV) systolic dysfunction and apical ballooning (figure), leading to a diagnosis of TCM. Conservative management was initiated, and follow-up echocardiography three days later showed full recovery of LV function. She was discharged without further issues.

Case series of Takotsubo syndrome following TEER

Table. Case Comparison

1" Author & Year	age/sex	onset	TEE findings	procedure outcome .	Journal
Anna L. S. 2023	83/male	P00 3	LVEF 25%	success, no complication	Arq Bras Cardol: Imagem cardiovasc
Ai-Ameen O. 2023	76/female	acute	LVEF 25-30%	success, femoral artery laceration	Chest (case report poster)
Shilla Z. 2021	92/mole	POD 2	LVEF 20-25%	success, no complication	JACC (case report poster)
Takahide K. 2021	86/female	POD 1	apical hypokinesi	s success, no-complication	Circ J
Takehiro N. 2020	87/male	POD 2	apical akinesis	success, no complication	EHJ-Case Reports
Joseph P. 2020	92/female	P00 1	LVEF 35%	success, oropharyngeal bleeding	Structural Heart

Note: MR, mitral regurgitation; PMR, primary MR, SMR, secondary MR; POD, post-operative day; LVEF, left ventricular ejection fraction

Discussion: TCM after TEER is a rare but recognized complication, with only case reports available. We compared the cases (table), and the proposed mechanisms include catecholamine surges or myocardial stress from the procedure or disease. Another possible mechanism is afterload mismatch¹ due to the loss of left atrial unloading from MR correction, leading to an acute rise in LV preload and transient myocardial dysfunction.

The long-term effects of post-TEER LV dysfunction remain inconclusive^{2,3} and require further study. Most cases show spontaneous recovery with conservative management, and prognosis is generally favorable with early diagnosis and supportive care.

- 3. Perl L et al. Acute Reduction in Left Ventricular Function Following Transcatheter Mitral Edge-to-Edge Repair. J Am Heart Assoc 2023.

Learning Points: This case illustrates the importance of considering TCM in TEER patients. Recognizing this condition promptly is essential for appropriate management and a favorable outcome.

32AP02-5

Intramuscularly applied regulatory macrophages positively influence microperfusion and prevent ulcer formation: findings from an ischemic mouse hindlimb model

<u>K. Zitta</u>¹, C. Heiner², S. Engels³, M. Steinfath¹, R. Berndt², M. Albrecht¹

¹UKSH-Kiel, Department of Anesthesiology and Intensive Care Medicine, Kiel, Germany, ²UKSH-Kiel, Clinic of Cardiovascular Surgery, UKSH, Kiel, Germany, Kiel, Germany, ³Ferring Ventures GmbH, Ferring Ventures GmbH, Hamburg, Germany

Background and Goal of Study: Regulatory Macrophages (Mreg) possess pro-angiogenic and regenerative potential and could represent potential candidates for cell therapy treatment in patients with Peripheral Arterial Occlusive Disease (PAOD)¹.

This study evaluates the therapeutic capacity of GMP grade Mreg (TRI-001) in a mouse model of hind limb ischemia.

Materials and Methods: Human monocytes were differentiated into TRI-001 using a GMP-compliant protocol² (Figure 1A). Immunodeficient mice underwent ischemic surgery on the right hind limb (Figure 1B) and were treated 24 hours later with intramuscular injections of TRI-001, Monocytes (cell control), or no-injection (sham control)

Blood flow and ulcer formation were monitored up to day 51, after which animals were sacrificed. Hind limb tissues were stained for CD31 using immunohistochemistry.

Results and Discussion: An immediate decrease of blood flow in the ischemic limbs after surgery was followed by a recovery of flow in all groups. On day 10, the flow values of the ischemic leg were approximately 50% of the values of the control leg. No significant differences were found between the treatment and control groups, indicating that neither Monocytes nor TRI-001 had a positive effect on macroperfusion.

However, histological analysis of neoangiogenesis revealed a significantly higher number of CD31 $^{+}$ vessels in the TRI-001-treated animals versus the Monocyte group (TRI-001: 8.78 \pm 2.58 vs Monocytes: 5.81 \pm 1.92; P = 0.004) and versus the no-injection control group (6.32 \pm 1.89; P = 0.043; Figure 1C).

In addition, the proportion of regenerative muscle fibers was by trend increased in the TRI-001 group (Figure 1C). A 20% incidence of non-healing ulcers was observed in the Monocyte and no-injection control group, while no ulcers were detected in the TRI-001-treated group (Figure 1C).

Conclusion(s): Intramuscularly applied TRI-001 enhance microperfusion and prevent ulcer formation. TRI-001 may serve as a promising cell therapy for ischemia-related conditions, such as PAOD.

32AP02-6

The impact of blood pressure and hypotension on the accuracy and trending ability of the fourth-generation FloTrac against continuous thermodilution in cardiac output monitoring

Y. Lam¹, R.V. Immink¹, D.P. Veelo¹, A.P.J. Vlaar², R.E.C. van den Dool1. E. Kho1,2 ¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Intensive Care Medicine, Amsterdam, Netherlands

Background and Goal of Study: Pulmonary artery catheter (PAC) thermodilution is often regarded as the clinical standard in cardiac output (CO) monitoring. However, its use has been criticised due to its highly invasive nature and the lack of evidence for improved outcomes. Less invasive techniques such as the widely used minimally invasive FloTrac system (FT) have been proposed, which estimates CO using arterial pressure waveform analysis. Currently, the effect of blood pressure (BP) on its performance. particularly during hypotension, remains unexplored.

This study aimed to evaluate the accuracy and trending ability of FT across a wide range of BP by utilizing unique data of patients who required prolonged periods of intraoperative hypotension.

Materials and Methods: Intra-operative CO measurements by PAC thermodilution (PAC-CO) and FT (FT-CO) were simultaneously collected in 33 patients, which yielded 4246 measurement pairs across mean arterial pressures (MAP) ranging from 16 to 120 mmHg. Data was stratified into MAP subsets of <40, 40-50, 50-60, 60-70 and >70 mmHg. Accuracy was assessed using Bland-Altman analysis and trending ability was evaluated using four-quadrant plots with a 20-minute interval and 15% center exclusion zone. Both analyses were executed on the entire dataset and on each subset.

Results and Discussion: Overall, FT-CO underestimated CO with a mean bias -0.87 L/min. The 95% limits of agreement were -3.30 to 1.55 L/min, the percentage error was 53.7% and the concordance rate was 78.0%. All MAP subsets showed similar results except for the subset with MAP >70 mmHg. FT demonstrated better performance in the subset with MAP >70 mmHg with a mean bias of -0.68 L/min, a 95% limits of agreement of -2.84 to -1.47 L/min, a percentage error of 44.4% and a concordance rate of 85.4%. There was clear relationship between (low) blood pressure and the performance of FT.

Conclusion(s): FT-CO is not interchangeable with PAC-CO at all predefined blood pressure ranges. However, FT performance did not worsen with decreasing MAP. These findings suggest that hypotension does not affect the performance of FT in estimating the CO.

32AP02-7

Anesthetic management in valve-in-valve-invalve transcatheter aortic valve replacement (TAVR): a case report and review of perioperative considerations

J.-H. Chang¹, K.-B. Chen¹, K.-W. Chen² ¹China Medical University Hospital (CMUH), Department of Anesthesiology, Taichung, Taiwan, 2China Medical University Hospital (CMUH), Division of Cardiology, Department of Internal Medicine, Taichung, Taiwan

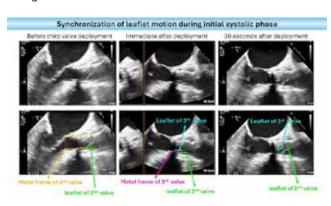

Background: TAVR is now a widely used therapeutic option, with favorable outcomes compared to surgical aortic valve replacement(SAVR). Over 20 years after first-in-man TAVR, more patients require second or higher-order re-implantations, presenting with complex conditions and challenging imaging. We report a TAVR-in-TAVR-in-SAVR case to examine the anesthesiologist's role in these complex scenarios.

Case Report: An 83-year-old male underwent SAVR(Freestyle, Medtronic) in 2005 for aortic stenosis. In 2018, he received TAVR(Evolute, Medtronic) due to degeneration of the surgical valve and the onset of aortic regurgitation(AR). In 2024, he was admitted for a third valve intervention due to TAVR valve degeneration causing recurrent AR. The key risk raised from the stacking of three valves, which may lead to coronary artery obstruction. Bilateral upper limb arterial access for coronary protection compromised continuous blood pressure monitoring during the procedure. The complexity of the aortic root increases technical difficulty, operative time, and contrast use, requiring careful renal protection and carrying a high risk of rupture. Continuous precise transesophageal echocardiography(TEE) monitoring is required for safety. A 3rd valve (Sapien 3, Edward) was deployed successfully. TEE revealed a unique phenomenon: the 2nd valve totally overhung the 3rd valve, and the latter one assisted in improving the dynamics of the former. We recorded valuable imaging showing the transition of leaflet motion of synchronization after deployment. The patient exhibited significant relief from heart failure symptoms and was discharged uneventfully.

Discussion: High-risk complex cardiac interventions are increasingly common, requiring anesthesiologists to have a thorough understanding of the pathophysiology, anatomy, procedures, and imaging diagnostics. Teamwork is essential for success.

Learning Points:

- 1. Both surgeons and anesthesiologists face significant uncertainties in complex procedures, making comprehensive teamwork and collaboration essential.
- 2. Most TAVRs now use transthoracic ultrasound without intubation, but TEE remains invaluable for detecting subtle, real-time changes.

32AP02-8

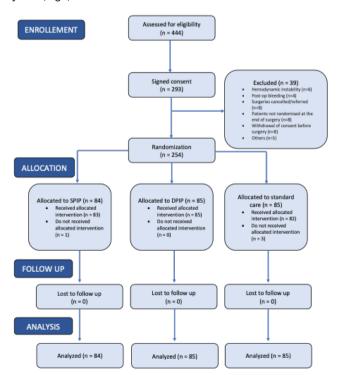

Effect of superficial and deep parasternal blocks on recovery after cardiac surgery with sternotomy: a randomized controlled trial

D. Achille¹, A. Jeanneteau¹, A. Blanchard-Daguet¹, S. Lasocki1, E. Rineau1, M. Léger1 ¹University Hospital Angers, Anaesthesiology and Critical Care Department, Angers, France

Background and Goal of Study: Regional anesthesia seems to be an interesting technique to reduce the pain after cardiac surgery, but its effectiveness in improving recovery has been poorly studied so far. The objective of this study was to compare the effectiveness of the Superficial and the Deep Parasternal Intercostal Plane blocks (SPIP and DPIP respectively), in addition to standard care, versus the standard care, on the Quality Of Recovery (QoR) after cardiac surgery.

Materials and Methods: This trial was registered on ClinicalTrials.gov NCT05345639, on April 26, 2022. Ethical approval was granted by French Institutional Review Board. This was a singlecenter, randomized, controlled, single-blind study with a 1:1:1 ratio. Inclusion criteria were adult patients who underwent cardiac surgery via median sternotomy. Patients were randomized into three groups: a control group with standard care and no regional anesthesia, a SPIP group and a DPIP group. Regional anesthesia was performed with 0.2% ropivacaine, 20 mL on each side. The primary endpoint was the value of the QoR evaluated by the FQoR-15 at 24 hours after the surgery.

Results and Discussion: We randomized 254 patients in one years (Fig.1).

Demographic data are comparable in all respects between groups. The FQoR (primary endpoint) was not significantly different between the 3 groups or between the control group and the group with a parasternal block (either SPIP or SPIP) (p=0.248). Postoperative pain and analgesic consumption were not different between groups, but the pain values were very low across all groups (NRS at 24h 2.0 [3.0-0.0]). However, the incidence of pneumothorax was higher in the DPIP group (p= 0.032). There was no difference in other complications.

Conclusion: Regional anesthesia using bilateral DPIP or SPIP after sternotomy was not associated with improved postoperative recovery compared with standard management. The SPIP seems safer, as the DPIP was associated with a higher occurrence of pneumothorax in our study.

Additional studies are therefore needed to confirm this security data and to identify painful patients who could benefit from a parasternal block after cardiac surgery.

32AP02-9

A rare case of sutureless aortic valve dislocation immediately after caridiopulmonary bypass

R. Sakuma¹, K. Kurooka¹, Y. Nakayama¹, M. Fuyuta¹, Y. Nakajima1

¹Kindai University Faculty of Medicie, Anesthesiology and Critical Care, Osaka, Japan

Background: Sutureless aortic valve replacement (AVR) is an innovative approach for patients who require surgery for aortic valve stenosis. It enables faster implantation with shorter cardiopulmonary bypass and operative time. However, reports regarding the complications associated with sutureless AVR remain limited. Case Report: A 72-year-old male was admitted for evaluation of repeated syncope over the last 2 months. After severe agrtic stenosis was diagnosed by cardiac echocardiography, surgical procedure with a Perceval sutureless valve was scheduled. During weaning from cardiopulmonary bypass (CPB), transesophageal echocardiography revealed a dislocated and dysfunctional left coronary cusp of the Perceval valve, along with a severe paravalvular leak that resulted in diastolic mitral regurgitation. In the second run of CPB, left coronary cusp of Perceval valve was confirmed to be dislocated to the cephalad, and a new sutureless valve was then placed.

Discussion: Sutureless AVR represents an alternative to both conventional AVR and transcatheter AVR. This innovative technique, which eliminates the need for suturing the new valve into place, has been introduced in recent years. Consequently, sutureless AVR warrants direct comparison with transcatheter AVR to evaluate its relative benefits and limitations.

Several reports suggest that sutureless AVR reduces certain complications associated with transcatheter AVR, such as the increased risks of postoperative stroke, atrioventricular block. and paravalvular leak. Additionally, the surgical approach facilitates the simultaneous correction of other valvular or coronary diseases.¹ In this way, while the benefits are often emphasized, reports on the various complications associated with sutureless AVR are still scarce.

Reference:

1.The Perceval Sutureless Aortic Valve: Review of Outcomes, Complications, and Future Direction. Ramsey Powell, et al. Innovations.2017;12:155-173.

Learning Points: Following artificial valve replacement, it is standard practice to assess perivalvular leakage and valve function immediately after CPB

In transcatheter aortic valve implantation, valve displacement can occasionally occur during surgery, leading to acute severe aortic regurgitation. However, there are few reports documenting such

occurrences in sutureless valve migration. Our observation revealed that even the Perceval valve can become dislodged during surgery, causing significant aortic regurgitation.

32AP02-10

Acute type A aortic dissection and successful surgical repair with cardiopulmonary bypass in a pregnant woman at 14 weeks of gestation

L. Puodziukaite^{1,2}, <u>U. Parchutikaite</u>¹, S. Pileikaite¹, A. Zorinas^{3,4}, K. Rucinskas^{3,4}

'Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Clinic of Anaesthesiology and Intensive Care, Vilnius, Lithuania, ²Vilnius University Hospital Santaros Klinikos, Department of Anaesthesiology and Intensive Care, Vilnius, Lithuania, ³Institute of Clinical Medicine, Faculty of Medicine, Vilnius University, Clinic of Cardiovascular Diseases, Vilnius, Lithuania, ⁴Vilnius University Hospital Santaros Klinikos, Department of Cardiothoracic Surgery, Vilnius, Lithuania

Background: Cardiovascular disease affects over 1-4% of pregnancies globally and poses serious health risks, with aortic dissection being a life-threatening complication for both mother and fetus (1).

Cardiac surgery with cardiopulmonary bypass (CPB) during pregnancy poses challenges due to its unknown long-term impact on the fetus, however, the mortality rate for untreated type A dissection rises by 1–3% per hour after presentation (2).

Case Report: We present the case of a 24-year-old pregnant patient at 14 weeks of gestation who was diagnosed with acute type A aortic dissection.

Following a multidisciplinary discussion with a cardiologist, cardiac surgeon, anaesthetist and obstetrician-gynaecologist, an urgent replacement of an ascending aorta was recommended. The patient's EuroSCORE II perioperative risk was 2.64%, and ASA class IV.

The patient underwent ascending aorta replacement under general anaesthesia with CPB. Induction was performed using midazolam, fentanyl, propofol, and rocuronium. Anaesthesia was maintained with sevoflurane, supplemented by propofol and fentanyl infusions. The patient was transferred to the ICU and extubated after 4 hours. The postoperative course was uneventful. At 27 weeks of gestation due to preeclampsia, a cesarean section was performed, resulting in the birth of a healthy male infant.

At the six-year follow-up, chest CTA showed stable aortic anatomy with no concerning progression. The child was reported to be in good health.

Discussion: Aortic dissection, occurring in 5.5 cases per million pregnancies, poses significant maternal and fetal risks. Pregnancy-related changes increase susceptibility to vascular complications, requiring swift intervention. While open-heart surgery and CPB can be lifesaving, their fetal impact remains uncertain, complicating treatment. This case emphasizes the importance of early diagnosis and prompt intervention for improved maternal and fetal survival.

Perioperative hemodynamic monitoring during the removal of an RVAD using the ProtekDuo cannula: a case report

E. Ardant¹, S. Pérez García¹, A.M. Gomez Caro¹, A. Arjona¹, A. Hostalot Sanchez¹, V. Cegarra Sanmartin¹ ¹Hospital Sant Pau, Anesthesiology, Barcelona, Spain

Background: The ProtekDuo cannula, connected to a pump such as the Levitronix CentriMag[™], provides effective right ventricular assist device (RVAD). However, its design and placement in the right heart chambers and pulmonary artery limit the ability to perform invasive hemodynamic monitoring using a Swan-Ganz catheter. We present a case that highlights these challenges and the strategies employed to manage hemodynamic during RVAD withdrawal.

Case Report: A 55-year-old man presented with an inferior myocardial infarction complicated by ischemic ventricular septal defect (VSD). Initially in cardiogenic shock within 24 hours, he was supported with veno-arterial extracorporeal membrane oxygenation (ECMO). Surgical closure of the VSD and a single coronary artery bypass graft (LIMA to LAD) were performed; however, biventricular dysfunction, predominantly right-sided, persisted, preventing ECMO weaning. After 26 days, ECMO was transitioned to RVAD with a ProtekDuo cannula and Levitronix CentriMag[™] pump.

The patient was excluded from heart transplantation due to comorbidities, directing the strategy towards bridge to recovery. After 55 days of RVAD support, the ProtekDuo cannula was removed under general anesthesia in the operating room. Perioperative hemodynamic monitoring relied on transesophageal echocardiography (TEE) to guide pharmacologic support adjustments. Pharmacologic support included inotropes (adrenaline, dobutamine), vasopressors (norepinephrine), and pulmonary vasodilators (inhaled nitric oxide and iloprost). Hemodynamic stabilization was achieved using echocardiographic parameters such as right ventricular to right atrial gradients with PAPs estimate, and ventricular functional indices (FAC, TAPSE, and LVOT VTI).

Despite severe right ventricular dysfunction, RVAD removal was successful. Over the next five days, the patient was weaned off inotropes under echocardiographic guidance.

Discussion: This case illustrates the complexities of perioperative hemodynamic management during RVAD withdrawal using the ProtekDuo cannula. The absence of invasive pulmonary artery pressure monitoring required reliance on echocardiographic and gasometric parameters to adjust pharmacologic support.

32AP02-12

Respiratory failure after cardiac surgery: a single-center retrospective data review

E. Novikova¹, A. Mazur²

State Institution «Amosov National Institute of Cardio-Vascular Surgery of The National Academy of Medical Sciences of Ukraine», Intensive Care for Adults, Kyiv, Ukraine, ²State Institution «Amosov National Institute of Cardio-Vascular Surgery of The National Academy of Medical Sciences of Ukraine», Anesthesiology & Intensive Care, Kyiv, Ukraine

Background and Goal of Study: Respiratory failure, particularly acute respiratory distress syndrome (ARDS), is one of the most threatening complications after cardiac surgery, which is followed by longer intensive care unit (ICU) stay and higher mortality rate. This study is aimed to evaluate the frequency of respiratory failure, to analyze the perioperative factors and their impact on the development of ARDS in patients undergoing cardiac surgery. Materials and Methods: The retrospective data review of 81 adult patients, who underwent cardiac surgeries at a single center, was conducted. The analysis included demographic characteristics, intraoperative parameters (cardiopulmonary bypass (CPB) duration, aortic clamping time, lactate levels), ventilation parameters (FiO₂, PEEP, dynamics of oxygenation index), blood transfusion details (fresh frozen plasma (FFP), red blood cell mass), and postoperative radiological changes. Statistical analysis methods were used to evaluate the correlation between these factors and the occurrence of ARDS.

Results and Discussion: The mean age of patients was 61.5 ± 11 years, and a weak positive correlation was found between age and the development of ARDS (r = 0.21; p = 0.04). The presence of ≥2 comorbidities increased the risk of ARDS (r = 0.30; p = 0.01). Pre-existing pulmonary diseases were associated with a higher risk of ARDS (r = 0.38; p = 0.005). ARDS developed more frequently in patients who underwent surgery with CPB (36.7%) compared to those who had off-pump surgery (10.0%; p < 0.01). The duration of CPB (mean: 140 ± 52 min) and aortic clamping (mean: 105 ± 37 min) were independently associated with the development of ARDS (p < 0.05). ARDS was more frequent in patients with a CPB duration over 150 minutes (r = 0.34; p = 0.01). Intraoperative lactate levels were significantly higher in patients with ARDS (3.1 \pm 1.2 mmol/L) compared to those without ARDS (1.9 ± 0.8 mmol/L), and these showed a moderate positive correlation with the development of ARDS (r = 0.42; p < 0.001). ARDS was strongly associated with mechanical ventilation in the ICU for more than 6 hours (r = 0.47; p < 0.001). Additionally, patients with ARDS had a lower oxygenation index prior to extubation (r = -0.29; p = 0.02). Transfusion of FFP over 600 ml was significantly associated with ARDS development (r = 0.35; p = 0.003), while the transfusion of red blood cell mass (>400 ml) did not show a significant impact (p = 0.08).

Postoperative radiological changes were present in 60% of patients with ARDS, compared to only 25% in the non-ARDS group (p < 0.001). The average length of stay in the intensive care unit (ICU) was significantly longer for patients with ARDS (7.4 ± 3.1 days) compared to those without ARDS (4.1 \pm 2.7 days, r = 0.39; p = 0.002).

Conclusions: ARDS after cardiac surgery is significantly associated with older age. CPB use, elevated lactate levels, largevolume FFP transfusion, and the existing comorbidities. The ICU stay duration is longer in patients with ARDS. These results demonstrate the importance of careful monitoring, protective ventilation, rational use of blood transfusions, and individualized care for patients undergoing cardiac surgery with ARDS risks.

Postprocedural aortic dissection after transcatheter aortic valve migration

K. Kurooka¹, R. Sakuma¹, Y. Nakayama¹, M. Fuyuta¹, Y. Nakaiima1

¹Kindai University Faculty of Medicie, Anesthesiology and Critical Care, Osaka, Japan

Background: Dislocation and migration of the valve during transcatheter aortic valve replacement (TAVR) is a critical and potentially catastrophic complication. If not promptly addressed, it can significantly worsen patient outcomes. As one possible complication, aortic dissection could theoretically be triggered by the aggressive retrieval of large devices beyond the aortic arch, although reports of such cases are rare.

Case Report: An 83-year-old male was admitted with severe aortic stenosis, confirmed by echocardiography, and TAVR was scheduled under general anesthesia. Despite the use of controlled ventricular pacing and fluoroscopic guidance, the selfexpanding valve immediately dislodged after deployment and migrated into the ascending aorta. Efforts to retrieve the valve percutaneously with a snare were unsuccessful. In response, a balloon-expandable valve was deployed to avert acute aortic regurgitation. Transesophageal echocardiography revealed a aortic dissection during the reinsertion interventions of the balloon-expandable valve. Despite the risk, the intervention was completed to avert acute heart failure due to severe acute aortic regurgitation, followed by urgent aortic replacement surgery performed by the cardiac surgical team.

Discussion: Cranial migration into the ascending aorta can result from various causes, including improper positioning, an undersized prosthesis, a tortuous or angulated aorta, heavily calcified or bulky leaflets, as well as post-dilatation performed in a borderline high position. Premature beats during rapid pacing or complete failure of pacing may also contribute. The embolization of the transcatheter heart valve can have devastating consequences, obstructing blood flow to vital organs, including the brain, and requiring immediate surgical intervention. Aortic dissection in the context of TAVR may occur due to several factors, including the mechanical forces exerted during the procedure, such as balloon dilation or the insertion of the valve prosthesis itself.1

References:

1. Surgery after Failed Transcatheter Aortic Valve Implantation: Indications and Outcomes of a Concerning Condition. Mohamed Salem, et al. J. Clin. Med. 2022, 11(1), 63

Learning Points: TAVR-related aortic dissection is a rare yet lifethreatening condition that may frequently remain undiagnosed. Nevertheless, we were able to promptly and accurately diagnose the aortic dissection through TEE.

32AP03-1

Brrrr its cold in the operating room! Clots forming while on cardiopulmonary bypass leading to a diagnosis of cold agglutin disease

<u>J. Shepherd</u>¹, C. Plambeck¹

'Medical College of Wisconsin, Anesthesiology, Milwaukee, United States

Background: Cold agglutinins in cardiac surgery may present with use of hypothermic cardiopulmonary bypass (CPB)

Case Report: 81 Y male hospitalized for acute bronchitis subsequently found to have severe coronary artery disease for which he underwent coronary artery bypass grafting. All anesthetic procedures and CPB were performed and initiated in standard fashion. While administering a dose of cardioplegia through the coronary sinus, perfusion quickly recognized that the cardioplegia line was filled with microscopic clots. Despite flushing the cardioplegia the clots continued forming within the line in the cardioplegia solution (See pictures 1&2). Cold agglutinin disease was suspected, and perfusion drew and performed a bedside ice syringe test providing additional diagnostic support (See pictures 3&4). No hemolysis was noted in urine and no change in hemodynamics occurred acutely. The decision was made to proceed with normothermic CPB and administration of warm cardioplegia at intervals of 10 minutes and the case proceeded as expected. The patient continued care in the CVICU where sedation was weaned and no neurological deficits identified. Labs resulted positive DAT complement with a negative IgG in setting of low haptoglobin and previous cold induced microthrombi/agglutination consistent with cold agglutinin disease. Despite creatinine peaking at 2.2 no hemolysis or dialysis postoperatively was required and he recovered as expected. There were no previous hematologic issues or family history of blood disorders and follow-up CT chest abdomen pelvis showed no underlying lymphadenopathy/lymphoproliferative disorder.

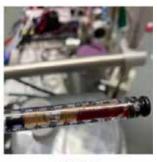

Picture #1

Picture #3

Picture #2

Picture #4

Discussion: This case highlights that a rare diagnosis of cold agglutin disease can present while on CPB. Early recognition and prior reviews suggest that patients can safely undergo normo-

thermic cardiopulmonary bypass at 37°C and warm cardioplegia without increased mortality or morbidity1.

Barbara DW, Mauermann WJ, Neal JR, Abel MD, Schaff HV, Winters JL. Cold agglutinins in patients undergoing cardiac surgery requiring cardiopulmonary bypass. J Thorac Cardiovasc Surg. 2013 Sep;146(3):668-80.

32AP03-2 Chest pain during late pregnancy: undiagnosed aortic dissection

R.J. Fabián Quillama¹, A. Capdevilla¹, S. Martínez-Otero¹, M. Pozo-Albiol¹, M. Castellà-Pericás², M. Gimenez-Milà¹ Hospital Clínic de Barcelona, Anesthesiology, Critical Care and Pain Medicine, Barcelona, Spain, ²Hospital Clínic de Barcelona, Cardiovascular Surgery, Barcelona, Spain

Background: Aortic (Ao) dissection during pregnancy is rare (0.0004%) but fatal (1). We describe an undiagnosed case during delivery, highlighting differential diagnosis and echocardiography. Case Report: 34-year-old woman, 35 weeks pregnant, with 4 days of chest pain radiating to the neck and back, abdominal pain, fever (37.8°C) and uterine contractions. She had cervical cerclage at 22 weeks, intrauterine growth restriction type I and RH-. Marfanoid features went unnoticed. ECG, X-ray, troponin and bedside transthoracic echocardiography (TTE) were unremarkable. Lab showed Hb 10.5 g/dL and D-dimer 4719 ng/mL. Labour was induced for suspected chorioamnionitis. An epidural catheter was placed but removed after delivery. The newborn required Neonatal Intensive Care for acute respiratory distress. Persistent chest pain and new hypotension prompted a CT scan, revealing a 59 mm Ao root dilation, 49 mm ascending aorta and a type A Ao dissection (Fig. 1).

Figure 1.

She was referred to a tertiary-level hospital where TTE revealed moderate Ao regurgitation due to a flap compromising Ao valve. Ao arch and mechanical valve replacement were performed under 22°C hypothermia, receiving 3 RBC units, 3 g fibrinogen and 500 IU prothrombin complex concentrate. She was discharged on day 15 without any complications.

Discussion: Diagnosing Ao dissection during pregnancy is difficult due to nonspecific symptoms and radiation concerns. Aortopathy is often identified post-dissection (50%) (2). Chest pain was attributed to chorioamnionitis after acute coronary syndrome was ruled out. Pulmonary embolism and Ao syndromes were reconsidered as symptoms worsened. Vaginal delivery with epidural analgesia is only recommended with Ao diameters <45 mm.

Learning Points: For unexplained chest pain in pregnancy, we should search for signs of aortopathies and perform a comprehensive TTE to exclude Ao syndromes and plan a safe delivery. References:

A rare complication during percutaneous pulmonary vein ablation: do not underestimate vour enemy

Á. Barranco de Santiago¹, M. Pozo-Albiol¹, S. Martínez-Otero¹, J.-B. Guichard², M.J. Carretero¹, M. Giménez-Milà¹

¹Hospital Clínic de Barcelona, Anaesthesiology and Critical Care, Barcelona, Spain, 2Hospital Clínic de Barcelona, Cardiology, Barcelona, Spain

Background: Intraprocedural transoesophageal echocardiography (iTOE), even if not extended to all centers, plays a critical role in the catheter ablation of arrythmias. It enhances the safety of transseptal punctures and enables the early detection of complications, such as thrombus formation in high-risk patients, particularly those with a patent foramen ovale (PFO) or a history of previous thromboembolic events.

Case Report: 59 year-old gentleman, with past medical history of paroxysmal atrial fibrillation who presented with transient ischemic attack (TIA) in 2019 and underwent a pulmonary vein ablation 3 years ago. Since then, he had been taking apixaban, and now, he presented to emergency room with atrial fibrillation recurrence. He was rescheduled for pulmonary vein ablation redo. Last dose of apixaban was scheduled 12 hours before the procedure, but the patient inadvertently held it for 24 hours instead. The initial iTOE did not show any endocavitary thrombus or pericardial effusion, but it did reveal the presence of spontaneous echo contrast in the right atrium (RA) and a previously undiagnosed PFO. The first transeptal puncture was performed under iTOE guidance without complications. During the second transeptal puncture, an image compatible with a 3 cm thrombus attached to the tip of the guidewire was observed.

According to our center protocol, 100 IU/kg of intravenous sodium heparin were administered. Given the high thromboembolic risk due to the history of TIA and the diagnosis of PFO, the medical team decided to withdraw all catheters under aspiration and postpone the procedure. The final iTOE did not show any thrombus or other complications. Emergence from anesthesia took place uneventfully and the patient was discharged the same day without any neurological deficit.

Discussion: Until recently, there has been little focus on intraprocedural guidewire thrombosis. This case highlights the relevance of strictly following anticoagulation prior to arrhythmia ablation, as the main international societies recommend uninterrupted or minimally interrupted oral anticoagulation¹. Despite variability between centers, it is also remarkable the crucial role of iTOE in diagnosing potential complications during the procedure, as recommended by the main European and American guidelines^{2,3}.

32AP03-4

Postoperative atrial fibrillation (POAF) after cardiac surgery: bridging the gap in detection with a wearable cardiac rhythm monitoring device

M. Heine¹, E. Schueth¹, S. Nasra¹, L. Mazuera¹, J.D. Muehlschlegel², J. Wollborn¹ ¹Brigham and Women's Hospital, Harvard Medical School, Department of Anesthesiology, Perioperative and Pain Medicine, Boston, United States, 2 Johns Hopkins University School of Medicine, Department of Anesthesiology and Critical Care Medicine, Baltimore, **United States**

Background and Goal of Study: POAF is one of the most common complications in patients undergoing cardiac surgery (rates ranging from 30 to 50%)1. However, there is a significant knowledge gap on the incidence of POAF after discharge. Continuous cardiac rhythm monitoring has shown enhanced detection of POAF during the initial 30 days after surgery2.

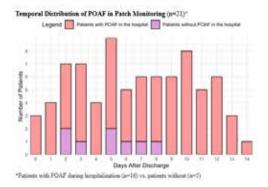

The aim of this study is to characterize the occurrence of POAF after discharge and to determine whether cardiac rhythm monitoring with a wearable patch device for 14 days after discharge is feasible in bridging the gap in POAF detection.

Materials and Methods: After IRB approval, 100 patients who underwent open-heart surgery using cardiopulmonary bypass were enrolled in this prospective clinical study. Shortly before discharge from the hospital, patients were asked to wear a portable ECG patch monitor (MultiVital ECG, vivalink) for two weeks. 77 patients were included in the analysis.

We reviewed charts and analyzed ECGs to detect POAF during hospitalization. ECG patch monitoring was used to detect AF after discharge, using both automated and manual ECG analysis. AF was considered relevant if it lasted longer than 30s, consistent with the diagnostic guidelines.

Results and Discussion: In our cohort, 42% of the patients developed POAF in the hospital and 27% were found to have AF on the patch. In 24% of patients with POAF, AF was first identified on continuous patch monitoring and was otherwise not picked up while hospitalized. In the majority of these cases (80%), AF was not diagnosed using alternative modalities until the 3-month follow-up. The majority of AF was paroxysmal AF, with many episodes lasting less than five minutes.

AF on patch* N=21 (27.3%)	No AF on patch* 30=56 (72.7%)
	1 (1.8) 55 (98.2)
16 (18.2) 5 (23.8)	16 (28.6) 40 (71.4)
AF on patch 10=19 (28.8%)	No AF on poich 30+47 (83.9%)
	1 (2.1) 46 (97.9)
	£ (42.1) 11 (57.9)

Conclusion(s): Almost a quarter of the patients with AF on continuous patch monitoring were not found to have POAF in the hospital. Without the ECG patch, these patients would likely have gone undiagnosed.

Our findings demonstrate that continuous cardiac rhythm monitoring for 14 days after surgery enhances the detection of POAF following cardiac surgery. The clinical significance of detecting POAF after discharge needs to be investigated in future studies.

32AP03-5

Real time quantification of atrioventricular coupling during the induction of general anaesthesia with cardiovascular MRI

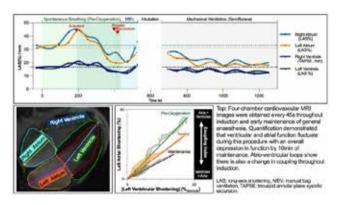

D. Kaiser¹, T. Schweizer¹, L. Grob¹, A.T. Huber². D.P. Guensch^{1,2}, K. Fischer¹ ¹Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, 2Inselspital, Bern University Hospital, University of Bern, Department of Diagnostic, Interventional and Paediatric Radiology, Bern, Switzerland

Background and Goal of Study: While the induction of general anaesthesia is associated with a higher risk for cardiac complications, the precise impact it has on all four chambers of the heart is unknown.

Applying novel cardiovascular MRI that acquires images continuously while free breathing, we investigated how left and right atrial (LA, RA) and ventricular (LV, RV) function and the atrio-ventricular coupling change throughout induction.

Materials and Methods: Three patients (ASA-PS≤II) scheduled for elective surgery underwent induction inside an MRI. Fourchamber images were acquired every 45s from the awake state until 10 min of maintenance. Long-axis-shortening (%) was calculated for the LA, RA and LV, while RV function was evaluated using tricuspid excursion (mm). Atrio-ventricular loops were created, and the slope defined the coupling index.

Results and Discussion: In comparison to the awake baseline (LV: -15.5±0.3%, RV: 20.6±3.2mm, LA: 30.7±4.2%, RA: 37.9±5.3%), preoxygenation increased function in all chambers (LV: -17.3±0.8%, RV: 24.0±2.5mm; LA: 41.7±6.8%, RA: 41.1±6.0%). Atrial function improved more than the ventricular function indicated by a steeper slope of the coupling loops (LA/LV: 1.6±0.2 to 2.0±0.5. RA/RV: 1.7±0.3 to 1.9±0.2). After induction and installation of mechanical ventilation, function continually dropped. By 10min of sevoflurane maintenance, a reduction in ventricular function was observed (LV: -13.7±0.6%, RV: 15.3±2.5mm). The largest depression was observed in the atria (LA: 16.6±4.0%, RA: 22.8±2.0%). By this point, the coupling indices had reversed, with the atrial function decreasing more in comparison to the ventricular decline (LA/LV: 1.2±0.1 RA/RV: 1.5±0.1).

Conclusion(s): Using perioperative cardiovascular MRI, we quantified that bi-atrial and ventricular function fluctuate throughout the induction of general anaesthesia with a significant drop in atrial function with maintenance, that was decoupled from the ventricles. These findings shed light on the rapidly changing conditions that all four chambers of the heart are exposed to and may help anaesthetists manage induction in patients with atrial or ventricular dysfunction.

32AP03-6

Safety of ultra-fast-track extubation in the Operating Room in adult minimally invasive and robotic cardiac surgery background

S. Aso¹, N. Fujita¹, S. Nagao², N. Shiromoto¹, S. Abe¹ ¹St.Luke's International Hospital, Anesthesiology, Chuoku, Tokyo, Japan, 2Shiga University of Medical Science, Department of Public Health Nursing, Otsu-Shi, Shiga, Japan

Background: Early extubation within 6 hours following cardiac surgery has been shown to shorten ICU stays and reduce resource utilization.1

However, ultra-fast-track extubation in the operating room (OR) remains controversial, with only a few facilities in Japan adopting this practice. Safety of extubation in the OR after minimally invasive cardiac surgery (MICS) including robotic surgery has not been fully established.

This study aims to evaluate the safety of ultra-fast-track extubation in the OR following MICS.

Methods: This single-center, IRB-approved retrospective study analyzed patients who underwent MICS at St. Luke's International Hospital between January 2011 and February 2024, Patients were categorized as follows:

- 1. Ultra-fast-track OR extubation
- 2. Ultra-fast-track OR extubation with NPPV (non-invasive positive pressure ventilation)
- 3. ICU extubation

Primary outcomes were ICU stay duration and total hospitalization length. Secondary outcomes included risk factors for NPPV after extubation in the OR.

Results: Of 120 patients (Mitral valve repair: 88, Aortic valve replacement: 6, Tricuspid valve repair: 11, Coronary artery bypass grafting: 15) included in the study, 6 were excluded due to reoperation or intraoperative complications. Of the remaining 114 cases, 61 were in the OR extubation group, 9 in the OR extubation with NPPV group, and 44 in the ICU extubation group. There were no cases of reintubation following extubation in the OR.

Body mass index (BMI) (25.3 vs 22.2 vs 23.0, P = 0.046), preoperative albumin levels (4.5 vs 4.2 vs 3.9 g/dL, P = 0.002), and intraoperative norepinephrine dosage (14.0 vs 4.9 vs 10.9 mL, P = 0.045) differed significantly between groups.

No significant differences were found in ICU stay (4.1±1.7 vs 3.1 ± 1.6 vs 4.5 ± 4.2 days; P = 0.117) or total hospitalization (10.1 ±4.3 vs 11.1±6.6 vs 16.8±25.3 days; P = 0.264).

Factors associated with need for NPPV after OR extubation included higher BMI (OR 1.33; 95% CI, 1.04 to 1.84; P = 0.045) and higher intraoperative norepinephrine dosage (OR 1.14; 95% CI, 1.03 to 1.29: P = 0.021).

Conclusion(s): Ultra-fast-track OR extubation after MICS was comparable to extubation in the ICU in terms of length of ICU stay and total hospitalization. BMI and norepinephrine dosage were risk factors for NPPV following OR extubation.

32AP03-7

Five years Follow-Up of Neurologic Outcome after Minimally Invasive Cardiac Surgery trial (FUNOMICS): is there evidence for late cognitive decline?

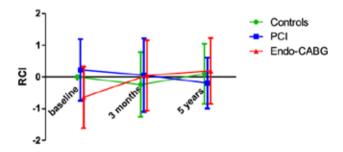

T. Treunen¹, J. Vandenbrande¹, I. Gruyters¹, M. Van Tornout¹, K. Nijs¹, B. Stessel¹ ¹Jessa Ziekenhuis, Anesthesiology, Hasselt, Belgium

Background and Goal of Study: Neurologic complications after cardiac surgery are a major cause of morbidity. In minimal invasive cardiac surgery, MICS, perfusion to the brain is often provided via retrograde cardiopulmonary bypass flow. As such, the brain is exposed to aortic atheroma located distal to the cerebral vessels. Stessel et al. demonstrated that the incidence of poor neurocognitive outcome until three months after endoscopic-CABG is low and comparable with percutaneous coronary intervention (PCI) (NOMICS trial). Three groups were prospectively followed: an endoCABG group, a PCI group and a healthy matched control group. A battery of neurocognitive tests was performed to establish the incidence of postoperative cognitive dysfunction (POCD) at baseline, 3 months and now also repeated 5 years after baseline.

Materials and Methods: All patients and volunteers who underwent three months follow-up in the NOMICS trial were invited to undergo the same battery of neurocognitive testing on 6 domains. Based on the Z-scores of the tests, the Reliable Change Index (RCI) was calculated. Late POCD was defined as an RCI ≤-1.645. Positive values indicate improvement.

Results and Discussion: Twenty patients in the endoCABG group, 18 in the PCI group and 17 controls underwent testing. In the endoCABG group, mean RCI increased from -0.64 (+/- 0.97) at baseline to 0.19 (+/- 1.04) at 5 years. In the PCI-group, mean RCI declined from 0.22 (+/- 0.97) to -0.19 (+/- 0.8) at 5 years follow-up. For the control group, baseline RCI was 0 per definition and evolved to 0.1 (+/- 0.95) at 5 years. P-values were 0.44 and 0.61 at 3 months and 5 years respectively.

Our results do not show any evidence for POCD 5 years after coronary surgery with retrograde perfusion. Also, both coronary artery diseased patient groups did not perform significantly worse 5 years after therapeutic intervention.

Conclusion: We did not find any evidence of late POCD 5 years after MICS with retrograde perfusion.

32AP03-8

Perspectives of anaesthesiologists on implementing findings from preexisting cardiovascular magnetic resonance imaging reports for perioperative risk assessment: an international survey

R. Harms¹, J.N. Fini¹, T. Schweizer¹, D.P. Guensch¹, K. Fischer¹

¹Inselspital, Bern University Hospital, University of Bern. Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background and Goal of Study: Cardiovascular magnetic resonance (CMR) has emerged as a powerful diagnostic tool, offering precise insights into cardiac structure and function. The likelihood of patients having diagnostic CMR findings available in their medical records is rapidly increasing, yet how anaesthesiologists utilize this data remain unclear. Therefore, we investigated anaesthesiologists' perspectives on CMR for risk stratifying patients for anaesthesia.

Materials and Methods: An anonymous online survey was distributed to anaesthesiologists worldwide. The survey included 42 multiple choice questions designed to assess anaesthesiologists' general knowledge and use of diagnostic CMR reports.

Results and Discussion: A total of 414 anaesthesiologists from 24 countries participated. Half (52%) indicated they work in cardiac, vascular or thoracic anaesthesia (CVA), Functional capacity was the most utilized cardiovascular risk-assessment tool (94%) followed by imaging in general terms (84%).

Specifically, 68% of respondents incorporated CMR reports into evaluations when these were available in patients' medical history. although it was more common for anaesthetists working in CVA to incorporate CMR (70% vs 60%, p=0.03). The majority understood and often implemented left (CVA: 63% vs non-CVA: 51%, p<0.01) and right (CVA: 55% vs non-CVA: 40%, p<0.01) ventricular anatomy and function.

CMR is well known for characterizing myocardial tissue features, and myocardial perfusion assessments of inducible ischaemia were assessed by half of the anaesthetists (CVA: 55% vs non-CVA: 41%, p<0.01) with even less using the presence of myocardial scar (CVA: 33% vs non-CVA: 21%, p<0.01).

Few knew and implemented modern CMR techniques characterizing diffuse myocardial fibrosis (CVA: 14% vs non-CVA: 7%, p<0.01) and oedema (CVA: 11% vs non-CVA: 4%, p<0.01). A majority recognized CMR's future potential for perioperative risk evaluation (75%) and expressed a desire to integrate it more into clinical practice (53%).

Conclusion(s): Anaesthesiologists worldwide, are using CMR data for perioperative cardiovascular risk assessments. Even anaesthesiologists not working in CVA incorporate CMR findings, although to a lesser extent than colleagues in CVA.

Nonetheless, application predominantly relies on traditional metrics, with modern tissue characterization techniques being less well understood. Consequently, CMR' full potential for perioperative risk stratification is not realized.

32AP03-9

Identification of preoperative risk factors for intraoperative hypotension during cardiac surgical interventions

J. Vuckovic¹, M. Tatić¹, S. Vicković¹, I. Stojanović², M. Preveden¹, Đ. Ubović³

¹Medical Faculty of Novi Sad. Department of Anaesthesiology and Perioperative Medicine, Novi Sad. Serbia, ²Institute for Cardiovascular Disease of Vojvodina, Cardiac Surgery Department, Sremska Kamenicase, Serbia, ³Institute for Cardiovascular Disease of Vojvodina, Department of Cardiac Surgery, Sremska Kamenica, Serbia

Background and Goal of Study: Intraoperative hypotension (IOH) is a common adverse effect of general anesthesia, with serious potential consequences, influenced by preoperative factors. This study investigates IOH and analyzes preoperative risk factors contributing to its occurrence during cardiac surgery.

Materials and Methods: This prospective study was conducted over one year, involving patients undergoing cardiac surgery at a single medical center. Preoperative data, including demographic information, comorbidities, and chronic cardiovascular therapy, were collected to assess their impact on IOH. Binary logistic regression was used to identify risk factors.

Results and Discussion: The IOH group consisted of 207 patients (34%), while the control group included 402 patients (66%). The average age was 65.56±9.56 years. Each year of age incrementally increased the risk of IOH (Odds ratio 1.047, p < 0.0005). Patients with ASA IV had a higher risk of IOH compared to ASA III patients (Odds ratio 8.323, p < 0.0005).

Preoperative discontinuation of ACE inhibitors or ARBs at least 12 hours before surgery was associated with a 70% reduction in complications (Odds ratio = 0.289, p < 0.003).

Conclusion(s): Preoperative risk factors for IOH include age. emergency surgery, higher ASA score, and use of ACE inhibitors or ARBs within 12 hours of surgery. Key cardiovascular predictors are Left Main stenosis, atrial fibrillation, myocardial infarction, and heart failure.

Comorbidities such as anemia, carotid artery stenosis, diabetes mellitus, and chronic renal insufficiency also significantly increase the risk of IOH.

Quantifying ventricular synchrony and diastolic function to predict patients who will develop pharmacological induced myocardial ischaemia in a diagnostic setting

B. Schmid¹, C. Heinisch², I. Reinmann¹, T. Kujawski², D. P Guensch¹. K. Fischer¹

¹Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, ²Hospital Centre of Biel, Cardiology, Biel, Switzerland

Background and Goal of Study: Many perioperative factors have vasodilating properties that can alter myocardial blood flow (MBF). In patients with underlying coronary artery disease, this can lead to unbalanced blood flow distribution across the myocardium and potentially trigger perioperative myocardial ischaemia. MBF changes under vasodilatory stimuli can be assessed using cardiovascular magnetic resonance (CMR) or nuclear imaging diagnostic stress tests.

However, few will undergo these expensive stress tests. Yet, most patients with a higher cardiovascular risk profile will have a preoperative non-stress cardiac imaging exam such as echocardiography or CMR to assess cardiac function at rest.

From both modalities, multiple advanced ventricular systolic and diastolic functional parameters can be quantified with strain. In a diagnostic setting with awake patients with suspected ischaemic heart disease, we investigated if modern strain parameters at rest provide insight into which patients are at risk for inducible myocardial ischaemia in the presence of pharmacological vasodilation

Materials and Methods: Patients (n=99) referred for a clinical CMR exam were prospectively recruited. Resting function images were measured for left ventricular ejection fraction and three longitudinal strain measurements: peak strain, mechanical dispersion and early diastolic strain rate. These were assessed for their association with inducible ischaemia defined as MBF<1.5mL/g/ min under hyperaemic stress (400µg regadenoson).

Results and Discussion: Inducible ischaemia was identified in 44% of the patients. Mechanical dispersion (contractile dyssynchrony) was able to best predict hypoperfusion (AUC=0.68, p<0.01), followed by early diastolic strain rate (AUC=0.65, p=0.01) and the systolic marker of peak strain (AUC=0.62, p=0.03).

Neither ejection fraction nor patient age could significantly predict inducible ischaemia (AUC=0.61, p=0.07 and AUC=0.58, p=0.18).

Conclusion: We demonstrate in awake patients with suspected cardiovascular disease that modern strain markers for quantifying ventricular contractile synchrony and diastolic function from cardiac images acquired at rest predicted the onset of myocardial ischaemia induced by pharmacological hyperaemia.

These measures can be acquired in standard exams with both CMR and echocardiography, and these insights could be helpful to enhance perioperative risk assessment to detect patients prone to hypoperfusion.

32AP03-11

Haemodynamic management of post-infarction ventricular septal defect in a diabetic patient: a diagnostic and therapeutic challenge

M.B. Perolada Beaus¹, L. Mora Gómez¹, M. Llobell Ruvira¹, O. Aznar Millán¹, L. Edo Cebollada¹, J. Hernández Laforet²

¹Hospital General Castellon, Valencia, Castellon, Spain, ²Hospital General Valencia, Valencia, Valencia, Spain

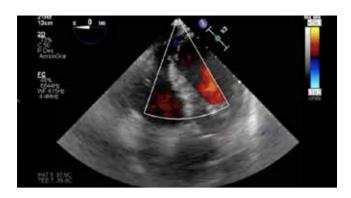

Background: Post-infarction ventricular septal defect (VSD) is a rare but serious mechanical complication of acute myocardial infarction (AMI), with a mortality rate above 60%. Surgical repair is the definitive treatment, though the optimal timing for intervention remains uncertain.

Case Report: A 64-year-old male with type 2 diabetes mellitus (T2DM) presented to the emergency department with a two-day history of abdominal and returned 48h later with acute pulmonary edema.

Echocardiography: mid-apical ventricular septal defect, and severely reduced left ventricular ejection fraction (LVEF). ECG: anterior-inferior STEMI. Given the extensive myocardial damage, revascularization was not possible, and an intra-aortic balloon pump (IABP) was placed for hemodynamic stabilization.

Two days later, the patient underwent surgical repair of the VSD. Preoperatively, he remained hemodynamically unstable, requiring dobutamine and levosimendan.

Advanced hemodynamic monitoring and cardiopulmonary bypass were used during surgery. The patient was transferred to the ICU, extubated 24 hours later, and gradually weaned from mechanical and inotropic support. He was discharged from the ICU on day six with a LVEF of 30%.

Discussion: VSD causes a left-to-right shunt, resulting in pulmonary volume and pressure overload and left-sided heart strain. The goal of management is to reduce the shunt by lowering afterload using devices such as IABP and vasodilators1.

Ventricular dysfunction often requires inotropes, and in severe cases, ventricular assist devices such as IMPELLA or VA-ECMO may be necessary. Surgical correction should ideally occur within seven days of VSD diagnosis to allow for myocardial stabilization and reduce myocardial friability.2

Diabetic patients often present atypically which delays diagnosis and increases the risk of complications.

References:

- 1. http://dx.doi.org/10.24875/recic.m22000334
- 2. http://dx.doi.org/10.1016/j.circv.2020.04.004

Learning points:

Management of VSD focuses on reducing the shunt through afterload reduction and improving contractility with inotropes and assist devices.

Delayed surgery after hemodynamic optimization offers the best outcomes.

32AP03-12

The dynamic optimal combinations of blood pressure and heart rate in critically ill patients: a time-dependent Cox proportional hazards model

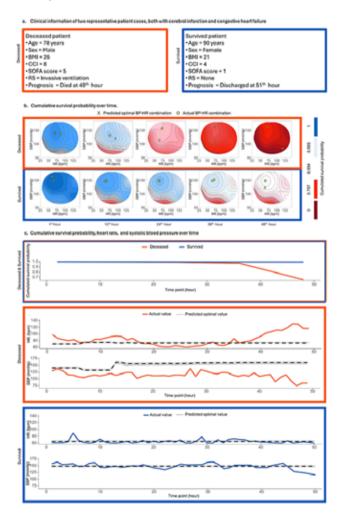

Y. Sun¹, J. Li², J. Su², Z. Liu², D. Sun³, L. Meng³ ¹Nanjing Drum Tower Hospital, The Affiliated Hospital of Nanjing University Medical School, Department of Anesthesia, Nanjing, China, Indiana University School of Medicine, Department of Biostatistics and Health Data Science, Indianapolis, United States, 3Indiana University School of Medicine, Department of Anesthesia, Indianapolis, United States

Background and Study Objective: Prior research has identified associations among blood pressure (BP), heart rate (HR), and intensive care unit (ICU) mortality. However, these investigations primarily analyzed BP and HR as independent variables, without considering their dynamic interaction or temporal changes during the disease progression. This study aims to explore the dynamic association between BP-HR combination and mortality in ICU patients comprehensively.

Materials and Methods: We utilized the eICU database as the training set and the MIMIC-IV and Indiana University Health databases as validation sets. A time-dependent Cox Proportional Hazards model was employed to evaluate the association between

the dynamic BP-HR combination and ICU mortality. The analysis was adjusted for demographic characteristics, comorbidities, and dynamic data. Based on our model, we predicted the personalized optimal BP-HR combination throughout the ICU stay.

Results and Discussion: The study included 114,636 patients from eICU, 50,761 patients from MIMIC-IV, and 3,839 patients from Indiana University Health. The model on training and validation sets achieved C-indices of 0.931, 0.906, and 0.839, respectively. These findings diverged from studies that BP and HR were analyzed separately. The model results revealed that the relationship between the BP-HR combination and ICU mortality may differ among patients and could fluctuate within an individual patient over time. Our model therefore offered personalized dynamic predictions of the BP-HR combination for individual patients, identifying the optimal BP-HR values associated with the lowest risk of mortality.

Conclusion(s): Our findings indicate that patients with greater deviations between their actual and optimal BP-HR combinations are at a higher risk of adverse outcomes. Furthermore, our study demonstrated that an individual patient's clinical status may influence their tolerance to fluctuations in the BP-HR combination. Overall, the predictions generated by our model offer dynamic and personalized clinical guidance, tailored to varying hemodynamic conditions, for the effective management of ICU patients.

32AP04-1

A comparison of European and non-European anaesthesiology practice for using cardiac troponins to monitor perioperative myocardial injury

K. Fischer¹, R. Harms¹, P. Schultheiss¹, L. Oertle¹, T. Schweizer¹, D.P. Guensch¹ ¹Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background and Goal of Study: Perioperative myocardial injury (PMI) is a known complication of major non-cardiac surgery. Typically, PMI is monitored by cardiac troponins (cTn). However, a variety of recent guidelines and recommendations differ on the need for and frequency of cTn.

Therefore, we aimed to assess the current trends of anaesthesiologists for using cTn to monitor PMI, and to compare if this practice differed between Europeans and non-European anaesthesiologists.

Materials and Methods: An international survey was distributed through anaesthesia societies and departments. Anaesthesiologists were asked if and how they use cTn to monitor PMI, and if they used dabigatran as treatment.

Results and Discussion: From an interim analysis of 189 responses, 68% were Europeans, 23% were non-Europeans, and 9% were undefined. When asked if they measure cTn to detect PMI in patients with a higher cardiovascular risk, not one anaesthesiologist (0%) answered "almost always", while 28% answered "usually", 42% "sometimes", 21% "rarely", and 9% "never".

Specifically, non-Europeans more frequently answered that they never monitor cTn in comparison to Europeans (21% vs 6%, p=0.05).

When cTn monitoring was used, 48% responded their most common trend was to measure cTn at three defined timepoints of 1) preoperative, 2) 24h postoperative and 3) 48h postoperative), while 6% indicated they apply routine sampling but at different timepoints, and 33% stated to measure cTn when the patient was symptomatic.

European's most common trend (56%) was the option to acquire cTn at the predefined timepoints corresponding to the 2022 ESC/ESAIC recommendations, while non-Europeans most commonly sampled cTn when patients were symptomatic (37%). When cTn monitoring was not used, non-European anaesthetists more often cited follow-up (33% vs 16%, p<0.01) or financial issues (28% vs 13%, p=0.03) than Europeans as the reason.

If PMI was detected, 3% answered they routinely use dabigatran as a treatment plan to improve patient outcome, 14% in select cases, while most (72%) do not. While rare, non-Europeans are more likely than Europeans (6% vs 2%, p=0.02) to routinely use dabigatran to treat complications from PMI.

Conclusion(s): There is currently a wide variation in the practice of anaesthesiologists concerning cTn surveillance practices for PMI. This underscoring a need for harmonized guidelines and enhanced awareness of evidence-based strategies to optimize PMI detection worldwide.

32AP04-3

A prospective comparison of ultrasound-guided brachial and radial arterial cannulation in patients undergoing cardiac surgery

D. Margulis¹, M. Semionov¹, A. Smirnov¹, Y. Ishay¹, M. Pugachov¹, S. Kropveld¹ ¹Soroka Medical Center, Ben-Gurion University of the Negev, Division of Anesthesia and Critical Care, Beer-Sheva, Israel

Background: Using the right radial artery for invasive blood pressure monitoring in patients undergoing cardiothoracic surgery is common practice. However, using the punctured right radial artery after angiography for invasive blood pressure monitoring has potential limitations, such as vasoconstriction and blood flow changes, which can affect the accuracy of arterial pressure read-

It forces us to perform an additional arterial line cannulation in one of the femoral arteries. It is also important to note if it happens, especially during the critical part of the surgery, while weaning off the cardiopulmonary bypass machine. These significant findings raise the question: can we trust radial artery pressure monitoring during cardiac surgery?

Methods: We recruited adult patients who underwent cardiothoracic procedures, such as coronary artery bypass graft surgery (CABG) and aortic, mitral, and tricuspid valve replacements (AVR, MVR, TVR), and randomly divided them into 2 groups. Group A included patients undergoing arterial cannulation of the right brachial artery, and Group B included patients undergoing arterial cannulation of the right radial artery. Then, we assessed the need for an alternative approach-femoral artery cannulation.

Results: The Chi-Square test was applied to statistically analyze categorical data. There is a significant difference between brachial and radial approaches, p-value = 0.012

Discussion: According to the data, the right brachial artery approach is superior to the right radial artery cannulation as a routine practice during cardiac surgery. In this study, there was less need for an alternative access-femoral artery cannulation.

Conclusion: We propose that brachial cannulation is a legitimate. less complicated, and reliable approach in patients undergoing cardiac surgery.

32AP04-4

Sudden cardiac arrest due to ventricular fibrillation as the initial presentation of mitral valve fibrosis: a case report

A. Rivera Vallejo1, I. Zaragoza García2, M. Rivilla Lizano¹, V. Cegarra Sanmartín¹, A.M. Gómez Caro¹, T. Koller Bernhard¹ ¹Hospital de la Santa Creu i Sant Pau, Anesthesiology, Barcelona, Spain, ²Hospital del Mar, Anesthesiology, Barcelona, Spain

Background: Mitral valve fibrosis, though rare, can cause sudden cardiac arrest (SCA) due to ventricular fibrillation (VF). This case highlights diagnostic challenges in a male with mitral fibrosis and SCA. Mitral valve prolapse (MVP) affects 2-3% of the population: mostly benign but malignant form, which involves mitral annular disjunction, bivalvular prolapse and fibrosis is linked to arrhythmias and sudden cardiac death (SCD). Identifying patients at risk requires clinical, electrophysiological and advanced imaging stud-

Case Report: A 52-year-old male without significant medical history was brought to hospital after being resuscitated from VF. Initial ECG and coronary angiography ruled out acute coronary syndrome.

Echocardiography showed chronic mitral regurgitation due to anterior MVP, with preserved left ventricular ejection fraction. Cardiac MRI confirmed MVP with inferolateral annular disjunction and significant fibrosis.

Therefore, he underwent mitral valve repair with annuloplasty and two neochords. The surgery was uneventful, requiring low doses of dobutamine and norepinephrine due to transient left ventricular dysfunction. He was discharged from ICU after 6 days.

Discussion: Mitral valve fibrosis and severe mitral regurgitation require multidisciplinary approach, combining surgical and nonsurgical options. Mitral valve repair is preferred but has a recurrence rate of 10-15% after 5 years, especially in severe mitral prolapse or advanced fibrosis. When repairing is not feasible, valve replacement is needed, with about 30% of patients with degenerative mitral insufficiency requiring it.

Minimally invasive techniques, like thoracoscopic surgery and transcatheter mitral valve replacement offer promising outcomes for high-risk patients for traditional surgery.

For non-surgical candidates antiarrhythmic drugs can manage atrial fibrillation and biventricular pacemakers may improve heart function in refractory cases. Implantable cardioverter-defibrillators (ICDs) are essential for primary prevention of SCD in at-risk patients.

Reference:

Singh M, Pal Y, et al. Fibrotic mitral valve disease and its role in sudden cardiac death. Heart. 2020;106(10):752-758.

Learning points:

- SCA can be the first sign of mitral valve fibrosis
- Cardiac MRI is essential for evaluating fibrosis
- ICD implantation is crucial for primary prevention of SCD
- Risk stratification for malignant MVP requires a combination of imaging and electrophysiological studies

32AP04-5

Perioperative clinical characteristics of pulmonary valve replacement for adult congenital heart diseases patients: single-centre retrospective research

O. Hisatomi¹, S. Osawa¹, Y. Nojiri¹, R. Kawasaki¹, K. Yamaura¹

¹Kyushu University Hospital, Anesthesiology, Fukuoka,

Background and Goal of Study: Pulmonary valve dysfunction and right ventricular failure are common long-term postoperative complications in adult congenital heart disease (ACHD) patients. Surgical pulmonary valve replacement (PVR) is the standard operation, though, the surgical induction differs. The differences in the perioperative clinical course of PVR depending on pathophysiological features remains unclear.

The primary aim of this study is to examine the perioperative characteristics of PVR surgery for ACHD patients, classified according to the types of valvular dysfunction.

Materials and Methods: A retrospective chart review was performed of PVR for ACHD patients between January 2021 and December 2023. The patients were classified into three groups: pulmonary stenosis (PS), pulmonary regurgitation (PR), and pulmonary stenosis and regurgitation (PSR). PS and PR were defined by the results of transthoracic echocardiogram. Statistical analysis included descriptive statistics and logistic regression.

Results and Discussion: 51 cases were analysed. The number of PS. PR and PSR patients were 11, 23 and 17 respectively. In preoperative parameters, cardiac magnetic resonance imaging indicated PR patients have larger right ventricular end-diastolic volume index compared to PS patients (p<0.001).

Systolic right ventricular pressure by the catheterization of PS and PSR patients were higher (p<0.001). As intraoperative features, cardiopulmonary bypass time and Aorta clamp time were longer for PS and PSR patients. PS patients were administered higher dose of dobutamine compared to PR patients intraoperatively (p<0.02). PS patients remained in the ICU longer than PR patients after the surgery (p<0.05).

Postoperative Nitric Oxide inhalation duration was longer for PS and PSR patients than PR patients (p<0.01). There was no significant difference in postoperative duration of mechanical ventilation, post-extubated respiratory support, inotropic agents' administration and hospitalization.

The different types of valvular dysfunction lead different mechanisms of right ventricular heart failure. The results of perioperative management and clinical courses in this study might have reflected the different pathophysiological features of right ventricular failure as the types of valvular dysfunction.

Conclusions: The pathophysiological difference of valvular dysfunction for PVR of ACHD patients might be an index for the perioperative clinical course and inotropic management.

32AP04-6

Prompt Diagnosis of Cardiac Tamponade in Type A Acute Aortic Dissection (AAD) Using Transesophageal Echocardiography (TEE): A Case Report

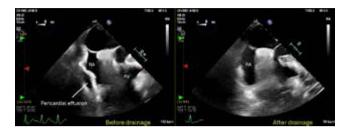

T.C. Chiu¹, Y.Y. Li¹, IA. Chen¹, K.F. Wang¹, C.C. Kuo^{1,2}, C.Y. Lu¹ ¹Chi Mei Medical Center, Department of Anesthesiology, Tainan, Taiwan, 2CTBC University of Technology, Leisure and Sports Management Department, Tainan, Taiwan

Background: Type A AAD is a surgical emergency and can be fatal if anatomic-related complications are not early detected. It is essential to distinguish between the potential causes of shock in this emergent situation.

Case Report: This 57-year-old male, weighing 136 kg (BMI 55.9 kg/m²), with a history of hypertension presented to emergency department complaining of acute onset of blacking out and chest pain prior to visit. On examination, he was hypotensive, hypoxemic, and tachypneic. EKG showed junctional bradycardia. Contrast-enhanced CT angiography revealed type A aortic dissection from aortic root to bilateral external iliac arteries; no coronary artery involvement or pericardial effusion was identified.

He was brought to operation room for emergent repair. In OR, shock with tachycardia was noted under norepinephrine infusion. Vigilant induction with endotracheal intubation under careful dosing of fentanyl, succinylcholine, and etomidate was performed. Elevated jugular venous pressure (33 cmH₂O) was noted.

We placed a TEE probe to survey extent of dissection and causes for hemodynamic instability. Large pericardial effusion was found, along with diastolic collapse of right atrium (RA) and right ventricle (RV). A diagnosis of cardiac tamponade was made. No regional wall motion abnormalities or significant AR was found. After surgical drainage of pericardial effusion, his CVP returned to normal range and tachycardia improved.

Discussion: TEE has been reported to help clarify the etiology of shock. For those with preoperative exam yielding proximal ascending aortic dissection with no definite etiology of shock, early utilization of TEE has therapeutic impact. Acute pericardial effusion can occur and cause cardiac tamponade if proximal portion of ascending aortic dissection ruptures into the pericardium.

Reference:

Prager et al. Indications, Clinical Impact, and Complications of Critical Care Transesophageal Echocardiography: A Scoping Review. J Intensive Care Med. (2023)

Learning points: Intraoperative TEE can facilitate appropriate surgical plan by promptly identifying life-threatening conditions in type A AAD with proximal aortic root involvement.

32AP04-8

ExtraCorporeal life support versus IMPELLA® pump as Bridge to Left ventricular **Assist Device (ECI-BLAD trial)**

O. Simon¹, P. Gaudard², F. Labaste³, P.-G. Guinot⁴, N. Nesseler⁵, A. Ouattara¹

¹University of Bordeaux, Department of Cardiovascular Anaesthesia and Critical Care, Pessac, France, ²University of Montpellier, Department of Cardiovascular and Thoracic Anaesthesia and Critical Care, Montpellier, France, 3University of Toulouse, Department of Cardiovascular Anaesthesia and Critical Care, Toulouse, France. 4University of Diion, Department of Cardiovascular Anesthesia and Critical Care, Dijon, France, 5University of Rennes, Department of Cardiovascular Anaesthesia and Critical Care, Rennes, France

Background and Goal of Study: Among patients treated by temporary mechanical circulatory support (tMCS) for refractory cardiogenic shock (rCS), some of them suffer from persistent cardiac dysfunction incompatible with a successful weaning [1]. In eligible patients, the heart transplantation is still the gold standard therapy. In the other, the left ventricular assist device (LVAD) represents an alternative therapy.

However, the best approach of tMCS as a bridge to durable LVAD remains to be defined. IMPELLA implantation through axillary approach allows early rehabilitation [2].

Conversely, femoral veno-arterial ECMO limit considerably the possibility of early mobilization even if ventilatory weaning remains possible. We tested the hypothesis that the use of IMPEL-LA® pump as bridge to LVAD, by allowing active rehabilitation, may improve patient's postoperative outcomes.

Materials and Methods: This muticenter retrospective study included adult patients, supported with IMPELLA® or VA-ECMO as a bridge to LVAD between 01/2012 and 03/2020 in 5 French cardiac intensive care units. IMPELLA group included patients exclusively treated by this device within the week prior to LVAD implantation whereas ECLS group included patient treated by ECLS associated or not to IMPELLA. The primary endpoint was the proportion of patients alive with a John Hopkins Highest Level of Mobility score = 8, out of critical care unit and not perfused at 30 days after LVAD implantation. Secondary endpoints included mobilization under tMCS, SOFA score and 6-month mortality. This study was approved by our ethics committee and registered on clinicaltrials (NCT04480151).

Results and Discussion: During the study period, 388 consecutive patients were implanted by LVAD. Among them, 92 patients under STMCS as bridge to LVAD were analyzed (IMPELLA group, n=48/ECLS group, n=44). Early mobilization on tMCS was more frequently achieved in IMPELLA group (seating 53% vs 5% and walking 20% vs 0%, p<0.01). The SOFA score was lower in IM-PELLA group the day of LVAD implantation (4 [3-7] versus 8 [5-10], p<0.01). More patients reached the primary endpoint in IM-PELLA group (54% vs 25%, p<0.01). The 6-month mortality rate was lower in IMPELLA group (19% vs, 39%, p=0.04).

Conclusion: IMPELLA as bridge to LVAD by allowing early mobilization may be associated with better outcomes in patients.

32AP04-9

Postinduction blood pressure trajectories: clustering and predictive modeling using machine learning

M. Glebov¹, M. Katsin¹, T. Lazebnik², H. Berkenstadt^{1,3}, D. Orkin¹

¹The Chaim Sheba Medical Center, Department of Anesthesiology, Ramat Gan, Israel, 2University College London, Department of Cancer Biology, London, United Kingdom, ³Tel-Aviv University, Faculty of Medicine, Tel Aviv, Israel

Background and Goal of Study: Induction of general anaesthesia (GA) often leads to significant blood pressure (BP) fluctuations, posing risks for perioperative complications. Current management strategies are reactive and fail to address the variability in BP responses.

This study aimed to identify distinct BP trajectories after GA induction and develop a machine learning (ML) model to predict these patterns.

Materials and Methods: This retrospective cohort study analysed data from 17,645 patients undergoing non-cardiac, non-obstetric surgery under GA. Blood pressure trajectories were identified using X-means clustering of mean arterial pressure (MAP) measurements within the first 10 minutes post-induction. A predictive model combining XGBoost and K-nearest neighbours (KNN) algorithms was developed to classify patients into trajectory groups based on preoperative and intraoperative variables.

Results and Discussion: A total of 17,645 patients were included in the final analysis. The median patient age was 48.3 years (IQR 34.2-68.0). The study included 9.437 men (53.5%) and 8.208 women (46.5%). The majority of patients had ASA-PS class II or III [6,233 (35.3%) and 6,789 (38.5%)], respectively. Of the total cohort, 14,720 (83,4%) patients underwent elective surgery. Five unique BP trajectories were identified:

Steady Staters (5618 patients, 31.8%) - with an initial MAP decrease but stable BP maintenance around the 80s:

Abrupt Decliners (5218 patients, 29.6%) - demonstrating the most significant BP drop, averaging 40 mmHg lower post-induc-

Gradual Decliners (3243 patients, 18.4%) - exhibiting a steady decline, often from higher pre-induction MAP;

Gradual Risers (1330 patients, 7.5%) - showing an initial MAP drop followed by a gradual recovery; and,

Low Steady-Starters (2236 patients, 12.7%) - with initially low BP and limited recovery post-induction. Our predictive model achieved an area under the curve (AUC) of 0.799, testing accuracy of 0.79, precision of 0.69, recall of 0.80, and F1 score of 0.74, demonstrating strong predictive capability.

Conclusion(s): This study demonstrates the feasibility of using ML to predict individual BP responses to anesthesia induction. The results pave the way for proactive and tailored hemodynamic management strategies, potentially improving patient outcomes.

32AP04-10

Developing the isometric handgrip exercise as a potential preoperative imaging test to quantify the impact of blood pressure changes on whole heart function

A. Zimmermann¹, J. Abegg¹, A.T. Huber², B. Jung², D.P. Guensch^{1,2}, K. Fischer¹

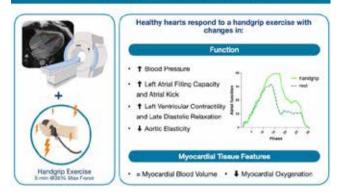

¹Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, ²Inselspital, Bern University Hospital, University of Bern, Interventional and Paediatric Radiology, Inselspital, Bern University Hospital, Bern, Switzerland

Background and Goal of Study: Haemodynamic fluctuations during anaesthesia can unmask cardiovascular dysfunction and are a significant contributor to perioperative ischaemia and heart failure. Anaesthetists rely on findings from diagnostic imaging stress tests to identify patients at risk. However, these stress agents have minimal influence on blood pressure. The isometric handgrip exercise is known to increase blood pressure. In awake healthy controls, we investigated the influence of an isometric handgrip exercise on whole heart function and tissue features to determine if there is potential for it to be a haemodynamic stress test.

Materials and Methods: Healthy volunteers (n=31) underwent a cardiovascular magnetic resonance exam where images were acquired before and during a handgrip exercise. Participants squeezed a dynamometer continuously at 30% of their maximum grip force (3-5min). Changes in myocardial blood volume (T1 maps) and oxygenation were measured. Functional images of the aorta, left atrium and ventricle were quantified with strain and long-axis shortening.

Results and Discussion: The handgrip exercise elevated systolic and diastolic blood pressure (106±10 to 120±13mmHg and 62±10 to 78±12mmHg, p<0.01), resulting in a reduced aortic elasticity (30.0±11.3 to 25.3±9.8%, p<0.01). Systolic function increased, marked by a rise in atrial filling (35.3±6.0 to 39.1±8.2, p<0.01) and ventricular contraction (-17.9±2.3, to -19.6±3.1, p<0.01). While there was no change in early diastolic function, late diastolic function increased with a rise in the atrial kick (11.5 \pm 4.5 to 14.6 \pm 5.3, p=0.02) and ventricular late relaxation (4.0±2.4 to 5.3±1.7, p=0.02). There was no increase in myocardial blood volume despite the higher workload (T1: 1188±26ms to 1193±24ms, p=0.47), and myocardial oxygenation dropped by 3.6±5.5% (p<0.01).

In combination with cardiovascular imaging, an isometric handgrip exercise has the potential to be a haemodynamic stress test to assess the impact of blood pressure changes on the heart.

Conclusion(s): A handgrip exercise significantly increased blood pressure resulting in changes to myocardial oxygenation and aortic, atrial and ventricular function. It can now be investigated as a potential tool to identify patients susceptible to cardiovascular dysfunction during perioperative haemodynamic fluctuations.

32AP04-12

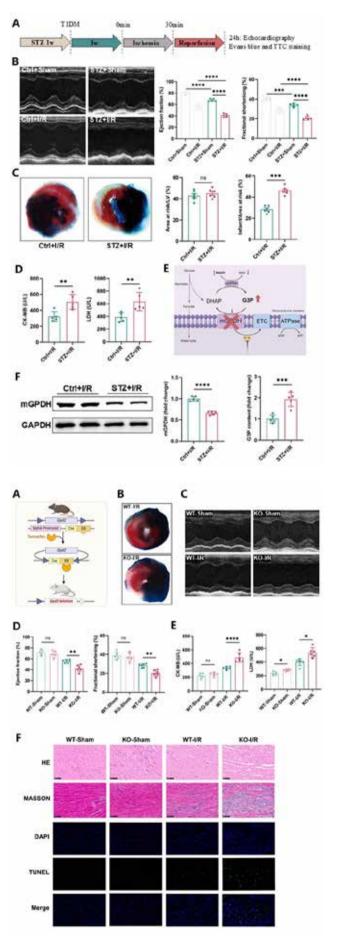

Glycerol 3-phosphate dehydrogenase deficiency sensitizes the diabetic heart to ischemia-reperfusion injury by promoting mitochondrial dysfunction

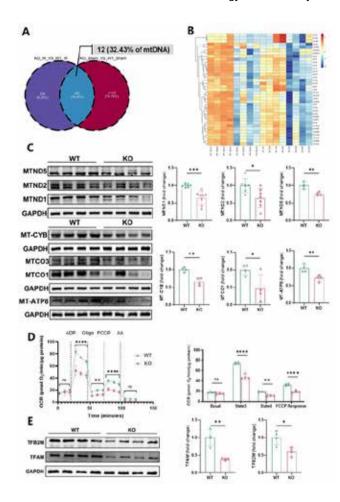

T. Sun¹, Y. Zhang¹, Q. Li¹ Sichuan University, Department of Anesthesiology, West China Hospital, Chengdu, China

Background and Goal of Study: Myocardial ischemia-reperfusion (I/R) injury causes cardiac dysfunction and the progression of diabetes increases the susceptibility to I/R injury. We previously found that mitochondrial glycerol 3-phosphate dehydrogenase (mGPDH) expression was downregulated in diabetic mice. This study aimed to characterize the role of mGPDH in mediating I/R injury sensitization and mitochondrial dysfunction.

Materials and Methods: In STZ-induced diabetic mice, the myocardial I/R injury model was established by ligation of the left anterior descending coronary artery. To discover the key molecular mechanism involved in I/R injury by cardiomyocyte deletion of mGPDH, we performed the RNA-Seq study.

Results and Discussion: We found that cardiac functional was significantly exacerbated s and mGPDH expression was reduced in the diabetic heart (Figure 1). Next, we established cardiomyocyte-specific mGPDH knockout mice. We observed that IR-induced cardiac contractile dysfunction and structural damage was aggravated in GPD2 KO mice (Figure 2).

RNA sequencing revealed mitochondrial genome transcription was inhibited, resulting in downregulation of essential subunits of mitochondrial ETC complexes in mGPDH KO groups. Further, we found that expression of TFAM and TFB2M were dramatically down-regulated in mGPDH KO mice (Figure 3).

Conclusion(s): These results suggest that mGPDH deficiency aggravate diabetic myocardial I/R injury and mitochondrial dysfunction via inhibiting transcription of mitochondrial DNA.

Perioperative myocardial injury in vascular surgery patients: incidence and outcomes

N. Cantón Caro¹, L. Bosch², A. Mases², S. Beltran², S. Sabate³, L. Larrañaga²

¹Pompeu Fabra, Medicine, Barcelona, Spain, ²Hospital del Mar, Anesthesiology, Barcelona, Spain, ³Hospital de la Santa Creu i Sant Pau, Anesthesiology, Barcelona, Spain

Background and Goal of Study: Patients with acute perioperative myocardial injury (PMI) have an increased risk of death and major adverse cardiovascular and cerebrovascular events (MAC-CE). Our aim was to investigate PMI in vascular surgery (VS) patients according to type of surgery and its effects in short and long-term morbidity and mortality.

Materials and Methods: Post-hoc analysis of the MINSMAR study, a prospective, single-center cohort study enrolling adults ≥45 years scheduled for intermediate and high-risk non-cardiac surgery. We analyzed PMI in open aortic surgery, iliac and infrainguinal bypass, supra and infracondylar amputation, carotid endarterectomy, endovascular repair of aortic aneurysm (EVAR) and peripheral angioplasty with anaesthesia. Baseline high-sensitivity troponin T (hsTnT), baseline N-Terminal Pro-B-Type Natriuretic Peptide (NT-proBNP) and hsTnT on the first 3 postoperative days were obtained.

PMI was defined by at least one hsTnT value ≥30ng/L provided there was a rise and/or fall of at least 20% of the baseline hsTnT concentration on the day of surgery or within the first three postoperative days. MACCE and mortality were registered at 30 days and 1 year after surgery.

Results and Discussion: Of 732 patients included, 247 (34%) underwent VS. Incidence of PMI in our risk population was 22%, of which 44% (71 patients) occurred in VS patients, mostly in men (81,7%). Distribution of PMI based on type of VS was: 39% iliac and infrainguinal bypass, 36% amputations, 23% carotid endarterectomy, 22% peripheral angioplasty, 20% aortic surgery and

Patients with PMI were older, had worse kidney function, lower haemoglobin levels, worse functional capacity, higher prevalence of heart failure and atrial fibrilation than those without PMI.

The prevalence of elevated basal NT-proBNP (≥300 pg/mL) was higher in patients with PMI than in those without PMI (66,2% vs. 31,8%; P <0,01) and elevated basal hsTnT (≥14 ng/L) was more frequent in patients with PMI (85,9% vs. 36,9%; P<0,01).

PMI was associated with a higher incidence of MACCE at 30 days and one year (14,5% vs 4%; p<0,01 and 24,1% vs 13%; p=0,06 respectively) and with 30 days and 1 year mortality (5,6% vs 1,1%; p<0.001 and 25.4% vs 7.4%: p<0.001).

Conclusion(s): PMI incidence in vascular surgery patients is high, especially in iliac and infrainguinal bypass surgery and major amputations. Patients with PMI have a much higher risk of MACCE and mortality in both the short and long term.

32AP05-2

High-flow nasal oxygenation during sedation for transcatheter aortic valve replacement: the **HIGH-OXY-TAVR** randomized-controlled trial

A. Manzano Valls¹, M. Gimenez Milà¹, S. Martinez Otero¹, T. Carnaval², P. Matute¹, M. Sabate³

¹Hospital Clinic de Barcelona, Anesthesiology, Barcelona, Spain, 2School of Medicine and Health Sciences, IDIBELL, University of Barcelona, Pharmacology Unit, Department of Pathology and Experimental Therapeutics, L'Hospitalet de Llobregat, Spain, 3Hospital Clinic de Barcelona, Cardiology, Barcelona, Spain

Background and Goal of Study: Transcatheter aortic valve replacement (TAVR) performed under conscious sedation is the standard of practice for most of the patients. However, sedation to this population could produce hypoxia and hypercapnia that can aggravate hemodynamic disturbances during the procedure1. Data on the efficacy of high flow nasal oxygenation (HFNO) in TAVR is inconclusive².

This study aims to asses HFNO benefit in hypoxia prevention and to explore an impact on any organ injury.

Materials and Methods: The HIGH-OXY-TAVR investigator-initiated, controlled trial, randomised patients requiring transfemoral TAVR 1:1 to the use of HFNO (flow rate of 50 L/min and FiO2 0.6) vs conventional oxygenation (via dry nasal specs).

The primary endpoint was the number of desaturation episodes defined as Sp02 <93% for more than 10 seconds. Secondary outcomes included changes in arterial partial pressure of oxygen (pO2) at 45 minutes. Serological biomarkers including neuronal specific enolase (NSE), creatinine (Cr), troponine (hs-CTnI) and NT-proBNP were registered before starting the procedure and 8 hours after.

Results and Discussion: 125 patients (64 in Intervention Group [IG] and 61 in Control Group [CG]) were rendered. Baseline characteristics were comparable between 2 groups. The number of desaturation episodes was superior in CG compared to IG (mean of 1.8 and 0.8 p<0.05) despite higher doses of propofol being used in IG than CG (174.06 mg and 147.57 mg p<0.05). Moreover, desaturation happened in 31 individuals (50.8%) in CG compared to 13 (20.3%) in IG (p< 0.005), relative risk reduction 0.39 (95% IC 0.23-0.68).

Multivariate regression model showed patients with BMI>30kg/ m2 to be at higher risk of desaturation (p<0.05). In contrast, HFNO patients were at a lower risk of desaturation (p<0.001) (Figure 1). Mean glomerular filtrate showed a significantly higher increase in the IG from baseline to 8 hours (+5±2.5 ml/min vs. -1.9±2.5 ml/min; p<0.05) while serum creatinine showed a significant decrease in the IG (-0.08mg/dl vs. +0.06mg/dl), reflecting an improvement in postoperative kidney function in HFNO group (Figure 2).

Conclusion(s): This study has demonstrated that HFNO provides a superior oxygenation profile compared to standard oxygen therapy, specially in obese patients. The possible beneficial effects on end-organ function will need to be confirmed on larger studies.

32AP05-3

Perioperative venous doppler as an indicator of systemic congestion in cardiac surgery patients

J. Duart Benavent¹, I. Zarragoikoetxea Jauregui¹, J. Agüero Ramon-Llin², P. Carmona García¹, A. Pajares Moncho¹, M.P. Argente Navarro¹ ¹Hospital La Fe, Anesthesiology and Critical Care, Valencia, Spain, 2Hospital La Fe, Cardiology, Valencia, Spain

Background and Goal of Study: Systemic venous congestion is a critical factor in adverse outcomes following cardiac surgery and traditional markers often fall short in predicting complications (1). Doppler ultrasound patterns and scoring systems assess venous congestion at various levels but face limitations (2), including interference from abdominal and pleural pressures, technical challenges, and limited studies comparing preoperative and postoperative changes (3).

This study evaluates the predictive value of perioperative Doppler parameters and their correlation with complications.

Materials and Methods: A prospective, observational study was conducted, including 18 cardiac surgery patients at Hospital La Fe, Valencia (May-December 2024). Preoperative echocardiography and venous flow analysis were performed for the internal jugular vein, inferior vena cava and portal vein. Respiratory-cycle diameters were measured and collapsibility indices calculated. Postoperative evaluations were done at admission to the critical area unit and at 12, 24, 48 hours. Biomarkers (lactate, NT-proBNP, troponins, nephrocheck, CA-125) were measured at the same intervals. The study was approved by the Ethical Research Committee at our centre. Statistical analysis was performed using IBM® SPSS® Statistics.

Results and Discussion: It is analysed 18 cardiac surgery patients (mean age 64.6 ± 10.1 years; 61.1% male). Hypertension (77.8%) and dyslipidaemia (61.1%) were the most common comorbidities. The median EUROSCORE II was 1.64 (IQR 1.27), indicating a lowrisk population. Preoperatively, 55.6% were classified as VExUS grade 1. At 48 hours, 38.9% had progressed to grades 2-3, indicating worsening systemic congestion in a subset of patients. Higher biomarker levels coincided with these congestion patterns, warranting further investigation. This pilot study highlights Doppler ultrasound's utility in perioperative risk assessment, but larger samples are needed to validate these findings and refine its integration into clinical application.

Conclusion: Initial data support the hypothesis that Doppler ultrasound parameters may be associated with postoperative outcomes. Ongoing analysis would further validate these findings in larger cohorts and refine their integration into perioperative protocols.

Echogenicity of the basal septum increases after surgery and aortic declamping at cardiopulmonary bypass as a possible sign of micro air bubble embolism

T. Schweizer¹, A.J. Brenken¹, C. Rose¹, M. Ramirez¹, K. Fischer¹, D.P. Guensch¹

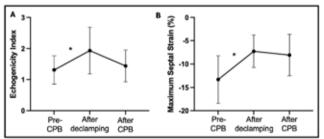

¹Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background: Micro air bubbles can occasionally enter the circulation during cardiac surgeries using a cardiopulmonary bypass (CPB). This can lead to ischemia in the affected myocardium, impairing function and potentially complicating separation from CPB. The right coronary artery, which supplies the septum, inferior wall and right ventricle, is considered the most at risk for micro air embolism due to its orifice being positioned at the highest point of the aorta cross section in a supine patient. Since air bubbles reflect ultrasound waves, myocardial territories impacted by micro air embolism appear brighter on transoesophageal echocardiography (TOE).

In this study we examine the echogenicity of the basal septum and assess septal strain depression as an indicator of impaired septal systolic function.

Methods: In this retrospective study, interim analysis includes 56 patients who underwent cardiac surgery on CPB. In TOE images that were routinely obtained during surgery, we determined the echogenicity index (echogenicity of the basal septum divided by echogenicity of the lateral wall) and the maximum septal strain before initiation of CPB, after declamping of the aorta, and after the end of CPB.

Results: Echogenicity index increased from 1.3±0.46 at baseline to 1.9±0.75 (p=0.02) after declamping of the aorta, indicating an exalted echogenicity of the basal septum. After CPB, the echogenicity index returned to baseline (1.4±0.5, p=0.32). In the same patients, maximum septal strain worsened from -13.3±5.1 at baseline to -7.3±3.5 (p<0.01) after declamping, after decannulation from CPB it stayed reduced at -8.1±0.7 (p=0.52).

A: Echogenicity index at the three timepoints. B: Maximum septal strain at the three time pints, a more negative value indicates a better strain. CPB, cardiopulmonary bypass. *p<0.05 between timepoints.

Conclusion: After aortic declamping during CPB, echogenicity of the basal septum exceeds that of the lateral wall compared to baseline. This is likely caused by an increase of micro air bubbles in the regional microcirculation of the right coronary artery. In the same segments a worsening in maximum septal strain was observed. After CPB, echogenicity returned to baseline, potentially indicating the wash out of air bubbles. Ongoing analysis will further investigate whether echogenicity and strain measurements are associated with weaning outcomes.

32AP05-6

Anesthetic management of trans-apical ablation for ventricular tachycardia in a patient with a history of valvular surgery: a case report

S. Oki1. K. Takahashi2

¹Jichi Medical University Saitama Medical Center. Department of Anesthesiology and Critical Care Medicine, Saitama, Japan, ²Institute of Science Tokyo Hospital, Department of Anesthesiology, Tokyo, Japan

Background: When antiarrhythmic drugs are ineffective, catheter ablation is the only treatment for ventricular tachycardia (VT). Management of catheter ablation for patients who underwent valvular surgery is not established.

Case Report: The patient is a 48-year-old man with the subcutaneous implantable cardioverter defibrillator (S-ICD) for VT. who had undergone aortic and mitral valve replacement with both mechanical valves and tricuspid annuloplasty 24 years ago. Recurrent slow VT led to frequent discharge of the S-ICD, and VT ablation was indicated.

As the endovascular approach to the left ventricle was expected to be difficult due to mechanical prosthetic valves, we planned endocardium and epicardium ablation via anterolateral submammary thoracotomy.

The procedure was performed under general anesthesia with sevoflurane, remifentanil, and fentanyl. A double-lumen endotracheal tube was inserted for one-lung ventilation. During the mapping, VT was induced for 205 minutes.

We administered noradrenaline for hemodynamic stability. An autologous blood salvage system was used to reduce blood transfusion. During the procedure, we checked lactate, central venous oxygen saturation, and cerebral regional oxygen saturation as a monitor of organ perfusion, and transesophageal echocardiography (TEE) was used for detecting cardiac tamponade.

Although the procedure was incomplete because of the extensive adhesion, no complications were observed intraoperatively.

Discussion: Anesthetic drugs that minimally affect arrhythmia induction should be used during ablation. Particularly for transapical ablation in patients who underwent cardiac surgery, heart team members should share the risk of life-threatening complications, such as damaging the apical structures, bleeding from the apex¹⁾, and acute ischemia from coronary vasospasm.

Monitoring of oxygen supply-demand balance and TEE could contribute to optimize hemodynamics and diagnosis of complications. Mechanical support should be prepared in case of circulatory collapse²⁾.

- 1. Bozorgi et al. Journal of Cardiothoracic Surg. 2024;19:12-17. 2. Fujii et al. Journal of Cardiothorac Vasc Anesth. 2018;32:1892-1910.
- Learning Points: Optimal anesthetic management of VT ablation requires understanding the effects of anesthetic drugs on arrhythmia, procedural technique, and its complications. Maintaining hemodynamic stability, monitoring for adequate organ perfusion, and early detection of complications are essential.

Influence of cardiopulmonary bypass on perioperative plasma and interstitial cefuroxime concentrations in patients undergoing cardiac bypass surgery - a controlled clinical trial

S. Nothofer¹, C. Dumps², C. Dorn³, A.R. Heller², P. Simon² Stefanie, Anesthesiology and Operative Intensive Care Medicine, Augsburg, Germany, ²University of Augsburg, Anesthesiology and Operative Intensive Care Medicine. Auasburg, Germany, 3University of Regensburg, Clinical Pharmacy, Regensburg, Germany

Background and Goal of Study: Cardiopulmonary bypass (CBP) can significantly alter the pharmacokinetics (PK) of surgical antimicrobial prophylaxis due to factors such as hemodilution, interactions with the extracorporeal circuit, altered protein binding. impaired renal function, and inflammatory responses.

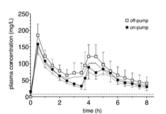

This controlled, prospective, single-center study aimed to investigate cefuroxime plasma and interstitial fluid (ISF) concentrations in patients undergoing elective coronary artery bypass graft (CABG) surgery.

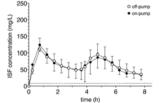

Materials and Methods: Ethical approval was granted by the Ludwig-Maximilian University of Munich (23-0076). All patients undergoing either on- or off-pump cardiac bypass surgery received a total of 4,5g cefuroxime. ISF concentrations were measured by placing two microdialysis probes into the subcutaneous tissue of both upper arms. Plasma and ISF concentrations were determined up to 8h after administering the first dose.

The primary endpoint was the area under the concentration-time curve (AUC_{0-8h}) in the plasma and ISF. PK analysis was performed by non-compartmental analysis.

Results and Discussion: 15 patients undergoing on-pump and 15 patients undergoing off-pump CABG were enrolled from 06/2023 to 04/2024. The mean age was 67±12 years, and the mean BMI was 28.1±5.0 kg/m². Baseline characteristics, cardiovascular risk profile, and preexisting comorbidities were similar in both groups. The mean surgical duration was 262±52min in the on-pump and 193±38min in the off-pump group, the mean bypass time was 97±26min.

There was no significant difference in plasma concentrations (mean AUC_{0-8h} \pm SD: 490.7 \pm 271.9 vs 650.0 \pm 36.4h·mg/L, p=0.072) or ISF concentrations (488.4±211.7 vs 507.7±209.0 h·mg/L, p=0.824) between the groups.

Conclusion(s): Plasma and ISF concentrations in all patients undergoing CABG on CBP exceeded the relevant minimum inhibitory concentrations (MIC) of pathogens associated with postoperative sternal wound infections (T>MIC=100% for E. coli and S. aureus at 4 and 8mg/L).

There is currently no need for cefuroxime dosing adjustments for surgical antibiotic prophylaxis in patients undergoing CABG with a mean CBP duration of 97 minutes.

32AP05-8

Early extubation after minimally invasive direct coronary artery bypass graft-the future becomes the present

I. Stojanovic¹, J. Vuckovic¹, D. Stojanovic² ¹Institute for Cardiovascular Diseases of Vojvodina, Cardiac Surgery, Novi Sad, Serbia, 2 Oncology Institute of Vojvodina, Nuclear Medicine Department, Novi Sad, Serbia

Background: Minimally invasive direct coronary artery bypass graft surgery is surgical technique performed in patients with isolated disease of left anterior descending artery.

Case Report: A 59-old-male patient was hospitalized because of persisting symptom chest pain with present ST elevation in electrocardiography reading. Coronary angiography procedure showed left anterior descending artery disease. The patient was prepared for minimally invasive direct coronary artery bypass graft surgery procedure (MIDCAB). Total intravenous anesthesia was used to induce and maintain general anesthesia. Single lung ventilation was used to collapse left lung to facilitate visualization and harvesting of internal mammary artery.

After finishing surgical procedure, patient is awakened and extubated in operating room. After 4 days patient was discharged from hospital.

Discussion: Rapid development of minimally invasive surgery provides developing of standard cardiac anesthetic techniques which allow early awakening and extubation (1).

Perioperative using of total intravenous and epidural anesthesia provide good pain control and postoperative haemodynamic stability (2).

Immediate postoperative awakening, extubation and mobilization of patient allow MIDCAB procedures to become non-intensive care surgery like percutaneous transluminal coronary angioplasty or stent grafting (3). Early discharging from hospital allows better organization of hospital resources, personnel and reduces surgical waiting lists.

References:

- 1. James L, Smith D, Galloway AC, Paone D, Allison M, Shrivastava S, et al. Routine Extubation in the Operating Room After Isolated Coronary Artery Bypass. Ann Thorac Surg. 2024;117(1):87-94.
- 2. Sherazee EA, Chen SA, Li D, Li D, Frank P, Kiaii B. Pain Management Strategies for Minimally Invasive Cardiothoracic Surgery. Innovations. 2022;17(3):167-76.
- 3. Monsefi N, Alaj E, Sirat S, Bakhtiary F. Postoperative results of minimally invasive direct coronary artery bypass procedure in 234 patients. Front Cardiovasc Med. 2023; 9:1051105.

Learning Points: Development of minimally invasive surgery should be followed by new anesthetic approaches promoting rapid postoperative recovery in patients undergoing minimally invasive cardiac surgery. Perioperative using of total intravenous and epidural anesthesia and immediate postoperative awakening, extubation and mobilization of patient allow MIDCAB procedures to become non-intensive care surgery.

Tailored anesthetic strategies in fontan physiology: continuous spinal block as a safe option

A.B. Guerreiro¹, <u>E. Ribeiro</u>¹, D. Zuzarte¹, A. Trabulo¹, M. Pimentel¹

¹Unidade Local de Saude Lisboa Ocidental, Anesthesiology, Lisboa, Portugal

Background: Patients with Fontan circulation present unique anesthetic challenges due to their non-standard hemodynamics. This case describes the use of continuous spinal anesthesia (CSA) in a patient with Fontan circulation, highlighting a tailored anesthetic approach that avoided hemodynamic instability.

Case Report: 40-year-old woman, ASA IV, 52Kg and 162cm, with a univentricular heart and Fontan circulation, was admitted for management of distal femur osteomyelitis complicated by septic shock. Following initial surgical debridement, she required stabilization in intensive care.

For a subsequent procedure (placement of an external fixator) CSA was employed to minimize hemodynamic fluctuations. Preoperatively, the patient was normotensive (septic shock resolved) and eupneic but presented with ascites and lower limb edema. Laboratory findings showed anemia, normal renal function and controlled inflammatory markers. CSA was achieved using fractionated boluses of 1.25mg bupivacaine (total 7mg) combined with 2.5mcg sufentanil. The procedure was conducted under sedation with midazolam and fentanyl, without vasopressor support. Hemodynamic stability was maintained throughout surgery (lowest MAP 74mmHg). Postoperatively, the patient remained stable, facilitating transfer back to the orthopedic ward within 24hours.

Discussion: The increasing survival rates of Fontan patients into adulthood demand advanced anesthetic strategies tailored to their unique physiology.

General anesthesia in these patients increases the risk of elevated pulmonary vascular resistance and venous congestion, potentially leading to hemodynamic collapse.

Regional anaesthesia is considered the preferred anaesthetic technique for these patients because it is the least likely to interfere with pulmonary vascular resistance and ventricular function. In this case, CSA allowed precise titration of local anesthetic, avoiding the systemic vasodilation and myocardial depression associated with general anesthesia, demonstrating its feasibility and safety in carefully selected scenarios.

References:

1. Perioperative Management of the Fontan Patient for Cardiac and Noncardiac Surgery, McNamara, John Richard et al. Journal of Cardiothoracic and Vascular Anesthesia, Volume 36, Issue 1, 275 - 285

Learning points:

- 1. CSA is a viable alternative for Fontan patients, minimizing hemodynamic perturbations.
- Precise anesthetic titration and close hemodynamic monitoring are essential for perioperative stability.

32AP05-10

Effects of exosomes on the cardiac protection of volatile anesthetics

S. Narasaki¹, Y. Ota¹, H. Miyoshi¹, T. Ikeda¹, Y. Tsutsumi¹ 'Hiroshima University, Anesthesiology and Critical Care, Hiroshima, Japan

Background and Goal of Study: Exosomes are membrane vesicles secreted from cells and play a role in transmitting information to cells and tissues. They are 30-150 nm in diameter and encapsulate proteins and nucleic acids. When exosomes are absorbed by cells, the proteins and nucleic acids in the exosomes act on and affect the cells.

However, there are no reports showing the involvement of exosomes in the myocardial protective effects of volatile anesthetics. Therefore, we investigated the effects of exosomes on the cardiac protection of volatile anesthetics.

Materials and Methods: Blood was collected from male C56BL6 mice, exosomes were extracted, and differences in blood exosomes were examined with and without volatile anesthetic exposure (1 MAC isoflurane for 30 min).

Next, hearts were retrograde perfused on a Langendorff apparatus and digested with collagenase. Isolated cardiac myocytes were then plated on laminin-coated dishes and were subjected to simulated ischemia-reperfusion (SI/R) using a special chamber. Myocytes were treated with isoflurane and/or GW4869, blockade of exosome generation, and the survival rates of myocytes were examined.

In addition, extracted blood exosomes were added to cultured myocytes to examine their effects on SI/R. All data are expressed as mean \pm SD.

Statistical analyses were performed by one-way ANOVA followed by Bonferroni test and statistical significance was defined as P<0.05.

Results: We investigated the expression of CD9 and HSP70 proteins, exosome-associated proteins, in blood extracted exosomes. Immunoblots revealed more expression of both CD9 and HSP70 by volatile anesthetics. Isolated adult cardiac myocytes were subjected to SI/R with and without isoflurane and/or GW4869 (n=5 per group).

Survival rates of myocytes decreased from 65.8 \pm 7.0% in the control group to 25.2 \pm 10.7% after SI/R, while isoflurane administration significantly increased the survival rates to 50.6 \pm 11.5% (vs SI/R).

Pre-administration of GW4869 abrogated the myocardial protective effects of isoflurane and reduced the survival rate to 33.2 \pm 13.5%. The addition of mouse blood-extracted exosomes resulted in a survival rate of 55.9 \pm 12.8%, and the myocardial protective effect was similar to that of isoflurane administration.

Conclusion: Our results suggest that exosomes released by volatile anesthetics were implicated in myocardial protection.

Anesthesia in the shadows of Brugada: safeguarding surgical patients at risk - a case

A. Nogueira¹, C. Pereira Pinto¹, S. Pereira¹, L. Ormonde¹ ¹ULS Santa Maria, Anesthesiology Department, Lisboa, **Portugal**

Background: Brugada syndrome is a genetic cardiac disorder characterized by ST-segment elevation in right precordial leads. which increases the risk of sudden cardiac death.^{1,2}

Anesthetic management for patients with this syndrome poses unique challenges.

Case Report: We present a case involving a 36-year-old male with an unremarkable medical history who was diagnosed with acute cholecystitis, requiring laparoscopic cholecystectomy. Preoperative evaluations revealed a type 1 Brugada pattern on the EKG, although the patient reported no symptoms.

Notably, there was a family history of early mortality, with the patient's father having died at age 30 from an unknown cause.

A consult with cardiology recommended avoiding several medications that could exacerbate the Brugada pattern. In the operating room, the patient was monitored according to ASA standards, EKG 5 leads and multifunction pads were applied from the monitor-defibrillator for safety.

Anesthetic induction and orotracheal intubation proceeded without complications, utilizing fentanyl, propofol, and rocuronium, maintained with sevoflurane.

The surgical procedure and subsequent emergency management were uneventful. A post-procedural cardiology evaluation indicated no changes in the patient's condition, recommending outpatient follow-up.

Discussion: This case highlights the critical importance of thorough preoperative assessments and collaborative efforts between anesthesiology and cardiology when managing patients with Brugada syndrome. The careful selection of anesthetic agents and vigilant intraoperative monitoring are vital to mitigate the risk of arrhythmias. A comprehensive understanding of the Brugada pattern enables the development of tailored anesthetic protocols.

References:

- 1. Cuttone G, Martucci G, Napoli R, Tigano S, Arcadipane A, Pappalardo F, Sanfilippo F. Anesthesiological management of Brugada syndrome patients: A systematic review. Saudi J Anaesth. 2023 Jul-Sep;17(3):394-400;
- 2. Dendramis G, Paleologo C, Sgarito G, Giordano U, Verlato R, Baranchuk A, et al. Anesthetic and Perioperative Management of Patients With Brugada Syndrome. Am J Cardiol. 2017;120: 1031-1036

Learning points: Anesthetic management of patients with Brugada syndrome requires meticulous attention to potential drug interactions and monitoring techniques. Early identification of the syndrome can promote interdisciplinary collaboration, enhancing patient safety during and after surgical procedures.

32AP05-12

Anesthetic management of a patient with patent ductus arteriosus and severe acute pancreatitis: a case report

J.A. Cortés Vásquez¹, L.J. Pinzon Lozano¹, A.A. Roncancio Fernández¹, M.C. Bautista González¹, J.R. Beltran Melgarejo¹, J.R. Navarro Vargas¹ ¹National University of Colombia, Anesthesiology and Resuscitation, Bogotá, Colombia

Background: A persistent ductus arteriosus (PDA) is a congenital heart defect in which the communication between the pulmonary artery trunk and the proximal descending aorta fails to close (1). It is more common in female and accounts for 6-11% of congenital heart diseases (CHD) (2).

Case Report: A 39-year-old woman, has a history of an uncorrected PDA (11x32 mm, Qs/Qp of 2.22), severe precapillary pulmonary hypertension, and heart failure. She presents with a diastolic murmur, acrocyanosis, emesis, and band-like abdominal pain. Abdominal CT shows severe acute necrohemorrhagic pancreatitis (Balthazar C) with 50% necrosis, Marshall 6, and APACHE 27 points. She was classified as ASA V, <4 MET and SOFA 7. An exploratory laparotomy was performed. Intraoperative TEE confirm a PDA with a left-to-right shunt, right ventricular hypertrophy and severe atrial dilation and severe pulmonary artery dilation.

There was significant hemodynamic instability with desaturation and elevated airway pressures, requiring norepinephrine, vasopressin, and milrinone. A right hemicolectomy, hemoperitoneum drainage, pancreatic necrosectomy, pancreatic cell packing were performed, and she was transferred to the ICU.

Discussion: Adults with PDA who undergo surgery pose an anesthetic challenge due to the impact of ventilation, oxygenation, and anesthesia on systemic and pulmonary blood flow. Patients are typically asymptomatic until the third decade of life, often presenting with compounded diseases (2).

In childhood, the management is either conservative (NSAIDs) or surgical (via catheter or open surgery). If not corrected, patients are at risk for heart failure, pulmonary hypertension, and endocarditis, the leading cause of death.

In adults undergoing surgery, it is crucial to avoid hypothermia, hemodilution, hypoxia, and hyperoxia. Monitoring SVR and PVR to regulate pulmonary blood flow. The latency of intravenous agents is prolonged, and the ventilatory goal it is a matter of debate (3).

References:

1. Anaesthesia. Painand Intensive Care. 2024 Apr 1;28(2):391-4 2. Anesthesiology. 2009 Aug; 111(2): 432-40

3.AnnCardAnaesth.2016Oct-Dec;19(4):750-751

Learning Points: The number of adults with CHD is increasing, particularly with PDA. Patients are usually asymptomatic until they develop comorbidities, and when undergoing surgery, they present a challenge. It is crucial to be aware of the anatomy, cardiopulmonary changes, and the impact of anesthesia to improve outcomes and prevent complications.

32AP06-1

The effect of ketamine on neurocognitive disorders, depression and inflammatory biomarkers in cardiac surgical patients

D. Scott^{1,2}, B. Silbert^{1,2}, K. Atkins¹, D. Ames³, S. O'Bryant⁴, L. Evered^{1,2,5}

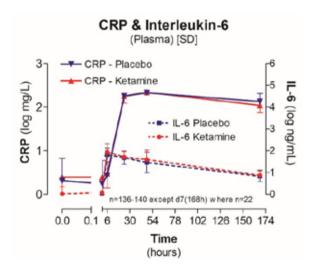

¹St. Vincent's Hospital Melbourne, Anaesthesia and Acute Pain Medicine, Fitzroy, Australia, 2University of Melbourne, Critical Care, Melbourne, Australia, 3University of Melbourne, Academic Unit for Psychiatry of Old Age. Kew. Australia. 4University of North Texas Health Sciences Center, Institute for Translational Research, Fort Worth, United States, 5Weill Cornell Medical College, Brain and Mind Research Institute, Department of Anesthesiology WCM, New York, United States

Background & Goals: Cardiac surgery patients often experience postoperative cognitive and mood changes in a setting of a significant inflammatory response. Ketamine has been suggested to reduce delirium and depression, and to have anti-inflammatory effects.

We investigated if ketamine given during cardiac surgery decreased postoperative delirium (POD), delayed Neurocognitive Recovery (dNCR) and depression, and whether this was associated with an anti-inflammatory effect.

Materials & Methods: In a double-blind randomised controlled trial, with ethics committee approval and informed consent, cardiac surgical patients received either intravenous ketamine (0.5 mg kg⁻¹) or placebo at anaesthesia induction.

Assessments were done for cognition, delirium, and depression at baseline, and postoperatively to day 7. Serial plasma samples were collected to 48 h for inflammatory biomarkers (interleukin-6 (IL-6), IL-8, IL-10, tumour necrosis factor alpha (TNFα), and Creactive protein (CRP). In a convenience sample, d7 plasma was collected.

Results & Discussion: 142 patients were enrolled and analysed - 72 ketamine, 70 placebo. POD incidence was 51.4%, with no difference between groups (p=0.867). At d7, there was no significant difference in the incidence of dNCR between groups (ketamine 40.1%, placebo 49.2%, p=0.467).

Postoperative depression was frequent, but there was no significant difference in incidence postoperatively between groups to d7 (VAS ≥ 50/100: ketamine 44.8%, placebo 47.8%; p=0.863).

There was no difference in inflammatory biomarker levels between ketamine treatment groups to d7 (figure). On univariable analysis, IL-6 peak value was associated with POD (IL-6: t=-2.06. p=0.042). Elevated CRP at baseline was associated with dNCR (p=0.001)

We confirmed a rise in inflammatory biomarkers following cardiac surgery and found an association with dNCR and baseline inflammatory state (CRP) and POD with peak inflammatory response

Conclusion(s): A single dose of ketamine at induction for cardiac surgery, consistent with that used in other studies including those related to refractory depression, had no effect on clinical outcomes or inflammatory biomarkers.

32AP06-2

The effect of intraoperative dexmedetomidine on inflammatory markers after coronary artery bypass graft surgery: a randomized controlled trial

R. Zdravkovic^{1,2}, S. Vickovic^{1,3}, M. Tatic^{1,4}, M. Preveden^{1,2}, M. Lukic Sarkanovic^{1,3}, A. Redzek^{1,2} ¹University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, ²Institute of Cardiovascular Diseases of Vojvodina, Clinic for Cardiovascular Surgery, Sremska Kamenica, Serbia, 3Clinical Center of Vojvodina, Clinic for Anesthesia, Intensive Therapy and Pain Therapy, Novi Sad. Serbia. ⁴Institute of Oncology of Voivodina, Department of

Anesthesiology, Sremska Kamenica, Serbia

Background and Goal of Study: Systemic inflammation is a common trigger for organ dysfunction in surgical patients. The aim of this study was to investigate whether intraoperative administration of dexmedetomidine can reduce the increase of inflammatory markers after coronary artery bypass graft (CABG) surgery.

Materials and Methods: This prospective experimental study included 70 patients undergoing CABG surgery. Patients in the experimental group (35 patients) received a continuous infusion of dexmedetomidine (0.5µg/kg/h) from anesthesia induction until the end of surgery, while the control group (35 patients) did not. Primary outcomes were the values of inflammatory markers on the first postoperative day (POD1).

Results and Discussion: The groups did not differ in baseline characteristics and comorbidities. In both examined groups, a postoperative increase was found for interleukin-6 (IL-6) (p<0.001), C-reactive protein (CRP) (p<0.001) and white blood cells (WBCs) (p<0.001), as well as neutrophil to lymphocite ratio (NLR) (p<0.001) and platelet to lymphocite ratio (PLR) (p<0.001), but not for fibrinogen. The increase of IL-6 on the POD1 (ΔIL-6) was 72.4 (45.3-94.2) pg/mL in the control group and 79.5 (54.3-107.5) pg/mL in the experimental group (p=0.601) (Figure 1). Δ CRP was 41.0 (20.1-62.1) mg/mL (control group) and 38.6 (24.7-58.9) mg/mL (experimental group) (p=0.979). ΔWBC was 8.2±0.6x10°/L (control group) and 6.7±3.5x10°/L (experimental group) (p=0.078). ΔNLR was 10.1 (6.9-15.0) (control group) and 10.0 (6.0-13.9) (p=0.452). ΔPLR was 95.7 (31.0-144.6) and 93.9 (48.1-162.9) (p=0.561). Δfibrinogen was 0.1 (-0.2-1.0) g/L (control group) and 0.2 (-0.4-0.6) g/L (experimental group) (p=0.472). Consumption of sufentanil and sevoflurane was significantly

lower in the experimental group (p=0.000).

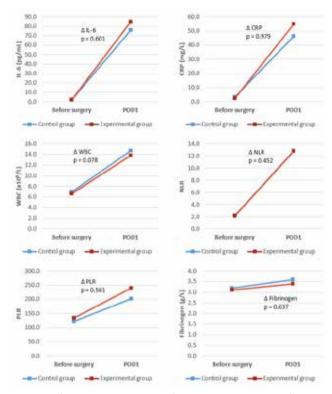

Figure 1. Inflammatory markers before surgery and on the first postoperative day (POD1)

Conclusion(s): Intraoperative administration of dexmedetodine during CABG surgery at a dose of 0.5µg/kg/h without a loading dose does not lead to a decrease in the intensity of the inflammatory response after CABG.

32AP06-3

Dexmedetomidine for reduction of delirium after cardiac surgery – a randomized controlled trial

M. Preveden^{1,2}, R. Zdravković^{1,2}, A. Preveden^{1,2}, J. Vučković^{1,2}, A. Redžek^{1,2}, M. Tatić^{3,2}

¹Institute of Cardiovascular Diseases, Department of Cardiovascular Surgery, Sremska Kamenica, Serbia, ²Faculty of Medicine, University of Novi Sad, Anaesthesia and Perioperative Medicine, Novi Sad, Serbia, ³Institute of Onkology, Anaesthesia and Perioperative Medicine, Sremska Kamenica, Serbia

Background and Goal of Study: Postoperative delirium is an acute mental disorder that develops after cardiovascular surgery with an incidence of 20-50%. This complication is associated with a longer hospitalization, longer stay in the intensive care unit (ICU), as well as increased morbidity and mortality.

The aim of this study was to determine whether dexmedetomidine versus propofol reduces delirium in patients undergoing cardiac surgery, and analyze their effects on the duration of mechanical ventilation (MV), length of stay in the ICU and total hospital stay.

Materials and Methods: This was a prospective, randomized, single-blinded, controlled clinical trial. All 120 patients included in the study were randomized in a 1:1 ratio into two groups of 60 patients. The first group of patients, upon arrival to the ICU, were

sedated with continuous dexmedetomidine infusion at doses 0.2-0.7 mcg/kg/h. The second group of patients were sedated with continuous propofol infusion in doses 1-2 mg/kg/h. Delirium in the postoperative period was assessed with the CAM-ICU score.

Results and Discussion: There were no significant differences in age and gender distribution and other baseline characteristics between the groups. Both groups had similar preoperative hemoglobin level, heart rate, and left ventricular ejection fraction. The incidence of delirium was 11.7% in the dexmedetomidine group, and 25.0% in the propofol group.

That difference was not significant (p=0.059). Patients who developed delirium had significantly longer duration of MV (12.6 \pm 5.4 vs. 9.3 \pm 2.5 hours, p=0.010). Also, patients who developed delirium had significantly longer total hospital length of stay (7.5 [7.0-9.0] vs. 7.0 [6.0-7.0]; p=0.021). A large controlled trial-DECADE, that included 798 patients, also did not prove that dexmedetomidine infusion decrease delirium in patients after cardiac surgery.

Conclusion(s): Postoperative sedation with dexmedetomidine in comparison to propofol did not decrease postoperative delirium in patients recovering from cardiac surgery.

References:

Dexmedetomidine for reduction of postoperative cognitive dysfunction one year after cardiac surgery – a randomized controlled trial

M. Preveden¹², R. Zdravković^{2,1}, J. Vučković^{2,1}, M. Klinovski², M. Tatić^{3,2}, S. Vicković^{4,2}

¹Institute of Cardiovascular Diseases, Department of Cardiovascular Surgery, Sremska Kamenica, Serbia,

²Faculty of Medicine, University of Novi Sad, Anaesthesia and Perioperative Medicine, Novi Sad, Serbia, ³Institute of Onkology, Anaesthesia and Perioperative Medicine, Sremska Kamenica, Serbia, ⁴Clinical Center of Vojvodina, Anaesthesia and Perioperative Medicine, Novi Sad, Serbia

Background and Goal of Study: Postoperative cognitive dysfunction (POCD) is a common complication of central nervous system in patients after cardiac surgery. The manifestations of POCD are subtle and may appear up to three months after surgical procedure. Because of that the diagnosis is most often established late, when the patient himself or family members notice difficulties in daily functioning at home or at work.

The aim of this study was to determine whether dexmedetomidine (DEX) versus propofol reduces POCD in patients one year after cardiac surgery.

Materials and Methods: This was a prospective, randomized, single-blinded, controlled clinical trial. All 60 patients included in the study were randomized in a 1:1 ratio into two groups of 30 patients. The first group of patients, upon arrival to the ICU, were sedated with continuous DEX infusion at doses 0.2-0.7 mcg/kg/h. The second group of patients were sedated with continuous propofol infusion in doses 1-2 mg/kg/h. A telephone survey was conducted with all subjects one year after surgery to compare differences in the patients' functional and cognitive status.

Results and Discussion: There were no significant differences in age and gender distribution and other baseline characteristics between the groups. By comparing the two examined groups, we found that memory problems were more common in the propofol group versus DEX group (39.3% vs. 15.4%, p=0.05). A statistically significant difference between the groups of patients sedated with propofol and DEX was also observed in concentration (25.0% vs. 3.8%, p=0.03) and sleep problems (35.7% vs. 7.7%, p=0.01). Other symptoms of POCD, the ability of patients to take care of themselves and move about independently, and mortality did not differ significantly between the two groups. In a meta-analysis that included 2183 patients DEX has been associated with a decrease in postoperative cognitive and behavioral dysfunction which is similar to our results.

Conclusion(s): Dexmedetomidine reduced the symptoms of POCD and has a beneficial effect on memory, concentration and sleep in the first year after cardiac surgery.

Does the use of loop diuretics before cardiopulmonary bypass improve kidney function during cardiac surgery?

S. Maruniak^{1,2}, O. Loskutov^{3,2}, B. Todurov⁴ ¹Heart Institute Ministry of Health of Ukraine, Department of Kidney Transplantations and Hemodialysis, Kyiv, Ukraine, ²P.L. Shupyk National HealthCare University of Ukraine, Anesthesiology and Intensive Care, Kyiv, Ukraine, ³Heart Institute Ministry of Health of Ukraine, Department of Anesthesiology, Kyiv, Ukraine, 4Heart Institute Ministry of Health of Ukraine, Department of Cardiac Surgery, Kyiv, Ukraine

Background and Goal of Study: The use of loop diuretics (LDs) during cardiac surgery with cardiopulmonary bypass (CPB) is debated, with some studies suggesting negative effects on nephron function, while others advocate for their renal protective role through forced diuresis [1.2].

The aim of this study was to evaluate renal function linked to the use of LDs before CPB by measuring partial urinary oxygen tension (PuO₂).

Materials and Methods: This prospective pilot study included 30 patients undergoing on pump coronary artery bypass grafting. The median age was 61 years (52-64 y.). Exclusion criteria: age <25 years or >65 years, glomerular filtration rate (eGFR) <90 mL/ min/1.73 m², and diabetes mellitus.

Patients were divided into two groups based on receiving 20 mg of furosemide before CPB: Group A (no furosemide) and Group B (with furosemide). Urine for PuO₂ were collected via a urethral catheter at three time points: T₁ - 10 minutes before CPB, T₂ - 20 minute of CPB, and T₃ – prior to ICU transfer.

Acute kidney injury (AKI) was diagnosed using the Kidney Disease Improving Global Outcomes criteria. Data were collected intra- and for 48 hours postoperatively.

Results and Discussion: There were no significant differences between the groups in terms of demographic characteristics, protocols of anesthesia or CPB. CPB duration (p=0.302), nadir hemoglobin level (p=0.381) and nadir DO₂ (p=0.391) did not differ between groups. ANOVA revealed no significant differences in PuO₂ across all time points for Group A (p=0.204).

Group B showed a decrease in PuO₂ during surgery (p=0.038). PuO₂ levels between the groups were similar at T₁ (p=0.830) and T_a (p=0.230) but differed at T_a (61.4±13.9 mmHg vs. 50.4±14.8 mmHg, p=0.044). No AKI was observed in both group during the first two p/o days.

However, Group A exhibited significantly lower creatinine levels on the 2-nd p/o day compared to Group B (87.4±13.5 µmol/L vs. 108.5±22.6 μmol/L, p=0.031).

Conclusions: Our findings suggest that the prophylactic use of LDs may impair renal oxygenation and function during CPB. PuO₂ is an informative criterion for assessing renal functional status during cardiac surgery.

Carbon dioxide insufflation-induced burst suppression during endoscopic cardiac surgery: a case report

L. Chi-Yuan^{1,2}

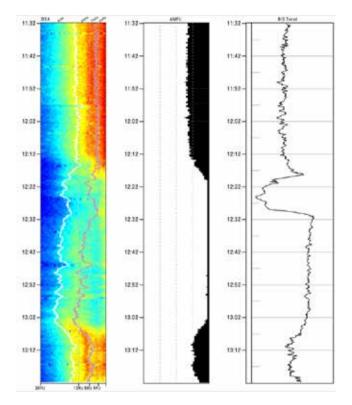

¹Taoyaun General Hospital, Anesthesiology, Taoyuan City, Taiwan, 2Taoyuan General Hospital, Anesthesiology, Taoyuan City, Taiwan

Background: The increasing use of endoscopy in cardiac surgeries is driven by their advantages of smaller incisions and faster recovery. In this case, BIS monitor revealed burst surpression caused by CO2 insufflation entering systemic circulation after an incision in the right atrium.

Case report: A 64-year-old male was diagnosed with severe mitral regurgitation and was scheduled for MICS (Minimal Incision Cardiac Surgery) mitral valve surgery. Preoperative examinations revealed no abnormalities. Intraoperative readings were stable until the surgeon open the right atrium for tricuspid valve repair. At this point, DSA monitoring detected significant burst suppression (shown in the attached figure, from approximately 12:20 to 13:07). The surgery was successfully completed at 14:30, and the patient was extubated at 17:00, with hemodynamic stability and normal oxygenation.

However, severe postoperative delirium, scoring 7 on the CAM-ICU-7 assessment and GCS: E4V5M6 was noted. After ICU observation, the delirium resolved by the following morning, and the patient was transferred to the general ward and discharged four

Discussion: In this case, despite no significant changes in inhalational anesthetic concentration or hemodynamic stability, the BIS monitor displayed burst suppression, a phenomenon linked strongly to postoperative delirium. Based on prior DSA pattern observations, this presentation closely resembles CO2 toxicity. We determined that CO₂ toxicity was caused by insufflated CO₂ entering the systemic circulation directly after the right atrium was incised during the endoscopic procedure.

References:

Carbon dioxide insufflation and neurocognitive outcome of open heart surgery. Asian Cardiovasc Thorac Ann. 2015.

Learning points: As endoscopic cardiac surgeries become more common and efforts to enhance postoperative recovery continue, this case highlights the importance of monitoring DSA patterns during right atrial incision. Prolonged CO2 toxicity should prompt discussions with the surgical team about adjusting CO2 port pressures to mitigate extended burst suppression, ultimately aiming for better postoperative recovery outcomes.

32AP06-7

Preoperative value of serum creatinine and intraoperative diuresis as indicators of acute renal insufficiency in cardiovascular surgery patients

J. Vuckovic^{1,2}, M. Tatić¹, S. Vicković¹, M. Preveden¹, A. Uram Benka¹, I. Stojanović² ¹Medical Faculty of Novi Sad, Department of Anaesthesiology and Perioperative Medicine, Novi Sad, Serbia, ²Institute for Cardiovascular Disease of Vojvodina, Department of Cardiac Surgery, Sremska Kamenica, Serbia

Background and Goal of Study: Acute renal insufficiency (ARI) is a common complication following cardiovascular surgeries, and early recognition can be vital. Despite renal function impairment, serum creatinine (sCr) levels may fall within reference values; hence, an exact sCr level as a threshold for ARI onset is not defined.

Objective: To determine whether preoperative sCr level in nondialyzed patients serves as a reliable indicator for ARI occurrence post-cardiovascular surgery with cardiopulmonary bypass. and whether intraoperative diuresis observed across operation phases (pre-extracorporeal circulation (ECC), during, and post), as well as total intraoperative diuresis, could be considered reliable markers for ARI onset.

Materials and Methods: A prospective observational study included 83 previously non-hemodialyzed patients undergoing elective cardiovascular surgery with cardiopulmonary bypass. Preoperative sCr levels were determined for participants, categorizing them into three groups:

Group 1, sCr <115 µmol/l;

Group 2, sCr 115-140 µmol/l; and,

Group 3, sCr >140 µmol/l.

Intraoperative diuresis was recorded across operation phases (pre-, during, and post-ECC), along with total intraoperative diuresis. Postoperatively, ARI development and need for hemodialysis were noted. Data analysis was performed using SPSS 17, with p < 0.05 considered statistically significant.

Results and Discussion: Significant differences were observed among the three patient groups regarding ARI development. Patients with preoperative sCr above 140 µmol/l notably experienced postoperative ARI (53.8%). ROC analysis indicated preoperative sCr in Group 3 patients (sCr >140 µmol/l) as a predictor for ARI (Area = 0.780; p = 0.016), with a cut-off of 191.5. Sensitivity was 71.4%, and specificity was 91.7%.

Both total intraoperative diuresis and diuresis pre-, during, and post-ECC showed statistical significance between patients developing ARI and those who did not. ROC curves suggested post-ECC diuresis (p < 0.0005; Area = 0.897; cut-off 55; sensitivity 82.6%; specificity 80%) and total intraoperative diuresis (p < 0.0005; Area = 0.839; cut-off 265; sensitivity 78.3%; specificity 76.7%) as predictors for ARI.

Conclusion(s): A preoperative sCr level above 140 µmol/l can serve as a marker for predicting ARI (Cut-off value 191.5 µmol/I), with a sensitivity of 71.4% and a specificity of 91.7%. Post-extracorporeal circulation diuresis as well as total intraoperative diuresis also represent reliable markers for the onset of ARI after cardiovascular surgery.

32AP06-8

The effect of red blood cell transfusion on oxygen delivery and oxygen consumption after cardiac surgery

P. Piirainen^{1,2}, H. Rousti^{1,3}, T. Erkinaro^{1,4}, J. Karhu^{1,5}, T. Ala-Kokko^{1,5}, T. Kaakinen^{1,4}

¹University of Oulu, Translational Medicine Research Unit, MRC Oulu, Oulu, Finland, 2Kainuu Central Hospital, Intensive Care Unit, Kajaani, Finland, 3Oulu University Hospital, Surgery and Anesthesia Center, Oulu, Finland, ⁴Oulu University Hospital, Heart Center, Oulu, Finland, ⁵Oulu University Hospital, Intensive Care Center, Oulu, Finland

Background and Goal of Study: Red blood cell (RBC) transfusions are commonly used during cardiac surgery. Clinical guidelines suggest that RBC transfusions should be based on the patient's hemoglobin (Hb) levels and clinical condition(1). However, it is unclear which aspects of the clinical condition are most relevant.

The aim of our study was to investigate how hemodynamic measurements (heart rate, blood pressure, cardiac output) and oxygenation parameters (Hb. mixed venous oxygen saturation [SvO2], and lactate) predict improvements in oxygen extraction ratio (O2ER) - the ratio of oxygen consumption to oxygen delivery - following an RBC transfusion. Our hypothesis was that SvO2 would predict improvement in O2ER.

Materials and Methods: We recruited patients scheduled for elective or urgent cardiac surgery. If RBC were transfused (transfusion threshold Hb < 80 g/L) in the intensive care unit after surgery, the following measurements were made 10 minutes before and 10 minutes after the transfusion: arterial - and mixed venous blood gas analysis, hemoglobin, cardiac output, blood pressure, heart rate.

The patient was considered to have benefited from the transfusion if O2ER decreased by at least 5%. AUROC values were used to evaluate the discrimination capacity of hemodynamic - and oxygenation variables.

Results and Discussion: A total of 156 patients were recruited for the study. Of these, 31 received RBC transfusions, and measurements were performed on 26 patients during 44 transfusions. None of the studied variables had reliable discrimination. The AU-ROC value for SvO₂ was the highest at 0.666 [95% confidence interval: 0.486-0.845], but this finding was not statistically significant. Using a threshold value of SvO₂ > 65%, the negative predictive value of the test was 81%.

Conclusion(s): Based on this study, no single hemodynamic - or oxygenation variable reliably discriminates between patients who benefit from RBC transfusions and those who do not. If SvO₂ is >65%, it is unlikely that a cardiac surgical patient will benefit from an RBC transfusion during intensive care.

Chişinău, Moldova, Republic of, 5Nicolae Testemitanu State University of Medicine and Pharmacy, Department of Anesthesiology and Resuscitation No. 1 "Valeriu Ghereg", Chişinău, Moldova, Republic of

Background: Acute kidney injury (AKI) is a common and severe complication following cardiac surgery, particularly when associated with multiple organ dysfunction syndrome (MODS). This case report highlights the successful use of continuous renal replacement therapy (CRRT) and CytoSorb in recovering a patient with severe AKI and MODS. The novelty lies in the integrated approach combining hemodynamic stabilization and innovative renal support.

Case Report: A 50-year-old male with severe heart failure (EF 22%), left ventricular aneurysm, and complex valvular insufficiencies underwent coronary artery bypass grafting, left ventricular aneurysmoplasty, tricuspid valve repair, and mitral valve replacement. Postoperatively, the patient developed cardiogenic shock, requiring intra-aortic balloon pump (IABP) support, Levosimendan, norepinephrine, and dobutamine.

AKI was diagnosed on postoperative day two and managed with CRRT and CytoSorb, restoring renal function within 96 hours. Hepatic dysfunction also resolved, and the patient was discharged from intensive care after 14 days without inotropic support, with EF improved to 30%.

Discussion: This case emphasizes the importance of advanced, multidisciplinary management in cardiac surgery patients with severe postoperative complications. The integration of CytoSorb in MODS treatment offers a promising adjunct for managing AKI and modulating systemic inflammation, addressing a gap in outcomes for such cases.

Learning points:

- Advanced therapies like CRRT and CytoSorb can be pivotal in managing AKI and MODS following cardiac surgery.
- Multidisciplinary approaches and technological innovation improve outcomes in complex cases.
- Early diagnosis and tailored intervention are critical for recovery and prognosis.

32AP06-10

Assessment of the effectiveness of intravenous lidocaine infusion on early rehabilitation of patients after heart valve surgery

D. Shabanov^{1,2}, O. Loskutov^{1,2}, B. Todurov^{3,4}, S. Maruniak⁵ ¹Heart Institute Ministry Health of Ukraine, Anesthesiology, Kyiv, Ukraine, ²P.L.Shupyk National Health Care University of Ukraine, Anesthesiology and Intensive Care, Kyiv, Ukraine, ³Heart Institute Ministry Health of Ukraine, Cardiac Surgery, Kviv, Ukraine, 4P.L.Shupyk National Health Care University of Ukraine, Department Of Cardiac Surgery, X-Ray Endovascular, and Extracorporeal Technologies, Kyiv, Ukraine, 5Heart Institute Ministry Health of Ukraine, Extracorporeal Methods of Treatment, Kyiv, Ukraine

Background and Goal of Study: Postoperative rehabilitation of patients undergoing heart valve surgery (HVS) remains an unresolved issue. Physical inactivity remains at high levels after cardiac surgery, reaching up to 50% [1], which may be associated with the surgical procedure, duration of cardiopulmonary bypass (CPB), mechanical ventilation (MV), and the protocols of anesthesia.

The aim of the study was to evaluate the effectiveness of intravenous lidocaine infusion as a component of multimodal anesthesia on early rehabilitation of patients after heart valve surgery.

Materials and Methods: The study included 90 patients (mean age 59±7.3) who underwent heart valve surgery. Patients were divided into two groups based on anesthesia management. Induction in both groups: propofol (1.5 mg/kg, 40 mg increments every 15-20 seconds), fentanyl (1-1.5 µg/kg), rocuronium bromide (0.1 mg/kg). In Group A (n = 45), anesthesia maintenance: sevoflurane (1-1.5 MAC), lidocaine (1 mg/kg bolus followed by infusion 1.5-2 mg/kg/h). In Group B (n=45), anesthesia maintenance: sevoflurane (1.5-2 MAC). Analgesia in both groups – fentanyl (15-20 µg/ kg for the entire surgery).

Results and Discussion: The need for postoperative analgesia was significantly lower in Group A compared to Group B (mean morphine dose: 8.2±1.8 mg vs. 12.4±2.5 mg, p=0.015). The duration of MV in Group A was 2.3±0.8 hours, which was shorter than in Group B (3.6±1.4 hours), (p=0.033). ICU stay was shorter in Group A (42.8±5.3 hours vs. 54.4±6.8 hours, p=0.017). The overallhospital stay didn't differ between groups (11.2±2.1 days vs. 12.4±3.7 days, p=0.105). CRP and IL-6 levels in Group A were significantly lower in the first 24 hours postoperatively, indicating a reduced systemic inflammatory response (CRP: 34.8±8.5 mg/L vs. 58.7±11.3 mg/L, p=0,038; IL-6: 66.3±12.1 pg/mL vs. 82.4±15.6 pg/mL, p=0.0011).

Conclusion(s):

- 1. Lidocaine infusion during heart valve surgery reduces postoperative pain, the duration of MV, ICU stay.
- 2. The reduction in CRP and IL-6 levels indicates an anti-inflammatory effect of lidocaine and may be a promising strategy to improve early rehabilitation after heart valve surgery.

Changes in systemic hemodynamics, cardiac energetics and cell signaling pathways induced by VA-ECMO alone or with left ventricular unloading devices

A. Beurton^{1,2}, E. Bordier^{1,2}, S. Veyret^{1,2}, F.-X. Herion^{1,2}, J. Imbault^{1,2}, A. Ouattara^{1,2} ¹University Hospital of Bordeaux, Cardiovascular

anesthesia and critical care, Bordeaux, France, 2INSERM U1034, Biology of cardiovascular disease, Pessacfraf, France

Background: Severe cardiogenic shock (CS) remains a significant clinical challenge. Veno-arterial extracorporeal membrane oxygenation (VA-ECMO) is the most widely used temporary mechanical circulatory support (tMCS) for patients with refractory CS. While VA-ECMO rapidly restores end-organ perfusion, it also increases left ventricular (LV) loading, myocardial wall stress, pressure-volume area (PVA), and myocardial oxygen consumption.

To mitigate VA-ECMO-induced LV overload, mechanical unloading strategies, such as intra-aortic balloon pump (IABP) or Impella, may be added. Beyond reducing LV load, these benefits may involve modulation of RISK and SAFE signaling pathways.

We hypothesized that adding IABP or Impella to VA-ECMO would alleviate LV overload, improve cardiac energetics, and beneficially modulate RISK and SAFE pathways in the myocardium.

Methods: Severe CS was induced in female Dorset sheep using coronary artery alcoholization. Animals were randomized into three groups: ECMO alone, ECMO+IABP, or ECMO+Impella. Hemodynamic parameters, myocardial injury markers, and phosphorylation of SAFE and RISK signaling proteins were assessed.

Results and Discussion: A total of 25 sheep were included: 9 in the ECMO group, 8 in the ECMO+Impella group, and 7 in the ECMO+IABP group, Ischemia lasted 349 ± 13 minutes, ECMO support 197±9 minutes, and anesthesia 526±12 minutes. CS was characterized by a 30± 3% decrease in mean arterial pressure (MAP), a 37± 2% decrease in cardiac output (CO), and a 52±10% increase in LV end-diastolic pressure (LVEDP).

In the VA-ECMO-only group, right atrial pressure (RAP) decreased dose-dependently with ECMO flow, while LV systolic pressure and end-systolic volume increased, and LV end diastolic pressure remained stable. PVA and potential energy increased with ECMO flow, reflecting heightened myocardial stress. Adding IABP or Impella to VA-ECMO reduced RAP, LVEDP, and PVA, indicating improved ventricular filling and reduced myocardial wall stress.Infarct size did not differ significantly between groups.

Apoptotic cell counts were unchanged across groups. Myocardial signaling analysis showed increased phosphorylation of Akt and ERK1/2 in specific groups and zones, indicating activation of survival pathways.

Conclusion: Combining VA-ECMO with IABP or Impella effectively mitigates ventricular overload, modulates cardioprotective signaling pathways, and improves cardiac function in severe CS.

From preoperatively diagnosed right atrial myxoma to intraoperatively diagnosed extremely rare pericardial tumor: the trick of transesophageal echocardiography

R. Zdravkovic^{1,2}, N. Kalinic^{3,4}, T. Cvjetkovic Tomanic⁴, S. Mirkovic⁴, S. Maric⁴, A. Redzek^{1,2} ¹University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, ²Institute of Cardiovascular Diseases of Vojvodina, Clinic for Cardiovascular Surgery, Sremska Kamenica, Serbia. 3University of Bania Luka, Faculty of Medicine. Banja Luka, Bosnia and Herzegovina, 4University Clinical Center of the Republic of Srpska, Clinic for Cardiac Surgery, Banja Luka, Bosnia and Herzegovina

Background: Primary cardiac tumors are rare, with an incidence rate of 0.0017%-0.019% in the autopsy series. The most common are myxomas, usually in the left or right atrium.

Case Report: We present a case of a 52-year-old male patient, for whom was consulted a cardiologist due to increased fatigue over the past few months. A tumoral change in the right atrium was seen on transthoracic echocardiography. Transesophageal echocardiography (TEE) confirmed a tumoral change, characteristic of myxoma, in the projection of the right atrium, size 35x31 mm, attached to the free wall of the right atrium above the mouth of the inferior vena cava (Figure 1).

Figure 1.

The heart team indicated surgical intervention. After pericardiotomy, a pericardial tumor was seen on the lateral wall of the right atrium and ventricle (Figure 2).

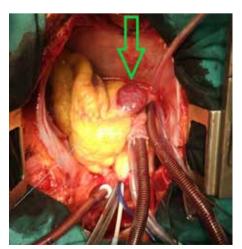

Figure 2.

A complete excision of the tumor was performed. Pathohistological analysis showed that it was an extremely rare tumor - pericardial hemandioma.

Discussion: Pericardial hemangioma is an extremely rare tumor. with just over 10 cases described in the literature. Knowing the exact location of a cardiac tumor is essential for the cardiac anesthesiologist in cases such as the placement of a pulmonary artery catheter or temporary pacemaker.

Very often, the choice of anesthetic drugs, or the adjustment of drug doses to avoid hemodynamic instability, also depends on the localization of the tumor.

Monitored anesthesia care and conscious sedation for trans-femoral Impella CP placement: An alternative to general anesthesia in patients with severe left ventricular impairment undergoing percutaneous coronary intervention with expected hemodynamic instability

T. Eldeeb¹, E. Amer¹, S. Abdou², A. AlHusil², K. Al Faraidy²

¹King Fahd Military Medical Complex (KFMMC), Cardiac Anesthesia, Dammam, Saudi Arabia, 2King Fahd Military Medical Complex (KFMMC), Cardiology, Dammam, Saudi

The Impella CP is a left ventricular assist device typically placed through trans axillary or trans femoral approach with fluoroscopic and echocardiographic guidance under general anesthesia to unload the left ventricle and to support the hemodynamics.

In this case report, we describe a patient who is diagnosed to have a multivessel coronary artery disease with severe cardiac failure (Left Ventricular Ejection Fraction is 15 %) with chronic obstructive pulmonary disease (COPD) undergoing a high risk percutaneous coronary intervention with expected hemodynamic instability as he was not fit to go for coronary artery bypass grafting surgery due to high risk of perioperative mortality and morbidity.

Here, we describe the successful placement of the Impella CP with sedation and regional anesthesia during the procedure in order to avoid general anesthesia and the possible sequelae of prolonged post procedure ventilation in such a frail patient. Impella placement was confirmed with point-of-care transthoracic echocardiography.

Monitored Anesthesia Care with conscious sedation and close hemodynamic monitoring with invasive blood pressure throughout the procedure until successful three coronary arteries intervention achieved using drug eluting stents followed by successful weaning and removal of Impella directly after the procedure.

The patient was discharged to Cardiac Care Unit (CCU) for one day and then discharged to Cardiac Ward (CW) for another one day then discharged home.

This case report demonstrates a novel anesthesia management for placing the Impella CP during coronary artery intervention procedure which can shorten patient's hospital stay, decrease the risk of morbidity and, more importantly, open the possibility to further prospective studies of this technique.

Early prosthetic valve endocarditis; how complicated can it be? A young man journey with severe infection; from pseudoaneurysm surgical repair to TEVAR

A.V. Espinosa¹, D. Hamamah², Y.A. Shadad³, M. Jain⁴, M. Maresch⁵, S.K. Motwani⁶

¹King Salman Specialist Hospital, Department of Anesthesia, Hail, Saudi Arabia, 2Mohammed Bin Khalifa Bin Salman Al Khalifa Specialist Cardiac Centre, Department of Cardiac Anesthesia, Awali, Bahrain, 3Mohammed Bin Khalifa Bin Salman Al Khalifa Specialist Cardiac Centre, Department of Perfusion Sciences, Awali, Bahrain, 4Royal Brompton Hospital, Department of Critical Care, London, United Kingdom. 5BDF Hospital, Royal Medical Services. Department of Vascular Surgery, Riffah, Bahrain, ⁶Eternal Hospital of Jaipur, Department of Cardiac Anesthesia, Rajeshtan, India

Background: Infective endocarditis (IE) is a rare but severe condition with increasing prevalence due to aging populations and frequent use of cardiac implants. Prompt diagnosis and multidisciplinary management are essential to reduce its high morbidity and mortality.

Case Report: A 37-year-old male presented with sternal wound dehiscence, mediastinitis, septicemia, and CKD two months after mitral valve repair. He reported wound discharge and fever but was hemodynamically stable. CT imaging revealed a substernal collection and pseudoaneurysm. Cultures identified Klebsiella pneumoniae and Enterobacter as pathogens.

The patient underwent emergency repair of an ascending aortic pseudoaneurysm under femoro-femoral bypass, coupled with sternal wound debridement. Postoperatively, he required broadspectrum antibiotics, mild inotropic support, and dialysis. On day four, a recurrent aortic leak caused by septicemia-induced tissue friability necessitated re-exploration and repair. After prolonged hospitalization under a multidisciplinary team (MDT), he was discharged stable.

Four weeks later, he was readmitted for a persistent pseudoaneurysm leak. Due to the high risk of a third open surgery, TEVAR (thoracic endovascular aortic repair) was performed successfully. Following two months of antibiotic therapy and hemodialysis, infections resolved, renal function normalized, and follow-up imaging showed no residual leak. The patient reported no complaints at subsequent follow-ups.

Discussion: This case underscores the complexity of IE, highlighting the importance of multimodal imaging (e.g., echocardiography and CT) for diagnosis, culture-sensitive antibiotics for infection control, and hybrid procedures like TEVAR for highrisk complications. A collaborative MDT approach was pivotal in achieving a positive outcome for this patient.

44, Issue 39, 14 October 2023, Pages 3948-4042 2. Manetta, F., Newman, J., & Mattia, A. (2018). Indications for Thoracic EndoVascular Aortic Repair (TEVAR): A Brief Review. The International Journal of Angiology, 27(4), 177-184 Learning points:

- · Infective endocarditis (IE) can cause severe complications, even in young, healthy patients.
- Management often requires prolonged care, surgery, or endovascular interventions.
- Hybrid procedures like TEVAR are valuable for high-risk cases.
- Multidisciplinary teamwork is essential.

Cellular localization of myocardial fibrosis and inflammation components in congestive heart failure following an aortocaval shunt in rats

V.D. Le¹, S. Mousa¹, M. Shagura¹, A. Beyer², M. Schäfer¹, S. Treskatsch1

¹Charité Universitätsmedizin Berlin, Department of anesthesiology and intensive care medicine, Berlin, Germany, ²Ludwig-Maximilians-University Munich, Department of anesthesiology, Munich, Germany

Background and Goal of Study: In previous works, it was shown that the modified model of infrarenal aortocaval fistula (ACF) causes a chronic ventricular volume overload, which results in congestive heart failure. The goal of this study was to investigate morphological changes of components in myocardial inflammation and fibrosis processes based on a chronic volume overload

Materials and Methods: After approval by the animal protection committee, an infernal aortocaval fistula was placed in male Wistar-rats with a 16G needle. After 28 days, the myocardial mophology and tissue fibrosis, as well as the localization and involvement of signaling pathways was checked with confocal microscopy, RT-PCR and Western Blot analysis.

Results and Discussion: Besides a ventricular hypertrophy and a pronounced myocardial fibrosis, the ACF-rats showed an increase in expression of inflammation and fibrosis markers such as e.g. Interleukin 1 beta (IL-1

), Tissue inhibitor of metalloproteinase 4 (TIMP4), macrophages, Transforming growth factor beta (TGF-□), Vimentin, Phospho-SMAD, Tenascin-C (TNC), Alpha-smooth muscle Actin (alpha-SMA), Collagen triple helix repeat containing 1 (CTHRC1), Cardiotrophin, Cartilage secreted frizzled-related protein 2 (sFRP2), oligomeric Matrix Protein (COMP), Collagen 1, Galectin, and Osteopontin. The ACF-rats also exhibited a doubling in heart- and lung-to-body weight indices while displaying a significantly reduced ejection fraction.

Conclusion(s): These findings suggest pronounced remodeling processes as a result of chronic volume overload with consecutive heart failure. The in this model for the first time proven myocardial inflammation and fibrosis processes allow a precise pathophysiological study of the underlying mechanisms and give hints for possible treatment starting points in the near future.

Changes in cardiac glucocorticoid receptor expression following volume overload-induced heart failure in rat

L. Seebacher¹, M. Shaqura¹, L. Dehe¹, A. Beyer², M. Schäfer¹, S. Treskatsch¹

¹Charite- Universitätsmedizin Berlin- Campus Benjamin Franklin, Department of Anesthesiology and Intensive Care Medicine, Berlin, Germany, ²Ludwig-Maximilians-University Munich, Department of Anaesthesiology, Munich, Germany

Background and Goal of Study: Cardiac glucocorticoids have been reported to play a regulatory role in both normal and pathological states, such as heart failure. However, the expression and localization of the corresponding glucocorticoid receptor (GR) in the context of chronic heart failure is still unclear (1).

Materials and Methods: By creating an infrarenal aortocaval fistula (ACF), an experimental heart failure model was established in rats through chronic volume overload. Twenty-eight days after ACF induction, adaptive GR expression in the left ventricle was assessed using reverse real-time PCR and Western blot analysis. Furthermore, the colocalization of GR with the mineralocorticoid receptor (MR), as well as with the membrane-bound Na/K-AT-Pase and the L-type calcium channel, was examined using dual immunofluorescence confocal microscopy.

Results and Discussion: Our Western blot and PCR analyses reveal a significant increase in GR mRNA and GR protein levels. respectively, in the left ventricle of ACF rats. Immunofluorescence microscopy demonstrated that GR is in close association with the membrane-bound Na/K-ATPase and the L-type calcium channel on the plasma membrane as well as the invaginated T-tubules of cardiomyocytes in the left ventricle.

Additionally, GR colocalized with MR in the sarcoplasmic reticulum of left ventricular cardiomyocytes. Furthermore, there was an upregulation of GR immunoreactivity within the cardiomyocytes of ACF rats.

Conclusion(s): This study provides initial evidence for an upregulation of GR expression and its central role in the functional adaptation of cardiomyocytes under conditions of cardiac stress due to volume overload-induced heart failure.

The colocalization with components of intracellular myocardial calcium homeostasis suggests a potential influence of glucocorticoids on these mechanisms.

32AP07-6 Isolated pulmonary stenosis: an anesthetic quandary

S. Garq¹, N. Pathak¹, N. Kachru¹ ¹ABVIMS & DR RML Hospital, Anesthesia, New Delhi, India

Background: Pulmonary stenosis refers to a dynamic or fixed anatomic obstruction to flow from the right ventricle to the pulmonary arterial vasculature. Isolated pulmonary stenosis forms about 10% of all congenital heart diseases. It can present directly in adulthood with more severe forms.

Case Report: We are reporting a case of a 45yr old female incidentally diagnosed with severe pulmonary stenosis posted for total abdominal hysterectomy with bilateral salpingo-oopherectomy post pulmonary valve balloon dilatation. To achieve the perioperative goals, invasive lines were secured to guide the anaesthesia management intraoperatively.

Our patient had an episode of bradycardia which was managed effectively in accordance with the ACLS bradycardia algorithm. Adequate analgesia was ensured to prevent the development of any post-operative complications.

Discussion: Pulmonary stenosis maybe valvular, subvalvular or supravalvular. The goals of hemodynamic management in the perioperative period are maintenance of right ventricular preload, left ventricular afterload and right ventricular contractility.

Sudden reduction in systemic vascular resistance reduces the cardiac output which in turn increases RV work and can precipitate heart failure.

References:

- 2. Sushma KS, ShAiKh S, Anaesthetic management of pulmonary stenosis already treated with pulmonary balloon valvuloplasty. Journal of Clinical and Diagnostic Research: JCDR. 2014 Jan:8(1):193.

Learning points: Pulmonary stenosis is a progressive condition and can manifest well into adulthood with severe features and hence, requires multidisciplinary approach, careful and meticulous planning in its management.

32AP07-8

Anesthetic management for heart transplantation in a patient with a ventricular assist device

A. Postiga¹, R. Silva¹, M.-L. Coutinho¹, J. Gonçalves¹ ¹Unidade Local Saude de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Heart transplantation is often the last line of treatment for patients with advanced heart failure. The introduction of ventricular assist devices (LVADs) has enabled prolonged survival by offering an alternative to transplantation.[1]

Case Report: A 68-year-old patient proposed for heart transplantation due to advanced heart failure caused by dilated cardiomyopathy of ischemic etiology.

Previously, due to advanced heart failure, a left ventricular assist device - HeartMate®3 - had been implanted as a bridge therapy to heart transplantation.

During the preoperative assessment, several particularities were identified that required special attention. It is a continuous flow device that does not generate a pulse, which significantly alters the patient's hemodynamics, making conventional clinical assessment of blood pressure and heart rate difficult.

Due to the low pulsatility caused by the device, invasive monitoring of mean arterial pressure through catheterization of the radial artery was carried out echographically using its location, wall characteristics and absence of collapsibility to identify it. A central venous catheter was also echographically placed in the internal jugular vein and central venous pressure was monitored. Anesthesia was induced with fentanyl, etomidate and rocuronium due to the risk of hemodynamic depression. During surgery, strict control of blood volume was necessary as adequate preload is essential for the LVAD to function correctly and increased afterload can decrease pump flow.

LVAD flow maintenance was monitored continuously to avoid alterations that could compromise coronary or cerebral perfusion. The heart transplant was successful and the patient was discharged from hospital on the 13th postoperative day.

Discussion: This case illustrates the complexity of anesthetic management in patients with LVADs and the importance of an interdisciplinary approach to ensure the success of heart transplantation. The integration of anesthetic strategies with the specific physiological characteristics of ventricular assist devices is fundamental to optimizing the clinical outcomes.

References:

1. Card Fail Rev. 2015 Apr;1(1):25-30.

Learning points: The anesthetic management of a patient with LVAD for heart transplantation is challenging for the anesthesiologist and requires a different and specific approach.

From monitored anaesthesia care to potential major intervention: Managing cardiac tamponade in a pregnant patient with cardiac angiosarcoma

J. Oliveira¹, M. Neto Martins², S. Lopes², M. Diva Sousa², L. Guedes²

¹Instituto Português de Oncologia do Porto Francisco Gentil, EPE, Anesthesiology, Porto, Portugal, ²Unidade Local de Saúde de São João, E.P.E., Anesthesiology, Porto, Portugal

Background: Managing anaesthesia in pregnant women undergoing urgent non-obstetric surgery is complex, especially with a viable but premature foetus. Cardiac tamponade, though rare, is life-threatening and carries a high risk of hemodynamic collapse. Cases involving third-trimester pregnancy and cardiac tamponade are particularly rare and educationally significant.

Case Report: A 39-year-old pregnant woman (32 weeks gestation) presented to the ER with dyspnoea and dizziness, later diagnosed with massive cardiac tamponade. The medical team opted for percutaneous drainage in the Operating Room.

All precautions were taken, including readiness for sternotomy, emergency C-section, and neonatal intensive care. The patient, tachycardic, tachypnoeic, and hypertensive, underwent the procedure under monitored anaesthesia care, including invasive blood pressure monitoring and IV analgesia for discomfort.

Over 1000 mL of hematic fluid was drained, and a pericardial drain was placed. She remained hemodynamically stable without vasopressors and was admitted to the ICU where she was diagnosed with an intracardiac mass (right atrium).

To enable further investigation and avoid foetal harm, a C-section was performed after lung maturation, under combined spinalepidural anaesthesia. The mass was later confirmed as cardiac angiosarcoma following biopsy.

Discussion: This rare case of cardiac tamponade in pregnancy caused by cardiac angiosarcoma emphasizes the importance of a multidisciplinary approach. Anaesthetic management was successful, guided by thorough preparation for worst-case scenarios. Coordinated efforts ensured favourable outcomes for both mother and newborn.

References:

Learning points: Intracardiac malignant masses are rare and carry a poor prognosis. When combined with pregnancy, they present unique challenges requiring meticulous multidisciplinary planning and management to optimize maternal and foetal outcomes.

32AP07-11

Preoperative assessment of inferior vena cava collapsibility as a predictor of postoperative complications after left ventricular device implantation

A. Kupiec1, M. Obremska2, B. Barteczko - Grajek1, G. Bielicki², R. Przybylski², W. Goździk¹ ¹Wrocław Medical Univeristy, Department and Clinic of Anaesthesiology and Intensive Care, Wrocław, Poland, ²Wrocław Medical Univeristy, Institute of Heart Diseases, Wrocław, Poland

Background and Goal of Study: Left ventricular assist device (LVAD) is used in end-stage heart insufficiency either as a bridge to heart transplantation, recovery, or destination therapy. With the development of new-generation devices, the one-year survival rate after surgery has increased. However, the risk for postoperative complications remains high. One of the risk factors for an unfavourable outcome is right ventricular insufficiency.

As stiffness of the vena cava inferior (VCI) may be the hallmark of right ventricular failure, we conducted a study to assess the influence of preoperative VCI measurement on postoperative complications.

Materials and Methods: Forty patients who were hospitalized at the University Hospital between 11.2021 and 12.2023 after LVAD implantation were enrolled in the study. Prior to the surgery, comprehensive echocardiography was performed by a cardiologist. VCI diameter was measured during expiration and inspiration. VCI stiffness was diagnosed if the decrease in VCI diameter during inspiration was less than 50%. Postoperatively, patients were assessed for complications, such as acute kidney injury (AKI), respiratory complications, and delirium.

Results and Discussion: VCI stiffness was found in 80% of patients (n = 32/40), and normal VCI collapsibility was found in 20% of patients (8/40). Respiratory complications occurred in 43% (n = 14/32) of the patients with VCI stiffness and in none of the patients with normal VCI collapsibility (p = 0,017). AKI was diagnosed in 37% of patients with VCI stiffness (n = 12/32) and in 25% (n = 2/8) of patients without VCI stiffness (p = 0,128). Delirium was found in 25% of patients with VCI stiffness (n= 8/32) and in one patient without VCI stiffness (p = 0,192).

There was a significant difference in the postoperative length of stay in the intensive care unit between patients with and without VCI stiffness (median, 5 vs. 2 days; p = 0,0002). However, a statistically significant correlation was found between increased inspiratory VCI diameter and the occurrence of postoperative complications. In the ROC analysis, the cut-off value for inspiratory VCI diameter was determined for AKI - 17 mm (AUC 0,77; p = 0,004), respiratory complications – 21 mm (AUC 0,83; p = 0,0001) and delirium - 20 mm (AUC 0,73; p = 0,023).

Conclusion: Echocardiographic assessment of VCI may help identify patients at risk for postoperative complications. Further studies with a larger group of patients are needed.

32AP07-12

Hypotension Prediction Index as a parameter for goal-directed hemodynamic management during kidney transplantation: a single center experience

C. Grillandini¹, A. Marabotti¹, M. Orlandi¹, A. Valletta¹, S. Batacchi¹, M. Bonizzoli¹

¹Azienda Ospedaliero-Universitaria Careggi, Anesthesia and Intensive Care Unit of the Emergency Department, Florence, Italy

Background: Kidney transplantation represents the treatment of choice in end-stage kidney disease, with superior survival and improved quality of life over dialysis. Delayed graft function (DGF), defined as the need for dialysis within the first post-transplant week, is a common early complication and it is associated with about 40% higher risk of graft loss. The aetiology of DGF is multifactorial, but maintaining an adequate perfusion pressure to the transplanted kidney is crucial.

Our aim was to evaluate whether the use of blood pressure monitoring based on Acumen Hypotension Prediction Index (HPI) of Edwards Lifesciences can support intraoperative decision making by protecting against DGF.

Materials and Methods: Fifty orthotopic kidney transplant recipients who underwent surgery between January 2024 and October 2024 were analyzed after approval by the Internal Board of the Regional Authority of Transplantation. Three cases were excluded due to intraoperative severe complications; the study therefore included a population of 47 patients, who received kidneys from donors either brain dead (86%) or cardiac dead (12%). Patients were randomly assigned to receive HPI monitoring or standard care and divided into two groups. Incidence of DGF in the two groups were then compared.

Results: Twenty-seven patients (57.45%) received intraoperative monitoring with HPI device, while twenty (42.55%) received standard monitoring provided by the approved internal anesthesiology protocol. Six patients in the HPI group (22.2%) experienced DGF versus six patients (30%) in the standard monitoring group (p=0.7365). In the HPI group, we found a non-statistical difference in mean intraoperative HPI between the DGF and regular function groups (32.16 versus 23, p=0.67982). The ROC curve of HPI values for DGF obtained an area under the curve of 0.611 (95% CI 0.391-0.83).

Conclusion: In our analysis, HPI monitoring does not reduce the risk of DGF compared to conventional monitoring. However, our results may be underestimated due to the small sample studied, the difficulty in assessing the characteristics and heterogeneity of cold ischemia during the organ allocation period and the consolidation of operators' confidence in the hemodynamic assessment method.

The strong reference of the hemodynamic assessment method to the principles of prevention of hypotensive events certainly deserves further investigation in the field of ex-vivo perfusion and in the management of marginal organs.

Anaesthetic challenges in a complex patient with Emery-Dreifuss muscular dystrophy and systemic sclerosis undergoing open tricuspid valve replacement surgery

J. Lee¹, S. Lye¹, Y.J. Thay¹

Singapore General Hospital, Division of Anaesthesiology and Perioperative Medicine, Singapore, Singapore

Background: Emery-Dreifuss Muscular Dystrophy(EDMD) is a rare genetic disease characterised by progressive muscle weakness, contractures and cardiac conduction defects. Its prevalence is estimated 0.39 per 100 0001. Systemic sclerosis(SSc), a chronic autoimmune connective tissue disorder, leads to multiorgan fibrosis. Co-existence of EDMD and SSc in a single patient presents unique challenges to the anesthetist.

Case Report: 57 year old male with EDMD and SSc presented with worsening dyspnoea and effort tolerance. Transesophageal echocardiography (TEE) showed left ventricular ejection fraction 40%, severe tricuspid regurgitation with flail posterior leaflet. Besides mild proximal weakness, he was pacing-dependent with cardiac resynchronization therapy defibrillator(CRTD) in situ. His SSc presented as chronic joint pain, limited skin sclerosis, interstitial lung disease(ILD) and pulmonary hypertension(PAH).

Key Steps:

- Cessation of immunosuppressant and stress dosing of steroids
- · Malignant Hyperthermia(MH) precautions and use of total intravenous anesthesia(TIVA)
- · Rapid sequence induction(RSI) in view of SSc related gastric reflux with train-of-four ratio(TOFR) monitoring
- CRTD programming
- Intraop TEE confirmed satisfactory valve function
- ROTEM done to correct coagulopathy related to SSc/cardiopul-

Discussion: In a patient with both EDMD and SSc. cardiac involvement such as conduction defects, cardiomyopathy and heart failure may be accelerated.^{1,2} Tricuspid valve dysfunction is significant in SSc, where right heart failure may be due to both PAH and direct cardiac fibrosis. Anesthesia considerations include optimisation of cardiorespiratory function, cardiac device management, early extubation and cardiopulmonary rehabilitation.

TIVA and avoidance of succinylcholine is necessary in view of susceptibility to MH or anaesthesia-induced rhabdomyolysis. Rocuronium for RSI and no further doses to avoid delay in muscle function recovery, prolonged weakness and post op respiratory complications. Residual blockade was noted at end of surgery despite single dose (TOFR 10% after 3hr surgery). TOFR was >90% prior to extubation in ICU.

- 2. Lambova S. Cardiac manifestations in systemic sclerosis. World J Cardiol. 2014;6(9):993-1005

Learning Points: In managing such complex patients, a multidisciplinary approach with thorough peri-operative planning can mitigate risks.

32AP08-2

Pharmacological support in patients undergoing left ventricular assist device implantation. First ten cases experience in our hospital

A. Gámez¹, S. González Suárez¹, P. Ciurana¹, J. Díaz Herrero¹, C. Iglesias¹ ¹Hospital Universitario Vall d'Hebrón, Anestesiología y Reanimación, Barcelona, Spain

Background and Goal of Study: The implantation of left ventricular assist devices (LVADs) has progressively increased as a bridge-to-transplant therapy as well as a destination therapy in patients with end-stage heart failure. Perioperative haemodynamic decompensations caused by a sudden decrease in left ventricular preload, an increase in left ventricular afterload, and elevated pulmonary vascular resistance are common and may precipitate right ventricular failure. After extracorporeal circulation (ECC) weaning, right heart failure may occur in up to 30% of patients, along with vasoplegia or cardiac arrhythmias.

The aim of this study is to describe and evaluate the use of pharmacological support in the first ten adult patients undergoing LVAD surgery in our hospital.

Materials and Methods: Retrospective study that included 10 adult patients undergoing LVAD placement. Descriptive statistics were generated to highlight the use of pharmacological support administered in these patients.

Results and Discussion: 10 HeartMate 3 were placed. Baseline sPAP were 44.70 ± 16.49 mmHg, LVEF 23 ± 6.18%, TAPSE 15.30 ± 2.49 mm. All patients received levosimendan before surgery. Pulmonary pressures were monitored during surgery with a Swan-Ganz catheter, ECG, SpO2, cerebral oximetry, BIS TM and TEE. Hemodynamic goals were MAP 65-80 mmHg, sPAP < 25 mmHg, CVP < 12 mmHg. Hemodynamic parameters obtained using a Swan-Ganz catheter, together TEE assessments of right ventricular size and contractility, were used as a guide to determine the need for inotropic or vasodilator therapy.

At the start of surgery, 100% of patients received inhaled nitric oxide, 90% nebulized prostacyclin and 50% intravenous sildenafil. Milrinone and dobutamine were administered in 10% and 100%, respectively. All patients received norepinephrine and vasopressin, and epinephrine was administered in 50%.

After withdrawal of cardiopulmonary bypass (CPB), one patient presented MAP <60 mmHg, with increased inotropic drugs, CVP >15mmHg, CI <2 L/min/m2, left septal deviation, and <4 L/ min LVAD flow at 2400 rpm, requiring placement of a right ventricular assist device. Inodilator and vasopressor therapy could be reduced after withdrawal of CPB. However, after surgery, all patients received norepinephrine and milrinone, 70% nitric oxide, 40% dobutamine, vasopressin and prostacyclin; and epinephrine and sildenafil were administered in 30%.

	Norepi- nephrine	Epi- neprhine	Vaso- pressin	Dobut- amine	Nitric oxide	Milrino- ne	lloprost	Silden- afil
Surgery	100%	50%	100%	10%	100%	100%	90%	50%
Post- surgery	100%	30%	40%	40%	70%	100%	40%	30%

Table 1: percentage of pharmacological support use in the intra and postoperative period of LVAD surgery.

Conclusion(s): The administration of vasopressor and inodilator therapy is important for these patients. This pharmacological support should be initiated before starting CPB, since placement of a LVAD may exacerbate right ventricular dysfunction.

Once ventricular support is established, the use of these agents should be reduced to the greatest extent possible. Furthermore, excessive afterload must be avoided, as it may lead to a decrease in LVAD flow.

32AP08-3

The role of NFAT pathway and shear stress on circulating T cells in the pathogenesis of calcific aortic valve disease

Y. Zhang¹, S. Frede¹, S. Zimmer², J.L. Kleiner¹, M. Coburn¹, C.K. Weisheit¹

¹University Hospital Bonn, Department of Anaesthesiology and Intensive Care Medicine, Bonn, Germany, 2University Hospital Bonn, Department of Medicine II, Heart Center, Bonn, Germany

Background and Goal of Study: Calcific aortic valve stenosis (AVS) is considered to be an active inflammatory disease. AVS is characterized by progressive fibro-calcific remodelling and thickening of the aortic leaflets causing severe cardiac outflow obstructions. Due to AVS progression circulating immune cells experience high shear stress (HSS), which is known to influence immune cell response (Baratchi et al. 2020).

In vivo T cell activation is a mechanical and biochemical process (Hope et al. 2022), in which Piezo1 as a mechanosensitive Ca2+permeable ion channel is involved. Ca2+ as an important 2nd messenger leads to T cell activation through nuclear translocation of the transcription factor nuclear factor of activated T cells (NFAT). The aim of this study is to explore the role of NFAT in HSS-induced T cell activation.

Materials and Methods: Blood was obtained from patients undergoing TAVI because of severe AVS. Circulating T cells were isolated using MACS-method. To model T cell activation in vitro Jurkat cells were activated by CD3/CD28 antibody stimulation and exposed to shear stress (20dyn/cm² and 200 dyn/cm²) for 3 hours. qPCR was performed for semiquantitative measurement of gene expression.

Results and Discussion: NFAT inducible genes are known to regulate T cell proliferation, differentiation and activation. Thus, we clustered them into genes responsible for proliferation and activation. The significantly elevated gene expression of Cyclin D1, IL2, IFNg along with TNFa in patients with AVS suggested the involvement of NFAT.

Acridine orange staining was used to assess whether HSS exposure impacts T cell viability. A 3-hour exposure to HSS did not result in a significant reduction in cell viability. Jurkat cells were subsequently exposed to HSS to evaluate any potential activating effect of HSS alone.

After 3 hours of HSS exposure no altered gene expression compared to static control was detected. The expression of IL2, IFNg. TNFa and Cyclin D1 increased only when HSS was used with antibodies together. Particular noteworthy is a gradual response to shear stress in the expression of IFNg.

Conclusion: HSS can enhance T cell activation when stimulated with CD3/CD28 antibodies. The NFAT pathway seems to be activated in HSS and AVS.

Unique anaesthetic protocol for successful management of OPCAB in patient with Addison's disease (due to adrenal gland tuberculosis) and left ventricular aneurysm

E. Daniel1

¹Sir Ganga Ram Hospital, Cardiac Anaesthesia, New Delhi, India

Background: Addison's disease combined with cardiovascular disease is infrequent only 10 cases in the literature. Addison's disease due to dysfunction of the adrenal gland, with abnormal secretion of glucocorticoids and mineralocorticoids, is rare. By inducing inflammation and disorder of water and electrolyte metabolism, Addison's disease may accelerate progression of coexisted CAD(1).

Case Report: 60 yr old male, was admitted with c/o breathless & angina on exertion, he is a k/c/o CAD with PTCA done to Left Circumflex & Ramus Intermediate in past. He is also a k/c/o HTN, DM & Hypothyroidism and on medical management.

In 1994 patient was diagnosed with Pulmonary Tuberculosis & Potts spine for which he was give anti-tubercular drugs for 12 months, same year he also c/o facial swelling & extreme tiredness, investigated & Addison's disease was diagnosed due to adrenal gland tuberculosis thereafter, patient is life-long on T.Wysolone 5mg to 10mg OD. Investigation: S. Cortisol < 0.07.

Discussion: Addison's disease caused by adrenal gland tuberculosis is very rare in developed nations but is seen in developing countries, patients are life-long on steroids to prevent Addisonian crisis and the disease is know to accelerate CAD in patients. OP-CAB is a challenging task to the surgeon during lateral & posterior wall grafting so the role of cardiac anaesthetics in maintaining optimal vitals during these grafts is pivotal, so to say hypertension & tachycardia are unacceptable conditions & this will lead to conversion from OFF to ON-Pump CABG (3).

As cardiac anaesthetist with in-depth knowledge of various drugs available we can create a "milieu" that can avoid cardiac pump, such as in this particular case, where avoiding pump & cardioplegia was a necessity, because of fluid overloading, electrolyte imbalances which could lead to grave complications of, "Addisonian crisis"(2) with increased mortality to the patient.

Learning Points: Meticulous choice of drugs.

The functional status of the heart and coronary blood flow during the induction of anesthesia in elderly patients with coronary heart disease

A. Vitovskyi¹, O. Loskutov², A. Mazur¹, R. Vitovskyi¹, V. Lazoryshynets1

¹National M. M. Amosov Institute of Cardiovascular Surgery of the National Academy of Medical Sciences of Ukraine, Department of Anesthesiology, Kyiv, Ukraine, ²Shupyk National University of Health Care of Ukraine, Department of Anaesthesiology & Intensive Care, Kyiv, Ukraine

Background and Goal of Study: With the global trend of population aging, modern medicine faces the urgent task of improving healthcare for elderly patients. This group often presents with reduced compensatory reserves and multiple chronic conditions. necessitating a more meticulous approach by anesthesiologists. The goal of this study was to evaluate the functional status of the heart and coronary blood flow in elderly patients with coronary heart disease (IHD) during the induction of anesthesia using various anesthesia methods.

Materials and Methods: This prospective, randomized cohort study included 60 patients (ASA III-IV; mean age 66.8±5.3 years) undergoing off-pump coronary artery bypass grafting (CABG). Participants were divided into two groups based on the induction agent used: Group 1: Propofol 1.5 mg/kg; Group 2: Propofol 1.5 mg/ kg plus ketamine 0.5 mg/kg. For analgesia, fentanyl (2.0 µg/kg) was administered in both groups, with neuromuscular relaxation achieved using pipecuronium bromide (0.1 mg/kg). Hemodynamic parameters, including stroke index (SI), ejection fraction (EF), cardiac index (CI), systemic vascular resistance index (SVRI), and coronary perfusion index (CPI), were recorded at four stages: 1. Upon arrival in the operating room (Stage I); 2. Before tracheal intubation (Stage II): 3. Immediately after intubation (Stage III): 4. 25 minutes post-intubation (Stage IV).

Results and Discussion: A statistically significant difference in SI was observed between groups at Stage III (31.96±4.07 mL/m² vs. 35.16±4.52 mL/m², p=0.0213) and Stage IV (27.83±3.7 mL/m² vs. 34.61±3.73 mL/m², p=0.00112). A significant difference in EF was found at Stage IV (43.78±6.18% vs. 52.86±5.78%, p<0.001). CI showed statistically significant differences at Stage III (2.39±0.3 $L/min/m^2$ vs. 2.69±0.45 $L/min/m^2$, p=0.02104) and Stage IV (1.97±0.3 L/min/m² vs. 2.63±0.34 L/min/m², p=0.00120). Significant differences in SVRI were noted at Stage II (2853.03±554.4 dyn·s·cm⁻⁵·m² vs. 3250.04±622.9 dyn·s·cm⁻⁵·m², p=0.0112). CPI also showed significant differences at Stage II (0.6±0.03% vs. 0.65±0.04%, p=0.0411) and Stage IV (0.69±0.01% vs. 0.77±0.03%, p=0.0011).

Conclusion(s): The addition of ketamine to a traditional propofolfentanyl combination in elderly patients with coronary heart disease improves the coronary perfusion index during induction of anesthesia and reduces the cardiodepressive effect of propofol on cardiac functional status.

32AP08-6

Differences in incidence of post-induction hypotension depending on the time of day: a post-hoc propensity score matched analysis

J.T. Tol¹, A. Meewisse¹, E. Kho¹, A.P. Vlaar², D.P. Veelo¹, J. Schenk^{1,2,3}, PREP Study Group ¹Amsterdam UMC, Anaesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Intensive Care, Amsterdam, Netherlands, ³Amsterdam UMC, Epidemiology & Data Science, Amsterdam, Netherlands

Background and Goal of Study: Many physiological processes show a diurnal rhythm, including sympathetic and parasympathetic tone, adrenal hormone secretion and blood pressure (BP). Since these physiological rhythms may affect the sensitivity to anaesthesia, we hypothesized that the time of day when anaesthesia induction occurs may affect the incidence of PIH.

Materials and Methods: This was a post-hoc propensity score matched analysis of prospectively collected BP data of 750 elective non-cardiac surgery patients receiving general anaesthesia. The primary endpoint was the incidence of PIH, defined as mean arterial pressure (MAP) < 65 mmHg for at least one minute. Secondary endpoints were a >30% decrease in MAP, and baroreflex sensitivity.

Results and Discussion: In the analysis of 237 propensity score matched pairs, PIH was more frequent if anaesthesia induction occurred in the morning (before 12:00 PM) (OR 1.48, 95% CI: 1.00 -2.20, p = 0.049).

Secondary analyses of the matched cohort showed that a >30% decrease in MAP was likewise more frequent in the morning than the afternoon (after 12:00 PM) (OR 1.45, 95% CI: 1.00 - 2.11, p= 0.050), but no differences in baroreflex sensitivity were observed. Conclusion(s): In this post-hoc propensity score matched analysis, PIH was more frequent after anaesthesia induction in the morning compared to the afternoon. While this finding is in line with the presumed physiological mechanisms, it may be affected by unmeasured confounding.

These findings should be replicated in larger, preferably randomized, studies to evaluate whether a causal relationship between the time of day of anaesthesia induction and PIH exists.

Opioid free anaesthesia-analgesia strategy in elective open abdominal aortic aneurysm repair: can it attenuate the stress response? Preliminary findings from a prospective randomized study

G. Papastratigakis¹, V. Nyktari^{2,1}, G. Stefanakis¹, G. Chamilos^{3,4}, A. Kafetzakis⁵, A. Papaioannou^{2,1} ¹University General Hospital of Heraklion, Department of Anaesthesiology, Heraklion, Greece, ²University of Crete, School of Medicine, Herakion, Greece, 3University of Crete. School of Medicine. Laboratory of Clinical Microbiology and Microbial Pathogenesis, Heraklion, Greece, ⁴Foundation of Research and Technology, Institute of Molecular Biology and Biotechnology, Heraklion, Greece, 5University General Hospital of Heraklion, Department of Vascular Surgery, Heraklion, Greece

Background and Goal of Study: The surgical stress response in open Abdominal Aortic Aneurysm (AAA) repair is significant. This study investigates if a perioperative Opioid-Free Anaesthesia-Analgesia (OFA-A) approach can effectively mitigate this stress response compared to the conventional Opioid-Based Anaesthesia-Analgesia (OBA-A).

Materials and Methods: Forty patients undergoing open infrarenal AAA repair were randomized in 2 groups, managed by OFA-A or OBA-A strategy. Blood inflammatory markers (IL-6, IL-8, IL-10, TNF-\(\Pi\), CRP, cortisol, AVP, WBC) were analysed at 4-time points. Haemodynamic data were recorded every 20 seconds intraoperatively. Parametric data were assessed via unpaired t-test and non-parametric data via Mann-Whitney U test. P-values for inflammatory markers and haemodynamic data were corrected with False Discovery Rate method (Q=5%) to ensure robustness

Results and Discussion: Preliminary data from 32 patients (16 in each group) show significant differences in cortisol (P=0.009, q=0.013), CRP (P=0.008, q=0.013), IL-6 (P=0.004, q=0.013) and IL-8 (P=0.014, q=0.015) 24 hours after clamp release (higher in OBA-A group). WBC, AVP, IL-10, and TNF- showed no significant differences at any time point.

Both groups received goal-directed fluid therapy with no significant differences in noradrenaline, phenylephrine, ephedrine, or fluid requirements. However, OFA-A patients had higher intraoperative urine output (P=0.003) and lower furosemide requirement (P=0.0007).

Haemodynamic data from 30 patients (14 OFA-A, 16 OBA-A) showed no significant differences in haemodynamic instability (defined as HR or BP ≥120% or ≤80% of baseline values, lasting ≥1 minute). The coefficient of variation (CV) for systolic BP (SBP) (P=0.022, q=0.025) and pulse pressure (PP) (P=0.023, q=0.025) was significantly lower in OFA-A group. The CV for HR, diastolic BP (DBP), and mean BP (MAP) showed no significant differences. The Average Real Variability of the averaged 5-minute values for SBP (P=0.003, g=0.008), MAP (P=0.053, g=0.047), HR (P=0.009, g=0.016), and PP (P=0.001, g=0.006) also showed statistically significant differences in favour of OFA-A.

Conclusion(s): Preliminary data suggest that the stress response in OFA-A group was attenuated, with less haemodynamic fluctuation. If these findings are confirmed in the final analysis, they could influence the management of surgical stress in open AAA repair and potentially other surgical procedures.

32AP08-8

The effect of HuaXi-1 cardioplegia on the whole heart ischemia/reperfusion injury in on-pump cardiac surgery: a retrospective cohort study

J. Tan¹, Y. Wang¹, X. Yu¹, D. Luo¹, C. Zhou², L. Du¹ ¹Sichuan University, Department of Anesthesiology, West China Hospital, Sichuan University, Chengdu, China, ²Guangdong Provincial Cardiovascular Institute, Department of Cardiovascular Surgery, Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou, China

Background and Goal of Study: Cardioplegic solutions arrest the heart during cardiopulmonary bypass to provide a stable surgical field but may cause ischemia/reperfusion injury. Effective solutions are key to reducing myocardial damage and aiding postreperfusion recovery. HuaXi-1 (HX-1), developed by West China Hospital, has been used clinically for 17 years without systematic evaluation.

This study compares its cardioprotective effects with the Histidine-Tryptophan-Ketoglutarate (HTK) solution.

Materials and Methods: This retrospective cohort study included adult patients undergoing cardiac surgery with cardiopulmonary bypass at West China Hospital and Guangdong Provincial People's Hospital between January 1, 2019, and June 30, 2021. Patients were divided into HX-1 and HTK groups based on the cardioplegia administered.

The primary outcome was defined as the incidence of major adverse cardiac events (MACE) from the day of surgery to discharge, including in-hospital death, extracorporeal membrane oxygenation (ECMO) support, or intra-aortic balloon pump (IABP) support.

Propensity score matching was applied to control for confounding variables, and logistic regression analysis was conducted to investigate the association between HX-1 and the risk of postoperative MACE. Subgroup analyses assessed the protective effects of HX-1 across various patient populations.

Results and Discussion: In the entire cohort, the HX-1 group exhibited a relatively lower risk of postoperative MACE (OR 0.16, 95%CI 0.11-0.24), including in-hospital mortality (OR 0.37, 95%CI 0.21-0.64), ECMO support (OR 0.15, 95%CI 0.07-0.30), and IABP support (OR 0.05, 95%CI 0.02-0.10) . After propensity score matching, the HX-1 group sustained a lower risk of postoperative MACE (OR 0.45, 95%CI 0.25-0.81).

Logistic regression analysis indicated a significant association between HX-1 usage and decreased postoperative major adverse events (OR 0.43, 95%CI 0.22-0.83).

Besides, HX-1 group showed lower troponin T levels, shorter total hospital stays, and postoperative hospitalization duration across all patients; these advantages persisted in the matched cohort (all P<0.001).

Conclusion(s): HX-1 cardioplegia effectively reduces the risk of postoperative MACE (including all-cause mortality, ECMO, and IABP) compared to HTK, demonstrating superior myocardial protection against ischemia/reperfusion injury. Large-scale, multicenter, randomized controlled trials are needed to validate these findings.

Hemodynamic and echocardiographic considerations to prevent left atrial appendage closure device migration: case report

I.M. Dammala Liyanage¹, S. González Suárez¹, S. Manrique Muñoz1

¹Vall d' Hebron Campus Hospital, Anesthesiology, Reanimation and Pain Management, Barcelona, Spain

Background: Percutaneous closure of the left atrial appendage (LAA) is not without complications, one of which is the migration of the LAA closure device to the mitral valve1. Migration of the device to the aorta is very rare.

Case report: A 54-year-old patient with anticoagulated atrial fibrillation and recurrent gastrointestinal bleeding with severe anemia (Hb 6.3 g/dl) required the implantation of an Amplatzer™ Amulet™ (28 mm) device in the LAA using the Sandwichtzerm technique under transesophageal echocardiography (TEE) and angiographic control with midazolam and fentanyl. Two days later, the patient developed progressive dyspnea, SpO2 85%, and sPAP of 45 mmHg.

Echocardiography diagnosed severe aortic insufficiency due to device migration, and surgical extraction was decided over percutaneous extraction due to the risk of valve injury and further migration of the device. At the beginning of surgery, the patient presented with BP 147/72 mmHg, HR 95-100 bpm, SpO2 92% (FiO2 0.35).

Anesthetic induction was performed with 20 mg midazolam, 0.15 mg fentanyl, and 70 mg rocuronium, followed by a norepinephrine infusion to maintain a MAP ≥ 60 mmHg. TEE confirmed device impaction on the aortic valve, causing severe aortic insufficiency, as well as perforation and prolapse of the non-coronary leaflet. After surgery, the patient was transferred to the ICU.

Discussion: The size of the LAA can vary depending on the patient's hydration status, and anemia and hypovolemia may have led to inaccurate measurements of the LAA structure, thereby facilitating device migration. The lobe of the Amplatzer™ Amulet™ device should be implanted 10-15 mm from the ostium of the LAA, with the disc completely covering the ostium.

1. Jose M González et al. Can J Cardiol 2013;29:1532.e5-7

Learning points: LAA closure device implantation should be performed under normovolemic conditions. A certain degree of device oversizing is also preferable, as it minimizes residual leak rates without increasing the risk of wall rupture. TEE is crucial for proper device selection and implantation, as well as for diagnosing and monitoring device migration.

On the other hand, although device migration typically does not extend beyond the mitral valve, the possibility of migration to the aorta must also be considered, even in patients without significant hemodynamic repercussions.

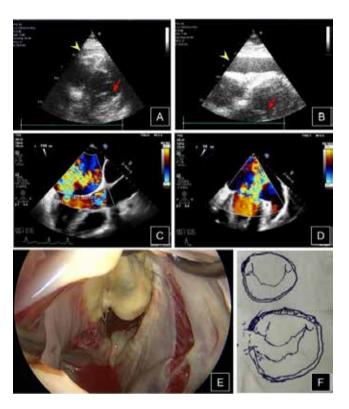

32AP08-10

Mitral annular disruption with severe mitral regurgitation and acute heart failure following blunt chest trauma

Z.-R. Wong¹, H.-C. Wang¹, N.-W. Huang², J.-C. Chang², C.-L. Lee¹

¹Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation and Tzu Chi University, Department of Anesthesiology, Hualien, Taiwan, ²Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation and Tzu Chi University. Division of Cardiovascular Surgery. Department of Surgery, Hualien, Taiwan

Background: Blunt chest trauma rarely induces valve injuries, with the majority involving papillary muscle or chordae rupture. Here we present a patient who underwent cardiorrhaphy after trauma but developed severe mitral regurgitation (MR) and heart failure due to an initially missed mitral annular lesion.

Case report: A 76-y/o man with HTN, congestive heart failure, Afib, COPD sustained a 3-meter fall onto his right torso. He was transferred to a tertiary center due to shock. In ER, he was conscious and relatively stable after resuscitation. CT revealed fractures in the right scapula, right ribs, pericardial effusion.

TTE confirmed hemopericardium (Fig A-B, arrowhead) with tamponade but normal mitral valve motion with coaptation (arrow). Urgent sternotomy repaired a left atrial base laceration.

Despite shock management, he developed pulmonary edema and hemodynamic instability.

Repeat TTE revealed severe MR, four-chamber dilatation, ventricular decompensation.

Urgent mitral valve repair was performed. Intraoperative TEE showed severe MR without leaflet coaptation (Fig C-D), severe tricuspid regurgitation, and a 25% LVEF. Surgical findings showed mitral annular rupture and anterolateral commissure distortion (Fig E-F). He underwent mitral ring annuloplasty with LVAD and ECMO support, and was transferred to the ICU. LVAD was removed on POD9: He was extubated on POD12.

Discussion: Only few cases exist regarding mitral annular disruption after falls; Surgery depends on patients' tolerance.1,2 The injury mechanism remains unclear, possibly involving increased intracardiac pressure or direct impact.1-3

In our case, the initial TTE showed normal mitral valve coaptation, assuming MR developed later due to progressive chamber dilation from decompensated heart failure, which aggravated an initially occult annular disruption.

Pre-existing heart failure may have predisposed our patient to the rapid decompensation.

Stellate ganglion: beyond pain: a therapeutic alternative for arrhythmic storm

E. Conesa¹, V. Del Prado¹, Z. Xia¹, J. Vigo¹, <u>L. Del Río¹</u>, E. García¹

¹Hospital 12 de Octubre, Anestesia, Madrid, Spain

Background: The management of recurrent ventricular arrhythmias in patients with dilated cardiomyopathy is often challenging for physicians. Ultrasound-guided stellate ganglion block (SGB) is a minimally invasive, simple, and safe therapeutic alternative.

Case report: A 48-year-old male with a history of dilated cardiomyopathy of unknown etiology initially presented with cardiac arrest, requiring ECMO support. Subsequently, he experienced several episodes of AS, necessitating shocks from the implantable cardioverter-defibrillator (ICD).

Following the last episode of sustained ventricular tachycardia with associated dizziness and palpitations, an ultrasound-guided SGB was proposed in the operating room using a lateral cervical approach, with administration of 20cc of 0.25% Bupivacaine. Four months later, stabilization of rhythm and symptoms was reported.

Discussion: SGB is used as a therapeutic tool for complex regional pain syndrome of the upper limb and trigeminal neuralgia, eliminating sympathetic innervation of the affected area. Left-sided sympathetic fibers innervate the AV node, the His bundle, and the ventricular myocardium, which serve as the substrate for most ventricular arrhythmias. When conventional treatments for these arrhythmias fail, as in the case described, SGB is considered a rescue technique.

The advantage of performing the procedure under ultrasound guidance with a lateral approach to the vascular bundle lies in its safety, avoiding the risk of vascular complications in these patients, who are often anticoagulated.

However, its limitations include limited evidence of long-term efficacy, as our patient was only followed for four months. Regarding the local anesthetic dose, the optimal amount to achieve prolonged effect while minimizing spread to adjacent neural structures remains unknown.

Nevertheless, favorable outcomes reported in case series, as well as the clinical benefit observed in the proposed case, suggest this technique as a rescue alternative for AS, avoiding more invasive measures such as thoracic epidural anesthesia or thoracoscopic sympathectomy.

References:

Ganesh A, et al. Stellate Ganglion Blockade: an Intervention for the Management of Ventricular Arrhythmias. Curr Hyp Rep. 2020 Oct 23:22(12):100

Learning points: Ultrasound-guided SGB with a lateral approach to the cervical vascular bundle is presented as a safe and effective technique for stabilizing cardiac rhythm in patients with AS refractory to conventional treatment.

32AP08-12

Dynamic approach with ECMO as a bridge to lung transplantation

I. Amantegui Fernández-Vega¹, B. Ybañez García¹, D. Benguria Puebla¹, M. Sánchez Velo¹, A. Iniesta Martín¹ ¹Hospital Universitario 12 de Octubre, Anestesiología y Reanimación, Madrid, Spain

Background: ECMO (extracorporeal membrane oxygenation) provides temporary cardiopulmonary support for critically ill patients unresponsive to medical therapy. Its use requires dynamic adjustments based on clinical changes. This case illustrates ECMO's multimodal application during a complex perioperative period.

Case Report: A 58-year-old male with familial idiopathic pulmonary fibrosis managed with Nintedanib and home oxygen. He presented with severe respiratory failure unresponsive to high-flow oxygen. VV (veno-venous) ECMO was initiated in the ICU as a bridge to lung transplantation.

Perioperative Course

Preoperative: Severe right ventricular dysfunction developed despite VV ECMO, necessitating conversion to VAV (veno-arteriovenous) ECMO, delivering 2.2 L/min to the internal jugular vein and 1.3 L/min to the femoral artery. Hemodynamic stability improved. VA (veno-arterial) ECMO was avoided due to preserved left ventricular function, preventing Harlequin syndrome (upper body hypoxia).

Intraoperative: Lung transplantation proceeded with cardiopul-monary bypass.

Postoperative: Right ventricular function improved, confirmed by echocardiography and pulmonary artery catheterization. ECMO was transitioned back to VV mode on postoperative day five to support lung adaptation.

Outcome: Decannulation occurred on day seven after successful weaning. The patient was discharged from the ICU on day twelve with supplemental oxygen and thoracic drainage tubes.

Discussion: This case highlights the strategic, multimodal use of ECMO to address the patient's evolving clinical needs. VV ECMO was employed initially for respiratory failure, then converted to VAV ECMO due to right ventricular dysfunction. VA ECMO was avoided to prevent Harlequin syndrome. ECMO cannulas were effectively utilized during cardiopulmonary bypass and in the immediate postoperative period, reverting to VV ECMO after right ventricular recovery.

This case underscores the importance of ECMO's adaptability in complex perioperative management.

References:

Hoetzenecker K, Benazzo A, Stork T, et al. Extracorporeal life support in lung transplantation, J Thorac Dis. 2018:10(Suppl 15) Granton J. Cheng D. Transitioning between VV and VA ECMO in perioperative lung transplant complications. Chest. 2020:158(5):1874-1882

Learning Points:

- ECMO's adaptability is crucial in dynamic perioperative manage-
- · Continuous hemodynamic monitoring enables tailored interventions.

32AP08-13

External and internal validation of a multivariate multimodal voting machine learning model of intraoperative hypotension

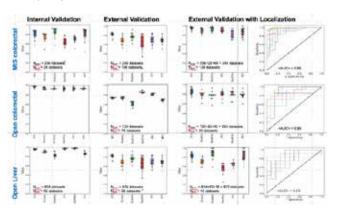

J. Cata¹, J. Soliz¹, B. Soni², S. Bhavsar¹, J. Siewerdsen² ¹MD Anderson Cancer Center, Anesthesiology and Perioperative Medicine, Houston, United States, ²MD Anderson Cancer Center, Institute for Data Science in Oncology, Houston, United States

Background: Intraoperative hypotension (IOH) is associated with significant postoperative morbidity.[1]

We previously demonstrated reliable IOH prediction using a multivariate random forest: static scenario: 11-fold cross-validation machine learning model in the context of open liver lobectomy.[2] In this work, we extend the method to colorectal and minimally invasive liver surgery, present external validation of the method by testing with a publicly available dataset, and investigate the ability to localize the model by re-training with a subset of data from the external database.

Methods: Data analysis was performed under an Institute Review Board approved protocol and according to the declaration of Helsinki's ethical principles for medical research involving human subjects. Internal validations were performed in a patients undergoing minimally invasive (MIS) and open liver resections and colorectal surgeries in our institution. External validations were done using the Machine Learning Outcome Validation and Evaluation Resource (MOVER) database.[3]

External validation following localization was also performed using MOVER. Model performance was evaluated using the following metrics: area under the curve (AUC), accuracy, sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV).

Results: In the MIS colorectal surgery context (n=284), internal validation performance was acceptable (AUC=0.85, Figure). The model generalized reasonably well directly to external data (n=198), localization with a small amount of external data vielded strong performance (AUC=0.95). For colorectal open (n=812), internal validation was strong (AUC=0.95, Figure 2).

External validation for open colorectal (n=55) and liver resections (n=17), did not generalize well directly (Figure), likely related to small populations to permit localization.

Conclusion: Internal and external validations of our novel ML model show moderate to strong performance. However, there was insufficient data in MOVER for external validation in the open colorectal and MIS liver context. There is a need for larger datasets for external validation with localization.

32AP09-1

Opioid-sparing anaesthesia in thymectomy using ultrasound-guided bilateral deep parasternal block: a case report

F. Sifaki¹, K. Delis¹, N. Michail², E. Koraki¹ ¹Papageorgiou General Hospital of Thessaloniki. Anesthesiology, Thessaloniki, Greece, ²Papageorgiou General Hospital of Thessaloniki, Cardiothoracic Surgery, Thessaloniki, Greece

Background: The novel bilateral deep parasternal block (DPB), is emerging as a valuable tool in cardiothoracic surgeries, including thymectomy, a procedure often associated with significant postoperative pain.

In this case report, the block was implemented preoperatively, demonstrating its potential to facilitate opioid-sparing anesthesia and perioperative pain management.

To our knowledge, this is the first report of its preoperative application in thymectomy.

Case Report: A 53-year-old male (BMI 29.1) with a history of substance use (marijuana, cocaine, alcohol abuse, 40 pack-years smoking) and psychotic disorder (on quetiapine and zopiclone) presented for elective thymectomy following a diagnosis of thymoma. Preoperative cardiologic echocardiography and laboratory tests were unremarkable.

The anesthesia plan included general anesthesia (GA) induction with fentanyl (0.2 mg), propofol, and rocuronium, combined with a bilateral DPB under ultrasound guidance (40 mL 0.375% ropivacaine total). GA was maintained with sevoflurane and additional analgesia consisted of paracetamol (1000 mg), dexamethasone (8 mg), magnesium sulfate (2500 mg), parecoxib (40 mg), and dexmedetomidine (100 mcg).

No additional opioids were administered intraoperatively. The surgery was performed via median sternotomy and lasted 90 minutes. Nociception and depth of anesthesia were intraoperatively monitored.

The patient remained hemodynamically stable throughout the procedure and was extubated promptly postoperatively. He was transferred to the post-anesthesia care unit for one hour and subsequently to the cardiothoracic ward.

Postoperative analgesia included paracetamol (1000 mg every 6 hours) and rescue tramadol as needed. The patient required 200 mg of tramadol on the 1st postoperative day, experienced no complications, and was discharged on the 4th postoperative day with satisfactory pain control and recovery.

Discussion: Thymectomy poses a risk of significant postoperative pain, necessitating effective analgesia to optimize recovery. DPB offers a safe, effective and promising method for reducing opioid reliance and their associated side effects, for contributing to stable hemodynamics, high-quality multimodal analgesia, and high quality of recovery.

Learning points: Preoperative DPB enhances analgesia and recovery after thymectomy. DPB is safe, simple and effective in reducing perioperative opioid use, while improving patient outcomes and satisfaction in cardiothoracic surgeries.

32AP09-3

Management of post operative complications in Jehovah's Witness patient after complex open cardiac surgery

I. Nikitin¹, A. Zhailauova², T. Li¹, T. Kapyshev¹, D. Alzhanov¹, N. Khissamutdinov³ ¹University Medical Center Heart Center, Cardiac anesthesiology and ICU, Astana, Kazakhstan, 2Nazarbayev University School of Medicine, Surgery, Astana, Kazakhstan, 3University Medical Center Heart Center, Cardiac Surgery, Astana, Kazakhstan

Background: Open cardiac surgeries in Jehovah's Witness patients are challenging due to inability to perform blood transfusions in case of hemorrhagic events. To minimize postoperative risks, it is important to reach pre-op Hb level of at least 12 g/dL. Here we demonstrate management of post-op complications in Jehovah's Witness patient undergoing complex valvular surgery along with LVAD implantation.

Case Report: A 56-year-old woman was admitted to the ICU with severe dyspnea, tachycardia, sharp decrease in exercise tolerance. She refused blood transfusions being Jehovah's Witness. Past history included: chronic rheumatic heart disease, AFib, MICS with mitral, aortic valves replacement and tricuspid valve repair (2008), ICD implantation (2016). In June 2023, she decompensated further and was hospitalized for aortic and mitral valves implantation along with LVAD. Cell saver was set up immediately after surgery. Post-op period proceeded with AKI, acute anemia (Hb 5.6 g/dL vs. 133 g/dL), hydrothorax, sepsis. She received treatment of severe anemia by 100 mg of Fe (III) i.v. daily. Pleural puncture proceeded with removal of 1600 ml fluid. Extracorporeal hemocorrection was performed for 4 days (HDF + HA) due to sepsis. Antibiotic therapy was selected. Hypoproteinemia (TP 5.28 g/dL, albumin 2.61 g/dL) was corrected by enteral nutrition. MAP of 70-80 mmHg was mainteined (flow=3.3 L/min, pump speed=4700 rpm). Over the course of ICU stay, her condition improved, Hb level (6.8 g/dL) rised and she was transferred to the department of cardiology.

Discussion: We demonstrated successful management of postop complications such as severe anemia, hypoproteinemia, AKI, hydrothorax and sepsis in a 56-year-old Jehovah's Witness that underwent implantation of aortic, mitral valves and LVAD. Although blood and albumin transfusion may accelerate recovery, current management was as effective resulting in complications resolution during 10 days.

Learning points: Jehovah's Witness patients require different approach of hemostasis correction in perioperative period. This poses additional mortality and morbitiry risks. In the current scenario, multidirected approach applied to the patient during postoperative period resulted in a successful patient's recovery. «This research is funded by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan (Grant No. AP19677596)»

32AP09-5 AF ablation rare complication gone right

I. Portugal¹, F. Costa¹, M. Pereira¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology department, Coimbra, Portugal

Background: Air embolism is a rare but dreadful complication of invasive medical procedures.(1) We present a case of transseptal puncture for atrial fibrillation (AF) ablation complicated with air stroke and its multidisciplinary approach.

Case Report: A 48-year-old female patient was submitted to an AF ablation procedure under general anesthesia. Immediately following extubation, the patient presented with aphasia and right-sided quadriparesis. High-flow oxygen was initiated, and Computed Tomography angiography and magnetic resonance imaging were performed, showing recent ischemia, but no significant changes in the major cervical or intracranial vessels, including occlusions. The diagnosis of ischemic stroke was established, likely attributed to air embolism and the patient was transferred to an hyperbaric chamber. She was discharged 3 days later with minor sequelae.

Discussion: Cerebral air embolism is rare but may result in severe neurological impairments, including stroke, anoxic brain injury or death.(1,2) During ablation procedures, several mechanisms are potential sources of air entry into circulation and the passage of air from the venous to the arterial system can occur through shunts or incomplete filtration in the pulmonary capillaries.(2) Air embolism requires immediate intervention such as identifying the entry point as expediently as possible by repositioning the patient or endovascular aspiration. To reduce potential ischemia and the size of air bubbles, high-flow oxygen must be implemented, preferably in a hyperbaric chamber, as it creates an hyperoxic environment and increases the solubility of air in the plasma.(3) Prompt suspicion and recognition by the anesthesiologist together with multidisciplinary team of cardiologists and neurologists allowed an unusual almost complete recovery.

- 3. Hyperbaric Oxygen: Its Mechanisms and Efficacy. Plast Reconstr Surg. 2011 Jan;127:131S-141S.

Learning points: Air embolism requires high suspicion levels from the anesthesiologist for diagnosis as well as prompt intervention, as the prognosis is time sensitive.

32AP09-6

Perioperative challenges in acute aortic thrombosis: Ischemia-reperfusion injury leading to cardiac arrest

J. Pereira¹, A.T. Morais Magalhães¹, J. Peixoto Fernandes¹ ¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Acute aortic thrombosis is a rare, but life-threatening condition. Rapid revascularization is essential to minimize ischemic damage, but post-revascularization complications, as ischemia-reperfusion injury and metabolic disturbances, often compromise outcomes.1

Anesthetic management plays a crucial role during these highrisk interventions.

Case Report: A 58-year-old male, ASA IVE, with a history of hypertension, type 2 diabetes mellitus, obesity and chronic alcohol abuse presented with acute bilateral lower limb ischemia secondary to infrarenal aortic thrombosis. He also had myocardial ischemia suggestive of Takotsubo syndrome. Vascular surgery proposed an emergency thromboembolectomy.

The patient was hemodynamically stable but had a severe pain and hypoxemia requiring supplemental oxygen. A general anesthesia was induced with continuous invasive arterial pressure monitoring. Short after, he necessitated a low dose of vasopressor support. Surgery partially restored bilateral lower limbs perfusion, shortly, the patient developed ischemia-reperfusion syndrome with metabolic derangements (hyperkalemia) requiring urgent correction.

Despite aggressive treatment, the patient developed refractory bradycardia, diffuse ST-segment elevation, and worsening hemodynamic instability, culminating in cardiac arrest - asystole. Six cycles of advanced life support restored spontaneous circulation, with arterial blood gases analysis showing severe acidosis and hyperkalemia. Given extensive arterial disease and prolonged arrest, the patient was deemed unsuitable for extracorporeal membrane oxygenation.

Surgery was interrupted, and the patient was transferred to the ICU. Complications included rhabdomyolysis, acute kidney injury and hypoxic-ischemic encephalopathy.

Discussion/Learning points: This case illustrates the intricate challenges of anesthetic management in acute aortic thrombosis, where hyperkalemia emerged as a critical factor in perioperative cardiac arrest, compounded by ischemia-reperfusion and severe metabolic disturbances.

Differentiating hyperkalemia-induced cardiac arrest from acute myocardial infarction was important because precise diagnosis enabled targeted interventions for effective resuscitation, however both could contribute to arrest.

1-Kaschwich, Mark et al. "Management of acute aortic thrombosis." The Journal of cardiovascular surgery vol. 58,2 (2017): 313-320. doi:10.23736/S0021-9509.16.09798-6

32AP09-7

Serratus anterior plane block in transaxillary valve replacement for ERAS application

O. Ananiadou¹, V. Apostologlou², K. Negrou², T. Karaiskos¹, I. Asouhidou^{2,3}

¹G.Papanikolaou General Hospital, Department of Cardiothoracic Surgery, Thessaloniki, Greece, ²G.Papanikolaou General Hospital, Department of Cardiothoracic Anesthesia, Thessaloniki, Greece, ³Aristotle University of Thessaloniki, Laboratory of Surgery and Clinical Anatomy, Thessaloniki, Greece

Background and Goal of Study: One of the criteria for application of ERAS protocol in patients undergoing minimal invasive valve surgery is the efficient pain management. The incision is performed usually in the area of 3rd or 4th intrercostal space. which receives rich innervation from the long thoracic and thoracodorsal nerve. Successful perioperative pain control is essential for less opioid consumption, less pain and stress and early extubation.

We report our experience of 60 patients undergoing valve surgery with right transaxillary thoracotomy under general anesthesia and serratus anterior plane block-SAPB.

Materials and Methods: Patients were admitted for elective aortic valve replacement through right transaxillary access. Anesthesia was induced with midazolam 4mg, fentanyl 2-3mcg/kg and rocuronium 0,6mg/Kg. Anesthesia was maintained with dexmedetomidine 0.7mcg/Kg/min and sevoflurane was adjusted in order to maintain a BIS value between 40 and 50. The block was performed under ultrasound guidance. The needle was placed in the 3rd and 4th intercostal space between serratus anterior muscle and pectoralis major muscle in order to block thoracodorsal and long thoracic nerve. A single injection of 10ml 0,5% ropivacaive in each space is adequate.

Before the end of the operation, following rib approximation, we introduce a continuous infusion catheter with 0,2% ropivacaine at a flow rate of 7-12 ml/h. Postoperative experience of pain was measured using a numerical pain scale (NRS 11[Numeric Rating Scale]).

Results and Discussion: 37 patients who underwent transaxillary valve surgery were enrolled in this study, 22 men and 15 women with mean age: 67.7±7.3. Time of extracorporeal circulation was 105± 18.5min and the aortic cross clamping time (Xclamp) was 60±15min. Total intraoperative fentanyl requirements were 0,4-0,7mg (0,2-0,3mg were administered at induction of anesthesia). All patients received 100mg tramadol at the end of the procedure. 10 patients were extubated in the operating room while the others in the following hours. None of them received opioids postopera-

Conclusion(s): Preemptive analgesia and treatment of pain is of particular importance for early extubation and rehabilitation of a patient undergoing valve surgery through thoracotomy. The serratus anterior plane block is a safe option to block the nerves that innervating the lateral thoracic wall, providing a postoperative course free of pain and opioids.

32AP09-10

Successful extracorporeal cardiopulmonary resuscitation and transcatheter aortic valve replacement in a patient with severe aortic stenosis

P. Bukirova¹, A. Zagrebelnyi¹, B. Zhakupbekov¹, I. Wachruschew¹, D. Ayaganov¹, O. Musali¹ ¹University Medical Center Heart Center, Cardiac anesthesiology and ICU, Astana, Kazakhstan

Background: Severe aortic stenosis is the most common valvular disease associated with a high mortality. Around three per cent of elderly people who reached 65 years suffer from aortic stenosis [1]. Causes include congenital (bicuspid/unicuspid valve), calcification, and rheumatic disease. Cardiogenic shock is one of the most serious complications before and during transcatheter aortic valve replacement (TAVR) procedures.

Case Report: A 58-year-old woman was admitted to an ICU complaining on severe dyspnea, chest pain, and mental confusion. Past medical history included: symptoms duration for 2 years, PCI, DM II, BMI41 kg/m2.

Physical exam revealed systolic murmur in the 2nd ICS along the right sternal border. ECG demonstrated sinus rhythm with STsegment depression in anterior and posterior leads. TTE parameters: LVEDV - 95 ml, EF - 52%; AV MG- 85.0 mm Hg. Thirty minutes min after admission refractory VF and cardiac arrest started. CPR was initiated.

Activities performed: Intubation, CPR (40 min), vasoactive and inotropic support, and then VA-ECMO. Peripheral VA-ECMO was implanted with technical difficulties due to patient's obesity. VF still persisted. On full ECMO, with vasoactive and inotropic drugs along with mechanical chest compressions, angiography ruled out any acute events.

Urgent TAVR was conducted. TEE final showed minimal paravalvular regurgitation. After TAVR, the patient was transferred to the ICU.

On the 2nd day: improved general condition, no neurological complications.

On the 3rd day: ECMO was explanted, duration comprised 2 days. On the 4th day: the patient was extubated and transferred from the ICU the following day.

Discussion: Patients with severe aortic stenosis should be closely monitored, especially in case of concomitant coronary artery disease which can deteriorate into refractory VF und cardiogenic shock. Application of ECMO is a preventative and protective for hemodynamics support during transcatheter aortic valve replacement.

Reference:

References: 1. Grimard, B., Safford, R., Burns, E. 'Aortic Stenosis: Diagnosis and Treatment' Am Fam Physician. 2016;93 (5):371-

Learning points: Successful ECPR with TAVR allowed complete patient's recovery in a short term without neurological complications

«This research is funded by the Science Committee of the Ministry of Science and Higher Education of the Republic of Kazakhstan (Grant No. AP19677596)»

32AP09-11

Challenges in balancing cardiac and renal care: A case of post-CABG deterioration linked to LIMA graft flow and AV fistula dynamics

P. Tapuria¹, A. Majeed¹, U. Puar¹, O. Oluwatosin¹ Glenfield Hospital, Cardiac Anaesthesia, Leicester, United Kingdom

Background: This case highlights the challenges of managing high-risk cardiac surgery in a patient with end-stage renal disease (ESRD) on hemodialysis via an arteriovenous (AV) fistula. A 71-year-old male with prior myocardial infarction (MI), multiple percutaneous coronary interventions (PCI), non-ST-elevation MI (NSTEMI), atrial fibrillation on novel oral anticoagulants (NOAC), and type 2 diabetes mellitus (T2DM) underwent elective coronary artery bypass grafting (CABG) with left internal mammary artery (LIMA) to left anterior descending artery (LAD) grafting, left atrial appendage occlusion, and ascending aorta replacement for a dilated aorta.

Case Report: Preoperative discussions addressed the risk of AV fistula dysfunction due to LIMA grafting. Postoperatively, the patient was stabilized on minimal noradrenaline support in the intensive care unit (ICU) and managed with continuous venovenous hemofiltration (CVVH) via a new right internal jugular vein vascath. After six days in the ICU, he was transferred to the ward, and dialysis resumed via the left AV fistula.

On postoperative day 10, the patient developed cardiogenic shock with poor left ventricular (LV) function and global hypokinesia, raising concerns about LIMA graft flow compromise.

Discussion: This case underscores the potential for AV fistula use to impact LIMA graft flow due to vascular steal or other hemodynamic factors, particularly in patients with ESRD.

While LIMA grafting offers long-term patency, its interaction with AV fistulas poses risks that are not fully addressed in current literature. A multidisciplinary approach and close monitoring are crucial to identify and address such complications.

References:

- 1. Loop FD et al., "Influence of the internal-mammary-artery graft on long-term survival after coronary artery bypass grafting,"
- 2. Galla JD et al., "Outcomes of coronary artery bypass grafting in hemodialysis patients," Circulation, 2004.
- 3. Watanabe Y et al., "AV fistula-related vascular steal and its impact on coronary artery bypass graft flow," Journal of Cardiac Surgery, 2019.

Learning points:

- · Preoperative planning for CABG should consider the impact of AV fistulas on LIMA graft flow.
- · Multidisciplinary collaboration is essential to mitigate risks in ESRD patients dependent on dialysis.
- · Early detection and management of graft insufficiency can improve postoperative outcomes.

Anesthesiology management during off-pump implantation of Left Ventricular Assist Device: case series

S. Tulegenov¹, A. Turarova¹, S. Novikova², Y. Zuparov¹, D. Zhuparkhan¹, D. Seydanov¹ ¹University Medical Center Heart Center, Cardiac anesthesiology and ICU, Astana, Kazakhstan, 2University Medical Center Heart Center, Cardiac Surgery, Astana. Kazakhstan

Background: The off-pump approach for HeartMate III (HM3) implantation offers potential advantages, including reduced complication rates, faster recovery times, and decreased exposure to systemic inflammation. However, the absence of cardiopulmonary bypass presents anesthetic challenge due to reduced hemodynamic stability. This case series describes our single-center experience managing three consecutive patients who underwent off-pump HM3 implantation from May 2024 to June 2024.

Our goal was to determine if this method was safe and feasible for patients with unique comorbidities requiring tailored perioperative strategies.

Case Report: Patient 1 had biventricular heart failure with coagulopathy secondary to cirrhosis, necessitating meticulous management of bleeding risk and coagulation. Patient 2 presented with a recent acute ischemic stroke, requiring careful hemodynamic control to minimize cerebral complications. Patient 3 had heparininduced thrombocytopenia and pulmonary embolism, posing significant challenges to maintaining adequate hemostasis without the use of a bypass machine.

Discussion: All patients demonstrated favorable outcomes. The median time to extubation was 10.8 hours, with a median intensive care unit (ICU) length of stay of 4.9 days. Hemodynamic improvements were observed, with a mean cardiac index increase from 1.6 L/min/m² pre-implantation to 2.0 L/min/m² postoperatively and a reduction in mean pulmonary artery pressure from 28 mmHg to 15 mmHg. No patients required mechanical support for the right ventricle.

Only the patient with thrombocytopenia required postoperative transfusion, receiving 3 units of platelets.

Notably, these transfusion volumes were significantly lower than those typically required for on-pump HM3 implantations at our center.

Learning points: In this single-center study, we describe the anesthetic considerations for off-pump HM3 implantation. Our results suggest that this approach is a safe and feasible alternative to traditional techniques, offering a potential benefit for high-risk patients with complex comorbidities.

32AP10-4

Case report: anesthetic management of retroperitoneal fibroma excision in a patient with complex congenital cardiomyopathy

M. Almeida Santos¹, P.M.M. Dias¹, S. Lourenço¹, M. Coelho¹, L. Ormonde¹ ¹ULS Santa Maria, Anesthesiology Department, Lisboa, **Portugal**

Background: Complex cardiomyopathies, present unique perioperative challenges. Even after corrective surgery, meticulous anesthetic and cardiovascular management is required.1 This report illustrates the anesthetic approach of a retroperitoneal fibroma excision in a patient with neurofibromatosis type II (NFII) and surgically corrected complex cardiomyopathy with tricuspid valve atresia, CIV, transposition of the great vessels and coartation of the aorta.

Case Report: A 22-year-old female with a history of Fontan procedure, and NFII, was proposed for laparotomic excision of a retroperitoneal fibroma. The patient's non-pulsatile pulmonary circulation and highly variable O2 saturation levels, ranging between 80-100%, made avoiding increase pulmonary pressure and consequent shunt effect and hypoxemia essential.

TIVA using Etomidate, fentanyl, lidocaine and rocuronium, for induction, followed by maintenance with propofol and remifentanil, was selected. Invasive blood pressure monitoring, and cardiac output was monitored using FloTrac system.

Targets of CO of 7.0L/min were set. Fluid therapy and the effects of mechanical ventilation were monitored and adjusted. A T9-T10 epidural catheter was placed, for postoperative analgesia. No hemodynamic instability, need for aminergic support or significant blood loss was registered.

On leaving the operating room, the patient was alert, extubated, with ventilation patterns and hemodynamic status within normal ranges. With adequate pain control, the patient was transferred to the ICU for monitoring. Postoperative recovery was without complications.

Discussion: This case highlights the anesthetic challenges in managing patients with Fontan physiology. The choice of TIVA minimized myocardial depression, while real-time cardiac output monitoring guided fluid and hemodynamic management. Existing literature supports the importance of tailored anesthetic plans in such high-risk patients.2

References:

1. Folley, Matthew MD*†; Colan, Steven D. MD†; Rhodes, Jonathan MD†; DiNardo, James MD*. Fontan Physiology Revisited. Anesthesia & Analgesia 121(1):p 172-182, July 2015. 2. Adler AC, Nathan AT. Perioperative Considerations for the Fontan Patient Requiring Noncardiac Surgery. Anesthesiol Clin. 2020 Sep;38(3):531-543.

Learning Points: Patients with Fontan physiology require precise anesthetic strategies. TIVA and advanced cardiac output monitoring are effective tools. Multidisciplinary planning is crucial for optimizing outcomes.

Placement of the Tendyne™mitral valve system: description of the first two cases

M. Grao Roca¹, S. González-Suárez¹ ¹University Hospital Vall d'Hebron, Department of Anesthesia, Barcelona, Spain

Background: The Tendyne™ mitral valve prosthesis is a selfexpandable, retrievable device, offering a potential solution for patients with severe mitral regurgitation (MR) who are not candidates for surgery. This valve supports three porcine pericardial leaflets and is anchored to the cardiac apex with a Teflon epicardial cushion. We report the first two cases of implantation at our hospital.

Case Report: Both patients were over 75 years old, hypertensive, with a glomerular filtration rate of 30 mL/min and ischemic heart disease. The first patient's echocardiogram showed LVEF 40%, dilated left atrium (LA) (57 mL/m2), severe MR with restrictive posterior leaflet, moderate pulmonary hypertension and preserved right ventricle function (RVF). The second patient had LVEF 26%, LA dilatation (80.9 mL/m²), severe MR, moderate tricuspid regurgitation and severely depressed RVF.

Anaesthetic monitoring included BP, CVP, SpO2, ECG, BIS™, cerebral oximetry and pulmonary pressures (Swan-Ganz in the second patient). Fentanyl, midazolam, etomidate and atracurium were used for anesthetic induction. Transesophageal echocardiography (TEE)-guided access using the finger test. Both cases required a left mini-thoracotomy with the collaboration of cardiac surgeons and interventional cardiologists. A Tendyne 33S LP prosthesis was implanted in the first patient and a 33M LP in the second, with positioning confirmed by 3D TEE.

Postoperatively, the first patient required levosimendan for heart failure and had a mean mitral gradient of 4.5 mmHg with moderate LVOT obstruction. The patient was discharged after two weeks. The second patient required reintervention due to bleeding, developed severe tricuspid regurgitation and cardiogenic shock, leading to death.

Discussion: The Tendyne[™] valve is indicated for patients with severe MR, life expectancy <5 years, LVEF ≥30%, LVEDD ≤7.0 cm and unsuitability for surgical repair (1).

While the device has a 97% success rate, postoperative complications, including morbidity and mortality, remain significant. Depressed RVF seems to be partially responsible for the poor postoperative outcome in the second patient.

Reference:

1. Cobiella. Rev Esp Cardiol 2021;74:881.2.

Learning Points: Multidisciplinary selection is crucial for high-risk patients who are not candidates for other interventions. Echocardiography plays a key role in assessing MR severity and mechanisms, pulmonary artery pressures and RVF, which are important prognostic factors.

32AP10-6

Anesthesia management in abdominal aortic aneurysm surgery in a 28-week pregnant patient: a case report

B.M. Hanedan¹, B. Hanedan¹ 1konya city hospital, Anesthesiology and Reanimation, Konya, Turkey

Background: Aortic aneurysm during pregnancy is a rare but highly fatal condition. Hemodynamic changes pose risks to both the mother and fetus. However, pregnancy limits the use of ionizing radiation traditionally employed during imaging in stent repair procedures.

Case Report: A 39-year-old woman at 26+4 weeks of pregnancy with a history of thyroid disease and two previous cesarean sections was diagnosed with an abdominal aortic aneurysm (AAA) during routine obstetric examination. Urgent abdominal ultrasound revealed an aortic diameter of 76 mm in a 13 cm-long segment. EF 55%, mild mitral and tricuspid regurgitation, PAP: 23 mmHg.

Simultaneous cesarean section and AAA surgery were planned for 28 weeks of gestation. General anesthesia was induced with propofol and rocuronium and maintained with sevoflurane. The obstetric team first performed the cesarean section first, delivering a live infant weighing 900 g with an APGAR score of 2 at 1 minute.

Following delivery, fentanyl and lidocaine were administered, and a remifentanil infusion was initiated. Due to uterine atony unresponsive to all medical and surgical interventions a supracervical hysterectomy and bilateral salpingectomy were performed.

Cardiovascular surgery addressed the aneurysmal aorta(13×7.5×7) with an iliac bifurcated graft. Tranexamic acid (10 mg/kg) was given during graft anastomosis, followed by a continuous infusion (1 mg/kg/h).

Blood loss was managed with a cell saver device, totaling 1300 mL, necessitating transfusion of one unit of erythrocyte suspension and one unit of fresh frozen plasma. Hypotension was treated with a norepinephrine infusion at 0.4 mcg/kg/min. The clamp time was 50 minutes, with stable arterial blood gas values.

The patient was discharged 20 days later with recommendations for cardiovascular surgery follow-up.

Discussion: Pregnancy-associated AAA is rare but carries a high risk of rupture, making early detection critical. This patient lacked common risk factors for aortic dissection, such as Marfan syndrome, Ehlers-Danlos syndrome, bicuspid aortic valve, or Loeys-Dietz syndrome.

Patients with an aortic root diameter of <4 cm may be considered for vaginal delivery, whereas cesarean delivery is recommended for those with a diameter >4 cm due to the risk of aneurysm progression and dissection.

Learning points: Early recognition and multidisciplinary planning are essential in managing AAA during pregnancy. Intraoperative anesthetic management and blood loss control, including the use of cell saver devices and vasopressors, are critical for maternal and fetal outcomes.

Anesthetic considerations in Libman-Sacks endocarditis with severe valve involvement and superinfection in a patient with systemic Lupus **Erythematosus: A Case Report**

L. Navarro Diez1, J.A. Cortés Vásquez1, J.R. Beltran Melgarejo¹ ¹National University of Colombia, Anesthesiology and Resuscitation, Bogotá, Colombia

Background: Libman-Sacks endocarditis (LSE) is a thrombotic endocarditis with sterile vegetations, typically affecting mitral (66%) and aortic valve (25%). It occurs in 10% of patients with systemic lupus erythematosus (SLE), often presenting with mild valve regurgitation and 4-6% require surgical intervention [1].

Case Report: A 34-year-old male presented with fever, jaundice. aortic murmur and a LVEF of 46% by TEE (bicuspid aortic valve with severe insufficiency), along with a filiform vegetation on the ventricular cusp (21x6 mm), without abscess. Blood cultures were negative and complement levels decreased, but Coxiella burnetii antibodies, rheumatoid factor and ANCAs were positive. He also had membranoproliferative nephropathy class IV.

The patient was diagnosed with LSE and bacterial superinfection, undergoing aortic valve replacement, left ventricular outflow tract enlargement and endocardial resection.

Anesthetic induction was uncomplicated, with 400 IU/kg of sodium heparin (UFH), an ACT of 426 and 1000 cc of Custodiol for extracorporeal circulation (ECC). The patient was weaned from CPB without complications. Postoperatively, he required norepinephrine, milrinone, 2 units of RBC and protamine (28,000 IU). A normal TEG was recorded. He was extubated on postoperative day 1, received hydroxychloroquine and methylprednisolone, being discharged on day 7.

Discussion: LSE is commonly associated with malignancies, SLE, and antiphospholipid syndrome. It is rare for SLE patients to present initially with LSE [3]. Superinfection is excluded, as its treatment could worsen disease progression and increase morbidity

Treatment includes anticoagulation, corticosteroids and surgery, particularly in cases with severe valvular dysfunction, large vegetations and recurrent embolization [3].

In patients requiring ECC, UFH dosage should be adjusted based on ACT, or if contraindicated, bivalirudin or argatroban may be

However, in APS patients with hypofibrinogenemia, ACT may be prolonged, leading to false positives, thus real-time viscoelastic testing is necessary for accurate monitoring [3]

References:

- 1. Medicine.2023Feb;102(7):e32979
- 2. ReumatolClin.2018Sep-oct;14(5):269-277
- 3. RheumatolInt.2022Dec;42(12):2097-2107

Learning Points: There is no consensus on intraoperative management of superinfected LSE in cardiac surgery. For anesthesiologists, monitoring anticoagulation and administering blood products is challenging due to the risk of thrombosis and bleeding.

32AP10-9

Anesthesia management and continuous positive airway pressure (CPAP) settings in thoracoscopic surgery with ventilated lung total collapse

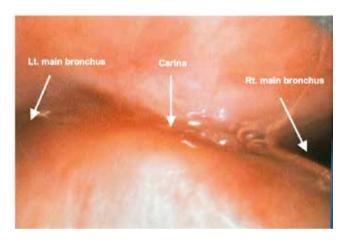

T.C. Lin¹, H.W. Cheng¹

¹Taipei Veterans General Hospital, Anesthesiology, Taipei, Taiwan

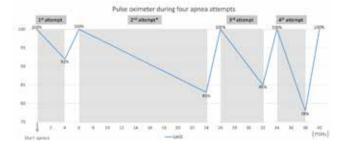

Background: Managing total collapse of the ventilated lung during video-assisted thoracoscopic surgery (VATS) poses significant challenges. This report highlights continuous positive airway pressure (CPAP) and intermittent apnea ventilation strategies to address these challenges and examines their impact on apnea duration.

Case Report: This is a 66-year-old female with non-small cell lung cancer of the right middle lobe (RML), undergoing VATS RML wedge resection.

A double-lumen endotracheal tube (DLT) was initially placed, but a fiberscope examination revealed total occlusion of the left main bronchus.

The DLT was replaced with a single-lumen endotracheal tube. During surgery, intermittent apnea ventilation was applied. Four apnea attempts were made, with FiO2 set to 100% and gas flow at 1.5 L/min. Apnea durations were 4, 17, 6, 5 minutes respectively. Continuous CPAP (APL valve 30 cmH2O) during the second apnea attempt significantly prolonged the apnea duration. Postoperatively, the patient was extubated and transitioned to a highflow nasal cannula.

Discussion: Potential options in this situation include extracorporeal membrane oxygenation support, intermittent apnea ventilation, and selective lobar bronchial blockade. Using bronchoscopic laser to open the collapsed bronchus is also viable(1). However, this method was unavailable due to a lack of equipment. Anesthesia management requires a balance between ventilation support and surgical needs, with continuous monitoring of arterial blood gases.

Reference:

 Ursula Galway. Anesthetic considerations for bronchoscopic procedures: a narrative review based on the Cleveland Clinic experience. J Thorac Dis. 2019 Jul; 11(7): 3156–3170.

Learning Points: This case present the efficacy of CPAP in extending the duration of apnea during VATS with total lung collapse, and provide a reference for similar clinical settings.

32AP10-10

The new role of the anesthesiologist in thoracic surgery: key to achieve better outcomes

L. del Río Prieto¹, C. Armesto Castro¹, E. Conesa López¹, F. López Lence¹, J. Vigo Garay¹, D. Benguria Puebla¹ ¹Hospital Universitario Doce de Octubre, Anesthesiology, Madrid, Spain

Background: In thoracic surgery, bronchial closure and anastomosis are tecnically simple; however, they concentrate most of the complications (fistula, stenosis, dehiscence) with high morbidity. The use of fibrobronchoscopy by anesthesiologists is frequent to check the correct placement of the double-lumen tube. Since the skill in handling it's increasing, it could be considered a useful tool to reduce complications.

Case Report: A 56-year-old woman with a diagnosis of endobronchial carcinoid tumor. In addition, Von Willebrand's disease, right bullectomy for recurrent pneumothorax in 2008 and pneumonia with hospital admission in 2024. Left upper lobectomy with bronchoplasty by thoracotomy under general anesthesia was performed without incident.

Prior to surgery, fibrobronchoscopy was performed to confirm the position and size of the lesion (Fig1). Subsequently, serial fibrobronchoscopies were performed for endoluminal control of the stump and to rule out complications in the surgical site (Figure).

Figure.

Discussion: This is a patient with a higher risk of bleeding and with a history of severe pneumonia, so the use of a tool such as bronchoscopy could be interesting to reduce the risks associated with surgery. Anesthesiologists are becoming increasingly skilled in the use of the fibrobronchoscope, and we consider that routine endoluminal control of the stump intraoperatively would help to evaluate possible narrowing of the bronchus and rule out active bleeding. In addition, bronchoalveolar lavage could protect the lung against infection and prevent postoperative complications.

Reference:

Geyik FD, Dogruyol T, Kahraman S, Arslan G, Saracoglu KT, Demirhan R. Short-Term Outcomes of Fiberoptic Bronchoscopyguided Resection and Anastomosis Control in Thoracic Surgery. Surgical Laparoscopy, Endoscopy & Percutaneous Techniques. diciembre de 2022;32(6):673-6.

Learning Points: Although further studies are needed, controlling the surgical bed with the fibrobronchoscope potentially reduces complications. Increasing the training of anesthesiologists with the fibrobronchoscope will improve outcomes in the future.

32AP10-11

A risk prediction score for acute kidney injury following thoracic surgery

T. Pipanmekaporn¹, K. Jomjai¹, P. Leurcharusmee¹, P. Lapisatepun¹, N. Bunchungmongkol¹, W. Sukhupragarn¹ ¹Faculty of Medicine, Chiang Mai University, Anesthesiology, Chiang Mai, Thailand

Background and Goal of Study: Acute kidney injury (AKI) is considered one of the most common complications following thoracic surgery. AKI is frequently associated with significant morbidity and mortality. The purpose of this study was to develop an AKI prediction score for patients undergoing thoracic surgery.

Materials and Methods: A retrospective cohort study was conducted. All consecutive patients undergoing noncardiac thoracic surgery at a tertiary university hospital between 2012 and 2022 were enrolled. The outcome of interest was AKI within 7 days after surgery. AKI was diagnosed based on serum creatinine criteria from the Kidney Disease Improving Global Outcomes (KDIGO). The univariable and multivariable logistic regression were analyzed and presented with odds ratio and 95% confidence interval (CI). Diagnostic function of the model was determined by area under the receiver operating curve (AuROC). Risk scores were categorized into three groups; low, moderate and high risk. Risk of AKI were presented as likelihood ratios of positive (LH+).

Results and Discussion: A total of 1568 patients were included over 12-year period, and 15.8% (241 of 1568 patients) developed AKI. The significant predictors for AKI were American Society of Anesthesiologist physical status 2 and 3, higher body mass index (> 25 kg/m²), low serum albumin (<3.5 mg/dL) reduced baseline estimated glomerular filtration rate (eGFR) < 60 mL/min/1.73 m², and low intraoperative urine output (<0.5 ml/kg/h). The summation of the score was 9.5 and had a discriminative ability for predicting AKI at AuROC = 0.67 (95% CI : 0.63–0.71). The model was well calibrated with a Hosmer-Lemeshow goodness-of-fit of 4.23 (p = 0.517). LH+ for AKI were: low risk = 0.77 (0.70-0.85) and high risk = 7.37 (0.70-0.85).

Conclusion(s): This study developed an AKI prediction score for thoracic surgery. This score can be used to identify high risk patients, adjust modifiable risk factors and apply preventive strategy in order to improve postoperative outcomes.

Severe intra- and post-operative lactic acidosis in robotic thoracoscopic surgery

M. Pugachov¹, A. Smirnov¹, M. Semionov¹, D. Frank¹, D. Margulis¹, S. Kropveld¹ ¹Soroka Medical Center, Ben-Gurion University of the Negev, Division of Anesthesia and Critical Care, Beer-Sheva, Israel

Background: Lactic acid accumulation in the blood can cause a high anion gap metabolic acidosis and precipitate negative hemodynamic and metabolic consequences. It happens when lactic acid production exceeds its clearance. It can also result from many conditions, such as impaired tissue oxygenation, decreased oxygen delivery, or a leak in mitochondrial oxygen utilization. There are rare cases of severe lactate elevation in the intraoperative period. Here, we will describe a rare case report during thoracoscopic surgery.

Case Report: A 72-year-old patient with a history of IHD, DM, and HTN was admitted for thoracoscopic robotic left upper lobe lobectomy due to SCC; he completed three courses of chemotherapy and immunotherapy with an excellent response. After two hours of surgery, the blood level of lactate unexpectedly rose to 2.5 mmol/L, progressively elevated, and peaked at the end of the surgery (overall, 8.5 hours), the lactate level reached 10.2 mmol/L with the development of severe lactic metabolic acidosis. Because of life-threatening conditions, fluid boluses were administered, with no improvement in lactate levels and elevation in urinary output. The patient was transferred to the ICU, where thiamine treatment was started.

Discussion: The pathogenesis of this state in our case is not fully clear, it could be induced by chemotherapy, during tumor manipulation by a surgeon "Warburg effect". The successful recovery of blood lactic levels after thiamine treatment might point towards thiamine deficiency as a possible cause of lactic acidosis.

Learning points: We propose that determining the thiamine blood level would exclude a probable thiamine deficiency from differential diagnoses in case of severe lactic acidosis before or during major thoracic surgeries. "Warburg effect" is a rare phenomenon of Lactic acid production by neoplastic cells, the effect of thiamine in lactic acid metabolism is well known, but the role of thiamine treatment is still debatable.

Thoracic Anaesthesia

33AP01-1

Challenge for the anaesthesiologist: management of tracheal perforation

J.A. Campov Moreno¹, D. Benguría Puebla¹,

J. Silva García¹, M. Mas Moraza¹, I. Merino Santana¹, P. González Pérez¹

¹Hospital Universitario 12 de Octubre, Anaesthesiology, Madrid, Spain

Background: Tracheal perforation is a rare but potentially lifethreatening complication that can occur following a variety of surgeries. Anesthetic management requires immediate control of the airway, minimising tracheal trauma and ensuring adequate ventilation.

Case Report: A 30-year-old woman, ASA I, with history of a laparoscopic cholecystectomy surgery two days earlier, presented with extensive subcutaneous emphysema and moderate dyspnea. A fibreoptic bronchoscopy (FOB) in ICU under sedation with dexmedetomidine revealed a 3 cm tracheal rupture near the carina.

The patient was taken to the operating room for repair through right thoracotomy. Rapid sequence induction and intubation was performed under direct laryngoscopy with flexometallic endotracheal tube No. 7, with selective FOB-guided intubation of the left main bronchus. The patient tolerated one-lung ventilation, without requiring ECMO support. After the procedure, she was transferred to the ICU for a controlled extubation in the following

Discussion: The management of tracheal injuries represents a significant anesthetic challenge. It is generally preferable to perform guided intubation with FOB to minimize additional airway trauma2.

In terms of ventilation, the objective is to achieve an appropriate balance between adequate oxygenation and protective ventilation. It is important to avoid increasing pressure, as this may aggravate the injury1,2.

It is recommended that volatile anaesthetics be avoided during maintenance to reduce inflammation, improve healing and prevent worsening of subcutaneous emphysema2.

Extubation is a critical point, a early extubation may increase the risk of dehiscence and prolonged ventilation increases the risk of barotrauma and infection.

References:

1. Schleicher A, Groeben H. Anesthetic Considerations for Tracheobronchial Surgery. Journal of Thoracic Disease. 2020;12(10):6138-6142.

2. Hatipoglu Z, Turktan M, Avci A. The Anesthesia of Trachea and Bronchus Surgery. Journal of Thoracic Disease. 2016;8(11):3442-3451.

Learning Points:

- · A multidisciplinary approach is essential to prevent life-threatening complications.
- · FOB-guided intubation is recommended to minimize tracheal
- · Anesthetic management and protective ventilation attempt to prevent worsening of the tracheal injury.
- · Postoperative care should maintain airway integrity and assess the risk/benefit of early extubation.

33AP01-2

Comparison of erector spina plan block and retrolaminar block for video-assisted thoracopic post-surgery analgesia

Y. Gudek¹, M.B. ESKİN¹

¹Gulhane Training and Research Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background and Goal of Study: In our study, it is aimed to compare the analgesia efficacy of these two blockades by performing ultrasound-guided erector spina block and retrolaminar block in patients undergoing video-assisted thoracoscopic surgery.

Materials and Methods: This study was started after obtaining ethics committee approval from Health Sciences University Gülhane Training and Research Hospital Clinical Research Ethics Committee. Fifty-four patients, ASA I-II, aged between 18-81 years, who would undergo video-assisted thoracoscopic surgery, were included in the study.

The patients were randomized by computer program and divided into 2 groups as Group ESP (n=27) and Group Retrolaminar (n=27). Retrolaminar and ESP blocks were applied to all patients under ultrasound guidance after general anesthesia and preoperatively.

The block fluids of the patients in both groups were adjusted to be 40 ml in total, as 30 ml of 0.5% bupivacaine and 10 ml of 2% lidocaine.1 gr Paracetamol iv was administered to all patients 30 minutes before the end of the surgery.

Postoperative side effects of the patients in the recovery room, the first postoperative analgesic requirement, VAS scores at 1, 6, 12 and 24 hours, total amount of tramadol and diclofenac consumed in 24 hours were recorded.IBM SPSS version 20 (Chicago, IL, USA) program was used for statistics and p<0.05 was accepted as statistical significance limit.

Results and Discussion: When the VAS scores at 1, 6,12 and 24 hours were compared between the retrolaminar group and the ESP group, no significant difference was found (p>0.05). Intraoperative remifentanil consumption was found to be significantly higher in the retrolaminar group compared to the ESP group (p<0.05). No significant difference was found between the groups in terms of nausea, vomiting and other side effects(p>0.05).

	Retrolaminar	ESP		
	Avarage ± SD Median (Min-Max)	Avarage ± SD Median (Min-Max)	Test Statistic	р
VAS 1.hour	4.11±1.98 3 (2-8)	5.33±2.40 6 (1-9)	261.0 °	0.069
VAS 6.hour	3.22±1.18 3 (2-7)	3.15±1.16 3 (0-7)	360.5 °	0.941
VAS 12.hour	2.22±1.28 2 (1-6)	2.70±1.54 2 (0-6)	291.5 °	0.192
VAS 24.hour	1.15±0.94 1 (0-3)	1.52±1.05 1 (0-3)	296.0 °	0.217
Test Statistic d	50.723	44.047		
p	<0.001	<0.001		
Post hoc	1.hr-6.hr p=1.000	1.hr-6.hr p=0.122		
	1.hr-12.hr p=0.007	1.hr-12.hr p=0.004		
	1.hr-24.hr p<0.001	1.hr-24.hr p<0.001		
	6.hr-12.hr p=0.092	6.hr-12.hr p=1.000		
	6.hr-24.hr p<0.001	6.hr-24.hr p=0.001		
c:Mann Whitney U test d:Friedman test	12.hr-24.hr p=0.019	12.hr-24.hr p=0.050		

Conclusion(s): In our study, no difference was found between the two groups in terms of postoperative analgesia consumption and VAS scores. Both blocks can be used as part of multimodal analgesia, but they are not effective alone to provide postoperative analgesia.

33AP01-3

Fluid therapy with gelatines and Cardiac **Surgery-Associated Acute Kidney Injury:** a retrospective observational cohort study

I. Garmendia¹, P. Zumarraga², A. Olalquiaga¹, P. Martinez³, J.A. Fernandez Molina³, M. Vives Santacana^{3,4} ¹Clínica Universidad de Navarra, Department of Anesthesia & Critical Care Medicine, Pamplona, Spain, 2School of Medicine. University of Navarre., School of Medicine. University of Navarre., Pamplona, Spain, 3Clinica Universidad de Navarra, Department of Anesthesia & Critical Care Medicine, Pamplona, Spain, ⁴Instituto de Investigación Sanitaria de Navarra, Instituto de Investigación Sanitaria de Navarra, Pamplona, Spain

Background and Goal of Study: Cardiac Surgery-Associated Acute Kidney Injury (CS-AKI) is among the most common causes of AKI in intensive care units. This study assesses the association between the administration of fluid therapy with gelatines and CS-AKI.

Materials and Methods: Patients who underwent cardiac surgery at the Clinica Universidad Navarra from the 1st of September 2022 to the 31st of August 2023 were consecutively collected. Data used in this study was extracted from either the surgical chart, blood analysis or previous medical cardiac reports. The primary outcome was acute kidney injury (AKI), defined by KDIGO. Pearson Chi-squared test, unadjusted Odds Ratio, and multivariable logistic regression model were developed sequentially in the statistical analysis.

Results and Discussion: 66 patients were included. The overall AKI rate was 33%. No difference in AKI was observed between groups (30.9% vs 37.5%). No difference in AKI rate was observed in the logistic regression analysis adjusting by age, sex, eGFR and EuroSCORE II (adjusted OR 1,66, 95% CI 0,47-5,85, p= 0,428). Patients developing CS-AKI had a higher rate of in-hospital mortality (0% vs 13.6%).

Conclusion(s): In our retrospective observational cohort study, fluid therapy with gelatins was associated with a tendency, not statistically significant, toward an increase in CS-AKI.

Anesthetic management of a patient with Morvan syndrome: A case report

J. Ariño Larrañaga¹, M.I. Zubelzu¹, A. Abad¹, M. Ibarguren¹, I. Hernandez¹. A. Arrequi¹

¹Osakidetza, Anesthesiology and Reanimation, Donostia, Spain

Background: Morvan syndrome (MvS) is an extremely rare autoimmune condition characterized by peripheral nerve hyperexcitability, dysautonomia and encephalopathy, with symptoms such as myokymia, autonomic instability and cognitive dysfunction. It is often associated with autoantibodies targeting voltage-gated potassium channels and frequently linked to thymoma. Anesthetic management is particularly challenging due to profound autonomic dysfunction and so the risk of perioperative complications. including cardiac arrest. Robotic thymectomy first described in 2021, may offer symptom resolution through autoantibody suppression.

Case Report:65 year-old-male with MvS scheduled for elective robotic thymectomy for a thymoma. Prior to surgery,he showed cognitive decline, hallucinations and dysautonomia. Initial treatment with immunoglobulins and steroids resulted in partial improvement, though cognitive symptoms worsened upon discontinuation.

Further investigation confirmed positive Caspr2 antibodies and axonal hyperexcitability. On the day of surgery, the patient showed severe cognitive impairment and respiratory distress.

Anesthesia management included a left-sided double-lumen endobronchial tube for one lung ventilation, a radial arterial line,Bispectral Index,regional oximetry and neuromuscular monitoring.Rocuronium was administered at standard doses. A right serratus intercostal interfascial plane block was performed.

During surgery, the patient showed cardiovascular instability, necessitating a norepinephrine infusion. Following thymectomy, the patient was successfully extubated in the operating room and was discharged to the ward after 24h at the PACU. His neurological condition improved significantly during the next days.

Discussion: MvS anesthesic approach can be challenging due to variable responses to neuromuscular blocking agents and risks of laryngospasm and cardiovascular instability.

Neurological monitoring is crucial due to potential myokymia and encephalopathy, which can affect BIS readings. In our case, no resistance to rocuronium was observed. Monitoring BIS and IN-VOS during surgery helped ensure proper oxygenation and neurophysiological stability.

Learning points: A comprehensive anesthetic approach is crucial and requires careful consideration of neuromuscular blockade. The use of short-acting sympathomimetics and opioids is advised for cardiovascular instability. Neurological monitoring should be interpreted with the understanding that myokymia can affect readings.

Respiratory stability and sedation efficiency of remimazolam in non-intubated video-assisted thoracic surgery: Insights from a retrospective cohort study

C.-K. Ting1, P.-Y. Huang1, P.-K. Hsu2 ¹Taipei Veterans General Hospital, Anesthsiology, Taipei, Taiwan, ²Taipei Veterans General Hospital, Surgery, Taipei, Taiwan

Background and Goal of Study: Single-incision video-assisted thoracoscopic surgery (VATS) is recognized for its safety, efficiency, and minimally invasive nature, offering fewer complications and shorter hospital stays. When combined with non-intubated spontaneous breathing, it further enhances recovery by reducing complications, operating time, and anesthesia duration. Remimazolam, an ultrashort-acting benzodiazepine, features a rapid onset and offset with minimal respiratory depression, making it a promising agent for non-intubated VATS (NIVATS).

Materials and Methods: This retrospective study conducted at Taipei Veterans General Hospital, Taiwan, included 62 patients undergoing single-port NIVATS. Between August 2019 and December 2021, 41 patients received propofol with dexmedetomidine, while 21 patients between January 2023 and December 2023 received remimazolam with dexmedetomidine. The primary outcome was the change in arterial carbon dioxide pressure (ΔPaCO2).

Secondary outcomes included anesthesia duration, surgery duration, and postoperative hospital stay. Propensity score matching was used to control for confounders. Subgroup analyses compared thoracic epidural anesthesia (TEA) with paravertebral block (PVB).

Results and Discussion: The remimazolam group exhibited a significantly smaller increase in PaCO2 (6.84 ± 6.01 mmHg vs. 14.42 \pm 11.55 mmHg; p = 0.0113) and shorter surgery duration (50.19 \pm 26.12 minutes vs. 83.54 ± 24.86 minutes; p < 0.0001) compared to the propofol group.

There were no significant differences in anesthesia duration or postoperative hospital stay. Subgroup analysis revealed consistent outcomes between TEA and PVB groups, supporting the flexibility of remimazolam-based sedation. Importantly, no patients required flumazenil reversal.

Conclusion(s): This study highlights the efficacy and superior respiratory stability of the remimazolam-dexmedetomidine combination in NIVATS.

These findings suggest remimazolam as a viable alternative to traditional agents in this setting. Further research is warranted to validate these results across broader surgical contexts.

Anaesthesia challenges for resection of monster sternal chondrosarcoma and reconstruction of rib cage with 3D implant and local flap. A case report

E.L. Cheng¹, S. Thangavelautham¹, L.W.-T. Kenny¹, S. Shah¹ ¹Singapore General Hospital, Anaesthesiology, Singapore, Singapore

Background: Massive sternal chondrosarcomas are rare malignant tumours arising from the cartilage of the sternum, presenting significant challenges for anaesthesia and surgery. An extensive surgery was performed in this case, involving cardiothoracic, orthopaedic and plastic surgeons.

Case Report: A 71-year-old male presented with a 8 cm sternal mass causing compression on the right heart. Surgical planning necessitated a multidisciplinary approach and operation involved bone marrow harvesting, bilateral VATS resection of sternal mass with bilateral rib resection, reconstruction of the pleural and chest wall defect using Gore-Tex membrane, 3D-printed osteopore implant, and local advancement flap closure.

Invasive arterial line and central venous access was established preoperatively before cardiostable anaesthesia induction. The airway was secured with double lumen endotracheal tube to facilitate one lung ventilation for alternating lungs. Surgery was completed successfully and postoperative period was uneventful.

Discussion: Intraoperative challenges:

- 1. One lung ventilation and ventilation strategies to prevent hypoxia during 12 hour long procedure.
- 2. Various surgical positions involving traction table for femoral bone marrow aspiration and then supine with various table tilts to facilitate VATS and reconstructive surgery.
- 3. Blood, colloid and crystalloid transfusions.
- 4. Analgesia, normothermia and postoperative intensive care. References:

Liu, D. et al (2021). Resection of a giant sternal chondrosarcoma and chest wall reconstruction: a case report. Annals of Translational Medicine, 9(22), 1706-1706.

Learning Points: Anaesthesia plays a critical role in the coordination of multiple disciplines and in providing an appropriate surgical conditions for successful outcome.

33AP01-7 **ESPB in VATS: will it make a difference?**

R. do Vale Miranda¹, N. Maia¹, M. Machado¹, P. Lima¹, M. Guerra¹, A. Santos¹ ¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background and Goal of Study: Video-assisted thoracoscopic surgery (VATS) has become the most widely used surgical technique for lung resection. Adequate multimodal analgesia is essential for patient comfort and preservation of lung function. Erector spinae plane nerve block (ESPB) stands out for its safety and simplicity of execution.

The aim of this study was to evaluate the impact of an ultrasoundguided ESPB on the quality of recovery (QoR) after VATS.

Materials and Methods: After study approval by the institutional ethics committee, a prospective study was conduct to evaluate the QoR after VATS. Exclusion criteria were inability to give consent, age under 18 and ICU admission.

For this study, patients were divided into two groups:

Group 1 received an ultrasound-guided ESPB performed by an anesthesiologist in addition to the standard protocol:

Group 2 followed the standard protocol, which consists of balanced general anesthesia and an intercostal nerve block.

Data collection was carried out from March to August 2024 through the application of the Portuguese version of the "Quality of Recovery 15" questionnaire (QoR15) at 24h after surgery. The QoR15 severity was classified as poor, moderate, good and excellent.1

Continuous variables were compared using the t-test for parametric data and the Mann-Whitney U test for non-parametric data. Categorical variables were analyzed using the chi-square test or Fisher's exact test. IBM® SPSS® v28 was used to perform statistics, with a significance level defined as p < 0.05.

Results and Discussion: Thirty-five patients undergoing VATS were included (60% men; median age of 64.5 years), 74% classified as ASA III. ESPB was performed on twenty-six patients (Group 1). The studied cohort had a mean QoR-15 score of 111.1 ± 30.1, with similar results in both groups. In terms of severity, 60% of the cohort had a moderate QoR-15 score, while 20% achieved excellent or good classifications, and 20% were classified as poor. Group 2 showed a higher percentage of patients with poor scores (33.3%) compared to Group 1 (15.4%), though this was not statistically significant.

Conclusion(s): In this small sample size study, despite the absence of a statistically significant difference, patients undergoing ESPB had a lower percentage of poor QoR-15.

33AP01-8

Estimation of right main stem bronchus length: a crucial criterion for choice of appropriate equipment for lung isolation

V. Apostologlou¹, O. Ananiadou², T. Karaiskos², G. Paraskevas3. I. Asouhidou1,3 ¹G.Papanikolaou General Hospital, Department of Cardiothoracic Anesthesia, Thessaloniki, Greece, ²G.Papanikolaou General Hospital, Department of Cardiothoracic Surgery, Thessaloniki, Greece, ³Aristotle University of Thessaloniki, Laboratory of Surgery and Clinical Anatomy, Thessaloniki, Greece

Background and Goal of Study: Double lumen Tube-DLT or bronchial blockers-BB are widely used for one lung ventilation-OLV. Anatomical variations of the length of the right main stem bronchus- RMB may lead to difficulties in the position of right sided double lumen tube-RDLT or BB. There are some specific clinical situations where the placement of RDLT is mandatory. Normally the length of the RMB is between 1,5-2,5cm. The RDLT has a weirdly shaped eccentric cuff, to prevent the occlusion of the right upper lobe bronchus.

The distance between the tip of the tracheal edge and the Murphy's eye is 2,5cm, even in the 35F DLT. If the length of the patient's RMB is short, then the risk of malposition is high. It is suggested that when the distance between the tracheal carina and the distal margin of the right upper lobe orifice is <23mm, a left sided DLT is more appropriate.

The aim of this study is to measure intraoperatively under fiberoptic bronchoscopy-FOB the distance between the tracheal carina and the middle of the orifice of the right upper lobe -RMBo, in patients undergoing elective thoracic surgery for lobectomy or heart valve replacement and to discuss the application of alternative methods for lung separation for OLV.

Materials and Methods: 20 patients (6 women-14 men) (32-84years old) with a mean height 1,69m (1,84-1,57m) undergoing thoracoscopic lobectomy or thoracoscopic transaxillary valve replacement were included in this study.

The patients were intubated with single lumen tube and before advanced the bronchial blocker for lung isolation we perform the measurements with a 3,8 mm external diameter FOB, in supine

The distance between the tracheal carina and the center of the orifice of the right upper lobe was measured. The measurements were performed twice by two different anaesthesiologists.

Results and Discussion: The RMBo was: 1,15cm (0,5-2,5cm) and it was not correlated with patient's height. Indeed, 4 patients had RMBo <0.8cm and only 2 patients had RMBo>2,2cm. If we consider that the distance between the tip of the tracheal edge and the Murphy's eye is 2,5cm, in only 2 of 20 patients we could introduce safely a RDLT, without the risk of herniation and inadequate ventilation.

Conclusion(s):: It is a pilot study, which however reveals the wide anatomical variation of the length of RMB, the increased percentage of malposition and occlusion of trachea with RDLT. Moreover. the length of the bronchial balloon in a bronchial blocker is 3cm. That means that we should also be careful in a patient with short RMB in order for the trachea not to be occluded, especially during surgical manipulations.

In our patients we have chosen to isolate the lung with Ez Blocker (Rush- Teleflex) because the Y shape makes it difficult to be misplaced and occlude the trachea.

33AP01-9

Impact of intraoperative platelet transfusion on the risk of primary graft dysfunction after lung transplantation: a single-centre retrospective study

X. De Mol¹, F. Carlier^{2,3}, A.-S. Dincq^{1,3}, R. Coulie^{1,3}, T. Planté-Bordeneuve^{2,3}, M. Hardy^{1,3} ¹CHU UCL Namur, Anesthesiology, Yvoir, Belgium, ²CHU UCL Namur, Pneumology, Yvoir, Belgium, ³Université Catholique de Louvain (UCLouvain), Institut de Recherche Expérimentale et Clinique (IREC), Louvain-la-Neuve, Belgium

Background and Goal of Study: Primary Graft Dysfunction (PGD) is a major cause of short- and long-term morbidity and mortality after lung transplantation (LT). Several donor, recipient and technical risk factors have been identified, including blood products transfusion, although evidence remains inconsistent.

We aimed to investigate the association between intraoperative platelet transfusion during LT and the incidence and severity of PGD as primary outcome, and 30-day mortality as secondary

Materials and Methods: This single-centre retrospective study included all adult patients who underwent single or two LT at CHU UCL Namur Hospital, Belgium, between January 2010 and March 2020, after approval from the ethics committee. The definition and grading of PGD were based on the 2016 ISHLT consensus. All chest radiographs performed during the first 72 hours after surgery were reviewed by three authors (XDM, FC, TPB). To determine whether platelet transfusion was an independent risk factor for PGD, multivariable logistic regression analysis was performed.

Results and Discussion: A total of 257 patients underwent LT during the study period. Among them, 51% presented at least one chest X-ray with bilateral diffuse infiltrates over the first 72 hours, compatible with the definition of PGD. Univariate analysis identified an association between PGD and platelet transfusion (p=0.005), preoperative mean pulmonary artery pressure (p=0.02) and intra-operative ECMO (p=0.004). The association between platelet transfusion and PGD remained significant in the multivariable analysis (p=0.02; OR=2.03, 95%CI 1.09-3.78), Platelet transfusion was also associated with PGD severity (p=0.003). Twelve patients died within the first 30 post-operative days with a statistically significant association with platelet transfusion (p<0.001, OR 2.80, 95%CI 1.72-4.56). The low incidence of death precluded multivariable analysis.

Several pathophysiological mechanisms support the association between platelet transfusion and PGD, including platelet-induced inflammation, endothelial dysfunction, microvascular damage, hypercoagulability and immune activation in the already vulnerable lung transplant.

Conclusion(s): This study identified platelet transfusion as a potential risk factor for PGD. Reducing patient exposure to heterologous platelets therefore seems a logical step to improve patient outcome after LT. The use of autologous platelet recovery systems could contribute to this goal.

33AP01-10

Massive transfusion protocol and Factor XIII administration in massive hemorrhage during immediate postoperative care following bilateral lung transplantation with ECMO support: a case report

I. Merino Santana¹. O. González González¹. M. Mas Moraza¹, J. López Buitrón¹, J.A. Campoy Moreno¹, J. Silva Garcia¹ ¹Hospital Universitario 12 de Octubre, Anesthesiology,

Madrid, Spain

Background: Lung transplantation is a definitive surgical treatment for patients with advanced pulmonary diseases; however, it may present a high rate of postoperative complications, with massive bleeding being one of the most severe events.

This can be related to the anticoagulation required during surgery, disseminated intravascular coagulation, and extracorporeal circulation support.

Case Report: A 67-year-old male with a history of diffuse interstitial lung disease underwent a bilateral lung transplant with venovenous ECMO support in the immediate postoperative period. Upon admission to the critical care unit, the patient was hemodynamically unstable, requiring vasoactive drugs, with an oxygen saturation of 86-87% and massive bleeding through chest drains, associated with intraoperative anticoagulation (aPTT > 400). The massive transfusion protocol was activated and Factor XIII was administered. This resulted in decreased bleeding and a significant hemodynamic improvement, allowing for a reduction in the need for vasoactive drugs.

However, due to persistent bleeding, surgical exploration was performed, identifying active bleeding from the right bronchial artery, which was successfully treated with direct sutures. The patient was extubated, removed from ECMO, and discharged without further hemorrhagic episodes.

Discussion: Managing massive bleeding in lung transplant patients with ECMO support represents a significant challenge due to the impact of anticoagulation and the hemostatic dysfunction in these patients. The use of Factor XIII in this case proved effective in stabilizing hemostasis in the context of refractory bleeding. Although the evidence for the empirical use of factor XIII in these scenarios remains limited, it should be considered in the management of patients with ECMO, particularly when other hemostatic measures fail to control bleeding.

References:

- 1. Noitz M. Acquired Factor XIII Deficiency Is Common during ECMO Therapy and Associated with Major Bleeding Events and Transfusion Requirements 2023
- 2. Ziegeler, S. Anesthesiological management of major thoracic surgery with intraoperative ECMO support in adults.

Learning points: The use of factor XIII can be beneficial in the management of refractory massive bleeding in patients with ECMO and lung transplantation and early activation of massive transfusion protocols, including blood products, fibrinogen, and tranexamic acid, is crucial for controlling hemorrhage in these patients.

33AP01-11

Effect of intraoperative goal directed fluid therapy on patient outcomes in patients undergoing thoracoscopic lobectomy in the Era of ERAS

M. Ceteci1, D. Lafli Tunay1, M. Ilginel1, E. Biricik1, F. Karacaer¹, M. Türktan¹ ¹Cukurova University, Anesthesiology and Reanimation, Adana, Turkey

Background and Goal of Study: We aimed to investigate the effect of goal-directed fluid therapy (GDFT) compared to conventional fluid therapy in thoracoscopic lobectomy surgery with ERAS protocol on intraoperative pulmonary oxygenation and 30-day patient outcomes including postoperative morbidity and mortality. The primary outcome measure of the study was the PaO2/FiO2 ratio (change in pulmonary oxygenation) during one-lung ventilation, and the secondary outcomes were postoperative morbidity, quality of recovery, 30-day re-admission, and mortality rate.

Materials and Methods: This randomized controlled study analyzed 80 adult patients who underwent thoracoscopic lobectomy surgery with the ERAS protocol. In addition to standard monitoring in the operating room, all patients underwent Pressure Recording Analytical Method (PRAM) monitoring.

Patients were randomly assigned to GDFT and conventional fluid therapy groups. In the GDFT group, fluid, inotropic agent and/or vasopressor therapy was administered by targeting stroke volume variation (SVV) and cardiac index (CI).

In the control group, fluid and/or vasopressor therapy was administered with the guidance of MAP 65-95 mmHg and urine output at least 0.5 mL/kg/hr. Intraoperative hemodynamic data, amount and types of fluid administered, inotropic and vasopressor agents were recorded. Vital signs, pulmonary, cardiac and other system morbidity, quality of recovery on days 1, 3 and 5, and re-admission to hospital and mortality within 30 days were recorded.

Results and Discussion: The groups were similar in terms of demographic characteristics and preoperative physical findings. Statistically similar results were obtained in the change of PaO2/ FiO2 ratio over time (p=0.282). Both groups were similar in terms of intraoperative hemodynamic data (p>0.05). Statistically similar results were also detected in both groups in terms of patient data on the 1st, 3rd, 5th and 30th days regarding quality of recovery, pulmonary, cardiac and other complications, length of hospital stay and mortality rates (p>0.05).

Conclusion(s): In thoracoscopic lobectomy surgeries with ERAS. intraopertive GDFT does not cause a difference in intraoperative pulmonary oxygenation, postoperative pulmonary, cardiac, renal and infectious complications, quality of recovery, length of hospital stay, 30-day hospital re-admission and mortality rates when compared with conventional fluid therapy.

Lung: Ventilation and Pulmonary Disease in the OR and ICU

33AP02-2

Investigation of the effects of lung protective mechanical ventilation in robotic surgeries performed in trendelenburg position

T. Esin¹, N. Bedirli¹, O. Kurtipek¹ Gazi University, Faculty of Medicine, Anesthesiology and Reanimation, Ankara, Turkey

Background and Goal of Study: Robotic surgery requires general anesthesia, pneumoperitoneum, and the Trendelenburg position, which can impair hemodynamic and respiratory function. Lung protective ventilation aims to reduce these effects.

In our study, we aimed to retrospectively investigate the effects of recruitment manoeuvres (RM) on blood pressure, heart rate, oxygen saturation, airway pressures, compliance and postoperative respiratory complications in intraoperative mechanical ventilation management in patients undergoing robotic surgery in the Trendelenburg position.

Materials and Methods: This study was approved by the Gazi University Hospital Ethics Committee. Robotic surgery patients operated on between 2012-2022 were retrospectively reviewed, 123 underwent fixed PEEP and 135 underwent recruitment manoeuvres with individualised PEEP. RM was performed with the "stepwise PEEP increase" technique during pressure-controlled ventilation; after intubation (T₁), after insufflation (T₂), after positioning (T₃) and after desufflation and position correction (T₄). Patients were divided into two groups as fixed PEEP (Group 1) and individualised PEEP (Group 2). SPSS 21.0 programme was used for statistical analysis. Hemodynamic and respiratory data and postoperative respiratory complications were evaluated by Mann-Whitney U test, Student's t-test and γ2 test. Complementary statistics were presented as frequency, percentage distribution, mean, and median.

Results and Discussion: In our study Group 1, no significant difference in mean arterial pressure(MAP) was observed. In Group 2, MAP was significantly lower at T3 compared to T1 and T4(P<0.05). In intergroup comparison, EtCO₂ was significantly lower in Group 2 than in Group 1 at T2 and T3.

Group 1 also had significantly higher EtCO2 than Group 2 at T3 and T4(P<0.001). Lung compliance was significantly higher in Group 2 than in Group 1 at all times. Respiratory distress was detected to be significantly higher in Group 1 than in Group

Lung-protective mechanical ventilation can reduce perioperative complications, but there is ongoing debate about the best approach. Individualised PEEP after RM, a lung-protective strategy, is crucial for determining when and how it should be applied during surgery.

Conclusion: Our study found that stepwise RM reduced atelectasis, improved compliance, decreased EtCO, while increasing PaO₂ and SpO₃, lowered postoperative respiratory complications in patients.

33AP02-4

Description of the incidence of atelectasis in robotic surgery under extreme Trendelenburg using Air-Test and lung ultrasound

S. Moreno Jurico¹, L. Zattera¹, M.Á. Duran González¹, M. Sangrà Puig¹, Á. Barranco De Santiago¹, M. Vendrell Jordà¹ ¹Hospital Clinic, Anaesthesiology, Barcelona, Spain

Background: The anesthetic-surgical process is associated with changes in respiratory function that can manifest as postoperative pulmonary complications. The most common are atelectasis (AT), that can lead to respiratory failure, ultimately increasing morbidity, mortality and healthcare costs. Certain surgical positions, such as extreme Trendelenburg (T>320), can worsen this phenomenon (1).

Novel methods such as the Air-Test (2) and lung ultrasound (LUS) (3) allow the anesthesiologist to detect AT early and manage them accordingly, either intraoperatively or postoperatively.

Primary objective: To evaluate the overall incidence of AT in patients undergoing urological surgery in the T>32° position.

Secondary objective: To study the performance of the Air-Test to detect postoperative AT diagnosed by LUS.

Materials and Methods: This is a single-center prospective observational study. Inclusion criteria were all patients >18yo undergoing robotic urological surgery in T>32°. Exclusion criteria were baseline oxygen saturation less than 97%, and refusal to participate.

Patient characteristics, as well as length of surgery and ventilatory parameters were recorded. LUS, AirTest and PaFI were performed at different time-points throughout surgery. AT was defined as an increase in LUS score (PACU timepoint - basal timepoint) greater than 2.

Mann-Whitney U test and Fisher's exact test were used for continuous and categorical variables, respectively. Diagnostic performance of Air-Test against LUS was evaluated by calculating sensitivity, specificity, positive predictive value, negative predictive value, and accuracy. Agreement was assessed using McNemar's test. A two-tailed significance level of 0.05 was considered statistically significant.

Results and Discussion: Between June and October 2024, we included 28 patients (92.9% males). Overall incidence of AT was 38.6%. Among factors associated with AT we found higher BMI (28.3 (26.9-30.2) vs 25.3 (24.0-27.5) Kg/m², p= 0.041), higher proportion of ASA III-IV status (5 (45.5%) vs 0 (0%) p= 0,001) and lengthier T>32° (190 (166.5-211.5) vs 116 (110-150) min, p<0.001). Sensitivity and specificity of the Air-Test to detect atelectasis by LUS were 40% and 81.2%, respectively, with a McNemar p value

Conclusion: in our cohort BMI, ASA status and T>320 time were associated with atelectasis. Air-Test performed as a reliable tool to diagnose postoperative atelectasis.

33AP02-5

Complications associated with high frequency jet ventilation (HFJV) during rigid bronchoscopy, a 5 years retrospective study

C. Maeyens¹, D. Leduc², J.-F. Fils³, T. Tuna¹, D. Schmartz¹ ¹H.U.B - Hôpital Erasme. Université Libre de Bruxelles (ULB), Dpt. of Anesthesiology, Bruxelles, Belgium, ²H.U.B - Hôpital Erasme, Université Libre de Bruxelles (ULB), Dpt. of Pneumology, Bruxelles, Belgium, 3Ars Statistica, Dpt. of Medical Statistics, Nivelles, Belgium

Background: HFJV is the standard ventilation for bronchoscopy. Few studies addressed the complications associated with HFJV. Fernandes et al showed that ASA 4 score and basal SPO₂ < 95 are associated with complications.(1)

In this study, we wanted to analyse the frequency and type of complications associated with HFJV, and determine the factors associated with the occurrence of complications.

Materials and Methods: After IRB approval and ClinicalTrial registration (NCT06285994), we reviewed the charts of 833 patients who underwent a bronchoscopy with HFJV in 2019-2023. For continuous data, the assumptions of the T-test were tested: determine if groups have comparable variances with Bartlett's test for homogeneity of variance and if the residuals of the T-test are normally distributed.

When one of the underlying hypotheses was not met, a nonparametric approach was used with Wilcoxon-signed-rank test. Categorical variables were analysed with Chi-square. Means and standard deviations or medians and interquartile ranges for continuous data are presented, as appropriate, and counts and percentages are presented for counts data. Univariate relationships were tested between groups with or without complications.

Significant variables (Height, basal SpO2, preop Oxygen and ASA class were entered into a multivariate regression and nonsignificant terms were removed one by one (backward selection procedure). R software (R Core Team, 2021), version 4.2.0. was used to produce the results.

	Complication of HFJV: Yes	Complication of HFJV: No
Hypoxemia	89 (10.75)	739 (89.25)
Severe hypoxemia ($SpO_2 \le 85\%$)	32 (3.96)	801 (96.04)
Moderate hypoxemia ($85\% < SpO_2 \le 90\%$)	57 (6.84)	776 (93.16)
Hypotension (Systolic arterial blood pressure < 90/60 mm Hg)	230 (27.74)	599 (72.26)
Cardiac arythmia	4 (0.48)	827 (99.52)
Laryngopasm	5 (0.60)	827 (98.80)
Bronchospasm	10 (1.20)	822 (98.80)
Baro or volotrauma	1 (0.12)	831 (99.88)
ICU admission	3 (0.36)	823 (99.64)

All values are expressed as N (%)

Table 1.

Multivariate logistic regression model									
Variable Estimate Standard error z value Pr(>lz									
Intercept	16.970	3.396	4.998	< 0.001					
Height	-0.024	0.008	-3.044	0.00233					
SpO ₂ (basal)	-0.141	0.032	-4.398	< 0.001					

ROC curve of the logistic regression model: AUC 61.93% (95%CI 57.94%-65.93%)

Results and Discussion: Complications are shown in Table 1. Overall, complications of HFJV were low, most frequent complications were arterial hypotension and hypoxemia. After multivariate regression, only small height and lower basal SpO₂ were associated with complications. The model gives an area under the curve (AUC) of 62%, so its predictive value is not very strong.

Conclusion(s): The frequency of complications with HFJV is low, small height and lower basal SpO, are the sole predictor of complications.

Automating surveillance for Ventilator **Associated Pneumonias in critical care**

M.A. Garcia Verstraete¹, G. Kostopoulos¹, B. Porter¹, C. Soanes², D. Clarke¹

¹Oxford University Hospitals NHS Foundation Trust, Intensive Care Unit, Oxford, United Kingdom, 2Oxford Brookes University, Oxford Critical Care, Oxford, United Kingdom

Background and Goal of Study: Diagnosing ventilator associated pneumonia (VAP) is challenging due to unclear diagnostic criteria in the literature. Manual VAP surveillance requires significant staff training and time, and in Oxford Critical Care (OCC) this has not been maintained due to resource constraints. In the US. CDC Ventilator Associated Event (VAE) criteria are widely used, with many areas automating the surveillance process.

This project aimed to manually audit VAP rates using CDC criteria to establish a baseline and develop an automated tool for quarterly reporting with minimal staff input.

Materials and Methods: Automated surveillance: An automated surveillance tool (AST) for ventilator associated events was developed using structured query language (SQL) and a clinical reporting system within the electronic patient record system (Phillips ICCA).

This tool retrospectively identified ventilator associated complications (VACs) and infective ventilator associated complications (IVACs) cases, validated against microbiological data. After manual validation, the tool was run for six months (24/01/2024 - 14/07/2024) to report VAC, IVAC and PVAP (possible VAP) fre-

Manual Validation: Over 14 days (05/06/2024 - 18/06/2024), OCC patients intubated for ≥ 48 hours with stable/decreasing FiO2/PEEP were monitored for increasing FiO2/PEEP as per CDC Ventilator-associated Complications (VAC) guidelines. Data for patient demographics, inclusion criteria, and VAC/IVAC/PVAP parameters were recorded in Excel.

Results and Discussion: Manual validation: 15 intubated patients were recorded, with no VAC identified. The AST flagged one pa-

AST: 14 ventilator-associated complications were detected over six months, including 5 IVAC cases. Clinical review confirmed only one true VAP, supported by microbiological and radiological find-

The median day of deterioration was day 2. OCC VAP rate, as per CDC criteria, is low and aligns with published data. Early VACs are common, reflecting our case mix of complex trauma and surgical

Each deterioration had an identifiable cause. The AST accurately identified VAC and IVAC cases and detected a VAP missed by manual audit.

Conclusion(s): Automated surveillance of VAE is a valid option on ICUs with an Electronic Health Record. Further work is planned to optimise the AST and validate it for prospective surveillance. This manual/automated comparison study should be repeated in 3 months.

33AP02-7

A case series of high nasal flow therapy for postoperative respiratory failure

V. Ntella1, S. Preka1, M. Moysidis1, S. Mitta1, E. Georgiou1, G. Galanopoulos1

¹Tzaneio General Hospital of Piraeus, Anaesthesiology Department, Piraeus, Greece

Background: Respiratory failure is the most common postoperative pulmonary complication, especially in patients undergoing major abdominal surgeries. Oxygen administration is routinely used postoperatively to prevent hypoxemia but cannot prevent hypoventilation and hypercarbia.(1)

High nasal flow cannula (HNFC) could be used postoperatively in high risk patients to prevent pulmonary complications.(2)

Case report: We describe our experience of three patients that were complicated with respiratory failure within the first 48 hours postoperatively and received HNFC therapy to prevent deterioration and intubation.

The respiratory status of the first two patients was aggravated within the first two postoperative days while the 3rd patient was complicated with type 2 respiratory failure just hours after surgery. HNFC was well tolerated by all three patients and was used for no more than 48 hours.

The oxygen administration was gradually de-escalated and all three patients were discharged. Two of them received home oxygen therapy.

Discussion: HNFC generates small amounts of positive endexpiratory pharyngeal pressure, increases inspiratory airflow and decreases dead space ventilation.

Postoperative patients suffer from decreased functional residual capacity (FRC) especially in the first postoperative day, which can lead to atelectasis, fever and pneumonia.(3)

HNFC providing positive end-expiratory pharyngeal pressure could help increase the FRC and reduce the incidence of postoperative respiratory failure if applied promptly.

Learning points: HNFC may be a promising postoperative ventilation mechanism for high risk patients undergoing major abdominal surgeries, preventing severe pulmonary complications and the need for intubation and mechanical ventilation.

33AP02-8

Correlation of impedance changes in EIT and tidal volumes and their influencing factors

A.R. Zitzmann¹, D.A. Reuter¹, A. Strübing¹, S.H. Böhm¹, F. Müller-Graf¹

¹University Medical Centre Rostock, Department of Anaesthesiology, Intensive Care Medicine and Pain Therapy, Rostock, Germany

Background and Goal of Study: Electrical impedance tomography (EIT) is a non-invasive functional imaging technique to monitor regional ventilation, especially distribution and dynamics of ventilation within different regions of the lungs. However, the quantification of clinically used ventilation parameters like tidal volume (VT) - as repeatedly requested by clinicians - has not been possible so far since EIT measures relative and not absolute changes in impedance (1).

Thus, the goal of this study was to evaluate the relationship between impedance changes (dZ) and the magnitude of VT in humans and to identify additional factors influencing this relation-

Materials and Methods: 27 patients scheduled for elective surgery under general anaesthesia and need for endotracheal intubation were equipped with a commercially available EIT belt. Measurements were performed at four VTs (6, 8, 10 and 12 mL/ BW, in randomized order) on each of four PEEP levels (0, 5, 10 and 15 cmH₂O, also in randomized order). Linear regression analysis was performed for normalized dZ and VT per ideal bodyweight (VT IBW) using the respective means.

To evaluate additional influencing factors, multiple regression analysis was performed with normalized dZ as dependent variable and VT_IBW, PEEP, gender, age, height and weight as independent variables.

Results and Discussion: Regression analysis for the individual patients showed good correlations between VT IBW and normalized dZ (mean R² 0.890 ± 0.15). However, for the group of patients, correlations were rather weak (R2 0.485).

Nevertheless, adding the abovementioned factors to multiple regression analysis improved the model (adjusted R² 0.767) with VT IBW having biggest impact (β: 0.998), followed by weight (β: -0.974), height (β: 0.629), and PEEP (β: 0.108); age did not contribute to it significantly. Increases in VT_IBW, PEEP, and height increased, while female gender and higher weight decreased normalized d7.

Conclusion(s): There was a strong linear correlation between normalized dZ and VT_IBW in the individual ventilated human that was not seen when analyzing the cohort. PEEP, gender, weight and height were identified as additional influences that need to be considered when estimating VT by dZ. An individual calibration might improve estimation of VT by dZ.

Impact of positive end-expiratory pressure on oxygenation, respiratory compliance, and hemodynamics in obese patients undergoing laparoscopic surgery in reverse Trendelenburg position: A systematic review and meta-analysis of randomized controlled trials

A. Meyerbekova¹, G. Yessenbayeva², S. Kim³, M. Zhumabayev^{4,5}, Y. Yukhnevich⁶, A. Yaroshetskiy⁷ ¹Nazarbavev University, School of Medicine, Astana, Kazakhstan, 2 National Research Oncology Center. Department of Scientific management, Astana, Kazakhstan, 3Multidisciplinary hospitals named after Professor H.J.Makazhanov, Department of intensive care and resuscitation, Karaganda, Kazakhstan, ⁴National Research Oncology Center, Department of intensive care and resuscitation, Astana, Kazakhstan, 5Astana Medical University, Pediatric Anesthesiology, Intensive Care and Emergency Medicine, Astana, Kazakhstan, ⁶Karaganda Medical University, Anesthesiology and ICU, Karaganda, Kazakhstan, ⁷Sechenov First Moscow State Medical University (Sechenov University), Pulmonology Department, Moscow, Russian Federation

Background and Goal of Study: High and individual positive endexpiratory pressure (PEEP) during laparoscopic surgery may improve oxygenation and respiratory mechanics. Goal of this study is to comprehensively evaluate the effects of fixed and individualized PEEP strategies on respiratory mechanics, oxygenation. and hemodynamics in obese patients undergoing laparoscopic surgery.

Materials and Methods: We searched RCTs in PubMed, Cochrane Library, Web of Science, and Google Scholar from January 2000 to December 2023 comparing the different intraoperative PEEP (low PEEP (LPEEP): 0-5 mbar: moderate PEEP (MPEEP): 6-9 mbar; high PEEP (HPEEP): >=10 mbar; individualized PEEP (iP-EEP): PEEP set by special physiological technique) on arterial oxygenation, respiratory compliance (Cdyn) or driving pressure, mean arterial pressure (MAP), and heart rate (HR) in patients during laparoscopic surgery in reverse Trendelenburg position. We calculated mean differences (MD) with 95% confidence intervals (CI), and predictive intervals (PI) using random-effects models. The Cochrane Bias Risk Assessment Tool was applied.

Results and Discussion: 8 RCTs (n=425) met the inclusion criteria. HPEEP vs LPEEP increased PaO₃/FiO₂ (+129.93 [+75.20; +184.65] mmHg, p<0.0001) with high variation of true effect (Chi² 34.92, p< 0.0001; I² 89%). iPEEP vs LPEEP also increased PaO₂/FiO₂ +130.23 [+57.18; +203.27] mmHg, p=0.0005) with high variation of true effect (Chi² 26.95, p< 0.0001; I² 93%). HPEEP vs LPEEP increased Cdyn (+15.06 [5.47; +24.65] ml/mbar, p=0.002) with high variation of true effect (Chi² 93.16, p< 0.0001; I² 96%). iP-EEP vs LPEEP increased Cdyn (+22.46 [+8.56; +36.35] ml/mbar, p=0.002) with high variability of the true effect (Chi² 53.92, p< 0.0001; I² 96%). HPEEP group had higher MAP as compared to LPEEP)+4.36[+0.36;+8.36], p=0.03), variability of the true effect was nonsignificant. HR did not differ between all comparisons.

Conclusion(s): In patients with obesity undergoing surgery in the reverse Trendelenburg position HPEEP and iPEEP may improve oxygenation, decrease driving pressure, and increase dynamic compliance compared to LPEEP with high variation of true effect without relevant hemodynamic compromise. Data with MPEEP comparisons is inconclusive.

33AP02-10

Do patients with obstructive sleep apnea benefit from the use of high-flow nasal cannula during endoscopic retrograde cholangiography procedures? A randomized controlled trial

J. Martinez Ocon¹, M. Perez-Rodriguez¹, J. Sanahuja¹, A. Calvo¹, M. Altamirano¹, E. Rivas Ferreira¹ ¹Clinic Hospital, Anesthesiology, Barcelona, Spain

Background and Goal of Study: Sedation during endoscopic retrograde cholangiography procedures (ERCP) increases the risk of hypoxemia and the need for respiratory support in Obstructive Sleep Apnea (OSA) patients. High-flow nasal cannula (HFNC), generates a positive end-expiratory pressure (PEEP) effect and may reduce hypoxemia during ERCP but the is not strongly evidenced.

Therefore, we aim to evaluate if HFNC improves pulmonary gas exchange compared to standard nasal cannula (NC) in OSA patients.

Materials and Methods: Randomized control trial, in patients undergoing ERCP with CO₂ insufflation at a tertiary hospital. After completing STOP Bang questionnaire, patients were randomized 1:1 with OSA stratification to either HFNC (60L min-1, Fio., 0.4) or NC (6L min-1). The procedures were performed under deep sedation with propofol and remifentanil target-controlled infusion. ECG, SpO₂, blood pressure, bispectral index (BIS), rescue airway maneuvers, and transcutaneous CO2 (TcPCO2). Additionally, a venous blood sample was obtained at the end of the procedure. The primary outcome was the occurrence of hypoxemic events defined as SpO₂ ≤ 90% during 15 s. The secondary were the need for airway rescue maneuvers and hypercapnia, defined by the maximum TcCO₂ values recorded.

Results and Discussion: A total of 191 patients were included in the analysis (73 OSA and 118 non OSA). 74 (38%) were females and 117 (62%) males with a median age of 67 [IQR, 57-79] v.o., and a body mass index of 25 [22-22] kg/m². 55% were ASA III. There were 8 hypoxemic events in OSA patients and 19 in non-OSA patients. In both groups, HFNC showed a tendency to reduce hypoxemic and the need for airway rescues events. Moreover, significantly reduced TcPCO2 values and venous PCO2 in both OSA and non-OSA patients, with this difference being more pronounced in OSA patients (Table 1).

Variable	0	SA (n=73)		Non-OSA (n=118)			
	HFNC (n=37)	NC (n=36)	P value	HFNC (n=55)	NC (n=63)	P value	
Hypoxemic events (SpO ₂ <90%), n	3 (8)	5 (14)	0.634	8 (15)	11 (18)	0.452	
Airway rescue events, n	12 (32)	17 (47)	0.202	12 (22)	23 (37)	0.080	
PtCO ₂ , mmHg	44.3 [30.4-69.7]	50.8 [18.7-94.9]	0.042	44.9 [10.9-61]	47.8 [27.9-129.5]	0.022	
PvO ₂ , mmHg	76.7 [62.1-101.7]	72.0 [56.3-91.8]	0.020	89.9 [64.8-113.1]	78.6 [62.5-110.0]	0.029	

The qualitative data are presented as n(%), and the numerical data are presented as the median [IQR]

Table 1.

Conclusion(s): In OSA patients undergoing ERCP, HFNC did not significantly reduce the incidence of hypoxemic events or the need of airway rescue maneuvers. However, HFNC significantly reduced patients' hypercapnia.

33AP02-11

Association of mechanical power with mortality in patients with ARDS: An individual patient data analysis

G. Dorland¹, F.L. van der Ven¹, S.G. Blok¹, M.J. Schultz¹, F. Paulus¹, D.M. van Meenen¹, ERICC-, LUNG SAFE-, PROVENT-COVID-, EPICCOV-, CIBERESUCICOVID-, SATI-COVID-19-investigators ¹Amsterdam UMC, Intensive Care, Amsterdam, Netherlands

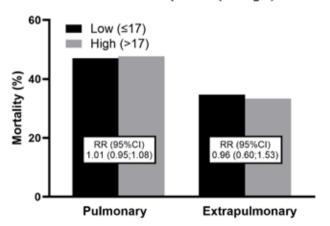

Background and Goal of Study: Mechanical power is associated with outcomes from acute respiratory distress syndrome (ARDS) (1,2). Pulmonary and extrapulmonary ARDS have distinct pathophysiological mechanisms, which may alter the impact of mechanical power on patient outcomes (3.4).

We aimed to assess the relationship between mechanical power and ARDS etiology on 60-day mortality.

Materials and Methods: Individual patient data analysis of six observational studies of mechanical ventilation in patients with ARDS. The primary endpoint was mortality at day 60 after start of invasive mechanical ventilation. Other outcomes included length of stay in hospital and ICU, duration of ventilation and ventilatorfree days at day 28.

Results and Discussion: Out of 7.934 patients with ARDS from either pulmonary or extrapulmonary etiology, 4.532 (57%) patients were survivors and 3.402 (43%) non-survivors. Mechanical power was independent associated with 60 day-mortality (P=0.004). There was no significant interaction between mechanical power and etiology of ARDS (P=0.39). Other respiratory factors associated with 60-day mortality included respiratory rate (P<0.001) and driving pressure (P<0.001).

Mechanical power (cmH₂O)

Conclusion(s): Mechanical power is independently associated with 60-day mortality in patients with ARDS receiving mechanical ventilation. There is no significant interaction between mechanical power and etiology of ARDS on mortality.

33AP03-1

The platelet glycoprotein lb-alpha receptor is a biomarker for ARDS mortality

A.M. Bernard¹, L.M. Serna-Higuita², P. Rosenberger¹, A. Koerner¹, H. Haeberle¹, V. Mirakaj¹ ¹University Hospital Tuebingen, Department of Anaesthesiology and Intensive Care Medicine, Tuebingen, Germany, ²University of Tuebingen, Institute for Clinical Epidemiology and Applied Biostatistics (IKEaB), Tuebingen, Germany

Background and Goal of Study: Immunothrombosis describes the process of platelet activation during inflammation. It partakes in organ and tissue damage through formation of mircothrombi. The glycoprotein receptor GPIb-α binds von-Willebrand factor (vWF) and potently mediates crosslinking of platelets. In a prospective cohort study in ARDS patients, we measured GPIb-□ serum levels on five consecutive days to determine its usage as a biomarker in ARDS fatality.

Materials and Methods: GPIb- α serum levels were measured on five consecutive days after study inclusion in 125 patients in a prospective multicenter trial. A multivariate Cox analysis was performed to identify risk factors for increased mortality. GPIb- α serum levels were compared between survivors and non-survivors via student's t-test. A Kaplan Meyer curve was created, stratified by GPIb- α levels which were compartmentalized by quartiles.

Results and Discussion: Diminished GPIb- α serum levels were identified as independent risk factor for increased mortality in our cohort. GPIb-α levels were significantly higher in survivors compared to non-survivors on day 3-5 after study inclusion. For the Kaplan-Meyer curve, patients with the lowest GPIb- α levels (0130 ng/mL) had a mortality rate of 53%; in patients with higher levels (341-850 ng/mL), the mortality rate was 10% (Fig. 1). Taken together, we are the first to report of GPIb- α as a biomarker with significance in ARDS. Lower levels are independently associated with an increased mortality, which might reflect increased consumption of GPIb- α during fatal ARDS.

Conclusion(s): GPlb- α might hold the potential to be a predictor for mortality in ARDS, with lower levels bringing with it a higher risk of death.

33AP03-2

Hypercapnia in Robotic Assisted Thoracic Surgery (RATS) for thymectomy: a new anesthetic challenge

A. Hostalot-Sanchez¹, A. Parera¹, S. Chavarria², J.C. Trujillo², A. Arjona Navarro¹, E. Ardant¹ ¹Hospital de la Santa Creu i Sant Pau, Anaesthesiology, Barcelona, Spain, ²Hospital de la Santa Creu i Sant Pau, Thoracic Surgery, Barcelona, Spain

Background and Goal of Study: RATS thymectomy (RT) is a recently introduced technique. We observed respiratory acidosis (RA) secondary to capnothorax in many patients undergoing RT. Considering that hypercapnia can lead to both intraoperative and postoperative complications, we decided to conduct this retrospective observational study to review a cohort of patients undergoing RT and describe their characteristics in order to identify potential risk factors for the development of severe intraoperative RA in further studies.

Materials and Methods: Retrospective review of patients undergoing RT from October 2022 to October 2024 in a tertiary hospital center. Demographic (age, sex) and clinical data (presence of obstructive respiratory pattern, bronchial hyperresponsiveness, myasthenia gravis, surgery length, occurrence of complications) were analyzed for all patients. In the subgroup who developed intraoperative hypercapnia measured by etCO2, arterial blood gases were obtained to measure pCO2 and ph.

Results and Discussion: The table shows the data obtained. Regarding complications, all patients were immediately extubated after surgery, although one of them required intraoperative ventilation with Evone® and postoperative noninvasive mechanical ventilation.

	Total sample (n=20)	Hypercapnia gr (n=13)	roup	Normocapnia group (n=7)
Age, Mean (years)	52,4 (23-80)	49,8 (23-80))	57,3 (31-79)
Men (%) Women (%)	30% 70%	38% 62%		14% 86%
Surgery length, Mean (minutes)	192 (100-340)	207 (100-315	5)	164 (120-340)
Myasthenia gravis (%)	25% (5/20)	31% (4/13)		14% (1/7)
Obstructive pattern (%)	25% (5/20)	31% (4/13)		14% (1/7)
Bronchial hyperreactivity (%)	20% (4/20)	23% (3/13)		14% (1/7)
		Mild (45-60 mmHg) (%)	38% (5/13)	-
		Moderate (61-74 mmHg) (%)	54% (7/13)	-
Hypercapnia (%)	65%	Severe (>75 mmHg) (%)	8% (1/13)	-
ттурстсартна (70)	(13/20)	Maximum arterial pCO2, Mean (mmHg)	62,8 (49,1-82,9)	-
		Minimum arterial ph, Mean	7,24 (7,16-7,33)	-

Conclusion(s): RT may be associated with the development of intraoperative hypercapnia, and this may be due to the need for high-pressure capnothorax (conditioning increased airway pressures) and to the sealed robotic ports, thus leading to increased CO2 absorption.

In this cohort there were more patients with hypercapnia than not, and among those with hypercapnia it seems to be a higher percentage of women, bronchial hyperresponsiveness and a longer duration of surgery. However, the main limitation of this study was the small sample size, so larger studies should be performed in order to draw firm conclusions.

33AP03-3

Development and validation of interpretable machine learning models for postoperative pneumonia prediction

H. Yang¹, B. Xiang¹, W. Zhang¹ ¹West China Hospital, Sichuan University, Department of Anesthesiology, Chengdu, China

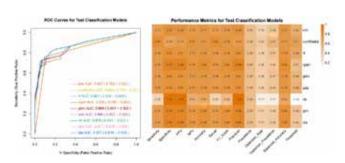

Background and Goal of Study: Postoperative pneumonia, a prevalent form of hospital-acquired pneumonia, poses significant risks to patients' prognosis and even their lives.

This study aims to develop and validate a predictive model for postoperative pneumonia in surgical patients using nine machine learning methods.

Materials and Methods: Retrospective data from electronic medical records was collected for 264 patients diagnosed with postoperative pneumonia and 264 healthy control surgical patients. Through correlation screening, chi-square tests, and feature importance ranking, 47 variables were narrowed down to 5 potential predictive factors based on the main cohort of 528 patients.

Nine machine learning models, including k-nearest neighbors, support vector machine, random forest, decision tree, gradient boosting machine, adaptive boosting, naive bayes, general linear model, and linear discriminant analysis, were developed and validated to predict postoperative pneumonia.

Model performance was evaluated using the AUC, sensitivity, specificity, accuracy, precision, recall, and F1 score. A distribution plot of feature importance and feature interaction was obtained to interpret the machine learning models.

Results and Discussion: Among 17,190 surgical patients, 264 (1.54%) experienced postoperative pneumonia, which resulted in adverse outcomes such as prolonged hospital stay, increased ICU admission rates, and mortality. We successfully established nine machine learning models for predicting postoperative pneumonia in surgical patients, with the general linear model demonstrating the best overall performance. The AUC of the general linear model on the testing set was 0.877, with an accuracy of 0.82, specificity of 0.89, sensitivity of 0.74, precision of 0.88, and F1 score of 0.80. Our study revealed that the duration of bed rest. unplanned re-operation, end-tidal CO2, postoperative albumin, and chest X-ray film were significant predictors of postoperative pneumonia.

Conclusion(s): Our study firstly demonstrated that the general linear model based on 5 common variables might predict postoperative pneumonia in the general surgical population.

33AP03-4

Postoperative pulmonary complications (PPCs) in gynaecological and urological patients. Does type of surgery matter?

T. Vermeulen¹, S. Hemmes^{1,2}, M. Schultz^{3,4,5,6}, M. Hollmann¹, D. van Meenen^{1,3} ¹Amsterdam University Medical Center, Anesthesiology, Amsterdam, Netherlands, 2The Netherlands Cancer Institute - Antoni van Leeuwenhoek Hospital, Anesthesiology, Amsterdam, Netherlands, ³Amsterdam University Medical Center, Intensive Care, Amsterdam, Netherlands, 4Medical University Vienna, Division Cardiac, Thoracic, Vascular Anaesthesia and Intensive Care, Vienna, Austria, 5Mahidol University, Mahidol-Oxford Tropical Medicine Research Unit (MORU), Bangkokttt, Thailand, 6University of Oxford, Nuffield Department of Medicine, Oxford, United Kingdom

Background and Goal of Study: In lower abdominal surgery, postoperative pulmonary complications (PPCs) are known to occur less often in gynaecological patients compared to urological patients. It is unclear whether this is due to PPC predicting variables at baseline, or to type of surgery itself.

Materials and Methods: Post hoc analysis of LAS VEGAS, an international observational study in patients undergoing intraoperative ventilation during general anaesthesia for surgery.

The primary endpoint was the incidence of any PPC, a composite endpoint of six individual PPCs.

The secondary endpoint was individual PPC incidence.

The composite included unplanned supplemental oxygen, pneumothorax, pneumonia, respiratory failure, new invasive ventilation and ARDS. To evaluate the role of surgery type, propensity score matching was used to create a cohort of patients with similar preoperative PPC risk.

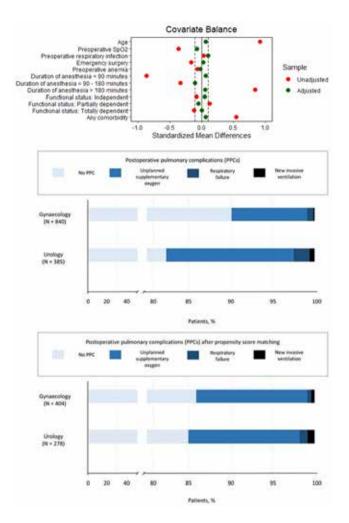

Variables with a known association with PPCs were implemented in the model and a Fisher's exact test was used for hypothesis testing.

Results and Discussion: The unmatched cohort consisted of 1225 patients; 840 (68.6%) gynaecological and 385 (31.4%) urological patients. Gynaecological patients were younger, had fewer comorbidities and shorter length of anesthesia. The incidence of PPCs was lower in gynaecological patients (9.8% vs 17.9%; OR 0.50[0.35-0.71]; P < 0.001).

Pneumonia, pneumothorax and ARDS did not occur. The incidence of unplanned supplementary oxygen was lower in gynaecological patients. After matching, covariates were well balanced. The matched cohort consisted of 404 (59.2%) gynaecological and 278 (40.8%) urological patients. Both composite PPC incidence (13.4% vs 15.1%; OR 0.87 [0.55-1.38]; P = 0.596), and individual PPC incidence were not different between groups.

	Unmato	hed cohort		Match	ed cohort	
	Gynaecological (N = 840)	Urological (N = 385)	Р	Gynaecological (N = 404)	Urological (N = 278)	Р
Any PPC, n (%)	82 (9.8)	69 (17.9)	< 0.001	54 (13.4)	42 (15.1)	0.596

Table 1: PPCs in gynaecological and urological patients

Conclusion(s): In lower abdominal surgery, gynaecological patients have a lower incidence of PPCs. However, this is likely due to pre-operative PPC risk rather than type of surgery itself.

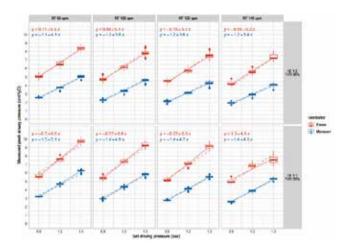

33AP03-5

A bench study comparing peak airway pressures during high frequency jet ventilation with two commercially available jet ventilators

M. Peters¹, S. Morrison¹, G. De Meyer¹, V. Saldien¹ ¹University Hospital Antwerp, Department of Anesthesiology, Edegem, Belgium

Background and Goal of Study: Jet ventilators inject low tidal volumes at high respiratory frequencies (RF) and at high driving pressures (DP). In this bench study we compared the peak airway pressures (PAP) between two jet ventilators (Monsoon IV, Acutronic Medical Systems AG, Hirzel, Switzerland and Evone, Ventinova Medical, Bizkaia, Spain). Clinical experience led us to hypothesize that the Evone produces higher PAPs at the same DP.

Materials and Methods: An oral WEI jet tube (Well Lead Medical Ltd., China) was interfaced with a 1 litre test lung (IMT Medical Easylung, IMT Analytics AG, Buchs, Switzerland, compliance 25mL/ H_oO, resistance 20cm H_oO/L/s). Airway pressures were measured in the lung, distal to the jet flow, on an indwelling non-compliant line. The ventilators were tested at room temperature with dry air for a range of settings: RF 80, 100, 120, 140 cpm; DP 0.9, 1.2, 1.5 bar and I:E ratios of 1:1 and 1:2 (Monsoon) and inspiratory time fractions (Ti/Tt) of 50% and 35% (Evone). Data was sampled at 250Hz (clip-on cap, Sensirion, Staefa, Switzerland), recorded for 2 minutes at each setting, filtered for peaks and linearly modelled ('R', v4.4, R consortium, Vienna, Austria).

Results and Discussion: The boxplot figure shows the spread of PAPs for each combination of settings. Full lines with equations (top left) represent linear models per scenario. Dashed lines are predictions from a linear regression model on all settings (R2=0.98), summarized as: PAP = 5.6*DP - 0.02*RF + 5.8*Ti/Tt - 1.7*monsoon - 1.3*DP*monsoon + 0.005*RF*monsoon - 0.3*Ti/ Tt*monsoon - 0.5.

PAP increased at higher DP or longer T/T, (p<.001), but decreased with increasing RF (p<.001). PAPs were higher with the Evone than with the Monsoon (p<.001) and increased disproportionally at higher DP (p<.001).

Conclusion(s): Compared with the Monsoon IV, the Evone generates higher PAP at similar DP and results in proportionally larger increases in PAP at higher DP. The reasons for these differences require further investigation. Studies are also necessary to determine the clinical relevance of these findings and their implications for ventilator settings and gas exchange in vivo.

33AP03-7

Impact of standard and prolonged prone positioning on ventilator-free days, mortality, and respiratory mechanics in COVID-19-associated **ARDS:** a retrospective cohort study

P. Rahimi¹, T. Yücel Yenice¹, D. Birtane¹, S. Aşar¹, Z. Cukurova¹

¹University of Health Sciences, Bakirkoy Dr Sadi Konuk Research and Training Hospital, Anesthesiology and Intensive Care, Istabul, Turkey

Introduction: Prone positioning (PP), high levels of PEEP, low tidal volume, and reduced driving pressure (DP) are recommended treatments as part of lung-protective ventilation in ARDS.

The aim of this study is to investigate the impact of prolonged prone positioning (PPP) and standard prone positioning (SPP) on ventilator-free days (VFD) and ICU mortality in patients with Covid ARDS.

Additionally, the effects of PPP and SPP on respiratory mechanics and oxygenation indices during the pre-prone, prone, and postprone periods will be compared.

Materials and Methods: We divided patients into two groups: Group A (n:149) (received PP for 16-24 hours) and Group B (n:168) (received PP for 25-36 hours). Arterial blood gas parameters were collected within 2 hours before PP, every 4 hours during PP, and within 2 hours after PP. Hemodynamic parameters, respiratory mechanics (FiO 2, PEEP, PaO, /FiO, ratio, oxygenation index (OI), oxygen saturation index (OSI), Mp tot , MP dyn , RR, PEEP, TV_e, MV_e, P_{mean}, P_{peak}, WOB_v, I/E ratio, compliance, DP), laboratory parameters, ICU length of stay, VFD, and Norepinephrine total daily dosage were recorded.

Results: In Group A, there was a statistically significant decrease in HR, PCO₂, OI and OSI during the prone and post-prone periods. Additionally, there was a statistically significant increase in PH, PaO₂/FiO₂ ratio and PF/PEEP values.

In Group B, there was a statistically significant decrease in HR, OI and OSI values during the prone and post-prone periods. Additionally, there was a statistically significant increase in PH, PaO /FiO₂ ratio, and PF/PEEP values.

In Group A, a statistically significant difference was found between the survivor and non-survivor groups in terms of age, total daily norepinephrine dose, K levels, P peak , DP, MP tot , MP dyn , ICU stay and VFD.

In Group B, a statistically significant difference was found between the survivor and non-survivor groups in terms of age, MAP, total daily norepinephrine dose, PCO2, PH, lactate, PaO, /FiO, ratio, OI, OSI, PF/PEEP, P mean, P peak, DP, MP tot, MP dyn, WOBy, compliance, prone duration, and APACHE II and SOFA scores at admission, ICU stay and VFD.

Conclusion: In C-ARDS patients, preventing VILI and achieving a persistent post-prone effect through several sessions of PP have positive effects on respiratory mechanics and oxygenation. We recommend incorporating both SPP and PPP as part of lung protective ventilation rather than as life-saving treatments.

33AP03-8

Mechanical ventilation practices in surgical ICU: a monocentric prospective study

S. Bellaftouh¹, A. Erragh², S. Chaabi², A. Nsiri², R. Al Harrar²

¹Ibn Rochd University Hospital Center, Anesthesiologyintensive care medicine department, Casablanca, Morocco, 2Ibn Rochd University Hospital Center, surgical intensive care unit, Anesthesiology-intensive care medicine department, Casablanca, Morocco

Background and Goal of Study: Mechanical ventilation (MV) is essential in critical care to support patients with acute respiratory failure, impaired consciousness, or prolonged anesthesia requirements. However, its use is associated with risks, including pulmonary injuries, nosocomial infections, and hemodynamic disturbances.

This study aimed to evaluate MV practices in the surgical ICU at CHU Ibn Rochd, focusing on indications, complications, ventilatory modes, and patient outcomes

Materials and Methods: A prospective descriptive study was conducted from September 2022 to September 2023, including 42 patients requiring MV. Data collected included MV indications, ventilatory parameters, duration, complications, and weaning outcomes. Statistical analyses assessed correlations between patient characteristics, MV practices, and clinical outcomes.

Results and Discussion: Among the 42 patients, the mortality rate was 52.38%, primarily due to septic shock (72.72%). The average MV duration was 7.97 days. Although demographic factors did not significantly influence outcomes, pre-existing medical conditions were associated with increased mortality risk (P=0.032).

Complications occurred in 66.66% of patients, primarily infections (33.33%) and renal issues (23.80%), but these had no significant impact on prognosis (P=0.252). Ventilatory parameters included tidal volumes of 6-8 ml/kg and peak pressures of 20-30 cmH2O in 83.88% of cases.

Prolonged MV duration correlated with older age (P=0.048) and altered consciousness (P=0.0311). Weaning was successful in 90.90% of patients ventilated for 7 days or more (P=0.0197). These findings highlight the need for individualized MV management and early identification of risk factors to improve outcomes. Conclusion(s): Optimizing MV practices and ensuring rigorous monitoring are critical to improving clinical outcomes and reducing mortality in ICU patients. Future efforts should focus on refining protocols to minimize complications and enhance weaning success rates.

33AP04-1

Evaluation of the respiratory effects of driving pressure-guided mechanical ventilation using electrical impedance tomography in patients undergoing robot-assisted laparoscopic radical prostatectomy

E. Budak Özyalçin¹, F. Altindas¹, I. Beyoglu¹, S.E. Erbabacan¹, ET Al¹ ¹Istanbul University, Cerrahpasa, Cerrahpasa Faculty of Medicine, Fatih, Turkey

Background and Goal of Study: Due to factors such as the Trendelenburg position and pneumoperitoneum applied during robotassisted laparoscopic radical prostatectomy (RALRP), postoperative pulmonary complications (PPCs) may occur.

The aim of our study is to evaluate the effects of personalized PEEP, based on driving pressure approach, versus fixed PEEP on lung gas distribution during RALRP using electrical impedance tomography (EIT), and to compare postoperative pulmonary complications (PPCs).

Materials and Methods: Our study is a randomized, controlled, prospective study, registered to ClinicalTrials.gov with the identification number NCT06540794. The study was conducted with 42 patients undergoing RALRP. Patients aged 18 to 80 years with an ASA score of 1 to 3 were included. In control group (Group S), standard-fixed PEEP of 5 cmH₂O was applied. "Personalized" PEEP value, which provided the lowest driving pressure as a result of decremental PEEP titration, was applied in the study group (Group K) The GI index and ROI3+ROI4 values, as well as PPC rates, were compared. Data analyses were conducted using IBM SPSS Statistics 21.0 and MS Excel 2007, with statistical significance set at p < 0.05.

Results and Discussion: The patient characteristics, hemodynamics, and surgery-related variables were similar in both groups. The GI indices were significantly lower in Group K at T5 and T6 (p<0.05), indicating more homogeneous ventilation in study group (Table 1). An increase in ROI3+ROI4 values, indicating enhanced dorsal ventilation, was observed in Group K compared to Group S at T5 (40.30 \pm 13.16 vs. 31.95 \pm 9.10, respectively; p < 0.05).

Our study demonstrated that personalized PEEP reduced PPCs. with a PPC rate of 26.1% in the personalized group compared to 63.2% in the standard group (p<0.05).

	GROUP K	GROUP S		
	(personalized PEEP) (n=23)	(standard PEEP) (n=19)		
	Mean ± SD	Mean ± SD	p (0	Group)
GI Index				
T0- Preinduction	0.40±0.03	0.39±0.03	t=0.673	p=0.505
T5- Before Extubation	0.40 ± 0.04	0.44±0.04	z=3.269	p=0.001
T6- After Extubation	0.38±0.03	0.43±0.03	z=4.152	p<0.001
p(time): $\chi^2=11.590$; p=0.0	003	F=16.176; p<0.001		

t: Independent Samples T-Test, z: Mann-Whitney U Test, χ^2 : Friedman Test, F: Repeated Measures ANOVA Test

Table 1. Comparison of GI index values by groups

Conclusions: In patients undergoing RALRP, driving pressureguided personalized PEEP provides more homogeneous lung ventilation compared to fixed PEEP, as demonstrated by the GI index calculated through EIT. It was concluded that personalized PEEP application reduced PPCs.

33AP04-2

Challenging use of anesthetics in the treatment of refractory bronchospasm in a patient with intracranial hemorrhage

K. Vrbica1, O. Hrdy1, P. Minarcikova1, H. Antoni1, R. Gal1

¹University Hospital Brno and Faculty of Medicine, Masaryk University, Department of Anaesthesiology and Intensive Care Medicine, Brno, Czech Republic

Background: Bronchospasm can be a life-threatening complication of invasive mechanical ventilation and its standard management in the ICU includes the use of nebulized bronchodilators, intravenous corticosteroids, and specific ventilator settings. If bronchospasm is refractory to standard treatment, additional therapeutic options include intravenous salbutamol, magnesium and aminophylline, paralysis, mucolytics, ketamine, inhalational anesthetic agents, heliox, and ECMO1.

The choice of additional treatment may be influenced by scarcity of resources and the patient's comorbidities.

Case Report: A 32-year-old woman with BMI of 49.3, without comorbidities, was admitted to the University Hospital Brno with a subarachnoid hemorrhage (Hunt-Hess grade II) caused by a rupture of an aneurysm of the anterior communicating artery. The aneurysm was scheduled for endovascular coiling under general anesthesia.

Following the induction of anesthesia, the patient developed severe bronchospasm, which was refractory to standard treatment. Ventricular dilatation complicated the situation, necessitating cerebrospinal fluid drainage via an external ventricular drain. The bronchospasm remained profoundly refractory to advanced treatment.

Despite the risk of intracranial pressure elevation, inhaled sevoflurane and intravenous ketamine were successfully utilized, leading to improved ventilation without any increase in intracranial pressure.

Discussion: Refractory bronchospasm presents a challenge, particularly in the context of intracranial hemorrhage and the risk of elevated intracranial pressure. The use of ketamine, whose effect on intracranial pressure remains unclear, is a potential alternative2.

The use of sevoflurane, which may increase intracranial pressure. can be challenging; however, we found it to be feasible and safe when intracranial pressure is carefully monitored.

References:

- 1. Gayen S, Dachert S, Lashari BH, et al. Critical Care Management of Severe Asthma Exacerbations. Journal of Clinical Medicine.2024: 13(3):859.
- 2. Gregers, M.C.T., Mikkelsen, S., Lindvig, K.P. et al. Ketamine as an Anesthetic for Patients with Acute Brain Injury: A Systematic Review. Neurocrit Care 33, 273-282(2020).

Learning Points: Treatment of refractory bronchospasm is challenging and influenced by the underlying illness and comorbidities. In patients with risk of high intracranial pressure the use of ketamine and sevoflurane is both feasible and safe if intracranial pressure is monitored.

33AP04-3

Flow control ventilation in robotic laparoscopic surgery and steep Trendelenburg positioning: case report

M. Roger Coscojuela¹, G. Ballout¹, M. Magaldi Mendaña¹, R. Berge Ramos¹, A. Duran¹, B. Tena Blanco¹ ¹Hospital Clinic de Barcelona, Anaesthesia Department, Barcelona, Spain

Background: Trendelenburg positioning during robotic-assisted laparoscopy associates reduced pulmonary compliance, atelectasis and worsened oxygenation 1.

Flow-controlled ventilation (FCV) employs a linear gas flow during both inspiration and expiration, reducing airway pressure fluctuations, dissipative energy and alveolar strain. Furthermore, active control of expiration with FCV allows better lung recruitment and oxygenation¹. However, its application in robotic surgery with Trendelenburg positioning remains unexplored.

Case Report: Patient 1: 72-year-old (y/o) man, body mass index (BMI) 26 kg/m2, ASA 2, scheduled for robotic cystectomy. Patient 2: 56 y/o man, BMI 25 kg/m2, ASA 2, scheduled for robotic prostatectomy. A radial arterial catheter was inserted prior to induction. Total intravenous anesthesia was administered.

After intubation, patients were ventilated with volume control ventilation (VCV), positioned in 32° Trendelenburg position and then switched to FCV and returned to VCV before emergence. During FCV, the anesthetist adjusted flow rate (F), positive endexpiratory pressure (PEEP), peak inspiratory pressure (PIP), and the fraction of inspired oxygen (FiO2). An exclusive pressure line

continuously measured airway pressure. The device determined the respiratory rate (RR) and tidal volumes (TV) based on the compliance of the respiratory system. No postoperative respiratory complications were observed.

Ventilatory and gas exchange parameters are shown in Table 1. **Discussion:** In these cases, FCV improved intraoperative airway pressure ensuring an adequate gas exchange during robotic laparoscopic surgery suggesting that FCV may reduce the negative effects of pneumoperitoneum and Trendelenburg positioning. Large-scale studies are needed to assess FVC role in enhancing perioperative respiratory care during these surgeries.

Reference:

1. Intensive Care Med Exp. 2023;11(1):49.

Learning points: FCV may be a promising ventilation strategy in patients undergoing robotic surgery.

33AP04-4

Atelectasis in major abdominal surgeries and the role of two different ventilation modes in decreasing it

M. Krishnan¹, N. Patel¹, R. Kumar¹, D. Bhoi¹ ¹All India Institute of Medical Sciences. Anaesthesiology, Pain Medicine and Critical Care, Delhi. India

Background and Goal of Study: Atelectasis is a common postoperative complication following open abdominal surgeries, caused by decreased functional residual capacity (FRC) due to factors like abdominal pressure, anaesthesia, and neuromuscular blockade. Pressure support ventilation (PSV) is proposed to reduce atelectasis by assisting breathing and maintaining adequate FRC. While PSV has shown effectiveness in laparoscopic and bariatric surgeries, there is limited evidence for its use in major abdominal surgeries.

This study compares PSV to spontaneous ventilation with intermittent manual assistance (control group) in patients undergoing major open abdominal surgeries.

Lung ultrasound (LUS) is used to assess atelectasis in both groups. The study hypothesizes that PSV during extubation will reduce the incidence of postoperative atelectasis compared to the control group.

Materials and Methods: In this randomized controlled doubleblinded trial, adult patients undergoing major abdominal surgeries were assigned to either the pressure support (n=67) or the control group (n=67). During emergence PSV was used in the pressure support group versus intermittent manual assistance in the control group.

Results and Discussion: The incidence of atelectasis at 30 minutes after extubation in PACU was significantly lower(16%vs 40% in Control) with p value of 0.003.PaO levels in the Pressure support group was significantly higher than the control group(88.4±10.6 mmHg vs 80.16 ±10.93 mmHg) with a p value<.0001. Events of SpO₂<92% and the need for oxygen support in PACU was significantly lower in the pressure support (27%vs

No significant difference was found in the incidence of atelectasis 24 hours after extubation, SpO₂<92% 48 hours after surgery, need for mechanical ventilation, CPAP or HFNO support, extubation time, postoperative pulmonary complications, duration of hospital stay between both groups.

Conclusion(s): This study demonstrates that PSV during emergence and extubation significantly reduces the incidence of postoperative atelectasis and improves oxygenation compared to control group.

33AP04-5

Perioperative pneumothorax: a case of hypoxemia following breast surgery

I. Queirós¹, C. Martins¹, V. Fernandes¹ ¹ULS São João, Anesthesiology, Porto, Portugal

Background: Pneumothorax is a well-recognized complication of breast surgery, with an incidence below 1%(1). Primary causes include local anesthetic infiltration, tissue expander placement and positive-pressure ventilation.

Case Report:: A 48-year-old female (ASA II) with ductal carcinoma underwent a right mastectomy and immediate reconstruction with tissue expander under general anesthesia with endotracheal intubation and PECS block. PECS blocks were performed under ultrasound, without problems. The surgery proceeded without complications but expander fill was difficult requiring multiple attempts.

During emergence, the patient desaturated. In the hypothesis of bronchospasm, deepening anesthesia, salbutamol, ipratropium and manual positive pressure ventilation were made. Pulmonary auscultation was normal and oxygen saturation improved.

The patient was extubated but required supplemental oxygen (FiO2 50%) to SpO2>92%. In the post-anesthesia care unit, despite hemodynamic stability, the patient remained hypoxemic and dyspneic.

Lung auscultation revealed decreased breath sounds in the right hemithorax. A chest X-ray confirmed right pneumothorax and a chest drain was placed. Follow-up image showed resolution within 8 hours and the patient was discharged on postoperative day 3. Discussion: Anesthesiologists must recognize iathrogenic pneumothorax as a potential complication of breast surgery. In this case, the patient presented with hypoxemia and dyspnea. Differential diagnoses included bronchospasm, negative pressure pulmonary edema and pneumothorax, with bronchospasm ruled out due to lack of response to treatment and suggestive pulmonary auscultation.

Imaging confirmed pneumothorax, likely caused during expander insertion. PECS block was a less probable cause due to the absense of complications during the technique: US-guided with correct visualization of the needle and dispersion of local anesthetic while maintained intraoperative stability despite positive pressure ventilation.

Reference:

Schneider LF et al.Incidence of pneumothorax during tissue expander-implant reconstruction and algorithm for intraoperative management. Ann Plast Surg. 2014 Sep; 73(3):279-81

Learning points: Anesthesiologists must be vigilant for pneumothorax as a potential cause of hypoxemia and respiratory distress in breast surgery patients. Possible etiologies include needle injury during local anesthetic infiltration, multiple attempts at tissue expander insertion and mechanical ventilation.

33AP04-6

Challenges in pulmonary veno-occlusive disease: ECMO as a bridge to double-lung transplantation

Care and Pain Medicine, Madrid, Spain

M.C. Puigserver¹, J. López Buitrón¹, O. González González¹, E. García Hernández¹, J. Herrero Parra1 ¹Hospital 12 de Octubre, Anaesthesiology, Surgical Critical

Background: Pulmonary veno-occlusive disease (PVOD) is a rare and aggressive subtype of pulmonary arterial hypertension characterized by pulmonary venous involvement, progressive pulmonary vascular resistance, hypoxemic respiratory failure and right ventricular failure. PVOD has a poor prognosis, limited response to standard PAH therapy with a high risk of severe pulmonary edema. Lung transplantation is the definitive treatment and should be considered at diagnosis [1].

Case Report: We present a 28-year-old male diagnosed with hereditary PVOD in 2020, confirmed by EIF2AK4 mutation. He declined lung transplantation due to personal reasons and was treated with dual oral vasodilator therapy and diuretics.

Over three years, his condition worsened with recurrent hospitalizations for decompensated right heart failure. In 2024, he presented in cardiogenic shock with suprasystemic pulmonary pressures and persistent low output despite inotropic support. Femorofemoral veno-arterial ECMO was initiated as a bridge to transplantation. Six days later, he underwent double-lung transplantation with CPB.

Intraoperatively, he experienced severe hemodynamic instability requiring vasoactive drugs and politransfusion. He was transferred to the ICU with VA ECMO and vasoactive drugs, where he experienced a slow but favorable progression.

Discussion: PVOD poses unique diagnostic and therapeutic challenges due to its aggressive progression and poor response to vasodilator therapy. This case emphasizes the importance of early recognition and timely initiation of advanced support measures, such as ECMO, to stabilize patients awaiting transplantation.

Early recognition, patient education, and timely decision-making are critical to optimizing outcomes. Lung transplantation remains a life-saving intervention for PVOD patients.

References:

1. Sourla E, Paspala A, Boutou A, Kontou P, Stanopoulos I, Pitsiou G. A case of pulmonary veno-occlusive disease: diagnostic dilemmas and therapeutic challenges. Ther Adv Respir Dis. 2013 Apr;7(2):119-23 doi: 10.1177/1753465812468042. Epub 2012 Dec 12. PMID: 23235992.

Learning points: PVOD is a rare and aggressive cause of PAH with limited response to standard therapies, necessitating early consideration of lung transplantation. ECMO serves as a vital bridge to transplantation in patients with refractory hemodynamic deterioration. Meticulous perioperative planning is essential to manage hemodynamic challenges and prevent catastrophic complications.

Flow-controlled ventilation in morbidly obese patients during laparoscopic surgery – two case

G. Ballout¹, M. Roger¹, R. Risco¹, R. Bergé¹, D. Capitán¹, E. Rivas1

¹Hospital Clínic de Barcelona, Anaesthesia Department, Barcelona, Spain

Background: Obesity decreases functional residual capacity that is impaired during general anaesthesia, leading to mechanical ventilation difficulties and respiratory complications. Flow-controlled ventilation (FCV) ventilator delivers a steady inspiratory flow of air and actively controls expiration, without flow pauses. Linearisation of airway pressure variation showed to improve lung recruitment1. There is no evidence about the use of FCV in morbidly obese patients having laparoscopic bariatric surgery.

Case Report: Patient 1: 48-year-old woman, body mass index (BMI) 58 Kg/m2, ASA 3, scheduled for sleeve gastrectomy. Patient 2: 45-year-old male, BMI 64 Kg/m2, ASA 3, scheduled for a Roux-en-Y gastric bypass. We inserted a radial arterial catheter before induction. Total intravenous opioid free anaesthesia and awake fiberoptic intubation were used. Patients were initially ventilated with volume control ventilation (VCV) and then switched to FCV. FCV continuously measures intratracheal pressure through a dedicated pressure line. The anaesthetist configures the flow rate (F), end-expiratory pressure (PEEP), peak inspiratory pressure (PIP), and fraction of inspired oxygen (FiO_a). Respiratory rate (RR) and tidal volumes (TV) are calculated according to the respiratory system's compliance. Ventilatory parameters and gas exchange during surgery are shown in Table 1.

				Patient 1						Patient 2		
Surgery Times	Basal (T0)	VCV (T1)	FCV (T2)	FCV Pneumo- peritoneum (T3)	FCV end surgery (T4)	30′ PACU (T5)	Basal (T0)	VCV (T1)	FCV (T2)	FCV Pneumo- peritoneum (T3)	FCV end surgery (T4)	30′ PACL (T5)
RR, rpm	-	15	18	12	8	24	-	15	24	18	21	22

PEEP, cmH ₂ O	-	8	8	8	8	-	-	8	8	8	8	-
PIP, cmH ₂ O	-	23	24	30	30	-	-	21	20	24	26	-
PaO ₂ ,/ FiO ₂ ,mmHg	510	161	170	290	216	390	390	170	227	290	200	405
PaCO ₂ , mmHg	35	43	42	45	41	45	37	45	45	45	58	52

Table 1.

Discussion: In patients with severe obesity, the use of FCV ventilator allows to choose the best ventilatory settings (TV, RR, PEEP) to ensure an adequate gas exchange during abdominal laparoscopic surgery without increasing the PIP. Additionally, our patients improved gas exchange and had no postoperative pulmonary complications. Large-scale studies are essential to thoroughly assess its benefits and define its role in optimizing perioperative respiratory management.

Learning points: FCV might be an option in morbidly obese patients undergoing abdominal laparoscopic surgery.

33AP04-9

Correlation between pixel/global impedance ratio and regional time delay methods for pendelluft calculation in spontaneously breathing patients with acute hypoxemic respiratory failure

F. Cinquegrana¹, M. Trevisani¹, A. Trentini², P. Ferrara¹, S. Spadaro¹, G. Scaramuzzo¹ ¹University of Ferrara, Department of Traslational Medicine, Ferrara, Italy, ²University of Ferrara, Dipartimento di Scienze dell'Ambiente e della Prevenzione, Ferrara, Italy

Background and Goal of Study: Pendelluft is a critical factor contributing to patient self-inflicted lung injury (P-SILI). Electrical impedance tomography (EIT) has been used to calculate pendelluft through different methods. The Impedance Ratio (IR) method [1] assesses the ratio between the pixel-level sum of impedance changes and the global impedance signal, while the Time-Based (TB) method [2] evaluates the difference in regional impedance between global and regional nadir. However, there is no consensus on the optimal method, nor is there data on the correlation between their results.

This study aimed to compare the IR and TB methods in spontaneously breathing patients with acute hypoxemic respiratory failure (AHRF) receiving non-invasive respiratory support (NIRS).

Materials and Methods: This prospective, single-center physiological study included patients with AHRF within 24 hours of ICU admission. All patients received NIRS (high-flow nasal cannula or non-invasive ventilation). Demographic, clinical, and outcome data were collected. EIT images were recorded for 20 minutes using a dedicated monitor (Dräger PulmoVista).

Pendelluft was calculated as per Menga et al. [1] for the IR method and Coppadoro et al. [2] for the TB method, expressed as a percentage of global impedance. Correlation between methods was analyzed using Spearman's rank correlation.

Results and Discussion: Eighteen patients (13 males) with a median age of 74 years [65-81], BMI of 27 kg/m² [25-30], and PaO₂/ FiO₂ ratio of 164 mmHg [105-222] were included. Median pendelluft values were 34.9% [21-50] for the IR method and 2.7% [0.6-6.9] for the TB method.

A significant correlation was observed between the methods (Rs = 0.84, p < 0.001), but Bland-Altman analysis revealed a bias of 28.98 ±10.35%.

When patients were classified into high and low pendelluft groups based on median values, both methods provided consistent classifications.

Conclusion(s): The IR and TB methods for pendelluft calculation are correlated in AHRF patients receiving NIRS but show limited agreement in absolute values. Method-specific cutoffs must be considered when interpreting pendelluft results.

The distribution of gas during mechanical ventilation appears to be improved with high respiratory rate in patients undergoing robot-assisted radical prostatectomy: initial observations

E. Wikström¹, O. Stengvist^{2,3}, S. Lindgren^{4,5}, H. Hjelmgvist¹, P. Jildenstål^{6,7,3,4,8,9,10}

¹Örebro University Hospital and School of Medical Sciences, Department of Anaesthesia and Intensive Care. Örebro. Sweden. ²University of Gotheburg. Department of Anaesthesia and Intensive Care, Institute for Clinical Sciences, Gothenburg, Sweden, 3University of Gothenburg, Institute of Health and Care Sciences, Gothenburg, Sweden, 4University of Gothenburg, Department of Anaesthesia and Intensive Care. Institute for Clinical Sciences, Gothenburg, Sweden, ⁵Sahlgrenska University Hospital, Hybrid och Intervention, Göteborg, Sweden, 6Region Örebro län, Department of Anaesthesiology and Intensive Care, Örebro, Sweden, ⁷Sahlgrenska University Hospital, Department of Anaesthesia, Surgery and Intensive Careswe, Göteborg, Sweden, 8Lund University, Department of Health Sciences, Lund, Sweden, 9Nord University, Faculty of Nursing and Health Sciences, Bodö, Norway, 10 Skåne University Hospital, Department of Anaesthesiology and Intensive Care, Lund, Sweden

Background and Goal of Study: Robotic-assisted surgery is associated with steep Trendelenburg position and pneumoperitoneum, which impair respiratory mechanics. This results in higher postoperative risks. Recruitment maneuvers (RM)and PEEP titration are essential to maintain oxygenation and ventilation (1).

These actions can however compromise circulation. Ventilation with higher respiratory rate (RR) and smaller tidal volume (TV) might be a solution that promotes uniform lung aeration (2) .The goal of our study is to investigate if a higher RR can improve the distribution of the TV.

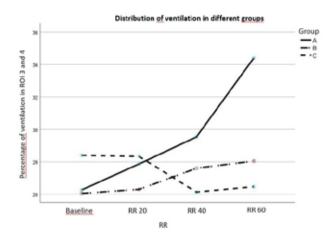

Materials and Methods: We studied ventilation during robotic prostatectomy. In tilted position RR was set to maintain normocapnia during volume-controlled ventilation. The patients were randomized to one of three groups with series of three RR (20, 40 and 60) in various order.

Demographics	Group A RR 20-40-60 (n=3)	Group B 20-60-40 (n=4)	Group C 60-40-20 (n=3)
Age, years (mean)	70	66,3	69,3
BMI, kg/m² (mean)	25,6	26,3	27,6
	ASA 1 (n=1)	ASA 1 (n=2)	ASA 1 (n=1)
ASA-class	ASA 2 (n=2)	ASA 2 (n=0)	ASA 2 (n=2)
	ASA 3 (n=0)	ASA 3 (n=2)	ASA 3 (n=0)

The distribution of ventilation was assessed with electric impedance tomography (EIT), that shows how the TV is distributed between four horizontal regions of interest (ROIs). We studied the % of ventilation reaching the two dorsal ROIs.

Results and Discussion: With the first 10 patients recruited to the trial the distribution of ventilation in ROI 3 and 4 increased from 26.8 % to 29.5% at RR 60. The effect differed between the three groups.

The results indicate that high RR alter the distribution of ventilation. When all participants have been analyzed the study hopefully will give further insights to the subject.

Conclusion(s): The initial observations indicate that RR might influence the distribution of ventilation.

Acute Respiratory Distress Syndrome (ARDS) as a rare complication after pneumonectomy. How can we avoid it?

V. Reig Calabuig¹, I. Vergés Montano¹, D. Benguría Puebla¹, J. Silva García¹, P. García Robledo¹ ¹Hospital Universitario 12 de Octubre, Servicio Anestesiología, Reanimación y Terapéutica del Dolor,

Background: Respiratory complications after pneumonectomy (eg. aspiration, pneumonia, and acute respiratory distress syndrome [ARDS]) are a frequent source of morbidity and mortality. They should be proactively prevented and aggressively treated. ARDS after pneumonectomy is a rare complication that occurs in only 4% of cases, however, the mortality rate is over 50%.

Case Report: A 71-year-old male, diagnosed with stage IV colon adenocarcinoma, with antecedent of a median, anterior and atypical lobectomy in the right lung.

In this case, he underwent an iterative right pneumonectomy and was admitted in our ICU.

At 48 hours, the patient experiences desaturation to SatO2 85% despite high-flow nasal prongs (FIO2 70% and 50 bpm), increased respiratory work, left crackles, and initial echocardiography showing good biventricular function with mild RV dilation, allowing an estimated PSP of 40-50 mmHg. At 72 hours, the patient requires sedation and orotracheal intubation due to respiratory deterioration.

Despite optimizing the respiratory parameters of MV, forcing negative fluid balance with continuous venous hemodiafiltration, corticosteroid therapy, vasoactive drugs, and triple pulmonary antihypertensive therapy, respiratory and hemodynamic failure with RV dysfunction persists.

On the 12th postoperative day, the patient showed progressive respiratory deterioration to PAFI 45 and elevated carbon dioxide levels: which led to his death with the main diagnoses of left ARDS associated with RV failure.

Discussion: Prevention of ARDS is a more effective strategy than treatment. Potential causative factors include volutrauma and hyperoxia during intraoperative single-lung ventilation, blood product transfusion, occult infection, occult aspiration, and unrecognized microemboli. Preventive measures in the operating room are based on MV with lung-protective strategies using the lowest FiO2 tolerated. Perioperative fluid administration fluid should be restricted, and the patient should be aggressively diuresed (with vasopressor support if needed). Once ARDS has set in, the only possible treatment is supportive.

Veno-venous ECMO to allow spinal surgery in patient with chronic rejection after bipulmonary transplant

J. Magalhães Pereira¹, C. Magalhães¹, C. Bispo¹, B. Azevedo¹

¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Patients with chronic rejection after a bipulmonary transplant present unique challenges when undergoing spinal surgery in ventral position especially in terms of ventilation. Venovenous extracorporeal membrane oxygenation (V-V ECMO) is a rescue tool recommended for patients with intact cardiac function with hypoxemic and hypercapnic respiratory failure.1

Case Report: A 66-years-old woman with a medical history of pulmonary transplant in 2011 with chronical rejection, since 2012; presenting with respiratory insufficiency with need of long duration oxygen therapy 2L/min.

The patient presented with fracture of the L3 vertebral body with marked compression of the spinal canal at L3, proposed for urgent kyphoplasty. Due to the patient's comorbidities, surgery positioning and need for organ support in the postoperative period, it was decided to cannulate pre-operatively for venous-venous extracorporeal membrane oxygenation.

The ECMO team, prepared the venous cannulation femoral-femoral in the ECMO unit, with strong fixation of the cannulas due to reposition needed and difficult access to them during surgery. The patient was transferred to the operating room and prepared for surgery.

Standard ASA monitoring, along with invasive arterial blood pressure, central venous pressure and depth of anesthesia monitoring were used and general intravenous anesthesia was induced, a wired endotracheal tube placed, and the patient was mechanically ventilated.

The induction proceeded in dorsal decubitus in the patient's bed and transferred carefully to the surgical bed in ventral decubitus. ECMO team was present during the positioning and the procedure for management and fast approach in case of decannulation with subsequent ultimate risk of severe spinal cord injury or even death. During the surgery, the patient needed one red blood cell concentrate and vasopressor support, with norepinephrine perfusion. The surgery proceeded without further complications and the patient was transferred to the ECMO unit.

Discussion: V-V ECMO ensures adequate gas exchange, lowers the risk of further damage to transplanted lungs and stabilizes respiratory parameters during a high-risk procedure.1

Reference:

1. Prasad A., Scialpi S. ATOTW 514 - Basics of ECMO: Part 1 (16 January 2024)

Learning points: V-V ECMO can be a lifesaving adjunct, should be used as a tool to allow certain high-risk procedures, after carefully balance the thrombotic and bleeding risk to optimize outcomes.

33AP05-2

Inhaled milrinone: an option in patients with pulmonary hypertension in non-cardiac surgery

M. Guarda¹, P. Branco¹, B. Sousa¹, N. Santos¹, T. Seixas¹ ¹Hospital Professor Doutor Fernando Fonseca, Anesthesiology, Amadora, Portugal

Background: Non cardiac surgery in patients with pulmonary hypertension (PH) is increasing and the estimated mortality after emergent general surgery is high (15-50%)1.

There are no evidence-based recommendations on the use of specific inhaled pulmonary vasodilators in the intraoperative period for non-cardiac surgery.

Case Report: We present a case of a 51 year-old woman with severe type IV pulmonary hypertension (PSAP 70 mmHg) chronically treated with sildenafil that underwent emergent laparotomic incisional hernia repair.

Under ASA standard monitoring and invasive blood pressure monitoring, 5 mg of inhaled milrinone was administered in conjunction with intravenous norepinephrine.

Anesthetic induction was performed with alfentanil, ketamine and etomidate and maintenance was carried out with sevoflurane and remifentanil perfusion. No complications related to PH occurred during surgery or in the postoperative period.

Discussion: Patients with PH undergoing non cardiac surgery are at increased risk of acute right ventricular (RV) failure and fatal complications². Milrinone is a selective phosphodiesterase-3 inhibitor which increases the cyclic adenosine monophosphate levels of smooth muscle cells. It has been used as an additional pulmonary vasodilator therapy in cardiac surgery and in neonates with pulmonary hypertension. In its inhaled form, milrinone causes selective pulmonary vasodilation, improving the V/Q ratio. Additionally, it has positive inotropic properties, increasing cardiac output, while minimizing adverse effects such as hypotension3.

Learning points: In patients with severe pulmonary hypertension undergoing non-cardiac surgery inhaled milrinone before anesthetic induction appears to be effective as a selective pulmonary vasodilator, improving right ventricular function.

33AP05-3

Iron status and the risk of idiopathic pulmonary fibrosis: a mendelian randomization study

J. Zhou¹, M. He¹, R. Wang¹, X. Li¹ ¹West China Hospital, Sichuan University, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: Idiopathic pulmonary fibrosis (IPF) is a fatal lung disease with unknown etiology. Both preclinical researches and clinical samples have shown an association of iron accumulation with a higher risk of IPF and a decline in lung function. Iron status might be a novel target for IPF therapy if a causal relationship exists. Using mendelian randomization, we investigated the putative causal role for iron status in IPF.

Materials and Methods: Single nucleotide polymorphisms (SNPs) for iron status were identified from a genome-wide association study (GWAS) on 48,972 individuals. The outcome data came from the IPF GWAS (1369 cases: 435866 controls) in UK Biobank. We conducted liberal analyses (using SNPs associated with at least one of the biomarkers of iron status) and conservative analyses (using SNPs with concordant change of biomarkers of iron status), with inverse variance weighted (IVW) method as the main analysis.

We then performed sensitivity analyses including weighted median, MR-Egger and MR-pleiotropy residual sum and outlier, as well as leave-one-out analysis to detect pleiotropy.

Results and Discussion: In the liberal analyses, IPF was associated with lower log-transformed ferritin using IVW method (odds ratio [OR] = 0.998, 95% confidence interval [95% CI] = 0.997 -0.999, p = 0.030).

There were no evidence of a link between iron, transferrin, transferrin saturation and the risk of IPF. In the conservative analyses, we found no evidence of association between four biomarkers of iron status and IPF using IVW method with OR 0.999 (95% CI: 0.998 - 1.001) per standard deviation increase in iron, 0.999 (95% CI: 0.996 - 1.002) in ferritin, 1.000 (95% CI: 0.999 - 1.002) in transferrin , and 1.000 (95% CI: 0.999 - 1.001) in transferrin saturation. Sensitivity analyses suggested no pleiotropy detected (all p > 0.05).

Conclusion(s): We provided potential genetic evidences for the causal associations of lower ferritin with increased incidence of IPF. However, the clinical implications of this finding warrant further investigation.

33AP05-4

Pulmonary edema in a healthy orthopedic patient: differential diagnoses

R. Pinto de Sá¹, J.F. Costa¹, A.T. Cruz¹, M. Pinto¹, P. Fragoso¹, C. Gomes¹ ¹ULS de Braga, Anesthesiology, Braga, Portugal

Background: Naloxone-induced pulmonary edema (PE) is a rare post-operative pulmonary complication, with an unclear mechanism. Negative pressure PE is more common, caused by acute negative intrathoracic pressure generated by spontaneous respiratory efforts against an obstructed airway.

Case Report: A 26-year-old healthy boy was submitted to humeral surgery under general anesthesia, which ran uneventfully and lasted 1 hour. The analgesic regimen included 250 mcg of fentanyl. After surgery, the patient was admitted in the post anesthetic care unit (PACU), where he presented obtunded, hypopneic, with miotic pupils, but hemodynamically stable. We suspected opioid intoxication and administered a bolus of 0,4 mg of naloxone, beside supportive measures.

As a result, he totally recovered consciousness and refered severe pain, for which an ultrasound-guided infraclavicular block was performed. However, the patient remained hypoxemic and developed a hemoptysis-associated cough, with an increase in respiratory rate. The ABG showed type 1 respiratory failure and, to confirm the diagnosis, an angio-CT was done.

The echocardiogram was normal. Assuming ARDS due to a noncardiogenic PE, the treatment included oxygen therapy, noninvasive ventilation and self-prone with progressive fast clinical improvement. The patient was discharged 3 days after surgery, fully recovered.

Discussion: We present a case of postoperative PE of unknow origin following naloxone administration to reverse fentanylinduced respiratory depression. Differential diagnosis included negative pressure PE and PE associated with naloxone.

Naloxone-induced PE is thought to involve an adrenergic crisis triggered by high-dose or rapid administration, although it has also been reported with low doses. This leads to excessive catecholamine release, causing pulmonary vasoconstriction and shift of fluids to the third space.

Alternatively, upper airway obstruction may cause negative pressure PE. Although no laryngospasm was documented and the ventilation was supported at the time of fentanyl-induced respiratory depression, it cannot be excluded.

Learning points: While the cause of this patient's PE may remain uncertain, it may have been exacerbated by elevated vasomotor tone due to pain.

In addition to effective pain management with opioid-sparing techniques, we suggest fractionated administration of naloxone, using the lowest effective dose to elicit the desired response.

Evaluation of the effect of different FIO2 values on perioperative atelectasia with lung ultrasonography in laparoscopic cholecystectomy operations

S. Ozyurek Yuce¹, A. Topal², H.N. Günay², S. Arican², R. Yilmaz², S. Yuce³

¹Konya City Hospital, Anesthesiology and Reanimation, Konya, Turkey, 2 Necmettin Erbakan University Faculty of Medicine, Anesthesiology and Reanimation, Konya, Turkev. ³Eregli State Hospital, Anesthesiology and Reanimation, Konya, Turkey

Background and Goal of Study: The main purpose of this study is to use lung ultrasonography to evaluate and ascertain the impact of variations in inspired oxygen fractions (FiO_o) in anesthetic management during laparoscopic cholecystectomy cases on perioperative atelectasis.

Secondary purpose is to monitor and determine how postoperative pulmonary complications (PPC) and hospital stay duration are affected by variations in inspired oxygen fractions (FiO₂).

Materials and Methods: Patients who underwent elective laparoscopic cholecystectomy, aged 18-80, with ASA physical status I-III was included. Patients were classified into two groups: Group D and Group Y based on the applied FiO2. The target SpO2 value in all patients was determined to be 94%; FiO₂ in anesthesia induction as D group 0.7 - Y group 1.0, intraoperative period as D group 0.3 - Y group 0.6, wake-up phase as D group 0.7 - Y group 1.0, and PACU as D group 2 - Y group 10 liters/minute oxygen via oronasal mask implemented with support.

Patients were evaluated using the Modified Lung Ultrasonography Score (MLUS) at two distinct times: 15 minutes before the procedure in the preoperative evaluation unit and 30 minutes after the operation in the PACU.

Results and Discussion: The postoperative MLUS score demonstrated a statistically significant increase in the high FiO_a group compared to the low FiO₂ group (p = 0.034). It was established that the postoperative MLUS score exhibited a statistically significant augmentation relative to the preoperative baseline in both groups (p<0.001).

Additionally, there were no statistically significant difference between the groups regarding intraoperative hypoxemia, postoperative pulmonary complication (PPC) incidence, and discharge duration.

Conclusion(s): This study demonstrated that high FiO, usage leads to a higher incidence of atelectasis compared to low FiO₂ usage according to the Modified Lung Ultrasound Score. Alveolar denitrogenation with oxygen promotes oxygen absorption at lectasis.

33AP05-6 Lung ultrasound in patients after lung transplantation

D. Martsinkevich¹, V. Estryna¹, A. Dzyadzko¹, I. Makhanouski², V. Hirdziuk³, V. Yaromchyk¹ ¹Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Anesthesiology and Intensive Care Unit No. 2, Minsk, Belarus, 2Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Anesthesiology and Intensive Care Unit No. 5, Minsk, Belarus, 3Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Anesthesiology and Intensive Care Unit No. 4, Minsk, Belarus

Background and Goal of Study: Lung transplantation is the only treatment for the terminal stage of lung diseases. In the early postoperative period, an important task is monitoring the condition of the lung graft. Ultrasound imaging has several advantages over other instrumental diagnostic methods for the early detection of postoperative complications associated with graft dysfunction.

Our aim was to evaluate the feasibility of using ultrasound to examine lung grafts in the early postoperative period for diagnosing pulmonary complications in patients after lung transplantation.

Materials and Methods: As part of a prospective study, 32 lung ultrasounds were performed on 7 patients after lung transplantation. Sonography was conducted using a four-point protocol on the first and third postoperative days. The results of ultrasound examination were compared with the patient's fluid balance, oxygenation and ventilation parameters, and chest CT scans.

Results and Discussion: A statistically significant correlation was identified between the number of B-lines and the fluid balance (r=0.71; p<0.001), between PEEP levels and B-lines (r=0.88; p<0.001), and between B-lines and FiO2 levels (r=0.79; p<0.001). The median number of B-lines observed on the first postoperative day was 4.63, with 100% of patients having a positive fluid balance. On the third postoperative day, the median number of B-lines was 2.0, and 63% of patients had a negative fluid bal-

Additionally, in patients with signs of lung graft dysfunction, ultrasound revealed varying degrees of atelectasis, subpleural consolidations, and pleural effusions, which allowed for rapid optimization of intensive care tactics and increased treatment efficacy.

Conclusion(s): Ultrasound findings in the diagnosis of lung grafts show a significant correlation with PEEP, FiO2, and fluid balance indicators. Ultrasound of lung grafts is an accurate (AUC=0.9±0.05 with 95% CI [0.72-1.0]; p<0.004), non-invasive, safe, and accessible method for assessing extrapulmonary fluid, atelectasis, pleural effusions, and consolidations. Sonography can be utilized for the rapid ultrasound diagnosis of pathological processes in lung grafts.

33AP05-7

Association between postoperative oxygen saturation within the first 2 days postoperative and the incidence of surgical site infection: Post-hoc analysis of 3 randomized trials

J. Borrell Vega¹, M. Linares¹, R. Marrero¹, J. Vallverdú¹, S. Martínez-Otero¹, E. Rivas^{1,2} ¹Hospital Clínic Barcelona, Department of Anaesthesiology, Barcelona, Spain, ²University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer- IDIBAPS, Barcelona, Spain

Background and Goal of Study: Surgical site infections (SSIs) are the most common hospital-acquired infections among surgical inpatients, increasing morbi-mortality. Oxygen saturation and perioperative oxygen therapy have been identified as potential preventive measures for reducing SSI rates.

We aim to assess whether minimum postoperative oxygen saturation during the first 48 hours is associated with the incidence of a composite of SSIs within 30 postoperative days.

Materials and Methods: This post-hoc retrospective study analysed data from three randomized clinical trials: iPROVE, iPRO-VEO2, and iPROVE-OLV. The main outcome was a composite measure of SSIs, including superficial, deep, or organ infections, septic shock, and anastomotic leaks within 30 postoperative days. The exposure was the lower postoperative oxygen saturation during postoperative days 1 and 2 while in the surgical ward, and the critical oxygen saturation (SpO₂<92%). Statistical analysis included U-Mann-Whitney and chi-squared tests. Data was analysed using SPSS.

Results and Discussion: Demographics and main outcomes are shown in Table 1. Of 1,456 patients, 257 suffered SSIs. Surgeries included mostly thoracic patients (36%), followed by GI-colorrectal (20%) and GI-non colorectal (20%). Lower oxygen saturation during the second postoperative day was significantly associated with SSIs (P<0.05). Moreover, a critical SpO₂ <92% on postoperative day 2 (POD2) was more prevalent in the SSI group (P<0.01) (Table 1).

	SSi (n=257)	Non-SSi (n=1199)	P value
Age, y.o	66 ± 12	63 ± 14	NS
BMI, Kg/m ²	27 ± 4	26 ± 4	NS
Active smoker n, (%)	31 (12)	607 (19)	NS
SpO ₂ POD1, %	96.6± 2.6	96.8 ± 2.4	NS
SpO ₂ POD2, %	95.8 ± 2.9	96.4 ± 2.4	P<0.05
Critical O, SpO, n, (%)	36 (14%)	98 (8%)	P<0.001

Table 1. Demographics and main outcomes

Conclusion: The lowest oxygen saturation values during the second postoperative day and an increased rate of critical SpO₂ <92% are associated with an increased incidence of surgical site infection. Future studies for the optimization oxygen saturation during the first two postoperative days to reduce SSI rates and improve patient outcomes are needed.

33AP05-8 How hard is to ventilate a miner, lesson learned: case report

M. Burmuzoska¹, S. Trenchevska², A. Kokareva¹, I. Kocevski3

¹University Clinic of Anesthesiology, Anesthesiology, Reanimation and Intensive Care, Skopje, North Macedonia, The Republic of, 2Clinic Hospital Dr. Trifun Panovski-Bitola, Anesthesiology, reanimation and intensive care. Bitola. North Macedonia. The Republic of. 3University clinic of neurosurgery-Skopje, Neurosurgery, Skopje, North Macedonia, The Republic of

Background: Interstitial lung fibrosis represents a condition highly demanding for perioperative and postoperative anesthetic management. Little is known about the best ventilatory strategy and its impact on mechanics of breathing.

Case Report: A 35 years old male patient was admitted due to intraventricular tumor for elective surgical removal. His history revealed PCA stenting, hypertension, smoking and BMI 36,7.

Next day, after placing a routine monitoring, he was induced in general anesthesia. After an uneventful intubation, there was difficulty for mechanical ventilation with high pulmonary pressures and low compliance.

Therapy with corticosteroids, aminophylline, MgSO4, spray salbutamol and deepening of anesthesia didn't improve his condition. Due to consequential risk of increased intracranial pressure and bleeding, it was decided to awake him and postpone the surgery. After extubation, his saturation improved from 85 to 95%. He revealed information previously not known, that he worked in a mine for 8 years. His auscultation before surgery showed weakened vesicular sounds and unremarkable chest X-ray.

After pulmonology consultation, lung diffusion test (DLCO) showed reduced diffusion and spirometry in favor of restrictive lung disease. He was prescribed corticosteroids and operated few weeks later. He could have been ventilated only with pressure control ventilation with stable surgical course and recovery.

Discussion: Lung fibrosis represents a great perioperative risk especially when it is accompanied with decreased vital capacity, high BMI, smoking, heart disease and occupational hazard1. Pulmonary prehabilitation measures optimize the patient for anesthesia. When it is possible, regional anesthesia is preferred, but when general is the only option restrictive fluid strategy and pressure controlled ventilation are facilitating perioperative management.

2. Marchioni A, Tonelli R et al. Ventilatory support and mechanical properties of the fibrotic lung acting as a "squishy ball". Ann Intensive Care. 2020 Feb 4;10(1):13. doi:10.1186/ s13613-020-0632-6.

Learning points: Allowing high PEEP and and exposing the lung of high pressures brings a risk of injury by so called forming of "squishy ball" lung areas with devastating effects2.

33AP05-9

Laryngeal mask airway: not immune to laryngospasm-induced negative pressure pulmonary edema

M. Cardiga¹, M. Brízido¹, L. Pacheco¹, M. Gusmão¹ ¹Hospital da Luz Lisboa, Anesthesiology, Lisbon, Portugal

Background: Postextubation negative pressure pulmonary edema (NPPE) results from upper airway obstruction and, although uncommon, it is a well-known potential complication of anesthe-

Usually, it is associated with endotracheal intubation and mechanical ventilation, but there are some reports showing that it can develop after laryngeal mask (LM) use2.

This case report underlines NPPE after LM use in a young and healthy patient.

Case Report: A 20-year-old male, ASA I, underwent bilateral inguinal hernioplasty under spinal anesthesia. Conversion to general anesthesia with an I-gel LM was performed due to patient agitation.

At the end of the surgery, after LM removal, inspiratory stridor and oxygen desaturation (SpO2 78%) were noted. Immediate measures included ventilation with face mask delivering 100% oxygen and positive pressure, resulting in clinical and oxygenation recovery (SpO2 97%).

In the post-anesthesia care unit, hypoxemia (SpO2 90-92%), persistent cough, pulmonary crackles and a PaO2 of 54 mmHg developed. NPPE was suspected and treatment with morphine, furosemide and oxygen via face mask (6-8 L/min) was initiated. A chest X-ray revealed bilateral interstitial infiltrates.

After 24 hours monitoring in the ICU, he was discharged home with complete resolution of radiological alterations and symp-

Discussion: NPPE results from forceful inspiratory efforts against airway obstruction, which increase pulmonary capillary pressure and fluid transudation into alveoli1.

Although rare with LM use, the development of NPPE should always be kept in mind, especially following airway obstruction events, most frequently laryngospasm. Chest X-ray plays a key role in confirming the diagnosis and guiding treatment1.

- 1. Ma J, et al. Negative pressure pulmonary edema. Exp Ther Med. 2023;26:455.
- 2. Vandse R, et al. Pulmonary edema with laryngeal mask. Int J Crit IIIn Inj Sci. 2012;2:98-103.
- 3. Moreira BL, et al. Acute dyspnea: negative pressure edema. J Bras Pneumol. 2022;48:e20220294.

Learning points: This case demonstrates that rapid recovery is possible with a quick diagnosis and intervention, including oxygen therapy, noninvasive ventilation and fluid management.

Young, healthy male patients are at risk for NPPE, due to their greater muscle mass that can produce high negative intrapleural pressures3.

33AP05-10

Loss of pleural fluid around the lungs during positive pressure ventilation

J. van Egmond¹, J.P. Mulier² ¹Radboud Iniversity Medical Centre, Anesthesiology, Nijmegen, Netherlands, ²University Gent, Anesthesiology, Gent, Belgium

Background and Goal of Study: Lungs, filled with air to FRC level, will float on water, the specific gravity of the lung being 0.3 and that of water (or pleural fluid) 1 g/cm3.

Materials and Methods: According to Casha the equilibrium between capillary forces and negative pleural pressure manages to maintain a thin layer of pleural fluid around the lung.

The relation between force F and thickness d of the layer, due to the surface tension γ , is determined by Jurin's law: F = $2.y.A.\cos(\alpha)/d$, here α = is the angle between the surfaces and gravity. Or $d = 2.\gamma . cos(\alpha)/P$ because force F over surface area Aequals pressure P, here pleural pressure. So there is an inverse relation between thickness and local pressure.

Moreover, a fluid layer is only sustainable when pleural pressure is negative. Casha calculated the thickness of pleural fluid layer to range from 20 µ (corresponding to a pleural pressure of about -10 cmH₂O) to about 200 μ (at a pressure of -1 cmH₂O) from the apex to the base of the lung.

Results and Discussion: During natural breathing the pleural pressure varies from about -6 to -10 cmH₂O, with lower pressures being observed during deep sighs or strenuous activities. Negative pressure ventilation replicates these negative pleural pressures while positive pressure ventilation has the opposite effect. In healthy individuals, the compliances of the thoracic wall and lungs are approximately equal.

This means that an increase in airway pressure by 2 cmH₂O typically raises pleural pressure by about 1 cmH_aO. For example, in a theoretical patient with pleural pressure of -10 cmH₂O at the lung apex and -1 cmH₂O at the base (with individual variation), an airway pressure of 2 cmH₂O will neutralize the pleural pressure at the base.

Further increases in airway pressure progressively eliminate negative pleural pressure at higher lung levels.

Conclusion(s): In ARDS patients[i], pleural pressures as high as +15 cmH₂O or more have been reported during mechanical ventilation, indicating that the entire lung is subjected to positive pressure. This disrupts the pleural fluid layer, leading to its disappearance[iii].

Consequently, the visceral and parietal pleurae, both covered with microvilli, are pressed directly against each other, impairing lubrication and disrupting homeostasis[i].

33AP05-11

Exploring rare terrain: Laparoscopic rectal surgery in a patient with Birt-Hogg-Dubé syndrome

G. Carreira¹, M. Pascoal¹, C. Ferreira¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Birt-Hogg-Dubé syndrome (BHDS) is a rare autosomal dominant disorder characterized by fibrofolliculomas, pulmonary cysts, and renal neoplasms. It results from mutations in the FLCN gene, which encodes folliculin.

Patients with BHDS require individualized perioperative management due to risks such as pneumothorax and renal dysfunction. Surgical interventions involving general anesthesia in BHDS are infrequently reported.

Case Report: A 71-year-old male with BHDS underwent anterior rectal resection via a laparoscopic approach under general anesthesia. His history included multiple pulmonary cysts without prior pneumothorax.

Anesthetic management prioritized minimizing barotrauma by employing lung-protective ventilation strategies. The laparoscopic technique was chosen for its minimally invasive nature, to reduce stress on pulmonary and renal systems.

The procedure was uneventful, with stable hemodynamics. Postoperative recovery was smooth, with no respiratory or renal complications, and the patient was discharged on postoperative day

Discussion: BHDS poses unique perioperative challenges due to multi-system involvement. Pulmonary cysts elevate the risk of barotrauma and pneumothorax, especially under positive-pressure ventilation. Renal dysfunction necessitates careful evaluation of nephrotoxic drugs.

In this case, multidisciplinary planning and a minimally invasive surgical approach facilitated a favorable outcome. The patient's smooth recovery underscores the importance of tailored perioperative strategies for rare syndromes like BHDS.

References:

1. Miranda C: Birt-Hogg-Dubé syndrome: a rare cause of pneumothorax complicating general anaesthesia. Wiley. 2. Crane JS, Rutt V, Oakley AM: Birt-Hogg-Dube Syndrome. StatPearls Publishing. Published Online First: 5 December 2024. 3. Oliveira RC, Tavares E, Sousa V, et alBirt-Hogg-Dubé syndrome: awareness is important! Case Reports 2017;2017:bcr-2017-221022.

Learning points:

- 1. Comprehensive preoperative evaluation is critical to address risks associated with pulmonary and renal manifestations of **BHDS**
- 2. Multidisciplinary planning and personalized anesthetic techniques, including lung-protective strategies, are essential.
- 3. Minimally invasive approaches reduce perioperative morbidity and enhance recovery in BHDS patients.

33AP06-2

Helmet continuous positive airway pressure (hCPAP) in patients with acute respiratory failure prospective observational study with modified helmet

L. Wroblewski¹, B. Sadownik^{2,1}, P. Andruszkiewicz¹ ¹Medical University of Warsaw, 2nd Department of Anaesthesiology and Intensive Care, Warsaw, Poland, ²Medical University of Warsaw, Department of Descriptive and Clinical Anatomy, Warsaw, Poland

Background and Goal of Study: The use of oxygen therapy and continuous positive airway pressure (CPAP) reduces the percentage of patients who will require mechanical ventilation due to respiratory failure in pulmonary edema, COPD, ARDS or COVID-19. Long-term use of standard masks for CPAP is limited by their intolerance. The use of a helmets allows to effectively maintain CPAP for up to few weeks, but the risk of CO₂ accumulation necessitates a high flow of gases (40-60I/min), increasing oxygen consumption and patient discomfort.

The aim of the study was to evaluate the efficacy, safety and tolerability of modified helmet for oxygen therapy in patients with acute hypoxemic respiratory failure.

Materials and Methods: Prospective observational study. A total of 80 patients with respiratory failure due to postoperative atelectasis, pulmonary edema or pneumonia with an oxygenation index of 150-250 and/or SpO₃<92% despite passive oxygen therapy were enrolled. Based on the results of computed simulation tests. test-stand measurements and tests on 40 healthy volunteers. the helmet was modified by changing the place of gas outlet to the central and limiting the gas flow to 30 I/min. Four methods of generating gas flow were used (gas regulators, gas mixer, CPAP machine and ventilator). Oxygen therapy was carried out in accordance with the ARDS Network scheme.

Patients vitals parameters were monitored with transcutaneous pCO₂ in addition. In-helmet CO₂ concentration, humidity and temperature were measured. Patients also rated the perceived noise, dryness and warmth.

Results and Discussion: After 60 minutes of hCPAP, 69% of patients had improved oxygenation parameters allowing for stay on passive oxygen therapy only, 21% improved but required continuation of CPAP, and 10% discontinued the helmet use at request.

The analysis of variance did not show significant differences for the selected method of generating gas flow. The CO2 concentrations in the helmet did not change significantly with an average value of <1%. The average assessment of the patient's noise perception remained low. No significant hypercapnia was reported in percutaneous measurements. No critical events occurred.

Conclusion: Modification of the position of the gas outlet allows for effective oxygen therapy with helmet CPAP in patients with respiratory failure with limited gas flow.

Severe respiratory failure in severe pneumococcal pneumonia: The role of differential lung ventilation and venovenous extracorporeal membrane oxygenation. A case report

S. Alonso Gómez¹, C. López Queijo¹, F. García¹, R. Iraburu¹, C. González¹, F. Aneiros Peña¹ ¹University Clinical Hospital of Santiago, Spain., Department of Anaesthesiology, University Clinical Hospital of Santiago, Spain., Santiago, Spain

Background: Pneumococcal pneumonia is a common but potentially severe disease. Both double-lumen tubes (DLT) for differential lung ventilation (VPD) and venovenous extracorporeal membrane oxygenation (VV ECMO) have been described in the literature as potential options in severe cases.

We present the case of a patient with tension pneumothorax and pneumococcal pneumonia who required both devices for management.

Case Report: A 41-year-old male with right tension pneumothorax and sepsis (pneumococcal origin) required pleural drainage and was admitted to the ICU. After 16 hours, his condition worsened, leading to respiratory failure, necessitating intubation. Despite mechanical ventilation, oxygenation failed, so a left DLT was placed, and VPD was initiated with two unsynchronized ventilators, improving oxygenation. Once stabilized with a P/F ratio <100, VV ECMO was started. A new pleural drain was placed.

After 24 hours, the DLT was replaced with a conventional endotracheal tube, and protective ventilation with high FiO2 was started. Severe sepsis and renal failure were treated with vasopressors and hemodiafiltration. As lung re-expansion progressed, FiO2 levels were gradually reduced, and ECMO was removed on day 13, with successful extubation to high-flow oxygen therapy two days later.

Discussion: Differential lung ventilation and venovenous extracorporeal membrane oxygenation are essential tools in managing severe respiratory failure. VPD stands out as an effective bridge to ECMO in cases of severe intrapulmonary shunt, allowing for oxygenation optimization before initiating extracorporeal support. Additionally, in resource-limited settings or when ECMO is not a viable option, VPD provides a cost-effective and accessible alternative using standard intensive care equipment.

Combined, as demonstrated in the presented case, these strategies are not mutually exclusive but complementary, enabling patient stabilization during critical stages and promoting recovery.

References:

Creech K T, Chaudhry U (May 20, 2021) One-Lung Ventilation in a Patient With Necrotizing Pneumonia Complicated by a Bronchopleural Fistula. DOI 10.7759/cureus.15138

Learning points:

Consider VPD in cases of severe shunt or refractory respiratory failure as a bridge to ECMO.

Understand VPD as an effective, more accessible, and cost-effective option in certain cases.

Consider VPD in severe shunt or respiratory failure cases that are not candidates for VV ECMO.

33AP06-4

Invasive pulmonary aspergillosis in previously healthy 48-year-old women

K. Kosz¹, M. Kurzeja¹, K. Ślusarczyk¹, P. Kutnik², J. Wasiewicz³, P. Piwowarczyk² ¹Teaching Hospital No 1, Department of Anaesthesiology and Intensive Care, Lublin, Poland, 2Institute of Medical Sciences, The John Paul II Catholic University, Faculty of Medicine, Lublin, Poland, 3Institute of Medical Sciences, The John Paul II Catholic University, Students' Scientific Association at Faculty of Medicine, Lublin, Poland

Invasive Pulmonary Aspergillosis (IPA) is a common but underappreciated cause of death among patients in Intensive Care Unit (ICU). It occurs in 2.8% of this population with mortality ranging up to 90%.

Case: A 48-year-old female was admitted to Intensive Care Unit (ICU) due to unexplained respiratory failure. For three weeks she was treated with beta-lactams, macrolides and fluoroquinolones for pneumonia symptoms. Vital signs in the ICU were: blood pressure 100/50 mmHg, heart rate 120/min, temperature 37° C, respiratory rate (RR) 50/min and arterial oxygen saturation 63%. Performed chest X-ray revealed diffused bilateral opacities and patient met criteria for severe Acute Respiratory Distress Sydrome. She was intubated and ventilated in pressure-regulated volume control mode with 60% of oxygen.

We initiated prone positioning, neuromuscular blockade and broadened pharmacotherapy with Voriconazole and Methyloprednizolone. All microbiological cultures, bronchoaspirate and serum for ELISA-based Aspergillosis revealed negative results. Second day, due to critical respiratory failure and lack of improvement after ventilatory manouvers, we started Veno-Venous Extracorporeal-Membrane-Oxygenation (ECMO). Mechanical ventilation with DuoLevel mode: P $_{\rm low}$ 13 cm H2O and P $_{\rm high}$ 28 cm H2O was applied and the static compliance was 16 ml/cm H₂O.

During ICU-stay the woman's general state remained critical, chest X-ray's progressed to total bilateral opacities and patient became fully ECMO-dependent. Woman died 11 days after ICU admission and 9 days after ECMO initiation. While cause of death initially remained unclear, the postmortem examination revealed the presence of IPA.

IPA affects not only immunocompromised patients and it is imperative to standardize management for non-neutropenic ICU population. Diagnosis might be challenging as radiological features such as "halo" or air crescent sign are rarely described and non-culture-based tests seems to have low diagnostic value. Even though obtaining histological tissue may not be feasible, it still remains a golden standard for proven diagnosis [1]

Referencs:

1. Bassetti, M. et al. Invasive Fungal Diseases in Adult Patients in Intensive Care Unit (FUNDICU): 2024 consensus definitions from ESGCIP, EFISG, ESICM, ECMM, MSGERC, ISAC, and ISHAM.

Learning points:There is an emerging need for further research concerning IPA diagnosis criteria. Early initiation of antifungal therapy is crucial for limiting mortality in ICU patients.

33AP06-5

Heart-lung interactions to predict hemodynamic tolerance to the Open Lung Approach

J.D. Jimenez^{1,2}, S. Spadaro^{3,4}, F. Escriba Alepuz¹, O. Díaz-Cambronero^{1,2}, M.P. Argente Navarro^{1,2}, G. Mazzinari^{1,5}

¹Hospital Universitari i Politecnic La Fe, Department of Anaesthesiology, Valencia, Spain, ²Universitat de València, Departament de Medicina, Facultat de Medicina i Odontologia, Valencia, Spain, 3University of Ferrara, Department of Translational Medicine, Ferrara, Italy, ⁴Azienda Ospedaliera Universitaria di Ferrara, Anesthesia and Intensive Care Unit, Emergency Department, Ferrara, Italy, 5Universitat de València, Department d'Estadística i Investigació Operativa, Valencia, Spain

Background: The open lung approach (OLA) uses recruitment maneuvers (RMs) to increase intrathoracic pressure and adjust individualized PEEP, which may reduce venous return. Heart-lung interaction (HLI) parameters, like pulse pressure variation (PPV) and tidal volume challenge (TVC), predict fluid responsiveness by assessing hemodynamic changes with lung volume variations. We hypothesize that HLI parameters may also predict hemodynamic response to OLA.

The main goal is to determine if HLI parameters (TVC and PPV), measured pre-RM, predict a ≥10% cardiac index (CI) decrease 5 minutes post-RM.

Further, we aimed to assess if CI changes correlate with mean arterial pressure (MAP), evaluating MAP's reliability in reflecting hemodynamic impact.

Methods: This prospective study includes adult surgical patients with normal cardiopulmonary function on invasive ventilation and hemodynamic monitoring. Eligible patients show adequate arterial waveform for pulse contour analysis (MostCare®) and potential RM benefit (positive air-test or clinical condition).

Exclusion criteria: pneumoperitoneum, open chest, or RM contraindications. HLI and hemodynamic parameters were measured pre- and post-RM. Patients were classified as TVC-positive (PPV increase ≥3) or TVC-negative.

Sample size calculated as 72. Logistic regression used PPV at 6 and 8 mL/kg Tv (PPV_g, PPV_g) and TVC as predictors, with ≥10% CI decrease as the binary outcome. Model performance assessed by sensitivity, specificity, predictive values, and AUROC. Pearson correlation evaluated CI-MAP relationships.

Results: Preliminary data from 33 patients (15 TVC + and 18 TVC -) show TVC significantly predicts a ≥10% CI decrease, with a coefficient of 0.68 (p<0.01) and an AUC of 0.85. PPV_8 and PPV_6 showed moderate and mild discrimination (AUC 0.75 and 0.64). No significant CI-MAP correlation was found pre- and post-OLA. Initial findings suggest HLI parameters may predict hemodynamic tolerance to OLA.

Thus, HLI-guided optimization may prevent CI decrease, as MAP alone cannot fully assess this hemodynamic impact.

Conclusions: Preliminary results indicate HLI parameters may enhance hemodynamic management during OLA.

Predictive value of perioperative amino-terminal brain natriuretic peptide for postoperative pulmonary complications in elderly patients undergoing non-cardiac surgery

Y. Zhu^{1,2,3}, F. Wang^{2,4}, H. Zhu¹, Y. Zhao², G. Chen², T. Zhu² ¹Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Emergency Department, State Key Laboratory of Complex Severe and Rare Diseases, Beijing, China, ²West China Hospital of Sichuan University, Department of Anesthesiology, Chenadu, China, 3Sichuan Cancer Hospital, Department of Anesthesiology, Chengdu. China, 4Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital, Department of Anesthesiology, Chengdu, China

Background and Goal of Study: To assess the predictive value of preoperative amino-terminal brain natriuretic peptide (NTpro BNP) for postoperative pulmonary complications (PPCs) in elderly patients.

Materials and Methods: Data were prospectively collected from 174 elderly patients undergoing non-cardiac surgery, and NT-pro BNP levels were measured 2 hours before surgery. Full subset regression was used for variable screening, and multivariable logistic regression was used to construct the model.

The predictive value of preoperative NT-pro BNP for PPCs was evaluated by area under the receiver operating characteristic curve (AUC) and decision analysis curve.

Results and Discussion: PPCs occurred in a total of 22 patients (12.64%). Full subset regression analyses were performed to screen the final variables, which were ultimately included in the multivariable logistic regression model as gender (OR=0.48, 95% Cl: 0.29-0.80), ASA classification (OR=2.89, 95% Cl: 1.69-4.94), activity tolerance (grade 2: OR=0.23, 95% CI: 0.12-0.44 OR=1.14. 95% CI: 0.58-2.23), breath-holding test classification (grade 2: OR=0.40, 95% CI: 0.16-1.00; grade 3: OR=2.13, 95% CI: 0.89-5.08), total fluid volume (OR=1.03, 95% CI: 1.01-1.06), type of surgery (pancreatic surgery) OR=6.44, 95% CI: 2.88-14.41; gastrointestinal surgery: OR=2.03, 95% CI: 0.97-4.24) and preoperative NT-pro BNP (OR=1.05, 95% CI: 1.03-1.06).

The preoperative NT-pro BNP increased the AUC of the multivariable logistic regression model from 0.777 to 0.815, a statistically significant difference (p<0.05). The results of the decision analysis curves showed a net clinical benefit from the multivariable Logistics regression model after the addition of preoperative NT-pro BNP at all risk decision thresholds.

Conclusion(s): The limited data available suggests that preoperative NT-pro BNP is an independent predictor of PPCs in elderly patients with non-cardiac surgery, which can significantly improve the predictive performance of the model and obtain a net clinical benefit, enabling early and accurate prediction and risk stratification of PPCs.

33AP06-7

The impact of different postoperative sedation strategies on the duration of mechanical ventilation after coronary artery bypass graft surgery: a retrospective observational study

R. Zdravkovic^{1,2}, S. Vickovic^{1,3}, V. Pavkov¹, M. Preveden^{1,2}, M. Vuletic¹, A. Redzek^{1,2}

¹University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, ²Institute of Cardiovascular Diseases of Voivodina, Clinic for Cardiovascular Surgery. Sremska Kamenica. Serbia, 3 Clinical Center of Vojvodina, Clinic for Anesthesia, Intensive Therapy and Pain Therapy, Novi Sad, Serbia

Background and Goal of Study: Mechanical ventilation (MV) is an indispensable part of the postoperative course after coronary artery bypass graft surgery. The aim of this study was to compare the length of MV in patients sedated with continuous infusion of propofol compared to those sedated with bolus doses of midazolam.

Materials and Methods: The research was conducted as a retrospective observational study at the Institute of Cardiovascular Diseases of Vojvodina in Sremska Kamenica (Serbia). The study included two groups of patients who underwent elective coronary artery bypass graft surgery. The Group P consists of patients operated on in the period from January 1, 2023, and October 31, 2023, who were postoperatively sedated with continuous infusion of propofol. The Group M consists of patients operated on between January 1, 2019, and October 31, 2019, who were sedated with bolus doses of midazolam.

Results and Discussion: A total of 915 patients were included in the study (481 patients in group P and 434 patients in group M). The groups did not differ in demographic and anthropometric characteristics. All comorbidities were equally represented except for chronic obstructive pulmonary disease and smoking, which were more common in the group P. The length of postoperative MV was significantly shorter in patients from group P (8.2h vs. 13.7h, p = 0.000). In the same group, the length of hospitalization (in days) was also shorter (7.3 vs. 9.1, p = 0.000). Group P had significantly more pleural effusions as a complica-

tion (p = 0.004), while group M had more respiratory failure (p = 0.022). Other postoperative pulmonary complications (atelectasis, pneumothorax, pneumonia, and reintubation) were equally prevalent.

Conclusion(s): Continuous sedation with propofol after coronary artery bypass graft surgery leads to shorter mechanical ventilation and shorter hospitalization, compared to intermittent administration of midazolam.

Prevalence, outcome and health care costs of postoperative ARDS compared to medical ARDS

M. Bardají Carrillo^{1,2}, P. Martínez-Jiménez^{1,2}, B. Sánchez-Quirós^{1,2}, E. Tamayo^{1,2}, R. López-Herrero^{1,2}, E. Gómez-Sánchez^{1,2}

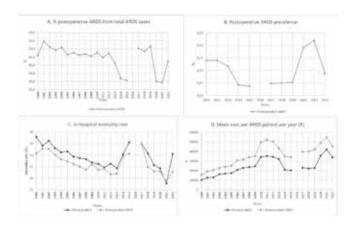

¹Clinic Universitary Hospital of Valladolid, Anaesthesiology and Critical Care, Valladolid, Spain, ²BioCritic, Group for Biomedical Research in Critical Care Medicine, Valladolid. Spain

Background and Goal of Study: Postoperative acute respiratory distress syndrome (ARDS) is a critical post-surgical complication with a reported prevalence of up to 20% and a mortality rate of up to 80%. Little has been published comparing postoperative ARDS with medical ARDS, showing postoperative ARDS lower mortality. We aimed to evaluate the prevalence, hospital mortality, and associated healthcare costs of postoperative ARDS in Spain from 2000 to 2022 and compare them with those of patients who developed ARDS from medical conditions.

Materials and Methods: We performed a nationwide, registrybased study of all hospitalizations for postoperative ARDS in Spanish hospitals from January 1, 2000, to December 31, 2022, using the Minimum Basic Data Set (MBDS) registry. We analyzed the prevalence, hospital mortality, and average health-care cost for postoperative and medical ARDS.

Results and Discussion: We identified a total of 93,192 ARDS patients of which 40.601 had post-operative ARDS. Postoperative ARDS prevalence varied between 0.05-0.22%, accounting for 45-50% of total ARDS cases. Hospital mortality was lower in postoperative ARDS compared with medical ARDS during the first phase (2000-2015) of the study (47.0% vs. 49.9%, p<0.001), converging during the second phase (2017-2022). In both cases, mortality declined throughout the study period, probably due to improvements in perioperative management and ARDS treatment.

Costs for postoperative ARDS were 1.5 times higher than medical ARDS, linked to 1.5 times longer hospital stay, a well-known driver of increased healthcare costs. ECMO use increased in both groups during the study period, accompanied by a decline in hospital mortality. However, the reduction in mortality was more pronounced in medical ARDS patients, suggesting that ECMO may be less effective in reducing mortality for postoperative ARDS patients.

Conclusions: This is the largest study on postoperative ARDS. The prevalence of postoperative ARDS has remained stable, except during the COVID-19 pandemic, and its hospital mortality has equalized that of medical ARDS. However, the costs associated with postoperative ARDS remain significantly higher.

Aneurysmal subarachnoid hemorrhage complicated with iatrogenic pneumothorax and neurogenic pulmonary edema - a case report

T. Nastasovic^{1,2}, M. Asonja¹, M. Minic¹, S. Bojic^{3,2}, I. Lazic^{1,2}, M. Aslani1

¹University Clinical Center of Serbia, Department of Anesthesiology and Resuscitation on Neurosurgery Clinic, Belgrade, Serbia, 2School of Medicine, Department of Surgery with Anesthesiology, Belgrade. Serbia, ³Clinical Hospital Center Dr Dragisa Misovic, Department of Anesthesiology and Intensive Care. Belgrade, Serbia

Background: One of the life-threatening complication of aneurysmal subarachnoid hemorrhage (aSAH) is neurogenic pulmonary edema (NPE). NPE has a high in-hospital mortality in patients with aSAH, especially if it is complicated with iatrogenic pneumo-

Case Report: A 50-year-old female patient was admitted to our hospital after rupture of basilar artery. On the next day after admission, embolization of bleeding artery was done in general anesthesia. Mechanical ventilation, continuous sedation with Midazolam and vasoactive therapy with Noradrenalin was continued. On the third day of hospitalization, a central venous catheter was placed through the right subclavian vein. Control chest X-ray verified the development of postprocedural right-sided pneumothorax. Chest tube was urgently placed. Control chest X-ray has shown completely re-expanded lung.

On the eighth day, cardiorespiratory deterioration occurred. Patient was still intubated, but tachypneic, dyspneic, with frothy tracheal aspirate. ECG shown sinus rhythm with bradycardia and negative T-waves in D2, D3, AVF, V2-V6 leads. Troponin T serum level was increased. Chest X-ray has shown bilateral pulmonary infiltrates. Diuretic therapy was immediately forced. Two days after, a decrease in value of cardiac markers was noticed as well as regression of chest X-ray infiltrates.

Twenty days after cardiorespiratory deterioration, patient was weaned from mechanical ventilation and chest tube was removed.

Discussion: aSAH can be complicated with pulmonary complications. NPE is well known and described. latrogenic pneumothorax can additionally deteriorate ventilation and oxygenation. Chest tube placement with supportive therapy and forced digresis are necessary for positive outcome of these patients.

1. Guo L, Yang X, Yang B, Tang G, Li C. Prevalence, in-hospital mortality, and factors related to neurogenic pulmonary edema after spontaneous subarachnoid hemorrhage: a systematic review and meta-analysis. Neurosurg Rev. 2023 Jul 11;46(1):169 2. Cavallo C, Safavi-Abbasi S, Kalani MYS, et al. Pulmonary complications after spontaneous aneurysmal subarachnoid hemorrhage: Experience from Barrlow Neurological Institute. World Neurosurgery 2018;119:e366-e373.

Learning points: Early recognition of NPE in aSAH patients is necessary because of high in-hospital mortality in patients with aSAH. Pneumothorax can compromise recovery. Careful management of mechanical ventilation is necessary for appropriate blood gas exchange.

33AP06-11

Examination of prognostic factors for severe COVID-19: Importance of arterial blood-end-tidal carbon dioxide partial pressure gradient

M. Fuyuta¹, Y. Nakajima¹, R. Sakuma¹, K. Kurooka¹ ¹Kindai University, Department of Anesthesiology, Osakasayams-shi, Japan

Background: More than four years have passed since the novel coronavirus disease (SARS-Cov-2) was discovered in December 2019 in japan. COVID-19 is still mutating repeatedly. Although the number of severe patients has been reported to decrease with the Omicron varia, a certain number of patients may become severe and require tracheal intubation.

We investigated prognostic predictors for patients with severe coronavirus pneumonia who underwent tracheal intubation at our hospital.

Case Report: A comparison was conducted on clinical backgrounds and the risk of death in relation to the arterial bloodend tidal carbon dioxide partial pressure difference (Pa-ET CO2: ΔCO2) in 20 patients who were diagnosed with novel coronavirus disease and underwent tracheal intubation.

Comparing the prognostic predictors between the survival and death groups, significant differences were observed in ΔCO2(P<0.05). Death was significantly observed in cases in which Δ CO2 deviated by 7.8 or more on the third day.

Discussion: Hypoxemia in severe COVID-19 is said to be due to cytokine storm and micropulmonary embolism. In micropulmonary embolism due to severe COVID-19, alveolar dead space increases, Δ CO2 is significant in the early stage of tracheal intubation. This study suggests that an increase in Δ CO2 may lead to a worse prognosis.

Reference:

Hall V, et al. Protection against SARS-CoV-2 after Covid-19 vaccination and previous infection. N Engl J Med 2022.

Learning points: We analyzed and examined the patient background and changes in ΔCO2 over time for severe COVID-19 from a retrospective perspective. It was suggested that the early changes in $\Delta CO2$ over time may be a predictor of prognosis for severe disease.

33AP07-2

Chronic pain incidence and risk factors after video assisted thoracoscopic surgery: retrospective study

İ. Özdemir¹, Y. Sincer², D. Yaylak², M. Manici², Y. Gurkan² ¹Koç University, Algology, Istanbul, Turkey, ²Koç University, Anaesthesiology and Reanimation, Istanbul, Turkey

Background and Goal of Study: Chronic postsurgical pain (CPSP) following video-assisted thoracoscopic surgery (VATS) is a prevalent complication, but its risk factors remain inadequately defined. This study aims to determine the incidence and risk factors for post-thoracotomy pain syndrome (PTPS) after VATS in a tertiary-care setting.

Materials and Methods: This retrospective single-center study included patients who underwent elective VATS at Koc University Hospital between January 2023 and January 2024. Eligible patients were contacted via phone to assess for the presence of pain persisting beyond three months at the surgical site. Univariate and multivariate binary logistic regression models were

Results and Discussion: Of the 328 patients, 195 met the eligibility criteria. Among them, 59 patients (30.3%) reported chronic postsurgical pain (CPSP) three months after VATS. Female patients had a 2.2-fold increased incidence of CPSP compared to males (p<0.05).

used to identify significant risk factors associated with PTPS.

Additionally, postoperative pregabalin use was associated with a higher risk of developing chronic pain compared to non-users (p<0.05). The regression model accounted for 12% of the variation in PTPS occurrence.

Conclusion(s): Female gender and postoperative pregabalin use are significant risk factors for PTPS after VATS. Clinicians should be aware of these risk factors to identify high-risk groups. Early consultation with a pain management specialist should be

considered in patients exhibiting signs of chronic pain after tho-

racic surgery. References:

Management of pain in severe thoracic trauma: a Retrospective review

A. Hernandez Quintanilla¹, G. Pujol Caballe¹, M. De la Rosa Estadella¹, C. Mestre Iniesta¹, C. Pallarés Fernández¹, A. Perdiguero Cosano¹ ¹Hospital Parc Taulí, Anaesthesiology, Sabadell, Spain

Background and Goal of Study: Severe thoracic trauma, especially involving rib fractures, presents significant challenges in perioperative management.

The goal of this study was to evaluate the management strategies for patients with three or more rib fractures, identify the risk factors associated with complications, and suggest potential areas for improvement in current practices.

Materials and Methods:

- Retrospective descriptive review conducted at our center.
- Data collection period: 1 year.
- Inclusion criteria: Thoracic trauma with ≥3 rib fractures.
- · Data reviewed: Demographics, associated injuries, complications, and mortality.
- · Variables analyzed using SPSS and Excel.

Results and Discussion: The sample showed an average of 5 fractures, with 25% of patients having bilateral fractures. Pain management strategies included: Conventional analgesia (30%): intravenous NSAIDs and paracetamol with subcutaneous morphine as rescue. Elastomeric pump (20%): tramadol and dexketoprofen or metamizole. PCA pump (25%): morphine. Epidural morphine (25%).

58% of patients required critical care unit admission. Mortality was 5.4%. Statistically significant factors (p<0.05) associated with mortality included conventional analgesia (correlation [Cor] 0.29) and traumatic brain injury (TBI) related to rib fractures (Cor

Complications occurred in 26%, including pneumonia, pulmonary embolism, acute respiratory failure, arrhythmia, bacteremia, and mechanical ventilation. Significant factors associated with complications were the number of fractures, bilateral fractures (Cor 0.28), conventional analgesia (Cor 0.33), elastomeric analgesia (Cor 0.21), and TBI (Cor 0.37).

Pain assessment was poorly documented; only 14% of records included a Visual Analogue Scale (VAS) score.

Conclusion(s): Complications were significantly associated with the number of rib fractures and bilateral fractures. Severe TBI with thoracic trauma was linked to increased mortality. Mortality (5.4%) was lower than reported in literature (~10%) 1.

The current multidisciplinary protocol for rib fracture management is adequate. Improvement areas would be to better document VAS pain in medical records and implement new analgesic techniques to enhance patient care.

33AP07-4

Peri-operative analgesia management of cardio-esophagectomy - Single centre clinical

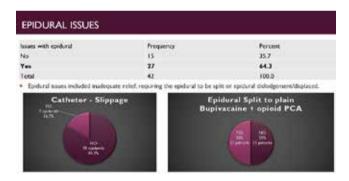

A.J. Fonseca¹, S. Sharma¹, S. Chandrashekaraiah¹ ¹Lancashire Teaching Hospitals - NHS Foundation Trusts, Anaesthesia, Preston, United Kingdom

Background: Thoracotomy incisions in transthoracic esophageal surgeries are among the most painful, highlighting the critical role of effective anesthetic techniques in postoperative pain management. This audit reviewed perioperative analgesia management following cardio-esophagectomy over one year.

Methodology: Data from anesthesia charts, CPET reports, prescription charts, ICU, and pain team documentation were analyzed using SPSS 20.0 and R programming.

Results: The audit included 48 patients (81.3% male, mean age 64.87 years, mean CPET score 11.81). Most patients (64.6%) were ASA class 2. Epidurals were attempted in 44 patients and successfully placed in 42 (87.5%), with 85.7% (36) being tunneled. Six tunneled epidural catheters dislodged, while stitched & tunneled epidurals (11.9%) showed no dislodgements but inadequate relief, necessitating switching to plain bupivacaine epidural & IV opioid. Six patients did not receive epidurals; four received spinal diamorphine (including two failed epidural attempts), while two had paravertebral blocks (PVB), rectus sheath catheters, & opioid PCA. Lidocaine patches were used in 62.5% of patients.

Inferential analysis using the Mann-Whitney U test revealed a significant difference in PCA infusion duration between epidural & non-epidural groups (p = 0.014). No significant relationship was found between epidural issues & vasopressor duration or PCA infusion duration and vasopressor duration.

Discussion: Thoracic epidurals, considered the gold standard, reduce ICU stavs & opioid use but are less effective for esophagectomy patients with abdominal wounds. PVB is a viable alternative when epidurals are contraindicated or challenging to place.

Conclusion: A well-functioning thoracic epidural significantly smoothens the perioperative course, although the success rate is around 50%. Stitching epidurals prevents catheter dislodgement. Continuous monitoring of regional anesthesia is crucial. Further multicenter RCTs and cohort studies are needed to compare thoracic epidurals with other analgesic modalities.

Impact of and individualized open-lung approach and surgical thoracic technique on postoperative pulmonary complications. a sub-analysis of the iPROVE-OLV

A. Carramiñana¹, G. Muñoz¹, S. Martínez¹, A. Jacas¹, O. Comino¹, R. Navarro-Ripoll¹ ¹Hospital Clínic Barcelona, Anesthesia & Critical Care, Barcelona, Spain

Background and Goal of Study: It is uncertain whether the application of a perioperative open-lung approach (iOLA) ventilation strategy, which includes recruitment maneuvers and an individualized PEEP trial, impacts on respiratory mechanics, gas exchange and postoperative pulmonary complications (PPCs) depending on the surgical technique (open lung resection [thoracotomy] vs Video-assisted thoracoscopy surgery [VATS]).

We aimed to compare ventilator mechanics, oxygenation levels and PPCs in patients ventilated with an iOLA strategy undergoing thoracotomy vs. VATS.

Materials and Methods: Secondary analysis of a randomized, international, multicenter controlled trial enrolling 1.380 patients scheduled for thoracic surgery using OLV1.

We analysed the iOLA group and compared patients submitted to thoracotomy vs. VATS. The main outcome was to analyse ventilatory mechanics, gas exchange and need of rescue maneuvers. To test categorical variables, Chi2test, relative risks (RRs) with 95% confidence intervals (CI) were calculated.

Composite primary-outcome was assessed as total occurrence within the observation window, or as yes/no occurrence. A twosided p<0.05 was considered statistically significant.

Results and Discussion: 670 patients were included in the analysis: 458 in the thoracotomy group and 187 in the VATS group. Baseline characteristics did not differ among groups. There were no differences in thoracotomy vs VATS neither PPCs [RR 0.63] (0.32-1.24)], PEEP values [8.19 (1.99) vs 8.01 (2.19), p=0.368] nor Driving Pressure [11.06 (4.64) vs 11.75 (11.32), p=0.464) or PaO₂/ FiO₂ratio [281.76 (130.95) vs 298.76 (130.95), p=0.139] between groups. Patients that underwent VATS approach needed less intraoperative rescue maneuvers, compared to thoracotomy [21 (5.6) vs 18 (11.6), p=0.025].

Conclusion(s): Patients who undergo thoracic surgery via thoracotomy vs. VATS, managed with a perioperative iOLA ventilation strategy did not show differences in PPCs, PEEP requirements, gas exchange or respiratory mechanics.

Patients treated via VATS needed less intraoperative rescue maneuvers. In conclusion, iOLA management is a safe perioperative strategy that is not affected regardless of the surgical technique. References:

Is donor lung preservation at 10°C during ischemic time in lung transplantation a safe alternative? Experience from a tertiary center

C. Esteban Lorente¹, M. Bermudez Ruiz¹, C. Guzman Cordero², J.R. Caro de Vera Gonzalez¹, D.O. Velandia Perez¹, P. Perez Navero^{1,3} ¹Hospital Universitario Reina Sofia, Anesthesiology, Cordoba, Spain, ²Hospital Universitario Reina Sofia, Pharmacology, Cordoba, Spain, 3 Hospital Universitario Reina Sofia, Anesthesiology, Cordobaspai, Spain

Background and Goal of Study: Preservation at 10°C extended ischemic times beyond the traditional 6-8 hours while maintaining survival rates consistent with the literature. However, ischemic times >14 hours for the first lung and >16 hours for the second were associated with higher PGD and mortality, underscoring the need for defined safety thresholds.

Hypothesis: Preservation at 10°C enables safe extension of ischemic times during lung transplantation without increasing severe postoperative complications, achieving outcomes comparable to 4°C preservation.

Materials and Methods: A descriptive observational study analyzed 47 bilateral lung transplants performed with preservation at 10°C. Lungs were transported on ice and transferred to a 10°C refrigerator upon arrival. Single lung transplants were excluded. Data collected included donor and recipient demographics, ischemic and refrigeration times, and postoperative outcomes: PGD incidence, ECMO requirement, ICU stay, and mortality at 30 and 90 days. Descriptive analysis was performed, presenting quantitative data as means or medians and qualitative data as frequencies or percentages.

Results and Discussion: Mean ischemic times were 13 hours for the first lung and 15 hours for the second. Overall survival was 83%. Ischemic times >14 hours for the first lung were associated with an increase in mortality from 10% to 25% and PGD from 20% to 35%.

For the second lung, ischemic times >16 hours increased mortality from 12% to 30% and PGD from 22% to 55%. Refrigeration times >7 hours (first lung) and >9 hours (second lung) were linked to higher mortality.

Pulmonary perfusion differentials >40% correlated with 44% PGD and 22% mortality. Severe pulmonary hypertension was associated with PGD rates of 67% and mortality of 33%.

Preservation at 10°C extended ischemic times beyond the 6-8 hours traditionally achievable with 4°C, achieving survival rates consistent with existing literature. However, ischemic times >14 hours for the first lung and >16 hours for the second were associated with increased PGD and mortality. These findings highlight the importance of defining safe ischemic thresholds to optimize outcomes.

Conclusion(s): Lung preservation at 10°C extended ischemic times to 13 and 15 hours with a 19% overall mortality. Exceeding 14 and 16 hours increased risks, underscoring the need for safe ischemic limits.

Evaluation of the effectiveness of analgesia provided with the catheterized ESP block in thoracic surgery

A. Perkonos¹, I. Lisnyy¹, V. Golovko¹, O. Hanol¹ ¹National Cancer Institute, Anesthesiology and Intensive Care, Kyiv, Ukraine

Background and Goal of Study: The sufficient level of analgesia in thoracic surgery is provided with a combination of opioids and regional methods of anesthesia. Thoracic epidural anesthesia (TEA) is considered to be the gold standard but it has a number of limitations due to technical complexity, antiplatelet/anticoagulant therapy, etc. ESP block has recently been considered as a possible alternative to existing regional methods of analgesia in thoracic surgery.

The aim of this study was to compare the catheterized ESP block and TEA in terms of the quality of analgesia in thoracic surgery and the development of side effects.

Materials and Methods: 88 patients with ASA II undergoing lobectomy, bilobectomy, segmentectomy were enrolled. Patients were divided into 2 groups: in Group.1 (Gr.1) TEA (bupivacaine 0.25%) was used, in Group.2 (Gr.2) catheterized ESP-block was used with the administration of bupivacaine 0.25% before the surgery and then every 4-6 hours after the surgery for the next 2 days.

Exclusion criteria were the presence of diabetes mellitus, lung resection in the past, patient refusal. TIVA was provided during surgery both in Gr.1 and Gr.2. NSAIDs, paracetamol, nefopam were routinely used for pain relief in the postoperative period, as well as morphine when needed.

To assess the quality of pain relief in the perioperative period glucose and cortisol levels in the blood were measured while the NRS and total dose of morphine were used to assess the level of pain postoperatively. Hemodynamic parameters during and after surgery, as well as the incidence of postoperative complications. were also evaluated.

Results and Discussion: The quality of postoperative analgesia in patients in Gr.2 (ESP) was comparable to that in Gr.1 (TEA), but patients in Gr. 2 had a greater need for additional opioid analgesia. There was no significant difference in the fluctuations of hemodynamic parameters (mean arterial pressure, heart rate, stroke volume, cardiac index) and the incidence of complications between two groups studied.

Conclusion(s): Catheterized ESP block is a safe method of regional anesthesia that is slightly inferior to TEA. It can be used as an alternative method of regional anesthesia in thoracic surgery to improve the quality of intra- and postoperative analgesia in case when TEA cannot be an option.

33AP07-8

Bronchial injury following double lumen endotracheal tube placement: a case report

M. Krunić¹, K. Rađenović Grgić¹, M. Kantar², D. Švraka¹ ¹University Clinical Centre of the Republic of Srpska, Clinic for Anaesthesiology and Intensive Therapy, Banja Luka, Bosnia and Herzegovina, ²University Clinical Centre of the Republic of Srpska, Clinic for Thoracic Surgery, Banja Luka, Bosnia and Herzegovina

Background: latrogenic Tracheobronchial Injury (ITBI) is an infrequent but severe complication of invasive medical procedures, with significant morbidity and mortality rates. The most common cause of ITBI is orotracheal intubation.(1)

The vast majority of ITBIs manifest with dyspnea, cough, subcutaneous emphysema, pneumomediastinum, unilateral pneumothorax and/or respiratory insufficiency.(2)

Case Report: We present a case of a 75-year-old patient who was hospitalised for elective thoracic surgery. The surgeon verified a 3cm laceration of the left main bronchus intraoperatively, following atraumatic placement of the left double-lumen tube via direct laryngoscopy. Tracheal and bronchial cuff pressures were not measured since the cuff manometer was not available. The laceration was surgically repaired upon completion of planned surgery with a pleural patch.

Discussion: To prevent ITBIs and ensure patient safety, medical professionals performing invasive procedures should thoroughly examine patients before the procedure and minimise possible external factors.

In some cases, like the one here presented, one of the contributing factors can be a lack of equipment. TBI requires early diagnosis and experienced evaluation.

Although surgical repair remains the gold standard of treatment, conservative and interventional treatment should also be considered in every individual patient.(3)

Learning points: We can not be sure whether an endogenous or exogenous factor directly caused the injury in this case, but we strongly believe that the cuff manometer should be used to maximise patient safety.

Pulmonary complications with titrated versus fixed PEEP in older patients recovering from lung cancer surgery: a randomized trial

J. Wu¹

¹Shanghai Jiao Tong University, School of Medicine, Anesthesiology, Shanghai, Xuhui District, China

Background and Goal of Study: Titrated intraoperative positive end-expiratory pressure (PEEP) improves respiratory function, but its effect on postoperative pulmonary complications (PPCs) in older lung resection patients remains uncertain.

Materials and Methods: We recruited lung cancer patients aged ≥60 years scheduled for open or video-assisted thoracic surgery using single-lung ventilation (SLV). Patients were randomly assigned to either individualized PEEP (PEEPIND) based on electrical impedance tomography (EIT) or a fixed PEEP of 5 cm H2O (PEEP5). PEEPIND was titrated during single-lung ventilation (SLV) before surgery and double-lung ventilation (DLV) after surgery.

Tidal volume was set to 6 mL/kg of predicted body weight, with respiratory rates set at 12-15 breaths/min, and lung recruitment maneuvers were used.

The primary endpoint was a composite of PPCs. Secondary endpoints included postoperative extra-pulmonary complications, postoperative hospitalization duration, and 30-day readmission

Results and Discussion: We randomized 200 patients per group (mean age 68 years, 56% female). The PEEPIND group had a PEEP of 11 (9 to 11) cm H2O during SLV and 9 (7 to 9) cm H2O during DLV, compared to 5 cm H2O in the PEEP5 group. PPCs occurred in 28% of PEEPIND patients (54/195) and 25% in PEEP5 patients (50/197) (RR 1.09 [95% CI 0.79 to 1.52], P=0.604).

In high-risk patients (ARISCAT score ≥43), PEEPIND showed a protective effect. Secondary outcomes showed no significant dif-

Conclusion(s): Among older patients undergoing lung resection with SLV, individualized PEEP did not reduce PPCs overall compared to fixed PEEP of 5 cm H2O but demonstrated a protective effect in high-risk patients.

33AP07-10

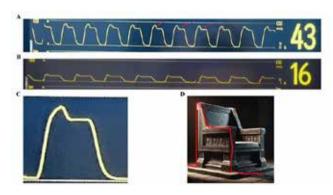

Evolving capnograph after disorder of pulmonary circulation during mechanical ventilation with double lumen tube: a case report

Y. Zhu^{1,2,3}, J. Shu⁴, F. Wang^{2,5}, H. Zhu¹, T. Zhu², G. Chen²

¹Peking Union Medical College Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Emergency Department, State Key Laboratory of Complex Severe and Rare Diseases, Beijing, China, ²West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China, 3sichuan cancer hospital, Department of Anesthesiology, Chengdu, China, ⁴Sichuan cancer hospital, Department of Anesthesiology, Chenadu, China, 5Sichuan Academy of Medical Science and Sichuan Provincial People's Hospital. Department of Anesthesiology, Chengdu, China

Background: Capnography is an indispensable tool for monitoring metabolic and respiratory functions[1]. This case report presents a "throne-like" pattern observed in capnography signalled a pulmonary circulatory disorder.

Case Report: A 69-year-old woman was admitted to hospital with haemoptysis and productive cough. On the third day after admission, thoracoscopic-assisted anterior segmental resection of the right upper lobe was scheduled under general anaesthesia, with a left DLT following induction. Before closing the surgical incision, bilateral lung ventilation was resumed, the capnogram displayed a shape resembling a throne (Figure 1A, C, D). However, with right OLV, a rapid decrease in end-tidal carbon dioxide (ETCO₂) values occurred (Figure 1B), accompanied by decreased blood pressure and a rapid reduction in peripheral capillary oxygen saturation (SpO₂) to below 70 (FiO₂ = 1.0). Upon re-establishing two-lung ventilation, the capnogram again displayed a throne-like appearance. Then, the surgeon found that a titanium nail in the right upper lobe was compressing the right pulmonary artery. The nail was removed, and surgical silk sutures were applied manually. Bilateral lung ventilation was resumed without the recurrence of the throne-like capnogram.

Discussion: This case identifies a novel abnormal capnogram, the throne-like pattern, which is indicative of disordered pulmonary artery circulation. DLTs are not routinely employed in endotracheal intubation. Hence, abnormal capnogram during DLT use are rarely reported. This unique throne-like waveform may signal pulmonary circulation impairment, which is similar with pulmonary embolism (PE). For patients at elevated intraoperative PE risk, DLT might be a better choice.

Reference:

- 1. Aminiahidashti, H, Shafiee, S, Kiasari, A Z, et al. Applications of end-tidal carbon dioxide (ETCO₂) monitoring in emergency department; a narrative review [J]. Emergency, 2018, 6(1): e5. **Learning Points:**
- 1. A throne-like pattern of capnogram during DLT use suggests a pulmonary circulation disorder.
- 2. For patients with a high intraoperative PE risk, DLT may be a preferable option for enhanced intraoperative detection.

33AP07-11

Postoperative pain treatment with repeated boluses of ropivacaine via Transversus Thoracis muscle Plane block (TTP) catheters with median sternotomy patients

R.A. Kuuskoski^{1,2}, T.I. Saari^{1,2}, B. Singh³, E. Löyttyniemi³, P. Uusalo^{1,2}, M. Peltoniemi^{1,2}

¹Turku University Hospital, Division of Perioperative Services, Intensive Care and Pain Medicine, Turku, Finland, ²University of Turku, Department of Anaesthesiology and Intensive Care, Turku, Finland, ³University of Turku, Department of Biostatistics, Turku, Finland

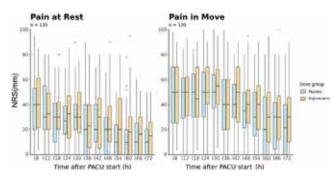

Background and Goal of Study: Median sternotomy causes major postoperative pain. Single shot TTP blocks may be effective to alleviate sternal pain. Previous results indicate that continuous infusion with ropivacaine could be beneficiary after sternotomy.¹ We hypothesized that repeated boluses of ropivacaine via TTP catheters would be associated with better and more durable pain relief, lower required cumulative dose of opioids, shorter ICU and hospital length of stay and less opioid related adverse effects in median sternotomy patients compared to placebo.

Materials and Methods: We conducted a double-blinded, randomized, placebo-controlled prospective trial with 120 patients (age 18–80 years) undergoing elective open cardiac surgery. After informed consent, patients were randomized to receive repeated boluses of either saline or ropivacaine via TTP catheters for 72 hours postoperatively.

Primary endpoint was the patient reported pain scores with numeric rating scale. Secondary endpoints were cumulative oxycodone dose, incidence of local anaesthetic systemic toxicity or other adverse events and the effect on ICU and hospital length of stay.

Results and Discussion: Patient reported pain scores did not differ between groups. Sternal pain was significantly more common in the placebo-group compared to the ropivacaine-group 24-hours postoperatively (p=0.039) but no other differences were seen in pain location. Cumulative oxycodone requirement did not differ between groups. Postoperative nausea and vomiting (PONV) was common in both groups (38%) and subgroup analysis revealed a higher incidence of PONV in the ropivacaine-group undergoing heart valve replacement (p-value 0.012), but no differences were recorded between the main groups. ICU or hospital length of stay were not affected.

Conclusion(s): Repeated boluses of ropivacaine via TTP catheters had no significant effect on pain recordings or cumulative amount of opioids compared to placebo. It remains unclear whether the timing or administration mode of the TTP blocks affect the success of postoperative pain therapy.

Robotic tracheobronchoplasty from the perspective of anesthetic assistance: a case report

G. Sanine de Carvalho¹, N. Nunes Santos²,

M. Aurélio dos Santos Carvalho², I. Mattarelli Souza Carli²,

G. Giroldo Badessa¹, B. Gonçalves Miron¹

¹São Camilo University Center, Anesthesiology, São Paulo, Brazil, ²São Luiz Hospital (Jabaquara / Rede D'Or - CMA), Department of Anaesthesia, São Paulo, Brazil

Background: Robotic Surgery is a growing trend, being used in many surgical specialties. This case report presents successful anesthetic management for an innovative technique in robotic thoracic surgery.

Case Report: A 61-year-old woman, 100kg and 1.60m, submitted to robotic tracheobronchoplasty under general anesthesia. History of severe, refractory asthma, complicated by tracheomalacia, using Beclometasone + Formoterol + Glycopyrronium and Salmeterol + Fluticasone.

3 Salbutamol puffs were administered just before anesthetic induction, which was performed with Fentanyl, Propofol and Rocuronium. Intubation was performed with a double-lumen endobronchial tube, and bronchoscopy was necessary for selective placement due to the patient's anatomical variations. An arterial line was placed for monitoring, and positioning was performed in left lateral decubitus. Maintenance was achieved with continuous infusion of Propofol, Remifentanil and Rocuronium. Adjuvants included Ketamine, Methadone, Magnesium Sulfate, Lidocaine and Dexmedetomidine. Tranexamic acid was administered to reduce risk of bleeding.

During the surgical procedure, selective ventilation and periods of apnea were required for tracheal suturing. Alveolar recruitment maneuvers and adjustments to mechanical ventilation were performed. Arterial blood gas samples showed adequate ventilatory control after sequential apneic periods and the patient was extubated in the operating room without incidents. She was discharged 7 days later without complications.

Initial	pH 7,38 PCO2 48 PO2 81 HCO3 28,4 SatO2 96
Post-apnea	pH 7,24 PCO2 66 PO2 80 HCO3 28,3 SatO2 93
Final	pH 7,38 PCO2 49 PO2 84 HCO3 29 SatO2 96

Discussion: Robotic-assisted tracheobronchoplasty has been first described in the last 10 years¹, and anesthesia for this procedure presents additional challenges with the use of the robotic

system, the need for immobility and intermittent ventilatory maneuvers. This case demonstrates a successful approach in challenging scenario.

References:

1. Lazzaro, Richard S., Byron Patton, et. al. 2019. "First Series of Minimally Invasive, Robot-Assisted Tracheobronchoplasty with Mesh for Severe Tracheobronchomalacia" Journal of Thoracic and Cardiovascular Surgery 157 (2): 791-800. https://doi. org/10.1016/j.jtcvs.2018.07.118

Learning points: This report highlights an effective anesthetic strategy in a novel environment and aims to encourage the exchange of clinical experiences in the use of new technologies.

Infection, Sepsis and Immunology

34AP01-2

The SPRED study - multiomic prediction of surgical site infections after major abdominal surgery

G. Bellan¹, J. Hédou², M. Le Guen³, B. Gaudillière², V. Franck⁴, D. Gaudillière⁵

¹SurgeCare, Data Science, Illkrich-Graffenstaden, France, ²Stanford University, Anesthesiology, Perioperative & Pain Medicine, Palo Alto, United States, 3Hôpital Foch, Anesthesiology, Suresnes, France, 4Hôpital Saint Antoine, APHP, Anesthesiology, Intensive Care, Paris, France, ⁵Stanford University, Surgery - Plastic & Reconstructive Surgery, Palo Alto, United States

Background and Goal of Study: Postoperative complications, including surgical site infections (SSIs), affect up to 44% of major surgeries, increasing mortality, hospital stays, readmissions, and socioeconomic costs. Predicting an individual's risk of postoperative complications is difficult, as established scores based solely on clinical factors, like the ACS NSQIP, have limited predictive power.

The SPRED study aimed to create a predictive model for SSI after major abdominal surgery1 by integrating clinical and biological factors measured before surgery, enabling personalized surgical management.

Materials and Methods: In a five-center prospective study of 164 adult patients undergoing elective major abdominal surgery in France, SSIs were tracked within 30 days post-surgery. Preoperative clinical data, including demographic and health variables, were collected. A plasma proteomic approach (Olink) measured 726 proteomic features in pre-surgery blood samples.

Sparse machine learning and data-driven feature selection² using the Stabl framework were applied to build a multivariable model predicting SSIs. Model performance was evaluated via Monte Carlo cross-validation (5-fold repeated 10 times) and compared to the ACS risk score3.

Results and Discussion: A multivariable model combining clinical and proteomic data outperformed the ACS model in predicting SSIs (area under the receiver operating characteristic curve, AU-ROC = 0.79; [0.70-0.88] vs. AUROC = 0.50 [0.38-0.63]). Stabl identified three proteins (CXCL14, NCAM1 and FABP6) and two clinical factors (ASA score and surgery indication) as key predic-

Conclusion(s): The integrative predictive model provides significantly greater accuracy in predicting SSIs compared to conventional clinical preoperative risk factors. Our analysis identified a concise set of biomarker candidates that could be used to personalize perioperative management. These findings highlight the potential of predictive approaches to identify high-risk patients before surgery, enabling targeted interventions to reduce SSIs and improve outcomes.

Effect of dexmedetomidine versus midazolam on short-term and long-term survival outcomes in patients requiring ventilation with sepsis: a retrospective cohort study with propensity score matching

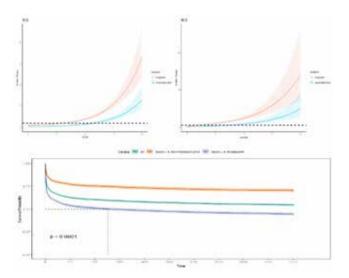

B. Xiang¹, H. Yang², W. Zhang¹

¹West China Hospital, Sichuan University, Department of Anesthesiology, Chengdu, China, 2West China Hospital, Sichuan University, Department of Anesthesiology, Intensive Care, and Perioperative Medicine, Chengdu, China

Background and Goal of Study: The impact of dexmedetomidine and midazolam on the survival outcomes of sepsis patients, particularly long-term survival, has not yet been conclusively estab-

Materials and Methods: We conducted a retrospective cohort analysis of sepsis patients requiring ventilation from 2008 to 2022, utilizing data from the MIMIC-IV database. Inclusion criteria were patients diagnosed with sepsis according to Sepsis-3 criteria after ICU admission. The exposure factors were dexmedetomidine or midazolam during ventilation.

The primary endpoint was 28-day mortality, while the secondary endpoint was 10-year mortality. To address baseline differences, propensity score matching (PSM) was used, along with multivariate logistic regression and Cox proportional hazards models to account for residual confounding.

Results and Discussion: The original cohort included 6,622 patients, and after PSM, 5,028 patients remained. In the original cohort, the 28-day mortality was 24.86% (1,646/6,622), while the 10-year mortality was 45.67% (3,024/6,622). Both in the original and matched cohorts, the midazolam group had higher 28-day and 10-year mortality rates compared to the dexmedetomidine group (31.2% vs. 13%, P < 0.001; 20.6% vs. 13%, P < 0.001 for 28day mortality, and 55.5% vs. 29.6%, P < 0.001; 40.9% vs. 29.6%, P < 0.001 for 10-year mortality). In logistic and Cox regression models, the dexmedetomidine group consistently demonstrated a protective effect against 28-day mortality, with odds ratio and hazard ratio significantly below 1, even after PSM and multiple weighting methods, such as IPTW, SMRW, PA and OW (P < 0.01

The Kaplan-Meier curves and restricted cubic spline curves further confirmed the protective effect of dexmedetomidine, and interestingly, the magnitude of benefit increased with higher SOFA score or lactate level.

Conclusion(s): The findings suggest that dexmedetomidine significantly improves both short-term and long-term survival outcomes in sepsis patients requiring ventilation, compared to midazolam. These results underline the potential for dexmedetomidine to be favored in ICU sedation protocols for sepsis management.

34AP01-4

Multidrug-resistant bacteria burden in ICU critically ill patients: where do we stand in the last 5 years?

J.P. Cidade¹, H. Moreira¹, J. Fustiga¹, I. Medeiros¹, D. Sousa¹, P. Póvoa¹ ¹Unidade Local de Saude Lisboa Ocidental, Intensive Care, Libsoa, Portugal

Background and Goal of Study: Multidrug-resistant bacteria (MDR) remain a health threat to Intensive Care Units (ICU) worldwide. These rates might have been further aggravated by the impact of the COVID-19 pandemic due to increased antibiotic prescriptions.

We aimed to describe the rate, characteristics, and outcomes of critically ill patients with MDR-causing ventilator-associated pneumonia (VAP) before and during the COVID-19 pandemic

Methods: We conducted an observational cohort study from 2018 to 2022. The study included adult, mechanically ventilated patients for > 48 hours with bronchoalveolar lavage (BAL) due to clinical suspicion of VAP. Patients were categorized based on having MDR-causing VAPs and considering being previous to or during the COVID-19 pandemic.

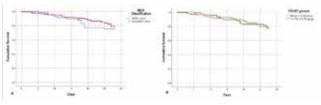

Figure 1.

Results and Discussion: A total of 217 patients were enrolled, with 65 (29.9%, 4 patients with Extensively Drug-resistant bacteria) included in the MDR cohort and 152 (70.1%) in the non-MDR cohort. Patients in the MDR cohort presented similar multiorgan support requirements, ICU lengths of stay, and mortality rates to those in the non-MDR group (Figure 1).

There was no difference between the rate of diagnosis of MDRcausing VAPs from 2018 to 2022. Patients were divided into the Before (91 patients) and the During COVID-19 groups (126 patients). Despite higher SAPS II and multiorgan organ support requirements in the During-COVID-19 group, no difference was found in the MDR profile and mortality rates between groups. The Cox regression modeling demonstrated no difference in mortality after adjustment (Hazard Ratio 1.010, 95% CI: 0.987-1.018, p=0.682) (Figure 1). Multivariable logistic regression analysis revealed a significant risk contribution of age and SOFA score to ICU mortality (OR 1.061 (95% CI: 1.020-1.103; p=0.003) and 1.271 (95% CI: 1.102-1.466; p=0.001), respectively).

Conclusion(s): Our findings indicate that the rate of MDR-causing VAPs remained stable over the years studied and did not independently predict worse clinical outcomes or increased mortality. Instead, overall illness severity, as reflected by age and SOFA scores, emerged as the primary determinants of ICU mortality.

34AP01-5

Diagnostic accuracy of presepsin for sepsis in severe burn patients: a prospective cohort study

D. Kym¹

¹Hangang Sacread Heart Hospital, Hallym University, Burn Surgery and Critical Care, Seoul, Korea, Republic of

Background and Goal of Study: Sepsis remains a leading cause of mortality in severe burns, with traditional diagnostic methods facing significant limitations. Blood culture testing often yields delayed or false-negative results, especially with early antibiotic administration. While conventional biomarkers like procalcitonin (PCT) and C-reactive protein (CRP) show limited utility due to burn-induced inflammation, presepsin has emerged as a promising biomarker.

This study aimed to evaluate the diagnostic value of multiple biomarkers, including presepsin, PCT, and CRP, for sepsis detection in severe burns, specifically analyzing their performance in both blood culture-positive and -negative cases.

Materials and Methods: A prospective diagnostic accuracy study was conducted at the Burn Intensive Care Unit of Hallym University Hangang Sacred Heart Hospital between January 2021 and December 2022. From 370 initially screened patients, 221 were included in the final analysis. Sepsis was defined according to Sepsis-3 criteria. Seven biomarkers were selected: presepsin, procalcitonin, albumin, CRP, PT, hematocrit, and cystatin C. Diagnostic performance was evaluated through ROC analysis, decision curve analysis, and reclassification analysis.

Results and Discussion: Presepsin demonstrated the highest overall diagnostic accuracy (AUC 0.810, 95% CI: 0.742-0.878), with optimal sensitivity of 82.6% and specificity of 72.2% at a cutoff value of 472.0 pg/mL. Its performance was significantly higher in blood culture-negative cases (AUC 0.846) compared to positive cases (AUC 0.604, p=0.015).

Decision curve analysis showed presepsin maintained positive net benefit across various threshold probabilities, particularly in culture-negative cases. Albumin showed significant improvements in both IDI (0.142, p<0.001) and NRI (0.609, p<0.001) when combined with presepsin. High antibiotic resistance rates were observed, with A. baumannii being the predominant pathogen (47.1%) and resistance rates highest for penicillins (84.6%).

Conclusion(s): Presepsin demonstrates superior diagnostic value for sepsis in severe burns, particularly in culture-negative cases. The study supports a combined biomarker approach, especially presepsin with albumin, for improved diagnostic accuracy. Given the high antimicrobial resistance and limitations of traditional diagnostics, presepsin-based strategies could enhance both diagnostic accuracy and antibiotic stewardship in burn-related sepsis management.

34AP01-6

The therapeutic potential of Irisin in preventing fetal brain damage and cognitive deficits caused by maternal inflammation

O.Y. Savran¹, A. Kucuk², F. Kar³, Z. Yigman⁴, C. Ozbayer⁵ ¹Hacettepe University, Department of Anesthesiology and Reanimation, Ankara, Turkey, 2Kutahya Health Sciences University, Department of Physiology, Kutahya, Turkey, ³Kutahya Health Sciences University, Department of Medical Biochemistry, Kutahya, Turkey, 4Gazi University. Department of Histology and Embriology, Ankara, Turkey, ⁵Kutahya Health Sciences University, Department of Medical Biology, Kutahya, Turkey

Background and Goal of Study: Maternal infections can cause severe complications, triggering inflammation that harms fetal brain development and leads to long-term neuropsychiatric issues. Exercise reduces neuroinflammation and enhances neurogenesis, with irisin playing a key role.

This study investigates the effect of maternal irisin injections on hippocampal apoptosis and learning in offspring, aiming to reduce brain damage from maternal infections.

Materials and Methods:12 female Sprague Dawley rats were divided into three groups: Control (C)(saline), lipopolysaccharides (LPS)(100 µg/kg), and Irisin+LPS (I+LPS)(2 µg/kg irisin on E16, E17, E18, followed by 100 μg/kg LPS). Offspring underwent novel object recognition tests at 30 days old. GFAP, Caspase-3 and cytochrome-c levels were analyzed immunohistochemically to assess apoptosis in hippocampus.

Statistical analysis was conducted using SPSS. Normality was assessed with the Shapiro-Wilk test. The Kruskal-Wallis test was used for non-normally distributed data, while One-Way ANOVA and paired t-tests were used for normally distributed data.

Results and Discussion: The C and I+LPS group spent more time exploring the novel object (p=0.03 and p=0.047, respectively). while the LPS group showed no preference. This suggests irisin may protect against LPS-induced cognitive deficits.

In the CA1 region, caspase 3 immunoreactivity was higher in the LPS group than the C, though not significantly. It was higher in the LPS group compared to I+LPS (p=0.001), with I+LPS showing lower levels than C (p=0.005). In the CA3 region, the I+LPS group had lower caspase 3 levels than LPS (p=0.000).

For cytochrome-C, the LPS group showed higher immunoreactivity in the CA1 (p=0.022) and DG (p=0.001) regions compared to the C, while the I+LPS group had lower levels than the LPS in the CA1 region (p=0.004).

The C group had fewer GFAP(+) cells than both LPS (p=0.000) and I+LPS groups (p=0.017).

Previous studies have shown that LPS administration leads to activation of phagocytic cells. In our study, LPS administration resulted in increased levels of apoptotic markers and phagocytic cells, while in the irisin-treated group, this increase was limited.

Conclusion(s): Irisin protects against LPS-induced hippocampal damage, enhancing cognitive function and reducing apoptosis in offspring. These findings suggest irisin as a potential therapeutic strategy to protect fetal brain development from maternal infection-related damage.

34AP01-7

The prognostic significance of the relationship between absolute neutrophil and lymphocyte counts (NLR) and C-reactive protein and lymphocyte counts (CLR) in patients with **COVID-19 infection**

J. Isakovic¹, I. Spasojević¹, I. Ergelašev^{1,2}, A. Uvelin², B. Jorović³, Z. Vidaković¹

¹Institute for Pulmonary Diseases of Vojvodina, The Thoracic Surgery Clinic, Novi Sad, Serbia, 2University of Novi Sad, Faculty of Medicine, Novi Sad, Serbia, 3 Clinical Centar of Vojvodina, Clinic for Anesthesia, Intensive Therapy and Pain Therapy, Novi Sad, Serbia

Background and Goal of Study: During the COVID-19 pandemic, it was crucial to predict the deterioration of the general condition of patients in the early stage of the disease. Better survival rates were achieved by identification of at-risk patients and by their early admission to the ICU. The purpose of this research was to determine whether the patients with potentially more severe clinical picture who required initial treatment in the ICU could be identified by monitoring simple and accessible laboratory parameters.

The aim of the research was to determine whether there is a statistically significant difference in the values of NLR(neutrophillymphocyte ratio) i CLR(CRP-lymphocyte ratio) between two groups of patients with confirmed COVID-19 infection, one treated in the ward and the other treated in the ICU.

Materials and Methods: This retrospective epidemiologic study investigated 398 patients treated at the Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica, Serbia during 2021. 26.6% of the patients were treated in the ICU, whereas 73.3% of the patients were treated in the ward. CBC, CRP, NLR and CLR were analyzed in all patients upon admission.

Statistical data processing was performed using SPSS version 23.0. In order to test for differences in the predictive capabilities of the examined parameters, the AUC ROC were compared with each other, determining whether there was a significant statistical difference between the areas under the ROC curves for specific parameters.

Results and Discussion: Both tested indices, NLR and CLR, were statistically significantly higher in the group of patients treated in the ICU compared to the ward group, as shown in Table 1.

Index	Admission to the ICU	Median	Interquartile range	р
NLR	No	7.02	3.778 - 13.276	0.003
	Yes	9.02	5.725 - 16.041	
CLR	No	95.28	34.099 - 186.083	< 0.001
	Yes	147.82	63.506 - 280.615	

Table1: Indices NLR and CLR in subjects treated in the ICU/ward

Conclusion(s): In our research, we have proven that NLR and CLR are significant for assessing the severity of COVID-19 infection. Due to their easy availability and simplicity, along with other clinical parameters, they are important for evaluating the need for treatment in the ICU, where the beds occupied by patients during the COVID-19 pandemic were referred to as "golden beds".

34AP01-8 FLUIDS: FLUid management and InDividualized resuscitation in Sepsis - study protocol

S. Ter Horst¹, T.J. Olgers¹, E. ter Avest¹, M. van Meurs¹, J.C. ter Maaten¹, H.R. Bouma¹ ¹University Medical Centre Groningen, Emergency Department, Groningen, Netherlands

Background: Sepsis is a life-threatening condition marked by organ dysfunction from an uncontrolled host response to infection. Early hemodynamic resuscitation is crucial to prevent organ failure and death, but current standardized approaches may result in prolonged shock or fluid overload.

This study evaluates personalized hemodynamic resuscitation guided by the Baxter Starling SV monitor for sepsis patients during the first six hours of emergency department (ED) admission compared to standard care.

Methods: This randomized open-label clinical trial, conducted in the ED at the University Medical Centre Groningen (UMCG), will enroll 174 adult patients with suspected infection in need of hemodynamic resuscitation over 16 months.

Participants will be randomly assigned to either the intervention group, utilizing the Starling SV monitor, or the control group receiving standard care. The intervention involves i.v. fluid resuscitation and vasopressor therapy based on fluid responsiveness assessment (i.e. Δcardiac index >10%) after a passive leg raise and fluid boluses measured by the monitor.

Standard care will be provided at the discretion of the treating physician, following the Surviving Sepsis Campaign (SSC) recommendation of administering 30 ml/kg of i.v. fluids.

Study endpoints: The primary endpoint is the volume of intravenous fluids administered within six hours of ED admission. Secondary endpoints include vasopressor use, organ failure, hemodynamic stabilization, length-of-stay, and adverse events.

Expected results: By dynamically assessing fluid responsiveness, we expect the intervention group to receive less intravenous fluid compared to the standard care protocol of 30 mL/kg/3h. Additionally, earlier initiation of vasopressor therapy is anticipated. This personalized approach aims to optimize sepsis management, reduce complications, and improve outcomes by tailoring fluid administration and timely vasopressor use to the individual hemodynamic state.

IRB approval is pending, last phase. Study will start in the course of 2025.

34AP01-10

The importance of aseptic techniques in invasive procedures: a case of iatrogenic immunosuppression and psoas abscess secondary to corticosteroid therapy

T. Barros¹, F. Santos¹, A.C. Barros¹, R. Fonseca¹, E. Valente¹

¹Local Health Unit of the Leiria Region, Anesthesiology Department, Leiria, Portugal

Background: Invasive procedures of the neuroaxis require stringent aseptic techniques to prevent rare, yet serious infectious complications. This report presents a case of a psoas abscess following multiple diagnostic lumbar punctures.

Case Report: A 66-year-old male, ASA II, was admitted to the neurology department with general malaise, muscle weakness in the lower limbs and progressive distal paresthesias, over two months. Multiple diagnostic lumbar punctures were attempted. The patient was diagnosed with Chronic Inflammatory Demyelinating Polyneuropathy, whose treatment involved five days of intravenous immunoglobulin, followed by five days of intravenous methylprednisolone.

Nine days post-discharge, he presented to the emergency department with persistent atraumatic left-sided pubic pain and fever. Imaging revealed a left-sided psoas abscess extending distally toward the ipsilateral thigh, with suspected femoral head osteomyelitis. Targeted antibiotic therapy was initiated based on microbiological findings.

He underwent the first stage of surgical intervention seven weeks later. This involved cephalic femoral resection, microbiologic sampling, debridement, and hemiarthroplasty with a PMMA-G-ciprofloxacin-stabilized spacer. Antibiotic therapy continued postoperatively. After favorable clinical and radiologic progress, the spacer was removed, and a total hip arthroplasty performed.

Discussion: Lumbar punctures are generally considered low-risk for infection, but repeated attempts in special populations may increase the likelihood of complications. Immunosuppression further predisposes patients to infections such as psoas abscesses, a rare but severe condition with potential complications like os-

This case underscores the importance of an aseptic technique in neuroaxis procedures, especially in patients with iatrogenic immunosuppression. Asepsis protocols and judicious use of corticosteroids are critical to ensure patient safety and reduce morbidity.

References:

1. Hebl, JR. The Importance and Implications of Aseptic Techniques During Regional Anesthesia. Reg Anesth Pain Med. 2006 Jul-Aug;31(4):311-23. doi: 10.1016/j.rapm.2006.04.004.

Learning Points: Strict aseptic technique is essential in invasive procedures, especially in patients receiving immunosuppressive therapy.

34AP01-11

Lemierre's syndrome: a rare condition with a possible devastating end

M. Fernandes¹, I. Bonito², T. Ferreira¹, V. Brito¹, S. Lança¹, A. Fernandes¹

¹Hospital Garcia de Orta, Serviço Medicina Intensiva, Almada, Portugal, ²Hospital de Nossa Senhora do Rosário - CHBM, Serviço Medicina Interna, Barreiro, Portugal

Background: Lemierre syndrome (LS) is a rare complication of oropharvngeal infection and involves infection spreading into the lateral pharyngeal spaces of the neck with subsequent septic thrombophlebitis of the internal jugular vein(s). It's associated with bacteraemia caused primarily by anaerobic organisms. The diagnosis of LS is often elusive on initial presentation.

Case Report: A healthy 18-year-old young man, with no medical history and allergies, begins with fever and odynophagia. Amoxicillin/clavulanic acid was prescribed, but was stopped after the first dose due to skin erythema. One week later, returned to the emergency room due to fever, prostration and eyelid oedema. He was observed by ophthalmologist and diagnosed with severe cellulitis.

On physical examination, Glasgow scale 13 with slurred speech and neck stiffness. Blood tests showed leukocytosis with neutrophilia and C reactive protein 31mg/dL. Head computerized tomography (CT) revealed cellulitis with post-septal involvement. Lumbar puncture: cloudy cerebrospinal fluid, 1200 cells, proteins 141 and glucose 10mg/dL. Blood cultures were done and was admitted to the intensive care unit and began antibiotic therapy with ceftriaxone and metronidazole.

Due to lack of improvement and right hemiparesis, underwent magnetic resonance imaging and a venous CT scan which identified subdural empyema; cavernous sinus, left internal and external jugular veins thrombosis and ischemic vascular lesions in the territory of the left middle cerebral artery.

Cervical and thoracic CT revealed abscesses of the peri-tonsillar space, right pneumothorax and bilateral pleural effusion. A chest tube was inserted, with pleural fluid suggestive of empyema. Anticoagulation was started, otorhinolaryngology and thoracic surgery was required to source control.

All microbiological tests were negative, and antibiotic therapy was ended after two and a half months due to evidence of focus control and was discharged to a rehabilitation clinic.

Discussion: LS can lead to a series of complications: thrombosis may spread superiorly into the cavernous sinuses; septic emboli can affect several organs; septic shock and ultimately death. Adequate antibiotic therapy, supportive care and monitoring play a significant role.

Learning Points: Despite the low incidence, this case highlights the importance of a high level of suspicion for the LS. Exhaustive investigation, early recognition and treatment is crucial to improving the prognosis.

34AP01-12

The double-edged sword of LRINEC: diagnostic hurdles in necrotizing fasciitis detection

A. Gámez¹, M. Cardozo Panoff¹, R. Blasco Mariño¹, J. Sellarés Nadal², P. Salmerón³, A. Biarnés Suñé¹ ¹Hospital Universitario Vall d'Hebrón, Anestesiología y Reanimación, Barcelona, Spain, ²Hospital Universitario Vall d'Hebrón, Enfermedades infecciosas, Barcelona, Spain, ³Hospital Universitario Vall d'Hebrón, Microbiología, Barcelona, Spain

Background: Necrotizing fasciitis (NF) caused by S. pyogenes is a rapidly progressing, severe, life-threatening condition often complicated by sepsis and multi-organ failure (MOF). Early clinical identification is challenging, as NF often resembles various soft tissue infections (STI) in its initial stages.

The Laboratory Risk Indicator for Necrotizing Fasciitis Score (LRINECs) is a scoring system that helps distinguish NF from other STI and includes these laboratory parameters: C-reactive protein, total white cell count, hemoglobin, sodium, creatinine, and glucose levels. Scores ≤5 indicate low risk, while scores of 6-7 and ≥8 correspond to moderate and high risk, respectively.

Case Report: A 38-year-old female with obesity, mitral valve replacement due to rheumatic heart disease (Acenocumaril as anticoagulant therapy), chronic heart failure, and ulcerative pancolitis presented to the emergency department with fever, odynophagia, and left ankle swelling following recent trauma. Initial laboratory tests revealed an INR of 10 and LRINECs of 5.

Eight hours post-admission, after partial INR correction, the patient developed sweating, tachycardia, and hemodynamic instability, prompting ICU admission. Blood cultures were positive for S. pyogenes. CT angiography revealed free fluid in deep tissue planes, subfascial fluid collections of deep anterior compartment of the leg involvement.

The LRINECs rose to 6 at this stage. A hematoma was suspected due to a history of trauma and coagulation disorder at admission. Eighteen hours after admission the patient progressed to MOF and died three days post-admission despite intensive care.

Discussion: The LRINECs is a diagnostic tool with a sensitivity of 68.2% and specificity of 84.8% when values are above 6 (1). In this case, excessive anticoagulation and presumed hematoma masked early NF signs, delaying definitive diagnosis.

Reference:

Fernando, S. M. et al. Necrotizing Soft Tissue Infection: Diagnostic Accuracy of Physical Examination, Imaging, and LRINEC Score. Ann Surg 269, 58-65 (2019)

Learning Points: The LRINEC score supports NF suspicion staging but should not replace clinical judgment and imaging. LRINECs helps in staging suspicion of NF. However, clinical experience and continuous patient reevaluation remain essential in providing rapid diagnostic and therapeutic guidance for patients with suspected NF.

*We own an exemption of consent from our center ERB and permission to submit from the ESAIC Secretariat.

Acute kidney injury in early-stage sepsis, an early alarm for increased mortality in emergency departments

T. van der Aart1, J.C. ter Maaten1,2, R. van Wijk2, S. Bakker³, H. Bouma^{1,4}, M. van Londen³, **Acutelines Study Group** ¹University Medical Center Groningen, Internal Medicine, Groningen, Netherlands, 2University Medical Center Groningen, Acute Care, Groningen, Netherlands, ³University Medical Center Groningen, Internal Medicine. Devision of Nephrology, Groningen, Netherlands, ⁴University Medical Center Groningen, Clinical Pharmacy and Pharmacology, Groningen, Netherlands

Background and Goal of Study: Sepsis is the most prevalent cause of acute kidney injury (AKI) and is associated with an increased risk of subsequent multiorgan failure, cardiovascular events and death.

This study explores the largely unknown impact of AKI on mortality and cause of death in early-stage sepsis within an emergency department (ED) population.

Materials and Methods: This cohort study utilized prospectively collected data from the cohort Acutelines (2020-2023). AKI was determined by the KDIGO criteria. Kaplan Meier curve analyses, univariable and multivariable Cox regression analyses were used to evaluate the association of AKI with all-cause mortality as primary endpoint, and in-hospital mortality and cardiovascular cause of death as secondary endpoints, with and without adjustment for potential confounders.

Results and Discussion: In this study 2 045 patients with earlystage sepsis (median age 67 years, 55% male) were included, of which 246 (12%) had AKI. Over a median follow-up of 346 days, 506 people (25%) died. AKI was associated with significantly higher all-cause mortality (38% vs. 23%:P<0.001), even in a subanalysis excluding patients who needed ICU care during hospitalization (P<0.001).

After adjusting for sex, age, comorbidities, and sepsis severity, AKI remained independently associated with an increased risk of all-cause mortality (HR 1.44, 95% CI 1.14-1.82, P=0.003). Moreover, AKI was linked to a higher in-hospital mortality (HR 1.64, 95% CI 1.16-2.34, P=0.006) and cardiovascular cause of death (HR 2.49, 95% CI 1.39-4.48, P=0.002).

Our study uniquely demonstrates that AKI's adverse impact on outcomes is evident already at the ED, even when considering only patients who received treatment exclusively outside the ICU. Our focus on the ED population bridges an important gap in understanding sepsis-AKI prognostication, extending the implications beyond ICU settings.

Our findings highlight the need to address sepsis-AKI already at the ED, since these patients may benefit from future targeted therapies and appropriate follow-up care, including monitoring for cardiovascular and kidney complications.

Conclusion(s): AKI is independently associated with all-cause mortality, in-hospital mortality, and cardiovascular cause of death in patients with early-stage sepsis at the ED. Notably, this is evident even in patients who did not require ICU care, underscoring that AKI's adverse impact on outcomes occurs early in the care continuum.

34AP02-2

Personalized fluid therapy in early septic shock: impact on volume and lactate clearance

I. Yakymenko¹, N. Matolinets¹

¹Danylo Halytsky Lviv National Medical University (LNMU), Department of Anesthesiology and Intensive Care, Lviv, Ukraine

Background and Goal of Study: Fluid resuscitation is a critical component of early management in patients with septic shock. The 2021 Sepsis Surviving Campaign (SSC) guidelines recommend administering 30 mL/kg of balanced crystalloids within the first 3 hours of diagnosis. However, this standard approach does not fully align with the principles of personalized medicine.

This study aimed to investigate whether dynamic hemodynamic assessment methods can individualize fluid therapy during the early phase of septic shock.

Materials and Methods: This randomized controlled trial included 47 patients with septic shock, enrolled within 3 hours of ICU admission and randomly assigned to one of two groups. In the Dynamic Assessment Group (Group 1, 23 patients), fluid resuscitation decisions were guided by Pulse Pressure Variation (PPV), measured every 15 minutes. If PPV exceeded 12%, a 400 mL bolus of balanced crystalloids was administered. In contrast, the Fixed-Dose Group (Group 2, 24 patients) received a standardized infusion of 30 mL/kg of balanced crystalloids.

The study compared the fluid volumes administered and lactate dynamics between the two groups during the first 3 hours of intensive care. Both groups received standard treatments in accordance with the 2021 SSC guidelines.

Results and Discussion: A statistically significant difference in fluid administration was observed between the groups (p = 0.0229).

Group 1, guided by PPV monitoring, had a lower average fluid administration (27.85 mL/kg) compared to the fixed 30 mL/kg in

The effect size (Cohen's d = -0.6796) indicated a moderate difference, with greater variability in fluid volumes in Group 1 (standard deviation = 4.47) versus Group 2 (standard deviation = 0.0). Despite these differences, lactate clearance outcomes were not significantly different between the two groups (p = 0.7648).

Conclusions: The study highlights significant variability in fluid requirements during the initial phase of septic shock. The standard fixed-dose approach results in higher cumulative fluid volumes, whereas an individualized approach reduces the fluid volume in most patients.

This personalized strategy allows clinicians to determine more precisely when a patient no longer benefits from additional fluids. However, no significant difference in lactate clearance was observed between the two methods. Further research is necessary to explore whether individualized fluid management improves long-term patient outcomes.

Exploring the potential of Netrin-1 as a prognostic indicator and therapeutic target in sepsis

K.F. Schreyer¹, L. Ziegon¹, J. Stettmer¹, R. Reuten², G. Schneider¹, M. Schlegel¹ ¹TUM University Hospital, Technical University of Munich, Department of Anesthesiology and Intensive Care Medicine, Munich, Germany, ²University of Freiburg, Department of Pharmacology, Freiburg, Germany

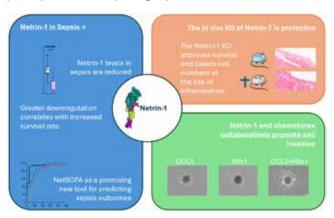

Background and Goal of Study: The neuronal guidance protein Netrin-1 has been recognized for its dichotomous role in the immune system: while it suppresses acute inflammation, it also promotes chronic inflammation. We demonstrated that netrin-1 is downregulated in septic patients, and patients with lower initial netrin-1 levels presented a better clinical outcome.

Furthermore, we found that inhibiting netrin-1 in septic mice improved survival. Currently, we are developing a new prognostic tool for sepsis patients, the NetSOFA score, and have uncovered in vitro a mechanism that explains the improved survival observed in septic patients with decreased netrin-1 level and in septic mice that lack netrin-1.

Materials and Methods: In a cohort of 39 critically ill sepsis patients and 18 controls, we measured plasma netrin-1 levels on day one alongside clinical parameters obtained from electronic health records (IRB 249/20 S-EB). We generated three tissue-specific netrin-1 knockout mouse models (IACUC: ROB-55.2,2532. Vet 02-21-206). Sepsis was induced using cecal ligation and puncture. In vitro, we evaluated the invasion of human cells from a spheroid into a collagen matrix under the influence of netrin-1 ± chemokines.

Results and Discussion: In patients surviving sepsis, we observed a decrease in netrin-1 levels. When combining the netrin-1 level with the SOFA score, the NetSOFA score demonstrates superior prognostic accuracy of survival compared to the individual parameters alone. In septic mice, wild-type animals showed significantly worse survival outcomes than neutrophil/monocyte-specific knockout animals. Moreover, wild-type littermates exhibited elevated immune cell counts in the peritoneal cavity, while chemokine concentrations remained comparable between groups. Additionally, we observed that netrin-1 and chemokines together orchestrate cell invasion in-vitro.

Conclusion(s): In summary, Netrin-1 emerges as a promising diagnostic marker for sepsis. Furthermore, its role in modulating immune responses suggests that targeting Netrin-1 may hold therapeutic potential for improving sepsis outcomes.

34AP02-4 Sexual dimorphism in neutrophil function

R. Kraus¹, M. Gruber¹, J. Rosenberger¹ ¹University of Regensburg, Anesthesiology, Regensburg, Germany

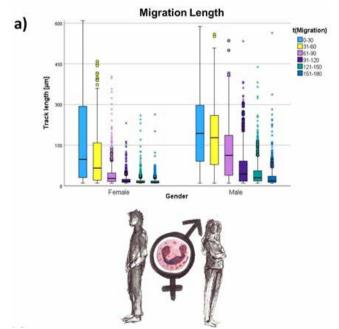

Background and Goal of Study: Women and men are different on many biological levels. Mounting evidence is now recognized that even the immune system has some significant sex differences. which are mainly cell-mediated.

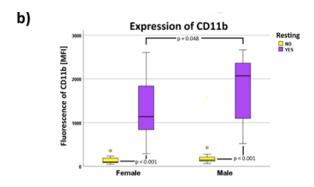

This study investigated sex-specific differences in function and regulation of polymorphonuclear neutrophil granulocytes (PMNs) in male and female healthy human donors to gain a deeper understanding of the immune response and potential sex-specific dimorphism in immunology [1].

Materials and Methods: PMNs were isolated from whole blood samples of healthy female and male donors by density centrifugation. Afterwards a µ-slide chemotaxis assay was conducted, where N-formylmethionin-leucyl-phenylalanine (fMLP) enticed PMNs' ability for chemotactic migration and production of reactive oxygen species (ROS), release of myeloperoxidase (MPO) and formation of Neutrophil Extracellular Traps (NETs) were measured. In addition, functional differences of surface epitopes CD62L, CD11b, CD66b and oxidative burst on PMNs from male and female donors were investigated with a flow cytometry as-

Results and Discussion: Sex specific differences of neutrophil function could be determined. Male-derived PMNs initially migrated further distances (figure 1a), while female-derived PMNs showed more targeted movement.

However, as the observation period progressed, male-derived PMNs began to exhibit more targeted migration, maintaining straightness towards the end. Differences in neutrophil surface marker expression were observed, with higher levels of CD11b (figure 1b) and CD66b on male-derived PMNs after 2 h resting. The different immune effects between the genders were seen in live cell imaging as well as in flow cytometry analyses.

Conclusion(s): The study found clear functional differences between PMNs from male and female donors. To gain reliable results in future PMN studies, it is crucial to take a donor's gender into account.

34AP02-5 SPP1 mediated synaptic damage through activation of microglia and promoted the occurrence of septic-associated encephalopathy

W. Liu¹, Z. Niu², X. Zhu¹, C. Zhang¹, C. Chen¹ West China Hospital, Sichuan University, Department of Anesthesiology, Chengdu, China, 2West China Hospital, Sichuan University, Department of Emergency, Chengdu, China

Background and Goal of Study:Osteopontin, also known as secreted phosphorylated protein-1, has cytokine, chemokine and signal transduction function. Previous studies have found that SPP1 is related to AD. However, there are few reports on whether SPP1 is associated with the occurrence of sepsis-associated encephalopathy(SAE).

Thus, the goal of this study is to explore the pathogenic mechanism of SPP1 in SAE.

Materials and Methods: Sepsis was induced by Cecal ligation and puncture (CLP) procedure. The open field test, Y maze and novel object recognition test were used to assess cognitive function. The expression of SPP1 in the hippocampus was examined by

gRT-PCR, western blotting and immunofluorescence.

Quantitative data are displayed as the means ± standard deviations and were analyzed by ANOVA. All experiments were carried out at least in triplicate. Student's t test was utilized as a post hoc test. P < 0.05 was considered statistically significant.

Results and Discussion: In the CLP model, the mice showed cognitive dysfunction (Figure A). The expression level of SPP1 in hippocampus of SAE mice was increased, the expression level of Synaptophysin was decreased, and microglia was activated (Figure B-C).

Conclusion(s) Sepsis mice showed cognitive dysfunction, increased expression of SPP1 in the hippocampus, microglial activation, and synaptic damage

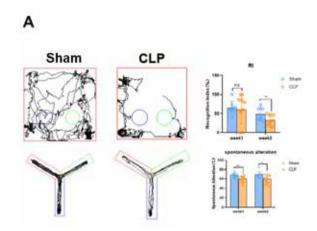

Figure A. Representative chart of Y maze and the novel object recognition.

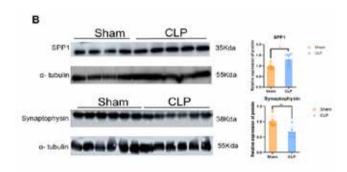

Figure B. Representative Western blotting images of samples.

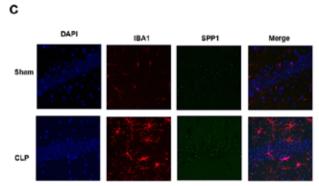

Figure C. Representative immunofluorescent images.

Revisiting the applicability of microRNAs as biomarker in sepsis associated acute kidney injury: a cohort-based analysis

T. van der Aart¹, M. Luxen²,³, M. van Londen⁴,
J.C. ter Maaten⁵,⁶, M. van Meurs³, H. Bouma⁻,¹,

Background and Goal of Study: Sepsis is a life-threatening body response to an infection which is frequently complicated by sepsis-associated acute kidney injury (SA-AKI). MicroRNAs, short non-coding RNAs, regulate key pathways implicated in SA-AKI pathophysiology.

This study aims to explore their potential as biomarkers in patients with early-stage SA-AKI in the emergency department (ED) and those with advanced disease in the intensive care unit (ICU). **Materials and Methods:** This is a post-hoc analysis of prospectively collected data. We utilized a hypothesis-driven panel of twelve microRNAs linked to sepsis, renal cell injury, and SA-AKI. Plasma samples were collected upon ED and ICU admission, analyzed for microRNA levels and normalized to the global mean. MicroRNA levels were compared across ED groups (no infection, sepsis, and SA-AKI) and ICU groups (sepsis and SA-AKI). Performance for SA-AKI differentiation and mortality prediction was assessed using odds ratios and area under the receiver operating characteristic (AUROC) analysis.

Results and Discussion: This study evaluated microRNA data of 193 ED patients categorized as non-infection (n=65), sepsis (n=67) and SA-AKI (n=61), and 47 ICU patients with sepsis (n=18) and SA-AKI (n=29). miR-21-5p was significantly upregulated in ED patients with SA-AKI and was associated with its occurrence (OR 2.28, 95% CI [1.40–3.73]; P<0.001).

Additionally, miR-21-5p demonstrated robust predictive value for in-hospital mortality, even after adjusting for age, sex, and disease severity (adjusted OR 3.42, 95% CI 1.69–6.94; P < 0.001), with an area under the curve (AUC) of 0.82 (95% CI 0.74–0.91; P < 0.001).

In the ICU population, miR-21-5p was the only microRNA significantly associated with SA-AKI (odds ratio [OR] 3.48, 95% confidence interval [CI] 1.27–9.53; P=0.02), achieving an AUC of 0.74 (95% CI 0.58-0.89). The modest performance of miR-21-5p and the overall lack of significant findings for the other microRNAs question the applicability of microRNAs as effective tools for early SA-AKI differentiation.

Conclusion(s): Our findings suggest that this microRNA panel has limited utility as biomarkers for SA-AKI in clinical settings. However, miR-21-5p may serve as a marker of overall disease severity, with potential predictive value for clinical outcomes in early patient presentations, particularly in initial presentations at the emergency department.

34AP02-7

Esophageal rupture secondary to vomiting with complicated hydropneumothorax: progression to septic shock and multiorgan failure

A. Plaza Saura¹, B. García Iniesta¹, M. Cano Castellote¹, A.I. Mateos Hernández¹, C.M. López López¹, R. González Celdrán¹

¹Hospital General Universitario Reina Sofía, Anaesthesiology and Intensive Care, Murcia, Spain

Background: Esophageal perforation is a rare but potentially lifethreatening medical emergency. The diagnosis is a challenge and usually delayed given its multiple etiologies and varying clinical.

Case Report: A 72-year-old woman with no relevant medical history presented with right-sided thoracic trauma and progressive dyspnea over a few hours. She denied additional symptoms except for vomiting over the past week.

On examination, she was in good general condition with vital signs within normal ranges. A chest X-ray revealed a right hydropneumothorax, leading to the placement of a chest tube that drained purulent fluid. Her initial course was favorable, allowing the resumption of oral intake.

However, drainage of alimentary content through the chest tube raised suspicion of esophageal rupture, likely secondary to vomiting (Boerhaave syndrome). A contrast-enhanced chest CT confirmed distal esophageal perforation with communication to the right pleural cavity. A second chest tube was inserted, and an esophageal stent was placed. Despite these measures, her condition deteriorated, progressing to septic shock and acute respiratory distress syndrome (ARDS).

An emergency thoracotomy was performed with pleural cavity irrigation. Despite intensive resuscitative efforts, including broad-spectrum antibiotics, renal replacement therapy, fluid resuscitation, and vasoactive drugs, the patient developed multiorgan failure and deceased.

Discussion: Half of esophageal perforations are iatrogenic and 15 percent are spontaneous or secondary to Boerhaave syndrome. This syndrome is associated with high morbidity and mortality and is fatal in the absence of therapy. The nonspecific symptoms may contribute to a delay in diagnosis and a poor outcome.

Thus, timely diagnosis and initiation of treatment is of essence. Management include fluid resuscitation, broad-spectrum antibiotics, repair and dranaige of any collection and nutritional support. The principal variables associated with mortality from an esophageal perforation include delay in diagnosis, type of repair, location of perforation, and etiology of the perforation.

Learning points: Complications of esophageal perforation can be severe, so early diagnosis and aggressive management are key to prevent fatal outcomes.

Clinical suspicion play an important role because of the rarity of esophageal perforation and the variability in clinical presentation.

Efficacy of MR-proADM and other biomarkers as early predictors of disease severity and mortality in patients with severe infection in ICU: preliminary results from a multicenter prospective observational study

R. Traversi¹, G.L. Bruno¹², L. Rodigari¹³, A. Della Selva², G. Mengozzi⁴, G. Montrucchio¹³
¹University of Turin, Department of Surgical Sciences, Torino, Italy, ²Michele e Pietro Ferrero Hospital, ASL CN2, Anestesia e Rianimazione, Verduno, Italy, ³AOU Città della Salute e della Scienza di Torino, Anestesia e Rianimazione 1U, Torino, Italy, ⁴University of Turin, Department of Laboratory Medicine, Torino, Italy

Background: Proadrenomedullin (pro-ADM) is a peptide expressed in various tissues upregulated by hypoxia, inflammatory cytokines, bacterial products and shear stress. Its precursor mid-regional pro-ADM (MR-proADM) is an effective and early biomarker of endothelial damage correlate, particularly promizing in sepsis¹, not already studied in Intensive Care Units.

Goal of Study: To evaluate MR-proADM for 28 days mortality compared to other inflammatory biomarkers in severe infections requiring ICU-admission.

Materials and Methods: prospective observational 2 centers study, including ICU-patients admitted for severe infections between December 2022 and June 2024. Continous variables were analyzed with t-test or Wilcoxon test, dicotomic variables were analyzed with Fisher or Chi-squared test.

Results and Discussion: 92 patients were enrolled. Mean SOFA and SAPSII values were 9 and 48, respectively. Sepsis and septic shock were reported in 76% and 95% of patients, respectively. Infections were microbiologically confirmed in 87% of patients (infection type: respiratory 38%, intraabdominal 38%, genitourinary 6.5%). 28-days and ICU-mortality were 33 and 29%. respectively. Among the scores, only the SAPSII was statistically different between the two groups (p-value 0.0148). All standard biomarkers (C-RP, PCT, lactate) failed to show statistical significance for primary outcome. MR-proADM value at ICU admission showed significant difference (p 0,0011). MR-proADM values at day3 (p 0,0126) and day7 (p 0,0010) from admission also showed significant difference. Lymphocyte count showed statistical difference at admission (p 0,0009), at day3 (p 0,0007) and day7 (p 0,0015). Although a decreasing trend seemed to carachterize survivors and increasing trend non-survivors patients, MR-proADM trend during time failed to show statistical significance.

In multivariate analysis, MR-proADM failed to show statistically significant difference (OR 1.075, CI 0.968-1.193, p 0,1748), as opposed to immunosuppression (OR 7.783, CI 1.504-40.269, p 0.0144), age (OR 1.048, CI 1.004-1.093, p 0.0305) and lymphocyte count at admission (OR 0.997, CI 0.993-1, p 0.0445).

Conclusions: In ICU-severe infections, MR-proADM values at admission and during ICU stay seems to correlate with 28 days mortality, suggesting a role for this biomarker in predicting disease severity. Further data are needed to corroborate our findings.

Associations between pre-operative iron deficiency and postoperative infection in patients undergoing major surgery (CARIPO): a prospective observational study

M. Campfort¹, <u>T. Perrault</u>¹, A. Blanchard-Daguet¹, E. Rineau¹, S. Lasocki¹

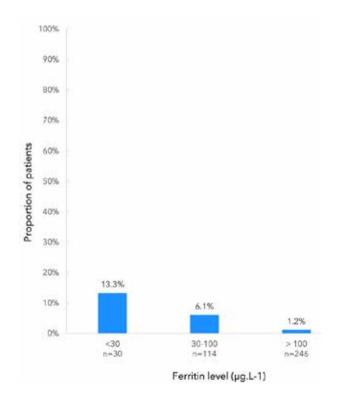

¹CHU Angers, Anesthesiology and Intensive Care, Angers, France

Background and Goal of Study: Iron deficiency, with or without anaemia, is common during the peri-operative period. It has been hypothesised that pre-operative iron deficiency is associated with an increased incidence of postoperative infection. We designed the CARIPO prospective observational study to assess the incidence of postoperative infection in patients with and without iron deficiency undergoing a variety of major surgeries.

Materials and Methods: We conducted a single-centre study in a tertiary, university-affiliated hospital in France. Iron deficiency was defined as a ferritin < 100 μ g.l⁻¹ or < 300 μ g.l⁻¹ with a transferrin saturation < 20%.

The primary outcome was incidence of any postoperative infectious complication measured at 90 days after surgery. Secondary endpoints included the incidence of individual infectious complications: surgical site infection; bacteraemia; pneumonia; urinary tract infection; peripheral line-associated bacterial infection; and all-cause postoperative complication.

	Iron deficient	Iron replete	р
A	(n=170)	(n=220)	value
Any postoperative infectious complication	27 (16%)	26 (12%)	0.25
Main type of infections			
Surgical site infection	11 (7%)	3 (1%)	0.01
Urinary	2 (1%)	4 (2%)	0.70
Pulmonary	5 (3%)	11 (5%)	0.44
Catheter	7 (4%)	5 (2%)	0.38

Results and Discussion: We recruited 390 patients. Of these, 170 (44%) had pre-operative iron deficiency and 220 (66%) were iron replete: 27 (16%) patients in the iron deficient group developed a postoperative infection compared with 26 (12%) in the iron replete group (p = 0.25). Surgical site infections occurred in 11 (7%) iron deficient patients and 3 (1%) iron replete patients (p = 0.01). Other types of infectious complication and all-cause postoperative complication were similar between groups.

Conclusion: Iron deficiency was not associated with a higher rate of postoperative infection relative to an iron replete state. While iron deficiency was associated with a higher rate of surgical site infection, this result is hypothesis-generating, and further prospective studies are required.

34AP02-10

A novel approach to predict the need for hemodynamic support therapy in sepsis: pulse oximetry plethymography in the emergency department

S. Ter Horst¹, A.D. Schoonhoven¹, R.J. van Wiik¹, R. Weitering¹, J.C. ter Maaten¹, H.R. Bouma¹, **Acutelines Research Group** ¹University Medical Centre Groningen, Emergency Department, Groningen, Netherlands

Background: Sepsis is the leading global cause of mortality, with septic shock mortality exceeding 40%. Hemodynamic instability in sepsis requires timely treatment to prevent organ failure. Current resuscitation strategies apply a one-size-fits-all approach, risking fluid overload or prolonged shock. Personalized approaches integrating macro- and microvascular changes could improve outcomes. Pulse oximetry photoplethysmography (PPG), a noninvasive technique measuring blood volume changes, may assess these changes. This study evaluates associations between PPG features measured during emergency department (ED) triage and vasopressor therapy within 24 hours in sepsis patients.

Methods: A secondary analysis of the Acutelines biobank included 325 sepsis patients requiring ED hemodynamic resuscitation. Pulse oximetry PPG waveforms from the first 20 minutes of ED admission were preprocessed and analysed. Principal component analysis (PCA) reduced dimensionality, and k-means clustering categorized patients into three clinical clusters. Multivariable logistic regression explored associations between PPG components and outcomes, with predictive performance evaluated through ROC analysis.

Results: Among 325 patients, 15.4% required vasopressors within 24 hours. PCA identified three components explaining 80.31% of variance. Clustering revealed three groups with distinct clinical characteristics. Cluster C had severe hemodynamic instability, elevated lactate, and higher rates of vasopressor use, ICU admission, and mortality. PPG components predicted vasopressor therapy within 24 hours, with an AUROC of 0.740, PPV of 0.927, and NPV of 0.346.

Conclusions: PPG features measured at triage provide valuable insights into sepsis-related macro- and microvascular changes, offering prognostic value for vasopressor therapy within 24 hours of ED admission. These findings support pulse oximetry PPG as a potential tool in developing personalized hemodynamic resuscitation for sepsis.

34AP02-11 Fever of unknown origin

K. Arslan¹, M. Oral¹, S. Oba¹, S. Değirmenci¹, H. Yamali¹ ¹Memorial Ankara Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Thermoregulatory centre, located in the hypothalamus controls our body temperature and could be damaged by pyrogenic cytokines, pyrogens, as a response to inflammation and infection. Regardless of fever is inflammatory reply amplifying the immunological response, high fever may harm patient [1].

Case Report: 58-year-old female patient weighs 135 kg, has breast cancer (right mastectomy), dementia, DM, CRF, HT, she is paraplegic care patient due to previous CVA. The patient had obesity surgery, has a port, she had been treated with antibiotics for urinary tract infection. She applied to our hospital with poor general condition, drowsiness, and fever, infection scan was performed (blood culture from port and peripheric ven). An increased opacity was seen on the base in the chest X-ray, atelectasis? Infiltration? aspiration pneumonia? Tazocin treatment was started. Staphylococcus hominis was seen in the blood culture sent from the port, vancomycin was added. Although the patient remained afebrile for the next 2 days, fever was seen again on the 3rd day. The patient underwent an echocardiogram, no vegetation was seen. The patient's port catheter was surgically removed. Contrast-enhanced thorax and abdomen CT was performed, the sigmoid colon showed an advanced redundant course, wall thickening reaching 2 cm and gas-stool distension were seen in the thickest part of the long segment of the distal descending colon, sigmoid colon and rectum. The patient underwent rectosigmoidoscopy, the patient's colon biopsy result was reported as pseudomembranous colitis. CMV excluded as CMV IgM was negativ. Tigecycline and flagyl treatment was completed in 7 days.Oral vancomycin and candisept were continued for 14 days.

Discussion: In our country, the most common cause of fever of unknown origin is infectious diseases. When routine tests and cultures do not yield results, further examinations and imaging should be considered [2].

References:

1. Sethi, N., Fever therapy in febrile adults: a systematic review with meta-analyses and Trial Sequential Analyses. 2021. 2. SOLAY, A.H., et al., Nedeni Bilinmeyen Ateş Olgularının Değerlendirilmesi: Klinik Tecrübelerimiz. FLORA, 2013. 18(4): p. 161-168.

Learning points: When investigating the etiology of fever, it should be remained that pseudomembranous colitis may occur in patients receiving long-term antibiotic treatment even in the absence of diarrhea.

Treatment of anaerobic infection in a patient with a mine blast trauma (MBT)

O. Sydiuk¹, O. Khomenko^{2,1}, S. Chechil¹, V. Antonenko¹, O. Usenko¹

O.O.Shalimov National Scientific Center of Surgery and Transplantology, National Academy of Medical Sciences of Ukraine, Anaesthesiology and Intensive Care, Kyiv, Ukraine, ²Bogomolets National Medical University, Surgery, Anaesthesiology and IC IPE, Kyiv, Ukraine

Background: Anaerobic infection is a severe wound infection caused by anaerobic microorganisms. Patients with anaerobic infection have high mortality rate[1]. This clinical case describes the diagnosis and treatment of anaerobic infection in injured combatant.

Case Report: A soldier was hospitalized with a diagnosis of mine blast trauma (MBT), gunshot wound to the left lower leg with a fracture of the tibia and fibula and a massive soft tissue defect in the left lower limb, injuries received during military operation. Patient underwent a Free Thoracodorsal Artery Perforator Flap (TDL) for the defect in the left tibia. Day1 after surgery patient deteriorated. On examination: thrombosis of the thoracodorsal artery and the TDL flap was removed. On Day2 patient unstable, on high doses of noradrenaline(≈ 0,4 mg/h). On CT - signs of subcutaneous and intermuscular emphysema of the right chest wall with spread to mediastinum, and presence of gas bubbles on the surface of the rhomboid major muscle. The lateral surface of the chest, the muscle tissue have dark color and is necrotic. On Day3 patient in septic shock, on mechanical ventilation (MV) (pressure control ventilation (PC) with FiO2 - 40%), hemodynamics was maintained by noradrenaline ≈ 0,54 mg/h. In wound culture - anaerobic infection - Clostridium perfringens sensitive to Linezolid, so antibiotic therapy was adjusted accordingly. Hyperbaric oxygen therapy (HBO) was not available. Patient required MV till Day15. He received daily wound care with necrotectomy and later, application of amniotic membrane to the rib area of the lateral surface of the trunk and subsequent autodermoplasty of the lateral surface of the trunk and lower leg. Patient was successfully discharged from the hospital on Day40.

Discussion: Sepsis and septic shock caused by anaerobic infection are critical conditions. Combatants are under the risk because of prolonged evacuation time between injury and medical care. Anaerobic infection is causes high mortality in Ukraine and the world, especially in countries with a military conflicts[2].

- 2. Jerome B. Buboltz. Gas Gangrene.https://www.ncbi.nlm.nih. gov/books/NBK537030/.

Learning Points: Timely diagnostics of wound infection is crucial for appropriate treatment of patients with MBT. Properly selected antibiotic therapy and daily surgical wound care have improved patient outcome.

34AP03-2

Extracellular vesicle mir150-5p as a biomarker for optimizing clinical management of sepsis and septic shock: a discovery and validation study

M. Espinoza Fernandez¹, L. Suárez Pérez¹, B. Martinez Rafael¹, O. Gorgojo Galindo², A. García Concejo³, P. Jorge Monjas¹ ¹Hospital Clínico de Valladolid, Anesthesiology and Surgical Critical Care, Valladolid, Spain, ²Hospital Clínico de Valladolid, Research Unit, Valladolid, Spain, 3Institute of Health Sciences of Castile and Leon, Research Unit, Soria, Spain

Background and Objectives: Sepsis and septic shock are significant contributors to mortality among surgical patients. The role of extracellular vesicles (EVs), particularly their primary content of microRNAs (miRNAs), has surfaced as a pivotal factor in the detection and understanding of these conditions. EVs-derived miRNAs have advantages over plasma miRNAs, such as a better diagnostic performance in some cases3. Thus, the purpose of this study was to analyze the profile of circulating plasma-derived EVs miRNAs in patients with sepsis and septic shock to identify differential biomarkers that can facilitate the management of these patients.

Methods: A multicentric study was conducted in 100 patients who were followed prospectively, 58 developed septic shock and 42 developed sepsis. EVs-derived miRNAs were isolated and massively sequenced to identify differentially expressed miRNAs between groups. Predictive performance was evaluated through area under curve values (AUC) using receiver operating curves (ROC). An additional validation cohort of septic shock patients (n=33) and sepsis patients (n=33) was used to validate our EVsderived miRNA results. Furthermore, we compared our data with an external cohort of plasma miRNA data.

Results: 18 SDE EV-miRNAs were identified between the two groups of patients. A total of 15 miRNAs were upregulated in septic shock patients and 3 were downregulated. Six EV-miRNAs had a good ability to predict septic shock. Low levels of hsa-miR-150-5p showed the best ability to predict septic shock (AUC: 0.852; 95% CI: 0.75-0.96; p<0.001) with a sensitivity of 86.96% and a specificity of 78.72%. The association of hsa-miR-150-5p with septic shock was validated in the validation cohort and confirmed its presence in plasma via qPCR.

Cconclusion: In conclusion, hsa-miR-150-5p levels exhibit a significant differential expression between patients with septic shock and those with sepsis without shock. This biomarker can aid physicians in managing post-surgical patients with sepsis. Furthermore, its integration into clinical laboratories is feasible, as PCR - a rapid, accurate, and routinely used technique - facilitates efficient detection.

References:

1. Martín-Fernández M, Heredia-Rodríguez M, González-Jiménez I, Lorenzo-López M, GómezPesquera E, Poves-Álvarez R, et al. Hyperoxemia in postsurgical sepsis/septic shock patients is associated with reduced mortality. Crit Care. 2022;26:4.

Navigating anaesthetic challenges of C1 esterase inhibitor type 1 patient during emergency dental extraction under conscious sedation: a case report

S. Khaliq¹, O. VijiyaKumar¹, R. Collman¹, T. Teemul¹, S. Khan¹

¹Hull University Hospitals, Anaesthesia, Hull, United Kingdom

Background: Hereditary angioedema (HAE), a rare disorder causing recurrent angioedema, poses significant perioperative challenges due to potential airway compromise from excessive bradykinin production. This case report details the successful management of an HAE type 1 patient undergoing emergency dental extraction under conscious sedation. Its significance lies in demonstrating effective multidisciplinary care, including proactive prophylaxis and careful sedation techniques, despite the patient's complex history and needle phobia, offering valuable insights into emergency management.

Case Report: A 24-year-old male with hereditary angioedema (HAE) type 1 presented with an acutely infected impacted mandibular molar, triggering facial angioedema. His HAE was diagnosed at age 8, with previous management including tranexamic acid and icatibant. He subsequently transitioned to Berotralstat, though adherence to scheduled appointments remained challenging due to needle phobia. The preoperative assessment revealed borderline elevated C-reactive protein, absent complement C4 and significantly reduced C1-INH antigen and function. Prophylactic intravenous C1-INH (1000 units) was administered 24 hours and 20 minutes prior to the procedure. Conscious sedation (midazolam, fentanyl, propofol) and local anaesthesia facilitated the uneventful extraction. Postoperatively, the patient experienced only mild facial flushing.

Discussion: This case highlights the successful perioperative management of an HAE patient undergoing an emergency dental procedure. Prophylactic C1-INH effectively prevented acute angioedema. The choice of conscious sedation minimized the risk of airway compromise, a crucial consideration given the patient's HAE. This successful outcome underscores the importance of proactive, individualized treatment plans and close monitoring in patients with HAE, particularly in emergencies. Further research is warranted to optimize management protocols for such scenarios.

Learning points: Successful perioperative management of hereditary angioedema (HAE) requires a multidisciplinary approach incorporating prophylactic C1-INH to prevent acute attacks, conscious sedation to minimize airway risk, and individualized care plans addressing patient-specific factors such as needle phobia. Patient education is critical for treatment adherence and optimal outcomes.

34AP03-4

Organ/space nosocomial infection after elective colorectal surgery: a retrospective analysis of microbiology and antibiotic coverage

M. Costa Murtra¹, M. Sadurní¹, A. Benítez-Cano¹, M. Puyada¹, I. Zaragoza¹, R. Adalia¹ ¹Hospital del Mar, Anaesthesiology, intensive care and pain medicine, Barcelona, Spain

Background and Goal of Study: organ-space infection (OSI) is a common complication after colorectal surgery, including anastomotic leakage and intra-abdominal abscesses. Prompt and effective treatment is critical to patient prognosis, and appropriate antibiotic therapy is essential. Knowing the microbiology of OSI at each center is key for optimal treatment. The aim of this study was to describe the most prevalent microbiology in our center and analyze antimicrobial sensitivity to three empirical antibiotic therapies.

Materials and Methods: after ethics committee approval, we retrospectively analyzed cultures of OSI cases following elective colorectal surgery over the past 10 years (2014-2023) in our hospital. Results were categorized into nine groups: extendedspectrum beta-lactamase (ESBL)-producing enterobacteriaceae, Pseudomonas spp, other Gram-negative bacilli (GNB), Enterococcus faecium, methicillin-resistant Staphylococcus aureus (MRSA), other Gram-positive cocci (GPC), anaerobes, polymicrobial flora, and fungi. Using this data, we explored the microbiological coverage of three empirical antibiotic regimens: Amoxicillinclavulanate. Piperacillin-tazobactam, and Meropenem+Linezolid Results and Discussion: of 1,334 colorectal surgeries performed, 99 (7.4%) developed OSI, and 77 had positive cultures. The microbiological results were:

- Pseudomonas spp.: 13%
- ESBL enterobacteriaceae: 7.8%
- Other GNB: 66%
- Ampicillin-resistant E. faecium: 33.7%
- MRSA: 1.3%
- Other GPC: 50.6%
- Anaerobes: 26%
- Polymicrobial flora: 8%
- Fungi: 20.8%

Taking into account the bacterial growth, the following percentages of patients would have been adequately covered by each antibiotic regimen:

- · Amoxicillin-clavulanate: 49%
- Piperacillin-tazobactam: 61%
- Meropenem + Linezolid: 93.5%

Notably, 20% had fungal isolation (Candida spp.), which would not be covered by any empirical therapy without adding antifungal treatment. Moreover, 32% of Candida isolates were resistant to fluconazole.

Conclusion(s): GNB, non-resistant GPC and anaerobes were the most frequent pathogens but ampicillin-resistant E. faecium, Pseudomonas spp., and ESBL-producing bacteria were also significant. Amoxicillin-clavulanate covered 49% of positive cultures, piperacillin-tazobactam increased sensitivity to 61% and Meropenem+Linezolid covered nearly all patients. Fungi (Candida spp.) were found in 20% cultures. Empirical antifungal therapy should be considered when OSI is suspected.

Septic shock of prostatic origin with immediate postoperative onset in the PACU - a case report

F. Santos¹, T. Barros¹, L. Gonçalves¹, M.H. Lima¹, E. Valente¹

¹Local Health Unit of the Leira Region, Anesthesiology, 2410-197, Portugal

Background: Transurethral resection of the prostate (TURP) is performed in a semi-sterile environment. Thus, urinary tract infections (UTI) are common complications (1). Progression to septic shock is rare and can develop insidiously (2).

Case Report: 75-year-old male, ASA III, with prostatic adenocarcinoma, set for elective TURP. History included severe obstructive sleep apnea, grade II hypertension, dyslipidemia, grade II obesity, and stable coronary artery disease. ASA monitoring standards were followed and urinary catheterization was established. Subarachnoid block was performed (8 mg 0.5% levobupivacaine, 2.5 mcg sufentanil, paramedian approach at L3/L4), followed by the administration of 2 g cefoxitin. Surgery lasted 1h20min with mild sedation applied (50 mg propofol, 20 mg ketamine). In the perioperative period, the patient kept hemodynamically stable, apyretic, with SpO2 >95% under O2 therapy with nasal cannula (3 L/min). One hour after surgery, in the PACU, the patient was sub-febrile, hypotensive, tachycardic, tachypneic, and without urinary output via Foley catheter. Physical examination revealed abdominal distension, tympany, diffuse pain, and abdominal guarding. Arterial blood gas showed hyperlactatemia (4.9 mmol/L). CT scan and angio-CT of the thorax, abdomen, and pelvis excluded perforation and bleeding. Empirical antibiotic therapy initiated (piperacillintazobactam, gentamicin). The patient was diagnosed with septic shock (prostatic origin) and transferred to the ICU, with invasive blood pressure monitoring and a central venous catheter in place for vasopressor support.S. hominis was isolated from cultures. The patient progressed favorably.

Discussion: UTIs are common complications after TURP and typically develop insidiously. Risk factors such as patient comorbidities and prostatic adenocarcinoma may have contributed to the onset of septic shock.

1. Yu SH, Jung, SI, Hwang EC., et al. Korean Multicenter Study of Infectious Complications after Transurethral Prostate Surgery in Patients with Preoperative Sterile Urine. Urogenit Tract Infect 2022;17:81-8. 2. Yamamoto H, et al. A case of sepsis that developed during transurethral resection of the prostate. J Anesth. 2002;16:242-4.

Learning points: It is important to quickly recognize and manage septic shock. Clinicians should keep a high index of suspicion with patients undergoing TURP.

34AP03-6

Limited utility of red cell distribution width in predicting post-surgical infectious complications

N. de Mul¹, G.E. Mondelli², L.M. Vernooij^{1,2}, S. Haitjema³, W.-J.M. Schellekens^{4,1}, O.L. Cremer⁵ ¹University Medical Center Utrecht, Anesthesiology & Intensive Care, Utrecht, Netherlands, 2St. Antonius Ziekenhuis, Anesthesiology & Intensive Care, Nieuwegein, Netherlands, 3University Medical Center Utrecht, Central Diagnostic Laboratory, Utrecht, Netherlands, 4Cantonal Hospital Aarau, Anesthesiology, Aarau, Switzerland, ⁵University Medical Center Utrecht, Intensive Care, Utrecht, Netherlands

Background and Goal of Study: Red Cell Distribution Width (RDW) measures the variability in red blood cell volume and is raised in conditions associated with chronic inflammation and oxidative stress. These factors may predispose surgical patients to postoperative infectious complications. We thus hypothesized that RDW might have utility in preoperative risk assessment of patients scheduled for elective surgery.

Materials and Methods: The study was conducted in a single tertiary center in the Netherlands. Consecutive patients undergoing elective, non-cardiac, non-intracranial intermediate- to high-risk surgery in an inpatient setting between 2012 and 2023 were included. The primary study outcome was all-cause infection occurring up to postoperative day 14. First, a core model was fitted including 13 known predictors of infection using logistic regression with backward covariate selection. The added predictive value of RDW was subsequently assessed by using Akaike's Information Criterion (AIC), and by comparing predictive performance of this core model to an extended model that included RDW, considering discrimination, calibration, overall accuracy, reclassification, and decision curve analysis.

Results and Discussion: A total of 14.165 patients undergoing 16,279 procedures were analyzed, of which 2561 (15.7%) were followed by postoperative infection. The core model demonstrated a c-statistic of 0.73 (95% CI 0.72 to 0.74). By contrast, univariable logistic regression analysis yielded a c-statistic of 0.60, indicating limited predictive accuracy of RDW for postoperative infection. Although extending the core model with RDW improved model fit based on the AIC, it did not result in meaningful improvements in predictive performance or reclassification (c-statistic 0.73, Integrated Discrimination Improvement = 0.0017, Net Reclassification Index = 0.006). Decision curve analysis further confirmed that there was no clinically relevant difference between the two

Conclusion(s): RDW did not improve the preoperative prediction of infectious complications after elective intermediate- to-highrisk inpatient surgery compared to a core model incorporating a comprehensive set of clinical predictors.

Prediction of mortality and correlation with APACHE II of fibrinogen/albumin, CRP/albumin, BUN/albumin, and lymphocyte/monocyte ratios measured in the first 24 hours in non-traumatic septic patients

N. Baydogan¹, M. Aksun², A. Şencan², B.E. Gölboyu², S. Girain²

Sehit Prof. Dr. İlhan Varank Sancaktepe Training and Research Hospital, Anesthesiology and Reanimation. İstanbul, Turkey, ²İzmir Kâtip Çelebi University Atatürk Training and Research Hospital, Anesthesiology and Reanimation, İzmir, Turkey

Background and Goal of Study: Sepsis is an organ dysfunction caused by an inappropriate host response to infection, with a 20-50% mortality rate. It is important to estimate the prognosis in sepsis. This study aimed to evaluate the success of some markers in predicting mortality in sepsis.

Materials and Methods: This study was planned retrospectively in 100 non-traumatic patients over the age of 18 who were admitted to İzmir Kâtip Çelebi University Atatürk Training and Research Hospital Anesthesia intensive care unit between 01/01/2021 and 21/09/2023 with the diagnosis of Sepsis. The patients' age, gender, chronic diseases, reason and date of intensive care admission, intensive care discharge type, intubation and inotropic support status were obtained from the hospital system. Arterial pH, PaCO2, PaO2, albumin, C-reactive protein, fibrinogen, procalcitonin, D-dimer, sodium, potassium, serum creatinine, blood urea nitrogen, hematocrit, leukocytes, lymphocytes, monocytes, platelets and GCS value at admission to intensive care were recorded. Afterwards, FAR (fibrinogen/albumin), CAR (CRP/albumin), BAR (BUN/albumin), LMR (lymphocyte/monocyte), APACHE-II score and Glasgow prognostic score were calculated and the relationship of these rates with mortality and correlation with APACHE-II were evaluated.

Results and Discussion: Of the 100 patients included in the study, 35% were female and 65% were male. The mean age of the patients was 69.81±13.97. 62% of the patients died. In the single logistic regression analysis performed for the effect of GKS. APACHE-II, GPS, FAR, CAR, BAR and LMR values on mortality, GKS, APACHE-II scores and BAR values were found to be statistically significant (p<0.05). In the multivariate analysis performed, only APACHE-II scores were found to be significant (p=0.019). In the ROC analysis performed, the AUC values of GKS, APACHE-II and BAR values were found to be significant and it was determined that APACHE-II had the highest predictive power for mortality.

Conclusion(s): In our study, the highest predictive markers for mortality in Sepsis were determined to be APACHE-II (70%), GKS (65%) and BAR (64.5%), respectively. In the evaluation of the mortality status of Septic patients admitted to the ICU; We concluded that various situations such as invasive mechanical ventilation and inotropic support should be evaluated at the time of admission, and that various scores and biomarkers can guide the clinician.

34AP03-8

Nocardia infection: a rare case report of a cerebellar mass

I. Azaharuddin¹, M.N. Mokhtar¹, Y.P. Su¹, M.I. Azmi², C.H. Ding3, F.H. Abdullah1 ¹Universiti Kebangsaan Malaysia, Department of Anaesthesiology & Intensive Care, Kuala Lumpur, Malaysia, ²Universiti Kebangsaan Malaysia, Department of Radiology, Kuala Lumpur, Malaysia, 3Universiti Kebangsaan Malaysia, Department of Medical Microbiology & Immunology, Kuala Lumpur, Malaysia

Background: Nocardia otitidiscaviarum infections are rare, particularly those involving the central nervous system (CNS).1 Such infections are challenging to diagnose and treat, especially in immunocompromised patients. This case highlights Nocardia sp cerebellar abscess in a patient with relapsed multiple myeloma. emphasizing the diagnostic challenges and management strategies.2

Case Report: A 53-year-old man with relapsed IgA Kappa multiple myeloma presented with altered consciousness and ataxia. His condition was complicated by multiple relapses and previous treatments including autologous stem cell transplantation and ongoing salvage therapy leading to suspicion of posterior circulation ischemic stroke. CT brain imaging revealed a left cerebellar mass with hydrocephalus. Initial cerebrospinal fluid analysis and cultures were inconclusive. Excision biopsy identified Nocardia otitidiscaviarum. Initial treatment included intravenous imipenem and bactrim, followed by a prolonged course linezolid and adjunctive bactrim. The patient experienced significant neurological recovery and a reduction in lesion size and eventually achieved stable neurological status upon discharge.

Discussion: Nocardia infections, although uncommon, are significant in immunocompromised patients due to diagnostic and therapeutic complexity. CNS involvement often mimics malignancies or other infections, delaying diagnosis. Neuroimaging plays a vital role, but definitive diagnosis relies on microbiological and histopathological findings. Treatment typically involves surgical excision combined with long-term antibiotic therapy. In this case, linezolid emerged as a critical option due to resistance patterns and treatment constraints. This report underscores the need for heightened clinical suspicion and a multidisciplinary approach in similar scenarios.

References:

- 1. Brown-Elliott, B.A. et al., 2020. Nocardia species: Susceptibility patterns and molecular analysis. Clinical Microbiology Reviews, 33(3), pp.432-450.
- 2. Beaman, B.L. & Beaman, L., 2019. Nocardia infections in immunocompromised patients. Journal of Infectious Diseases, 210(4), pp.528-532.

Learning points: Nocardia infections should be considered in differential diagnoses for cerebellar masses, especially in immunocompromised patients. Neuroimaging and histopathological findings are crucial for diagnosis.

Surgical intervention combined with tailored long-term antibiotic therapy can yield favorable outcomes

34AP03-9 Post epidural paravertebral phlegmon: a case report

R. Pinto de Sá¹, J.F. Costa¹, M. Gonçalves¹ ¹ULS de Braga, Anesthesiology, Braga, Portugal

Background: Epidural phlegmon (EP) is a rare complication of epidural catheter insertion. The typical presentation includes fever, back pain, and antalgic gait. Late diagnosis or inadequate treatment may lead to severe long-term incapacity. We present a case of paravertebral phlegmon post-epidural block in an elderly patient.

Case Report: A 76-year-old patient, ASA II, underwent total knee arthroplasty under combined spinal-epidural anesthesia. The procedure was performed under aseptic conditions without immediate complications. The epidural catheter was removed on postoperative D3. On D20, she reported newly onset back pain unresponsive to oral analgesics, with no neurological deficits or fever. Examination revealed a 4-centimeter reddened, edematous, and painful area. CT imaging showed cellulitis and paravertebral myositis at L2-L3, with possible intervertebral phlegmon. She was admitted for empiric antibiotic treatment with ceftriaxone and vancomycin. Blood cultures were negative, and a control MRI on the 5th day showed shrinking of the paravertebral collection and signs of acute osteomyelitis in the spinous processes. Ten days later, the pain subsided, inflammatory markers normalized, and the patient was discharged home to complete a month of antibiotics. During follow-up, she reported no lumbar pain or infection recurrence.

Discussion: This patient had no risk factors for post-epidural paravertebral phlegmon, such as systemic infection, compromised immunity, challenging puncture or prolonged epidural catheterization. Preventive measures during puncture were followed, including hand disinfection, sterile attire, applying 0.5% chlorhexidine skin spray and allowing it to dry, as the latest guidelines recommend. It is crucial to remain vigilant after any neuroaxial approach. This case also highlights the rapid progression of EP and the importance of early radiological diagnosis for timely treatment. EP without neurological deficits can be managed with antimicrobial therapy alone, as in this patient. While surgical intervention was avoided, we emphasize the importance of monitoring for neurological decline that could signal the failure of medical treatment.

Learning points: Aseptic conditions must always be maintained when performing a neuraxial technique. In all patients submitted to neuraxial analgesia, a high level of suspicion for EP should be maintained when symptoms arise, and prompt treatment should be administered to prevent further complications.

34AP03-11

Cerebral abscess revealing nocardiosis in a patient with systemic lupus erythematosus: a challenging diagnosis

S. Bellaftouh¹, T. Hessani², S. Chaabi², A. Erragh², A. Nsiri², R. Al Harrar²

¹Ibn Rochd University Hospital Center, Anesthesiologyintensive care medicine department, Casablanca, Morocco, 2Ibn Rochd University Hospital Center, surgical intensive care unit, Anesthesiology-intensive care medicine department, Casablanca, Morocco

Background: Nocardiosis is a rare opportunistic infection caused by the gram-positive bacterium Nocardia, primarily affecting immunocompromised individuals. Its clinical presentation is highly variable, ranging from pulmonary to disseminated infections, including cerebral abscesses. Diagnosing nocardiosis is challenging due to its rarity, non-specific symptoms, and difficulty in pathogen isolation. This case highlights the diagnostic and therapeutic complexities of nocardiosis in a patient with systemic lupus erythematosus (SLE) and cerebral abscesses.

Case Report: A 29-year-old woman with a 9-year history of SLE on corticosteroid and hydroxychloroquine therapy presented with left-sided hemiparesis and fluctuating cutaneous lesions unresponsive to empirical antibiotics. She developed severe headaches and dysarthria. A brain CT scan revealed multiple abscesses with hydrocephalus (Figure 1). Initial treatment included external ventricular drainage and broad-spectrum antibiotics. Despite these measures, her condition deteriorated, necessitating surgical drainage. Prolonged cultures identified Nocardia farcinica. Treatment was adjusted to trimethoprim-sulfamethoxazole and amikacin. Subsequently, the patient developed a subcutaneous abdominal abscess requiring surgery. Despite aggressive medical and surgical interventions, she succumbed to septic shock and multiorgan failure on the 20th day of hospitalization.

Discussion: Nocardiosis is rare but increasingly recognized in immunocompromised patients, with SLE being a significant risk factor (1). CNS involvement occurs in 20-44% of cases, with mortality rates exceeding 50% in disseminated forms (2). Diagnosis often requires invasive sampling and prolonged culture incubation, with molecular tools like metagenomic sequencing emerging as faster alternatives (3). Therapy typically involves trimethoprimsulfamethoxazole, often combined with other agents for severe cases. Despite timely treatment, mortality remains high, emphasizing the need for early suspicion and intervention.

Mycotic aneurysm of the abdominal aorta secondary to Salmonella infection: a case report

S. Rubín Alduán¹, A. Azzam López¹, M. Encuentra Cruz¹, S. Claver Garcinuño¹, M. Carballo Delgado¹, E.M. Salvador Casabón1 ¹Ramón y Cajal University Hospital, IRYCIS, Anesthesiology, Madrid, Spain

Background: Infectious aneurysms are rare but are associated with high morbidity and mortality due to nonspecific clinical manifestations, rapid growth and the urgent need for treatment caused by the potential rupture of the arterial wall.

Case Report: A 55-year-old man presented two months of lumbar pain and a 72-hour fever. Laboratory tests revealed leukocytosis and elevation of CRP and procalcitonin. CT imaging showed a saccular aneurysm of the infrarenal abdominal aorta (45x44x45mm) and a lesion in the left kidney.

Empirical antibiotic therapy with meropenem and daptomycin was initiated. Surgery included aorto-aortic bypass, left nephrectomy and cholecystectomy, revealing perforated purulent aortitis contained and aorto-enteric fistula. Blood cultures identified Salmonella D and ascitic fluid cultures showed Enterococcus durans. Candida albicans and Salmonella D. Anidulafungin was added to the treatment.

In the first few days postoperatively, the patient developed septic shock (SOFA score 14). A laparotomy revealed diffuse peritonitis, retroperitoneal hematoma, duodenal perforation and necrotizing pancreatitis. An aortic endoprothesis and a pericardial patch for the duodenal perforation were placed. A postoperative biliary fistula required external biliary drainage.

Discussion: The infrarenal segment of the aorta is the most commonly affected site1. The infectious aneurysms are categorized into four types: mycotic, microbial arteritis, infection in pre-existing aneurysms and infected post-traumatic false aneurysms. For diagnosis CT is the imaging test of choice complemented by microbiological testing². Treatment combines surgical repair and antimicrobial therapy.

- 1. Aday, A et al. Vascular Medicine: A companion to Braunwald's Heart Disease. 2020.
- 2. Pérez Burkhardt, J. Aneurismas micóticos: particularidades diagnósticas y de tratamiento. Angiología. 2015;68(1):46-54.

Learning points:

- Diagnosis requires clinical suspicion, imaging and microbiological isolation.
- Management involves urgent surgery and prolonged antimicrobial therapy.
- In the presented case, complications like peritonitis, septic shock and duodenal fistula prolonged recovery.

34AP04-1

Proteomic analysis approaching sepsis-induced diaphragm atrophy

W. Lai^{1,2}, C.-Y. Chang³, C.-J. Huang^{2,4}

¹Taipei Medical University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan, 2Wan Fang Hospital, Taipei Medical University, Anesthesiology, Taipei, Taiwan, 3Wan Fang Hospital, Taipei Medical University, Medical Research, Taipei, Taiwan, 4 Taipei Medical University, Graduate Institute of Clinical Medicine, Taipei, Taiwan

Background: Sepsis-induced diaphragm atrophy increases ventilator dependency and mortality. While mitochondrial dysfunction is a key factor, other mechanisms remain unclear. This study employed proteomic analysis to investigate these processes.

Materials and Methods: Polymicrobial sepsis was induced in male C57BL/6 mice using cecal ligation and puncture (CLP). Diaphragm samples were collected 7 days post-CLP for histological and proteomic analyses.

Results and Discussion: Histological analysis confirmed diaphragm atrophy with reduced muscle bundle cross-sectional area (p = 0.010) and increased bundle density (p = 0.006) (Fig. 1).

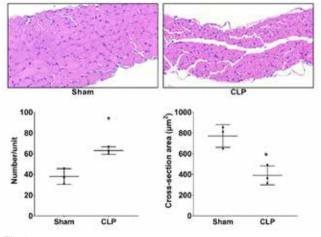

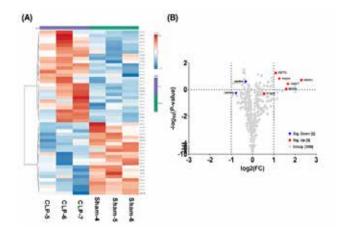

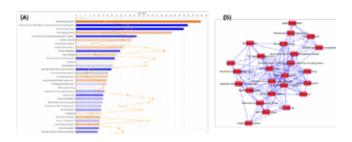

Fig. 1

Proteomic analysis revealed 379 differentially expressed proteins between CLP and Sham groups (Fig. 2A). A volcano plot highlighted key proteins with significant fold changes (Fig. 2B).

Pathway analysis indicated upregulation of mitochondrial dysfunction (oxidative phosphorylation, respiratory electron transport), metabolic pathways (fatty acid oxidation, glycolysis), and neutrophil signaling (extracellular trap formation, degranulation, granzyme A activity) in CLP mice (Fig. 3A). These interconnected pathways suggest mitochondrial, metabolic, and immune responses as drivers of diaphragm atrophy (Fig. 3B).

Conclusion: Pathways related to mitochondrial dysfunction, metabolic processes, and neutrophil signaling contribute to sepsisinduced diaphragm atrophy, providing potential targets for therapeutic intervention.

Acknowledgements: This study is party supported by Taipei Municipal Wanfang Hospital grant (grant no. 113-wf-eva-25).

34AP04-3 Foodborne botulism intoxication treatment-case report

K. Stefanov^{1,2}, D. Ivanova¹, Y. Nikolova- Petkova¹, M. Atanassova^{1,3}, A. Stanoevski^{1,2} ¹University Hospital "Sv. Anna", Anaesthesiology and Intensive Care, Sofia, Bulgaria, ²Medical University, Anaesthesiology and Intensive Care, Sofia, Bulgaria, 3South-West University "Neofit Rilski", Faculty of Public Health, Healthcare and Sports, Blagoevgrad, Bulgaria

Background: Botulism is rare and potentially life-threatening neuroparalytic syndrome caused by a toxin, produced by the bacterium Clostridium botulinum. This syndrome courses initially with symmetrical cranial nerve palsy and may progress to descending flaccid paralysis and ultimately to respiratory arrest.

Case report: A 42-years old female is admitted in the emergency department with history of headache, nausea, vomiting, double vision, dysphagia, dysarthria and gait abnormalities. Shortly after admission her mother and sister were reported with similar symptoms. Upon arrival the patient is conscious. During physical examination dysphonia, dysarthria, ophthalmoparesis were observed. No data for meningo-radicular irritation. Based on the history of homemade canned egg-plant consumption food botulism intoxication was hypothesized.

The patients rapidly deteriorated with hypotension, worsening of the flaccid palsy, dysarthria and dysphagia and respiratory failure developed, which lead to ICU admission, early tracheostomy and mechanical ventilation. The neurotoxin was not isolated from blood or faeces. The can was tested and Clostridium botulinum was isolated, which confirmed the diagnosis.

The treatment included heptavalent antitoxin immunoglobulin, antibiotics, symptomatic medications, volume management and physical rehabilitation. The three patients evolved favorably with total functional recovery.

Discussion: Botulism is a rare yet life-threatening syndrome which should be suspected on a patient who develops acute and afebrile symmetric cranial nerve palsy, typically bulbar palsies, followed by symmetrical flaccid palsy of volunteer muscles and engaging the respiratory muscles resulting I respiratory failure. The botulism diagnosis is based on clinical presentation and epidemiological context.

Reference:

Foodborne botulism-two case reports https://jmedicalcasereports.biomedcentral.com/articles/10.1186/s13256-017-1523-9 https://pmc.ncbi.nlm.nih.gov/articles/PMC7846414/

Learning points: Botulism is rare, yet deadly syndrome affecting all ages which can be successfully treated by immediate antitoxin administration when diagnosed promptly. The disease should be taken under consideration in the differential diagnosis when flaccid palsy with cranial nerve engagement is observed along with basilar occlusion syndrome, excluded by the clinical evolution and imaging techniques and other neurological condition such as Guillain-Barré syndrome, Myasthenia gravis.

34AP04-4

Effects of hemoadsorption therapy on short-term mortality and vasopressor dependency in severe septic shock with acute kidney injury: a retrospective cohort analysis

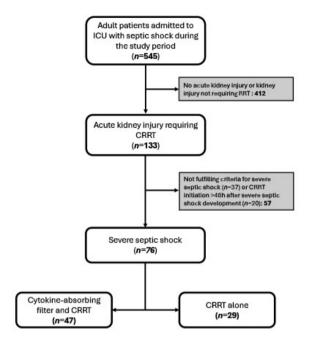

D. Epstein^{1,2}, K. Badarni¹, Y. Bar-Lavie^{1,2} ¹Rambam Health Care Center, Critical Care Division, Haifa, Israel, ²Technion, Ruth and Bruce Rappaport Faculty of Medicine, Haifa, Israel

Background and Goal of Study: Sepsis, a life-threatening condition resulting from a dysregulated immune response to infection, continues to pose significant challenges in intensive care units (ICUs). This study investigates whether the combination of hemoadsorption therapy and continuous renal replacement therapy (CRRT) can reduce ICU and short-term mortality in patients suffering from severe septic shock and acute kidney injury (AKI) requiring CRRT.

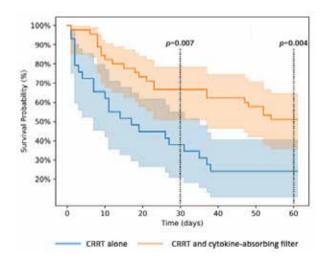

Materials and Methods: A retrospective cohort study was conducted at Rambam Health Care Campus in Haifa, Israel, between January 2018 and February 2024. The study included ICU patients with severe septic shock and AKI requiring CRRT. Patients were categorized into two groups: those treated with hemoadsorption therapy alongside CRRT and those treated with CRRT

alone. The primary and secondary endpoints assessed were ICU mortality, 30- and 60-day mortality, vasopressor dependency index (VDI), and lactate levels.

Results: Out of 545 patients with septic shock, 133 developed AKI requiring CRRT, and 76 met the inclusion criteria.

The hemoadsorption group (n=47) showed significant reductions in blood lactate levels and VDI after 24 hours compared to the CRRT alone group (n=29). ICU mortality was significantly lower in the hemoadsorption group (34.0% vs. 65.5%, p=0.008), as was 30 and 60-day mortality (34.0% vs. 62.1%, p=0.02 and 48.9% vs. 75.9%, p=0.002). Multivariate analysis confirmed hemoadsorption therapy as independently associated with lower ICU and 30-day but not 60-day mortality.

Conclusion: The combination of hemoadsorption therapy with CRRT in patients with severe septic shock and AKI requiring CRRT is associated with enhanced lactate clearance, decreased vasopressor requirements, and reduced ICU and 30-day mortality rates. High-quality randomized controlled trials are warranted to validate these results.

34AP04-5

Isolated hemadsorption with Oxiris as a new therapeutic option in management of two patients with refractory endotoxic shock

<u>D. Smirnova</u>^{1,2}, M. Klibus^{1,2}, R. Serzans², A. Škesters³, V. Liguts², O. Sabelnikovs^{1,2}

¹Riga Stradiņš University, Department of Clinical Skills and Medical Technology, Riga, Latvia, ²Pauls Stradiņš Clinical University Hospital, Department of Anesthesiology and Reanimatology, Riga, Latvia, ³Riga Stadiņš University, Institute of Occupational Safety and Environmental Health, Scientific Laboratory of Biochemistry, Riga, Latvia

Background: Oxiris as a hemofilter is traditionally used for adsorptive hemofiltration. However, its high immunoadsorption capacity allows to use it as an isolated hemadsorption device for endotoxin and cytokines clearance via a slow continuous ultrafiltration mode without fluid removal and under heparin anticoagulation. To date, no studies have reported the use of Oxiris in this modality for patients with septic shock.

Case Report: Two patients with Gram-negative septic shock were admitted to the Intensive Care Unit (ICU) following infection source control. Both had elevated inflammatory markers (interleukin-6 (IL-6) 399 and 162 pg/mL; procalcitonin (PCT) 11 and 22ng/mL; endotoxin 0.5 and 1.55 EU/mL), required high norepinephrine (NE) support (0.35 and 0.5µg/kg/min) and were refractory (defined as Dynamic Score System1 > 6 points in the first 12 hours) to standard treatment. As renal replacement therapy was not required, a 12-hour session of isolated hemadsorption with Oxiris was initiated to reduce the inflammatory response. Clinical improvements were observed after treatment: reduction in inflammatory markers (by 42% and 79%, 41% and 29%, 62% and 14% for IL-6, PCT and endotoxin, respectively) and NE support (by 63% and 22%). Neither patient had complications related to hemadsorption or required additional renal replacement therapy during treatment. They were discharged from the ICU on days 23 and 4 without the need for organ support therapy.

Discussion: Isolated hemadsorption with Oxiris may offer a therapeutic option for patients with refractory endotoxic shock by stabilizing the immune response and hemodynamics, thereby protecting against further organ damage. Tailoring the modality based on patient characteristics, such as the severity of the clinical course and renal function, could enhance the efficacy of immunoadsorption therapies and support their integration into clinical practice.

Reference:

Kogelmann, K et all. Evaluation of a New Dynamic Scoring System Intended to Support Prescription of Adjuvant CytoSorb Hemadsorption Therapy in Patients with Septic Shock. J. Clin. Med. 2021. doi.org/10.3390/jcm10132939

Learning Points:

- 1. Oxiris is traditionally used for renal function replacement and has potential for isolated hemadsorption due to its high immunoadsorption capacity.
- 2. Early and tailored use of isolated hemadsorption with Oxiris can stabilize hemodynamics and modulate immune response and prevent progression of multiple organ dysfunction.

34AP04-6

Predictive value of the heparin-binding protein (HBP) for mortality in patients with confirmed or suspected bacterial infection in ICU

A. Plecas-Djuric^{1,2}, R. Popovic^{3,2}, B. Radanovic², T. Tubic^{3,2}, I. Radosavkic⁴, V. Cabarkapa^{5,4}

¹Faculty of Medicine, University of Novi Sad, Department of Nursing, Novi Sad, Serbia, ²University Clinical Centre of Vojvodina, Clinic for Anesthesia, Intensive Care and Pain Therapy, Novi Sad, Serbia, ³Faculty of Medicine, University of Novi Sad, Department of Anesthesiology and Perioperative Medicine, Novi Sad, Serbia, ⁴University Clinical Center of Vojvodina, Center of Laboratory Medicine, Novi Sad, Serbia, ⁵Faculty of Medicine, University of Novi Sad, Department of Pathophysiology and Laboratory Medicine, Novi Sad, Serbia

Background and Goal of Study: This study evaluated the relationship between Heparin binding protein (HBP) values and 28-day mortality in septic patients in the intensive care unit (ICU). It also compared HBP with other sepsis markers, white blood cell count (WBC), procalcitonin (PCT), and C-reactive protein (CRP), as well as the correlation between organ dysfunction (using the SOFA score) and mortality.

Materials and Methods: The prospective observational study included 41 adult surgical patients in the ICU who met SEPSIS-3 criteria. Inflammatory markers were measured at admission, 24, and 72 hours, SOFA and APACHE II scores were calculated accordingly.

Results and Discussion: HBP levels were significantly higher in non-survivors at all time points, particularly at 72h, where the levels were 86.17 \pm 11.73 compared to 42.85 \pm 10.49 in the survivors (p = 0.04). Conversely, HBP levels in the survivor group significantly decreased from admission to 72h, with initial values recorded at 73.6 ± 67.72 upon admission and dropping to 42.9 ± 56.24 by 72h (p = 0.03). These findings underscore the potential role of HBP as a biomarker for patient recovery. ROC analysis further substantiated the predictive capability of HBP for mortality. HBP values obtained at 48 hours could significantly forecast mortality, at a cutoff value of 63.48, HBP had an AUC of 0.739 (p = 0.02), a sensitivity of 69.2%, a specificity of 73.9%. SOFA score at 72 hours emerged as a significant predictor of mortality, with a cutoff value of 8.5, and an AUC of 0.77 (p = 0.01), yielding a sensitivity of 91.3% and a specificity of 69.2%. PCT levels assessed at 72h reinforced the significance of mortality prediction, at a cutoff of 1.85, PCT had an AUC of 0.781 (p = 0.01), a sensitivity of 78.3%, and a specificity of 76.9%. HBP at 48h also significantly correlated with PCT (r = 0.346, p = 0.01). In univariate analysis predicting ICU days, only HBP values at 48h were significant (β = 0.659, p = 0.01).

Conclusion(s): Assessing the dynamics of HBP and PCT within 72 hours of admission presents an insightful approach for predicting clinical outcomes in critically ill sepsis patients in the ICU. Adding HBP levels assessed at 48h to the SOFA score can serve as a valuable component to the prediction model and potentially enhance our understanding of patient prognosis. Our studies suggest that HBP could be an important early biomarker of organ dysfunction in the ICU.

Background and Goal of Study: Early detection of sepsis is essential for its successful management. Although genome-wide association studies (GWAS) have shown potential in identifying sepsis-related genetic variants, they often involve heterogeneous patient groups and use single-locus analysis methods. We aimed to identify new sepsis susceptibility loci using an explainable artificial intelligence (XAI) approach applied to GWAS data.

Materials and Methods: GWAS was performed in 750 post-operative patients with sepsis and 3,500 population controls. We applied a novel XAI-based methodology to single nucleotide polymorphisms (SNPs) to predict sepsis and identify new genetic variants associated with sepsis susceptibility. We assessed functional and enrichment effects using empirical data from integrated software tools and datasets, with the top-ranked variants and associated genes.

Results and Discussion: Our XAI-GWAS approach showed an excellent performance in predicting sepsis, with an area under the receiver operating characteristics curve of 0.985, using 3,761 SNPs with P-values $\leq 5 \times 10^{-3}$. Our approach pinpointed SNPs

(such as rs17653532, 3:15115369, and rs74707084) with higher contribution to sepsis prediction and facilitating the discovery of sepsis risk loci with important functional implications related to gene expression regulation, DNA replication, cyclic nucleotide signalling, cell proliferation, and cardiac dysfunction. Key genes, such as ARHGEF10, PRIM2, SYNPR, RBSN, could provide potential targets for personalized sepsis interventions in surgical patients.

The figure shows the 20 SNPs with greater impact in sepsis predictions, SNPs that had not been reported previously. AX-15408387 (gene ARHGEF10) and AX-169104641 (gene PRIM2).

Conclusions: The combination of GWAS and XAI identified loci associated with sepsis susceptibility and established a powerful predictive approach. We identified potential biomarkers that might help in risk stratification, early detection of sepsis in postoperative patients, and targeted interventions.

Septic shock in obstetric ICU: clinical profile and prognostic factors from a decade of experience

S. Bellaftouh¹, A. Raja², Y. Hafiani³, S. El Youssoufi², S. Salmi4

¹Ibn Rochd University Hospital Center, Anesthesiologyintensive care medicine department. Casablanca. Morocco, 2Ibn Rochd University Hospital Center. surgical intensive care unit, Anesthesiology-intensive care medicine department, Casablanca, Morocco, 3lbn Rochd university Hospital center, Anesthesia and Critical Care Unit for Obstetric and Gynecological Emergencies Anesthesiology-intensive care medicine department, Casablanca, Morocco, 4Ibn Rochd University Hospital Center, Anesthesia and Critical Care Unit for Obstetric and Gynecological Emergencies Anesthesiologyintensive care medicine department, Casablanca, Morocco

Background and Goal of Study: Septic shock in obstetric ICU settings is a rare but life-threatening condition, posing a high risk of maternal and fetal mortality. It requires early recognition, multidisciplinary management, and aggressive therapeutic interventions to prevent organ failure. This study aimed to describe the clinical characteristics and identify prognostic factors associated with mortality among obstetric patients admitted for septic shock to better understand morbidity and mortality determinants.

Materials and Methods: This retrospective descriptive study was conducted over a 10-year period (2013–2022) in the obstetric ICU at CHU Ibn Rochd, Casablanca. It included 108 patients admitted for septic shock during pregnancy or the postpartum period. Data collected encompassed demographic information, medical and surgical history, clinical presentation at admission, severity scores (Glasgow Coma Scale and SOFA), organ dysfunctions, therapeutic modalities, and obstetric outcomes. Statistical analyses were performed to identify factors associated with severity and complications.

Results and Discussion: The mean age of patients was 35.1 years. Common clinical signs included fever (98.15%), tachycardia (>90 bpm in 81.48%), and hypoxemia (18.52%). Obstetric factors, such as a high number of interventions and elevated parity, were significantly associated with increased mortality (P=0.003 and P=0.025, respectively). Poor prognostic biological markers included leukopenia (P=0.030), elevated urea (P=0.004) and creatinine (P=0.002), and hyponatremia (P=0.019). Clinically, a mean arterial pressure <65 mmHg (P=0.005) and tachypnea (P<0.001) were strongly correlated with higher mortality. Therapeutic indicators of severity included the use of mechanical ventilation (P=0.000) and inotropes (P=0.012), while metronidazole therapy significantly reduced mortality (P=0.001).

Conclusion(s): Septic shock in obstetric patients remains a severe complication requiring prompt, multidisciplinary intervention. Identified risk factors, such as specific clinical and biological markers, should guide therapeutic strategies, including intravascular volume management, optimal oxygenation, and rapid administration of appropriate antibiotics to improve maternal outcomes.

Urgent seven-level arthrodesis for mixed mycobacterium osteoarthritis: anesthetic management in a high-risk patient

M. Sierra Martín¹, E. Lopez¹, M. Aguilar¹, E. Vila¹ ¹Hospital del Mar, Anestesiología, Reanimación y Terapéutica del Dolor, Barcelona, Spain

Tuberculosis remains the leading infectious cause of death globally¹, with vertebrae being the most commonly bone affected². However, less than half of cases result in neurological deficits. We present a unusual case of a 29-year-old Bangladeshi woman presented after a one-year delay misdiagnosed with mechanical pain. Progressive neurological symptoms led to a diagnosis of thoracic osteoarthritis secondary to tuberculosis; three-level thoracic osteoarthritis, extensive epidural abscess from T4 to C5, and severe spinal stenosis led to profound motor deficits (3/5 on the Daniels Scale) and urinary incontinence. The abscess extended into the cervical region, causing dysphagia. Despite severe rest pain (VAS 7-8), no prior opioid analgesia had been administered. Emergency surgical intervention involved a seven-level arthrodesis with abscess debridement, utilizing intraoperative neurophysiological monitoring (INM).

Preoperative optimization included hemoglobin stabilization and airway management avoiding neural cord injury.

A multimodal intraoperative anesthetic strategy was employed, including 200 mcg of intradural morphine despite the presence of epidural abscess. Advantages and disadvantages were discussed.

Boluses of lidocaine, magnesium sulfate, and dexmedetomidine were also administered, ensuring no interference with INM. Postoperative pain was managed with patient-controlled analgesia Postoperatively, the patient was transferred to the Intensive Care Unit (ICU) in a hemodynamically unstable state, where stabilization and extubation were achieved within an hour. Pathological analysis confirmed a dual infection with Tuberculosis and Mycobacterium avium complex. During her hospital stay, total intravenous morphine use was 29 mg. Pain scores dropped to 0 at rest and 8 during movement. The patient was discharged home within one week without complications. Significant motor function improvement (4+/5) has been observed.

This case underscores the vital role of anesthesiology in optimizing outcomes for high-risk, complex spine surgeries in infectious settings. It demonstrates how meticulous planning, innovative anesthetic techniques, and interdisciplinary collaboration can ensure patient safety, effective pain management, and rapid recovery.

34AP05-3 Death during septic shock

S. Chaabi¹, A. Erragh¹, S. Bellaftouh¹, <u>S. Haddady</u>¹, A. Nsiri¹, R. Alharrar¹ ¹CHU IBN Rochd, Surgical Emergency Resuscitation, Casablanca, Morocco

Background and Goal of Study: Septic shock is a major public health issue associated with a significant mortality rate in critically ill patients. Despite the recent advances in the management of this situation, the latter remains very challenging to handle.

Lot of studies were conducted in order to estimate the mortality associated to septic shock; the majority objectifies a variable rate which led us to consider the presence of several factors enabling to improve the prognosis.

The main objective of this study was to evaluate the mortality related to septic shock in our population and identify the risk factors that may influence this parameter.

Materials and Methods: This is a retrospective observational study, including all patients admitted initially for, or developed, a septic shock during their stay in the surgical intensive care unit of a tertiary care hospital centre over a period of 4 years from January 2015 to December 2018.

Mortality rate was evaluated according to demographic data, biological disorders, antibiotic therapy, and vasopressor prescription modalities.

Results and Discussion: 117 cases of septic shock were identified out of a total hospitalization of 1349 patients with an incidence of 8.6%. The average age of the patients was 54.48 years. The most common infectious site was the abdominal one (85%) with peritonitis accounting for 63% of these cases and a significant predominance of gram-negative bacilli.

The mortality rate in this population was estimated at 67.2% with male predominance.

A disturbed renal assessment and a low prothrombin Time were associated with a significantly higher mortality rate.

Early and adequate duration of antibiotherapy helped reduce the mortality.

The initial SOFA score, the number of organ failures and the doses of noradrenaline prescribed also influenced mortality rate in this population.

Conclusion(s): During this study, we were able to detect several factors that were associated with a significantly higher mortality during septic shock.

A clear understanding of these factors will help improve the management of this critical condition in order to improve its prognosis.

34AP05-5

Is postoperative oxygen saturation and the implementation of rescue ventilatory support associated with the incidence of surgical site infections? Post-hoc analysis of 2 randomized trials

M. Linares Torras¹, J. Borrell-Vega¹, R. Marrero¹, J. Vallverdú¹, R. Pujol¹, E. Rivas¹ ¹Hospital Clínic of Barcelona, Department of Anaesthesia and Intensive Care, Barcelona, Spain

Background and Goal of Study: Surgical site infections (SSI) after major surgery are still common. Oxidative killing by neutrophils is the main defense against bacterial infections and it highly influenced by tissue oxygenation. We aimed to assess whether postoperative oxygen saturation and the implementation of ventilatory support are associated with the incidence of surgical site infections within 30 postoperative days.

Materials and Methods: This is a post-hoc analysis of two randomized clinical trials (IPROVE, IPROVE-O2). The primary outcome was a composite of surgical site infections (superficial, deep, or organ space infections), septic shock, and anastomotic leakage occurring between 7 and 30 postoperative days. The exposure was the airTest result, defined as positive if pulse oximetry £96%, or negative if pulse oximetry >96% while breathing ambient air in postaneshesia care unit (PACU); and the per protocol implementation of rescue ventilatory support lasting 6 hours in patients with positive airtest (CPAP/HFNC).

Results and Discussion: Our sample included 1701 patients. The overall incidence of the composite of SSI was 17%. Patients with negative airtest were younger and with lower BMI (Table 1). Patients with unrescued positive airtest had higher incidence of SSI than patients with negative airtest (24% vs 18%; p<0.05). Notably, patients with rescued positive airtest had lower incidence than patients with negative airtest (16% vs 18%; p<0.05). Finally, lower oxygen saturation during postoperative day 1 was associated with SSI within 90 postoperative days (p<0.05).

	Negative AirTest (n=1164)	Positive AirTest Rescued (n=131)	Positive AirTest Not rescued (n=95)	P Value
Age, y.o	64 ± 13	68 ± 12	68 ± 12	P<0.05
Sex male/female n, (%)	723(62)/442(38)	86 (66)/ 45 (34)	62 (65)/33 (35)	NS
BMI, Kg/m ²	26 ± 4	27 ± 4	28 ± 5	P<0.05
Active smoker n, (%)	139 (12)	37 (28)	16 (17)	NS
SpO2 airtest, %	98.2 ± 1.1	92.8 ± 2.6	94.5 ± 1.6	P<0.05
SpO ₂ POD1, %	97.0 ± 2.1	95.6 ± 3.3	95.5 ± 2.6	P<0.05
Composite of SSI, n, (%)	211 (18)	21 (16)	23 (24)	P<0.05

Conclusion(s): Low oxygen saturation while breathing ambient air at PACU may allow us to detect patients at risk of SSI. Providing respiratory support might decrease this risk.

34AP05-8

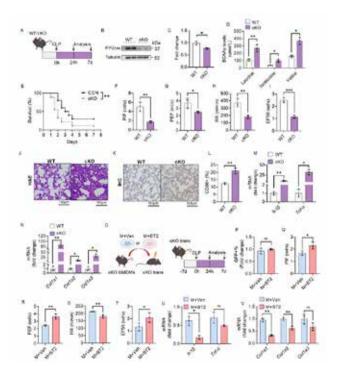

Macrophage with impaired BCAAs catabolism exacerbates alveolar epithelial injury post-sepsis by activating mitochondria-localized AGEs-RAGE mediating mtDNA release

Y. Hong^{1,2}, J. Liu^{1,2}, K. Luo^{1,2}, Y. Xu^{1,2}, C. Jiang^{1,2}
¹West China Hospital, Sichuan University, Department of Anesthesiology, Chengdu, China, ²West China Hospital, Sichuan University, The Research Units of West China (2018RU012)-Chinese Academy of Medical Sciences, Chengdu, China

Background and Goal of Study: Lung is the foremost vulnerable organ during sepsis. Accumulating evidence shows impaired BCAAs catabolism couples with macrophage activation. AGEs-RAGE interactions trigger oxidative stress and disproportionate inflammation. In this study, we explored the molecular mechanisms underlying the exacerbated sepsis-induced lung injury aroused by impaired macrophages BCAAs catabolism, which leads to increased mitochondria-localized AGEs-RAGE interactions facilitating mtDNA release and exacerbates alveolar epithelial barrier damage.

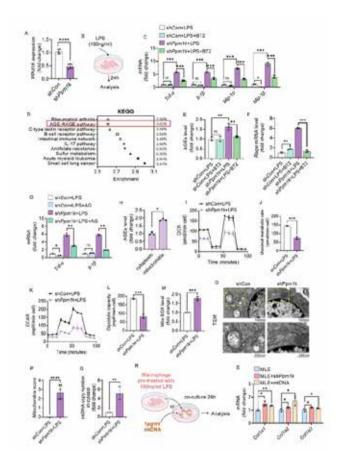

Materials and Methods: Ppm1k^{Lyz2}-/- (cKO) mouse was used to construct sepsis model. Lung injury was inspected by H&E dyeing, CD86+ cells by immunohistochemistry, and inflammatory cytokines q-PCR. Mitochondrial is tested by TEM and Seahourse energy analyzer.

Results and Discussion: Deteriorated ventilation, increased lung lesions and CD86 $^{+}$ macrophage fraction were detected in cKO lungs together with high inflammatory state proved by high IL-1 \square and TNF- α levels.

AGEs-RAGE interaction was upregulated by defective BCAA catabolism and AGEs in the mitochondria played a predominant role. TEM showed obvious mitochondrial damage in shPpm1k (KO) macrophages. The mitochondrial respiration and glycolysis assessed by OCR and ECAR was decreased in KO macrophages

accompanied by mtROS production and mtDNA release. Co-culturing alveolar epithelial cells with KO macrophages or mtDNA improves the level of Col1a1, Col1a2 and Col1a3.

Therefore, our study reveals a critical role of the AGES-RAGE interactions in sepsis-induced lung injury under impaired BCAAs catabolism and identifies mtDNA as a potential therapeutic target

Conclusion(s): In summary, impaired macrophage BCAAs catabolism predisposes the mouse lung to alveolar epithelial damage due to mitochondria-localized AGES-RAGE interactions triggering mtDNA release.

34AP05-11 Life-threatening cold agglutinin syndrome: case report

A. Barabasz¹, S. Dudek¹, M. Zawadka¹

'Medical Univeristy of Warsaw, 2nd Department of Anaesthesiology and Intensive Care, Warsaw, Poland

Background: Cold agglutinin syndrome (CAS) is rare subset of autoimmune hemolytic anemia estimated incidence of 1:100 000 adults (1) occasionally complicating specific infections (e.g. Mycoplasma pneumoniae or Epstein–Barr virus) or malignancies. Cases of CAS with life-threatening anemia are reported in the literature by a limited number of cases.

Case Report: 20-year-old male was admitted to the intensive care unit (ICU) with severe hemolytic anemia and cold agglutinins identified at a referring hospital a few days before. The direct antiglobulin test was positive with C3d complement deposition while the eluate was non-reactive. Further testing revealed presence of cold-reactive IgM autoantibodies. The patient was diagnosed with a life-threatening hemolytic crisis secondary to autoimmune hemolytic anemia associated with cold agglutinins likely triggered by an infection. He had history of an upper respiratory tract infection accompanied by jaundice and hepatosplenomegaly 10 days prior to admission.

Tests performed on ICU admission revealed signs of severe hemolysis: hemoglobin 4,0 g/dl, total bilirubin 26.6 mg/dL with direct 20.3 mg/dl, LDH 3137U/l. Initial treatment in the ICU comprised corticosteroid therapy, two of therapeutic plasma exchange (TPE), intravenous immunoglobulin (IVIG) administration, transfusion of blood products and continuous warming.

After 3 days in the ICU, the patient's condition gradually improved and he was transferred to the hematology department for further management. Bone marrow biopsy excluded malignancy. Serological testing confirmed recent EBV infection and concurrent Mycoplasma pneumoniae infection.

Due to persistent anemia, the patient received rituximab on day 12 of hospitalization. He was discharged home and subsequently readmitted for additional rituximab infusions. The patient remains under close supervision at the Hematology Outpatient Clinic.

Discussion: The case highlights complexity of diagnosing and managing severe hemolysis caused by cold agglutinins. The patient had these two etiological factors of CAS therefore their synergistic effect cannot be excluded

Learning points: The case underscores the importance of recognizing infection-associated autoimmune hemolytic anemia with cold agglutinins. Targeted therapies, including TPE, IVIG, and rituximab are crucial in preventing further hemolysis

Hepatobiliary and Kidney

35AP01-1

Prediction of acute kidney injury in the immediate postoperative period following liver resection

J. Abou Jamous¹. S. Ferreira Guerra^{2,3}. Z. Haida⁴. M. Girard^{1,5,6,7}, S. Turcotte^{8,9}, F.M. Carrier^{1,2,5,6} ¹University of Montreal, Department of Anesthesiology and Pain Medicine, Montreal, Canada, 2Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CHUM), Innovation and Health Evaluation Hub, Montreal, Canada, 3McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, ⁴University Laval, Medicine, Quebec, Canada, ⁵CHUM, Department of Anesthesiology, Montreal, Canada, 6CHUM, Department of Medicine, Critical Care Division, Montreal, Canada, ⁷Centre de Recherche du CHUM, Imaging and Engineering, Montreal, Canada, 8University of Montreal, Department of Surgery, General Surgery Division, Montreal, Canada, 9CHUM, Hepatobiliary, Pancreatic and Hepatic Transplantation Service, Department of Surgery, Montreal, Canada

Background and Goal of Study: Restricting fluid administration to target a low central venous pressure or using intraoperative phlebotomies have become common practices to reduce intraoperative blood loss and perioperative complications in liver resec-

Following these surgeries, acute kidney injury (AKI) is a frequent, morbid, yet potentially reversible complication. Identifying early postoperative reversible AKI may be important to ensure sustained clinical benefits from commonly used intraoperative fluid management strategies.

No predictive model of postoperative AKI following liver resection has assessed the role of oliguria in the Post-Anesthesia Care Unit (PACU).

Our objectives were:

- 1. To develop and internally validate a predictive model of postoperative AKI using variables available in the PACU,
- 2. To assess the additive predictive value of PACU urine output, and;
- 3. To estimate the association between PACU oliguria and AKI.

Materials and Methods: We conducted a retrospective study of patients who underwent elective liver resection at the Centre hospitalier de l'Université de Montréal between may 2010 and novembre 2022. Our outcome was 7-day postoperative AKI. Oliguria was defined as a PACU urine output under 0.5 mL/kg/h.

Two sets of candidate predictors (17 and 11 variables respectively) were used to develop a predictive model for postoperative AKI. We fitted multivariable logistic regression models with a least absolute shrinkage and selection operator.

We reported oliguria risk ratios (RR) with 95% confidence interval (CI) and optimism-corrected model performance properties.

Results and Discussion: We included 1520 patients. Both the incidence of 7-day postoperative AKI and the prevalence of oliguria in the PACU were 11%. Being oliguric in the PACU was associated with AKI (RR = 1.74 (95% CI [1.20, 2.50]).

Both developed models had good discrimination (AUROC curve of 0.775 and 0.766 respectively) and excellent calibration. PACU urine output increased models' discrimination.

Conclusion(s): We developed good models to predict 7-day postoperative AKI following liver resection. PACU oliguria was associated with 7-day postoperative AKI and its use improved discriminative properties of our models.

35AP01-2

Effect of acute hypervolemic hemodilution and fluid restriction on bleeding in hepatectomy: a retrospective cohort study

X. Pan¹, Y. Fu¹, P. Liang²

¹Sichuan University, Department of Anesthesiology, West China Hospital, Sichuan University, Chengdu, China, ²Sichuan University, Department of Anesthesiology, West China Hospital, Chengdu, China

Background and Goal of Study: Reducing bleeding in hepatectomy improves the prognosis of the patients. Fluid restriction based on the low central venous pressure (LCVP) is commonly recommended in hepatectomy to decrease intraoperative bleeding, but its safety and efficacy are still debated. Although acute hypervolemic hemodilution (AHH) is used to protect blood during a variety of procedures, there is no research on its application in liver surgery. The purpose of this study is to examine how AHH and fluid restriction affect blood loss during hepatectomy.

Materials and Methods: In this historical cohort study, patients who had hepatectomy procedures at Sichuan University's West China Hospital between July 2017 and November 2022 were categorized into either fluid restriction group or AHH group to see whether the blood loss in these two groups varied. Propensity score matching (PSM) was performed to adjust the group's imbalance.

Results and Discussion: Prior to PSM, 358 patients were enrolled based on eligible criteria, while 162 patients were enrolled following 1:1 PSM. Blood loss did not differ statistically significantly between the two groups following PSM. Yet there was significant difference between the fluid restriction group and the AHH group in terms of intraoperative urine [141.4 (70.9,142.2) mL/h versus 141.4 (117.1,187.5) mL/h, P=0.03], intraoperative infusion [2800(2100,2993) mL versus 2993(2750,3750) mL, P<0.01], and norepinephrine use rate (33.3% versus 18.5%, P=0.04).

Conclusion(s): The effects of restricted infusion and AHH on blood loss in hepatectomy did not differ significantly, while the use of AHH was linked to a lower rate of norepinephrine use and an increase in intraoperative urine. The notion that fluid infusion should be limited during hepatectomy is disproved by this study, and a novel fluid management approach is offered that could help with circulation control during partial hepatectomy.

The association between perioperative hemodialysis timing and postoperative complications

L. Lim1, C. Kang2, H. Lee1, H.G. Ryu1,2 ¹Seoul National University, Department of Anaesthesiolgy and Pain Medicine, Jongno-gu, Korea, Republic of, 2Seoul National University Hospital, Department of Critical Care Medicine, Jongno-gu, Korea, Republic of

Background and Goal of Study: End-stage renal disease (ESRD) patients undergoing surgery face high perioperative risk. While the timing of preoperative hemodialysis (HD) is considered crucial, the optimal timing remains unclear. Though various expert groups have recommended different guidelines, supporting evidence is limited. This study aimed to analyze the impact of HD timing on postoperative complications and provide supporting evidence for optimal timing recommendations.

Materials and Methods: This study included adult ESRD patients who underwent surgery under anesthesia at Seoul National University Hospital between January 2011 and December 2020. Only patients who had scheduled HD within three days prior to surgery were included, while those undergoing same-day surgery, kidney transplants, or surgeries requiring cardiopulmonary bypass were excluded. With preoperative hemodialysis timing, baseline, surgical and intraoperative variables were collected.

The primary outcome was the association between preoperative HD timing and a composite outcome, which included ICU admission, mechanical ventilation, continuous kidney replacement therapy (CKRT) within seven days, and in-hospital mortality.

Results and Discussion: A total of 1,935 patients were analyzed. Baseline characteristics were similar, but surgical risk and several intraoperative variables varied across the groups. Multivariate analysis showed that HD on the day of surgery was independently associated with an increased risk of the composite outcome, ICU admission, and ICU discharge within 7 days, even after adjusting for confounders (Figure 1).

on the day	13/458 (2.8)	1.78[0.90, 3.57]		0.1

Subgroup analysis of patients who underwent general anesthesia further demonstrated that HD on the day of surgery was linked to a higher risk of postoperative complications compared to HD performed 2-3 days before surgery.

Conclusion(s): HD on the day of surgery before surgery was associated with significantly higher risks of postoperative complications compared to 2-3 days prior. Optimal HD timing should be considered to mitigate hemodynamic instability or electrolyte disturbances during the perioperative period.

35AP01-5

Risk factors associated with postreperfusion syndrome in pediatric liver transplantation after living donation: a retrospective study

D. Costard¹, A. Dieu¹, L. Benoit¹, L. Gérard¹, T. Pirotte¹, A. Stevaert1

¹Cliniques Universitaires Saint-Luc, UCLouvain, Anesthesiology, Brussels, Belgium

Background and Goal of Study: Postreperfusion syndrome (PRS), defined as a drop in mean arterial pressure of ≥ 30% from its baseline value, lasting at least one minute during the five minutes after unclamping, is frequent in adult liver transplantation and is associated with a higher incidence of postoperative complications and an increased risk of early allograft dysfunction (EAD). There is currently no data on PRS in living-donor liver transplantation (LDLT) in child recipients.

This study assesses the incidence and identifies factors associated with PRS in this population.

Materials and Methods: The medical records of 185 consecutive children (≤ 12 years) who underwent LDLT between January 2012 and December 2022 were retrospectively reviewed. Children were divided into PRS and non-PRS groups. Pre-, intra- and postoperative data were summarised as median (IQR) or numbers (%) and compared between the two groups. Predictive factors for PRS were identified using univariate and multivariate logistic regression after variable selection with a backward stepwise method.

	Non-PRS (n = 138)	PRS (n = 47)	Total (n = 185)	p-value
Recipient's age (months)	19.5 (27.2)	11.2 (13.5)	16.6 (21.7)	0,0007
PELD score	11.5 (16.9)	20.2 (17.4)	12.2 (15.5)	0.0024

After multivariate logistic regression, PRS was associated with a longer duration of warm ischemia, a lower serum Ca2+ before reperfusion, and a higher graft-to-recipient weight ratio.

	Non-PRS (n = 138)	PRS (n = 47)	Total (n = 185)	OR for PRS	95%	6CI	p-value
Warm ischemia duration (min)	39 (13)	42 (15)	40 (13)	1.03	1.01	1.06	0.0130
Serum Ca ²⁺ before reperfusion (mg/mL)	4.6 (0.6)	4.4 (0.6)	4.5 (0.6)	0.45	0.24	0.85	0.0106
Graft-to-recipient weight ratio (%)	2.52 (1.66)	3.32 (1.51)	2.75 (1.64)	1.78	1.29	2.46	0.0002

Children with PRS had higher transfusion and vasopressor requirements and longer ICU stays without increased EAD or death at 6 months.

	Non-PRS	PRS	Total	p-value
	(n = 138)	(n = 47)	(n = 185)	
Fresh Frozen Plasma (ml/kg)	0.0 (29.2)	33.6 (63.7)	11.3 (39)	0.0001
Red Blood Cells (ml/kg)	25.8 (29.7)	37.6 (45.7)	27.7 (30.6)	0.0003
Noradrenalin max (µg/kg/min)	0.09 (0.10)	0.12 (0.13)	0.10 (0.12)	0.0009
ICU stay (days)	3 (3)	4 (5.5)	3 (4)	0.0334
Early Allograft Dysfunction	32 (23,2%)	12 (26,1%)	44 (23,9%)	0.6917
6-month survival	135 (97,6%)	44 (93.6%)	179 (96.8%)	0.1888

Results and Discussion: PRS occurred in 47 children (25.4%). Patients affected by this syndrome were younger and had significantly higher PELD scores.

Conclusions: PRS occurs in a quarter of children undergoing LDLT. Further studies are needed to determine whether optimising identified risk factors could reduce the incidence of this syndrome and its associated complications.

35AP01-6

The beneficial effects of hydrogen inhalation on renal glycocalyx degeneration after haemorrhagic shock in a rat model

S. Yasuda¹, A. Kimura¹, K. Suehiro¹, T. Mori¹ Osaka Metropolitan University Graduate School of Medicine, Anesthesiology, Osaka, Japan

Background and Goal of Study: The vascular endothelial glycocalyx (GCX), located on the endothelial surface, maintains vascular homeostasis but is easily damaged after ischaemia-reperfusion injury. Shedding of GCX due to massive haemorrhage can lead to vascular leakage during fluid resuscitation. Additionally, kidney injury caused by massive haemorrhage is also a major concern. Recently, beneficial effects of hydrogen inhalation on haemorrhagic shock have been reported. However, the effectiveness of hydrogen in preventing kidney injury remains unclear. In this study, we evaluated the effect of hydrogen inhalation in mitigating GCX shedding in the kidneys during haemorrhagic shock using a rat model.

Materials and Methods: Rats under general anaesthesia were divided into three groups: the sham, haemorrhagic shock, and 3% hydrogen groups. Except for the sham group, bloodletting was performed to maintain blood pressure below 80 mmHg for 60 minutes. In the 3% hydrogen group, 3% hydrogen inhalation was initiated before bloodletting. GCX in the kidneys was measured before and 30 and 60 minutes after haemorrhagic shock. Additionally, reactive oxygen species were measured by d-ROMs test before and 60 minutes after bleeding. GCX thickness was evaluated using the GlycoCheck system (Microvascular Health Solutions, Orem, Utah, USA) by assessing the perfused boundary region (PBR) of red blood cells. GCX and d-ROMs were evaluated using two-way ANOVA, with p<0.05 considered statistically

Results and Discussion: An increase in PBR indicates glycocalyx degeneration. The hydrogen group significantly suppressed the increase in PBR compared to the shock group at both 30 and 60 minutes (p<0.001), indicating that hydrogen has a protective effect on renal GCX after haemorrhagic shock. The increase in d-ROMs was also significantly reduced in the hydrogen group compared to the shock group (p<0.001).

Conclusion: This study demonstrated that hydrogen inhalation in a haemorrhagic shock model attenuates renal injury by preserving GCX thickness.

Clinical and hemodynamic factors associated with hemoglobin levels in patients with liver cirrhosis

J. Vidal Sánchez¹, N. Jiménez-Esquivel², J. Sanahuja¹, J.C. García Pagán3, A. Blasi1, E. Reverter2 ¹Hospital Clinic de Barcelona, Anaesthesiology and Critical Care Department, Barcelona, Spain, 2Hospital Clinic de Barcelona, Liver and Digestive ICU, Hepatology Department, Barcelona, Spain, 3Hospital Clinic de Barcelona, Hepatic Hemodynamics, Hepatology Department, Barcelona, Spain

Background and Goal of Study: Liver cirrhosis with portal hypertension leads to hemodynamic alterations, including hydrosaline retention, increased plasma volume, increased cardiac index (CI) and decreased systemic vascular resistance (SVR). The effect of these hemodynamic changes on hemoglobin (Hb) levels has not been specifically evaluated. Previous studies suggest that anemia may worsen hyperdynamic circulation, though it remains unclear whether anemia is a cause or consequence of this condition.

The aim was to study the association between Hb levels and clinical as well as hepatic and systemic hemodynamic variables in cirrhotic patients, both at baseline and in relation to temporal changes in these variables.

Materials and Methods: A retrospective cohort of cirrhotic patients was analyzed, all of whom had undergone two serial hemodynamic assessments (hepatic and systemic) separated by at least 3 months. Between these two assessments, most patients received treatments that modulate hemodynamics. Baseline clinical and hemodynamic variables associated with Hb levels were studied, along with the association between changes in Hb and changes in other variables.

Results and Discussion: 242 patients were included: 88 with HCV eradication, 71 with TIPS placement, 33 with β-blocker initiation, and 50 with no significant events between assessments. At baseline, various clinical and hepatic function variables (prothrombin, albumin, Child score, MELD score, sodium, ascites), systemic hemodynamics (CI, SVR, mean arterial pressure (MAP)), and hepatic hemodynamics (HVPG, wedge hepatic venous pressure (WHVP)) correlated with Hb levels. In multivariate analysis, albumin (β =0.41), ascites grade (β =-0.24), and CI or indexed SVR (β =-0.20 and β =0.23, respectively) were correlated with Hb (adjusted R2=0.38).

In analyzing changes between hemodynamic assessments, changes in Hb correlated with changes in albumin (β=0.45), CI (β =-0.21), and MAP (β =0.13) (or indexed SVR, β =0.24); global adjusted R2=0.34. Changes in hepatic hemodynamics did not independently correlate with changes in Hb. Subgroup analysis showed similar results. Albumin had the strongest correlation with Hb and its changes across all comparisons.

Conclusion: Hemoglobin levels and their temporal changes in cirrhotic patients are largely correlated with albumin levels and variables related to hyperdynamic circulation and hydrosaline retention, suggesting a significant dilutional component in its values.

New methods in pain management after HPB surgeries. Can we lower opioid consumption? Randomized controlled trial

V. Traskaite Juskeviciene¹, U. Valanciute¹, D. Trepenaitis¹, A. Macas¹

¹Lithuanian University of Health Sciences Hospital Kaunas Clinics, Department of Anaesthesiology, Kaunas, Lithuania

Background and Goal of Study: Patients after HPB surgery endures high levels of pain which causes negative neurohumoral response. Patients who receive standard post-op pain management receive high doses of NSAIDs and opioids which have negative impact on respiratory system, induce nausea and vomiting, obstipation, urinary retention [1]. Therefore, close patient's monitoring is required, which is difficult in surgery unit. Our study's aim is to lower opioids intake with interventional method consisting of abdominal wall catheters and Ropivacaine infusion.

Materials and Methods: patients were enrolled November 2022 - November 2023 after bioethical permission was obtained. Inclusion criteria: patient's consent; patients, 18 years old or older, transverse laparotomy incision. Exclusion criteria: opioid-dependent patients, underaged patients, hepatic insufficiency (Child-Pugh C) or chronic kidney disease (>3 st.), refusal to participate. Included patients were randomized into two groups: interventional (I) (abdominal wall catheter with Ropivacaine infusion) and standard (SM) (systemic analgesics). Opioids' requirement and consumption was documented during day of surgery and 2 postop days. Different opioids doses were converted into Morphine equivalents.

Results and Discussion: During this period 34 patients were enrolled to the study. Two groups did not differ significantly. In both groups patients were treated with opioids and NSAIDs. Opioid consumption was significantly higher in SM group in PACU and 2 postoperative days on the ward. Total opioid requirement was also significantly higher in SM group. We observed no difference in opioid consumption during surgery.

Morphine equivalents	SM group (n=20)	I group (n=14)	p value
Surgery	47,5(0-70; 45,75)	45(35-60;46,43)	0,937
PACU	10(0-45;13,29)	2,5 (0-20; 5,3)	0,02
Day 1	10(0-200; 19,25)	0(0-10; 1,79)	<0,001
Day 2	12,5(0-200; 21,5)	0(0-5; 1,79)	<0,001
Total	75(30-470;99,79)	57,5(36,25 -75; 55,3)	<0,001

Conclusion(s): Patients who received pain management with abdominal wall catheters and Ropivacaine infusion required significantly less opioids compared to SM group. It is likely that those patients would also experience less opioid related adverse reactions but further investigation is needed.

Optimization of donor kidneys with sevoflurane during normothermic machine perfusion

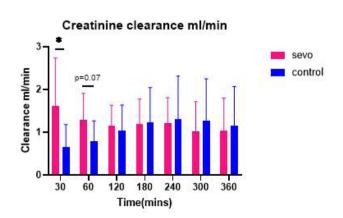

S. Yang¹, P. Günkel¹, M. Jabaudon², M. Struys¹, H. Leuvenink³, G. Nieuwenhuijs-Moeke¹ ¹University Medical Center Groningen, Department of Anesthesiology, Groningen, Netherlands, ²University Hospital Clermont-Ferrand, Department of Perioperative Medicine, Clermont-Ferrand, France, 3University Medical Center Groningen, Department of Surgery, Groningen, Netherlands

Background: Volatile anesthetics, like sevoflurane, have shown to reduce ischemia reperfusion injury in multiple studies. The potential mechanisms of protection involve inhibition of opening mitochondrial permeability transition pores, protection of the endothelial cells and glycocalyx, inhibition of inflammation. Normothermic machine perfusion (NMP) of kidneys creates a therapeutic window of opportunity to add pharmacological substances to reduce injury, enhance repair and evaluate organ function before transplantation.

We hypothesize that administration of sevoflurane during NMP reduces injury and improves kidney quality.

Method: We set-up a slaughterhouse porcine model with administration of sevoflurane using a vaporizer during NMP and tested the feasibility. Then executed 16 experiments (8 paired kidneys, n8/group), with or without sevoflurane. Kidneys were retrieved and underwent 30mins warm ischemia time then flushed with UW solution, preserved cold storage for 24h, after which 6h NMP was initiated. Sevo-group (n=8) was treated with 4% sevoflurane for the first 1h during the 6h NMP while the Control-group was treated without sevoflurane. Perfusate, urine, and tissue samples were collected and physiological measurements were recorded.

Results: There were no differences in intrarenal resistance. flow rate, fractional sodium excretion, lactate, weight gain between two groups. The Sevo-group showed higher urine production at 30mins (p=0.04) and higher oxygen consumption at 60mins (p=0.01). Total protein and cumulative protein in urine in Sevogroup were increased at multiple timepoints. Creatinine clearance in Sevo-group was also higher than Control-group within the first hour. Both AST and LDH in the perfusate of Sevo-group showed significantly higher levels compared to the Control-group at multiple timepoints. Sevo-group 30mins fractional potassium excretion was reduced (p=0.04) while urea in the urine was increased statistically (p=0.05).

Conclusion: Administration of sevoflurane during the kidney normothermic machine perfusion is feasible. Vaporizer setting 4% of sevoflurane can promote glomerular filtration rate but may cause potential renal cell damage.

35AP01-11

Modification of the MEAF score to predict allograft liver failure after transplantation

J.M. Sanahuja Blasco¹, R. Mellado-Artigas¹, E. Reverter², J. Vidal¹, A. Blasi¹, A. Hessheimer³ ¹Hospital Clínic, Anestèsia, reanimació i tractament del dolor, Barcelona, Spain, 2Hospital Clínic, Institut de malalties digestives i metabòloiques - UCI Hepàtica, Barcelona, Spain, 3Hospital la Paz de Madrid, Cirugía, Madrid, Spain

Background and Goal of Study: There are many scores in the literature that try to predict liver function in the postoperative liver transplant setting. In our cohort the one that better predicts the outcome is the MEAF score (E pareja et al. Liver transplantation 2015), by its simplicity and good accuracy. We want to improve this accuracy by adding the need of transfusion (more than 3 intraoperative red blood cells packages) and the presence of postreperfusion syndrome in the original formula.

Materials and Methods: All patients undergoing liver transplantation from 2008 to 2018 were included retrospectively. Demographyc data, RBCp intraoperatively administered, presence of post-reperfusion syndrome, and follow up until day 90,180, 365 were recorded, mortality and retransplantation. MEAF score was calculated and then we added the item of more than 3 RBCp transfused in a logarythmic way and the dycothomic variable of the presence of post-reperfusion syndrome to the formula.

Results and Discussion: The MEAF score has an accuracy in predicting liver failure in the first 90 days of 0.7 in our cohort. By adding these two parameters (more than 3 RBCp administered during the surgery and the presence of reperfusion syndrome) the accuracy of this score improved to 0.82.

Conclusion(s): The addition of two intraoperative data to the MEAF score, improves its accuracy keeping the simplicity of the original formula. Prospective and external validation is still needed.

To transplant or not transplant: decision-making and intraoperative management in liver transplantation of a patient with severe portopulmonary hypertension

F. Lopez¹, D. Benguria Puebla¹, J. Ruiz De Las Heras¹, L. Del Rio¹, L. Tisner¹, J. Vigo¹ ¹Hospital 12 de Octubre, Anesthesiology, Madrid, Spain

Background: This case presents a liver transplant performed on a patient with severe portopulmonary hypertension (PPH).

Case report: A 68-year-old male with a history of hypertension, type 2 diabetes, cirrhosis of mixed etiology (alcoholic, HCV, metabolic), and severe PPH. He was on triple vasodilator therapy with Sildenafil, Macitentan, and continuous infusion of Treprostinil, His mean pulmonary artery pressure (PAPm) was 32 mmHg and pulmonary vascular resistance (PVR) was 2.76 uW, with good right ventricular function on echocardiography.

On the day of the transplant, his condition was reassessed with echocardiography, showing good biventricular function. Before the induction pulmonary artery catheter was placed, showing a PAPm of 49 mmHg and PVR of 3.2 UW. Optimization was performed with 80 mg of Furosemide and 10 mg of Sildenafil, improving the PAPm to 38 mmHg, before induction.

Intraoperatively, hemodynamic monitoring was performed using invasive blood pressure, central venous pressure (CVP), and transesophageal echocardiography (TEE). Inhaled nitric oxide, repeated doses of inhaled lloprost, and intravenous treprostinil were administered. PAPm was maintained between 29-46 mmHg. and right ventricular function remained stable . The patient required intraoperative norepinephrine, blood transfusions and bolus of epinephrine during the suprahepatic clamp.

After the procedure, he was transferred intubated to the ICU, on norepinephrine, intravenous treprostinil, and nitric oxide.

Discussion: PPH increases the risk of intraoperative and postoperative mortality in liver transplantation, making a risk-benefit balance essential1. In moderate to severe PPH cases, assessing right ventricular function and the response to vasodilator therapy is crucial. Perioperative management is challenging due to the risk of hemodynamic instability.

The goal is to maintain adequate right ventricular function and achieve a balance in PAPm, with continuous monitoring2.

- 1. Krowka MJ et al. Hepatopulmonary syndrome and portopulmonary hypertension: a report of the multicenter liver transplant database. Liver Transpl. 2004 Feb;10(2):174-82 2. F. Acosta Villegas et al. Hepatopulmonary syndrome
- and portopulmonary hypertension Gastroenterol Hepatol 2004;27(Supl 4):15-20

Learning points: PPH significantly increases morbidity and mortality in liver transplantation.

Proper preoperative optimization and effective intraoperative hemodynamic management are crucial.

Different pain management methods after HPB surgeries in the long perspective. Patients' interview 3 months after randomized controlled trial

V. Traskaite Juskeviciene¹, U. Valanciute¹, A. Macas¹ Lithuanian University of Health Sciences, Department of Anaesthesiology, Kaunas, Lithuania

Background and Goal of Study: patients after HPB surgeries experience high levels of pain which could have an impact in longer perspective. Postoperative pain impacts patients' socioeconomic well-being and their possibility to fully recover from major abdominal surgery. During initial study two pain control methods were compared: standard management (SM group) and abdominal wall catheters with Ropiyacaine infusion (intervention, I group).

Aim of the study was to evaluate patients' ability to fully recover after HPB surgeries depending on pain management method.

Materials and Methods: patients, eligible to participate in the initial study (patient's consent; >18 years old, transverse laparotomy, not opioid-dependent, no hepatic insufficiency (Child-Pugh C) or chronic kidney disease (>3 st.)) were contacted by phone 3 months post-op. Interview questions included chronic pain after surgery, constant need of analgesics, time of full recover, residual effects and overall experience of pain management. Qualitative data management methods were used. Bioethical permission was obtained before the study and patients were informed about the upcoming contact.

Results and Discussion: 56 patients were contacted 3 months post-op. 40(71,43%) interviews were successful, 8(14,29%) interviews failed and 8(14,29%) patients were already dead at that time. All patients fully or partially returned to their normal activities in 3 months after the surgery.

	l group (n=19)	SM (n=21)
Fully satisfied	17(89,47%)	17(80,95%)
Abdominal discomfort	3(15,79%)	4(19,04%)
Pain	1(5,26%)	1(4,76%)
NSAIDS	4(21,05%)	1(4,76%)
Bowel movement disorders	4(21,05%)	1(4,76%)
Abdominal numbness	1 (5,26%)	2(9,52%)
Reactions after chemo	5(26,32%)	5(23,81%)
Surgical complications	1(5,26%)	3(14,29%)

Conclusion(s): effective pain management is one of the most important factors for patient well-being and overall satisfaction after surgery. Data from interviews revealed that patients were equally satisfied and adverse effects were mostly related to consecutive chemotherapy rather than postoperative pain management methods.

Effect of the strategy that transesophageal echocardiography-guided unrestricted fluid combines with dobutamine on hepatic venous blood flow velocity in patients undergoing laparoscopic hepatectomy

Y. Fu¹, X. Wei¹, P. Liang^{1,2}

¹West China Hospital of Sichuan University, Anesthesiology Department, Chengdu, China, ²West China Hospital of Sichuan University, Day Surgery Center, Chengdu, China

Background and Goal of Study: Current recommendations suggest limiting fluid to achieve low central venous pressure during laparoscopic hepatectomy to reduce bleeding, but this may cause circulatory instability and tissue hypoperfusion. The key is to enhance hepatic venous blood return. So we will assess the effect of the strategy that transesophageal echocardiography(TEE)-guided unrestricted fluid combines with dobutamine on hepatic venous blood flow velocity in these patients.

Materials and Methods: 52 patients undergoing partial hepatectomy from November 2023 to March 2024 were randomly assigned to dobutamine or control group, each with 26 patients. The dobutamine group received 3 μg/kg/min dobutamine after anesthesia induction, guided by TEE to maintain normal preload, while the control group received normal saline and 3-4 mL/kg/h of equilibrium solution. Hepatic vein blood flow spectra, including maximum velocity (VmaxS and VmaxD) and velocity time integral (VtiS and VtiD) of the S wave and D wave, were recorded at four time points: after anesthesia induction (T1), 10 minutes post-administration (T2), after pneumoperitoneum (T3), and after hemostasis (T4). Data were analyzed using generalized estimating equations.

Results and Discussion: At T2, differences were found in VmaxS (P=0.002), VtiS (P=0.03), and VmaxD (P=0.008) between the two groups. At T4, VmaxS (P=0.006), VtiS (P=0.02), VmaxD (P=0.001), and VtiD (P<0.001) also differed (Fig. 1). No differences were found at T1 and T3. Intraoperative bleeding was lower in dobutamine group (356±198mL) than in control group (470±381mL), but this was not statistically different. The area under the curve for hypotension showed no difference (P=0.77), but the use of vasoactive drugs was significantly lower in the dobutamine group (P=0.02).

Conclusion(s): Intraoperative TEE-guided unrestricted fluid combines with dobutamine improved hepatic venous blood flow and decreased the use of vasoactive drugs in laparoscopic hepatectomy patients. This challenges the conventional fluid restriction approach, indicating that future research should prioritize low hepatic venous flow over low central venous pressure.

Effects of dobutamine on hepatic blood flow: results of the DobuWhipple trial

J. van Limmen¹, J. Leyman¹, P. Wyffels¹, F. Berrevoet², S. De Hert1, L. De Baerdemaeker1 ¹University Hospital of Ghent, Anesthesiology and perioperative care, Gent, Belgium, 2University Hospital of Ghent, General and hepatobiliary surgery, Gent, Belgium

Background and Goal of Study: Hepatic blood flow (HBF) is influenced by adrenergic stimulation, Dobutamine (DOBU), a commonly used inodilator, may impact HBF directly but also indirectly by enhancing cardiac index (CI).1 While previous studies have shown an increase in overall intestinal blood flow, its specific effects on HBF remain uncertain. This study aimed to assess the impact of DOBU administration on HBF.

Materials and Methods: Following approval from the ethical committee and obtaining written informed consent, patients scheduled for pancreaticoduodenectomy were enrolled in the study. Anesthesia was administered to all participants using targetcontrolled anesthesia with propofol (Schnider) and remifentanil (Minto). Hemodynamic data were measured, monitored, and recorded using Pulsioflex™. HBF was assessed using ultrasound transit time (Medi-Stim AS). Baseline measurements (T1) were taken before initiating dobutamine (DOBU) at 2 mcg/kg/min (T2), which was then increased to 5 mcg/kg/min (T3). A minimum interval of 10 minutes was maintained between each measurement. Hemodynamic variables, indexed hepatic arterial flow (HAFi), and indexed portal vein flow (PVFi) were measured and recorded simultaneously. Statistical analysis was performed using linear mixed modeling.

Results and Discussion: A total of 30 patients were included. DOBU dose-dependently increased CI and heart rate (HR). The predicted increase in PVFi was 87 ml.min-1.m-2 (+/- 16 ml.min-1.m-2) at T3 (p < 0.05) and the predicted decrease in HAFi was 38 ml.min-1.m-2 (+/- 11 ml.min-1.m-2) at T3 (p < 0.05). This resulted in a predicted increase in total HBFi was 49 ml.min-1.m-2 (+/- 16 ml.min-1.m-2) at T3 (p < 0.05). This effect was dose-dependent and more pronounced at higher dosages of DOBU. (see table) Tabel: Data are mean (SD)

	T1	T2	Т3
Total HBF _{indexed} (ml.min-1.m-2)	515 (182)	538 (137)	564 (154)#
Total HBF _{relative} (% of CI)	16.8 (5.9)	16.2 (4.3)	16.2 (4.3)
HAFi (ml.min-1.m-2)	183 (116)	169 (92)	145 (87)#*
HAF _{relative} (% of CI)	6.0 (3.9)	5.2 (2.9)#	4.3 (2.5)#*
PVFi (ml.min-1.m-2)	332 (110)	369 (120)#	418 (141)#*
PVF _{relative} (% of CI)	10.8 (3.6)	11.1 (3.5)	12.0 (3.8)#*
CI (L.min-1.m-2)	3.1 (0.5)	3.4 (0.5)#	3.5 (0.6)#
HR (bpm)	78 (9)	89 (14)#	111 (14)#*

Conclusion(s): DOBU in incremental dosages had an opposing effect on PVFi and HAFi. The net effect on total HBF was a small significant increase.

Digital twin with generative artificial intelligence: personalized dynamic management of renal risk in ICU

A. Gatz¹, J. Cai², X. Liu³, J. Li³, L. Meng⁴, J. Su³ ¹Indiana University School of Medicine, Department of Medicine, Indianapolis, United States, ²Purdue University, Department of Computer and Information Technology, West Lafayette, United States, 3Indiana University School of Medicine. Department of Biostatistics and Health Data Science, Indianapolis, United States, 4Indiana University School of Medicine, Department of Anesthesia, Indianapolis, United States

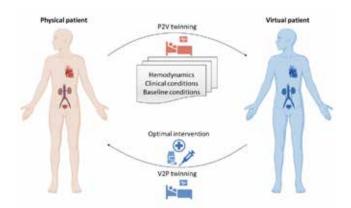

Background and Goal of Study: Managing renal functions to reduce acute kidney injury (AKI) risk is crucial in ICU settings. Cardiorenal interactions significantly impact hemodynamics management and ICU interventions. Conditions like sepsis, insufficient cardiac output, and nephrotoxic drugs increase AKI risk, especially in those with chronic kidney disease. Renal injury often signals multiple organ failure and is linked to high mortality. Advances in health digital twins (HDT) using generative AI (GAI) and ICU monitoring data offer promising solutions for personalized AKI risk management.

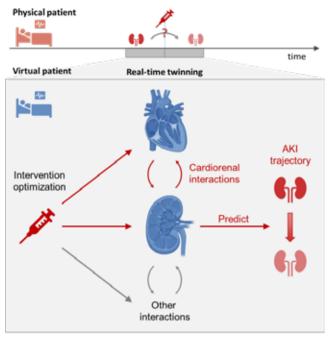

This study aims to utilize digital twin technology to guide ICU treatment, preventing or resolving AKI instances.

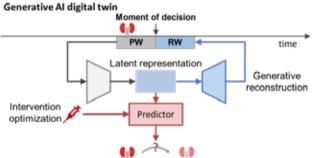

Materials and Methods: We developed a GAI-based HDT model to dynamically evaluate ICU interventions' impact on AKI risk. The model includes vasopressors, fluid management, diuretics, and antibiotics for sepsis treatment, all affecting renal functions. For each patient, a virtual twin is created based on demographic and clinical data at ICU admission. During the ICU stay, clinical conditions, vital signs, organ functions, and interventions are updated in real-time to the virtual twin via P2V twinning, represented in GAI's latent space. Potential treatments' effects on AKI risk are predicted and evaluated on the virtual twin before implementation on the physical patient.

Results and Discussion: Our GAI HDT model was trained and tested with MIMIC IV ICU data and validated with ICU patients at Indiana University Health (2021-2024). The primary outcome is the 24-hour AKI progression trajectory score post-intervention. The preliminary model achieved a concordance index of 0.73 (CI: 0.72-0.74), demonstrating promising performance.

Conclusion: This preliminary study shows the potential of using GAI HDT for personalized, dynamic ICU management to estimate and reduce renal risk.

Ultrasound assessment of abdominal wall muscle thickness: a comparative study of sarcopenia in liver transplant recipients and healthy donors

S. Aqhi1

¹Institute of Liver and Biliary Sciences, Anaesthesia, New Delhi. India

Background and Goal of Study: Sarcopenia is strongly correlated with postoperative mortality in living donor liver transplant recipients. Sarcopenia has previously been assessed based on CT findings. However, measurement of abdominal muscle thickness for assessment of sarcopenia in liver transplant recipients has not been attempted before. We expect to ascertain abdominal wall thickness in cirrhotics by the use of ultrasound and correlate values with standard markers of sarcopenia (handgrip strength and L3-SMI), disease severity scores, and also with post-operative outcomes

Materials and Methods: All adults undergoing LDLT from October 2023 until April 2024 were included. L3 SMI on abdominal CT (Figure 1), hand grip strength and ultrasound guided abdominal muscle thickness measurements (Figure 2) were performed for all recipients and donors preoperatively. Postoperative outcomes and mortality were recorded during the 30-day follow-up. Abdominal muscle thickness of recipients was compared with donors and correlation calculated with disease severity scoring and postoperative outcomes. Also, ROC curves were used to calculate cut-offs to define sarcopenia using abdominal muscle thickness.

Results and Discussion: The prevalence of sarcopenia in our study population was between 63% to 83%, varying with the method of measurement. Donors had significantly thicker abdominal muscles compared to recipients with cirrhosis. The extent of muscle thinness correlated linearly with the severity of liver disease on CTP score and also independently with the volume of ascitic fluid accumulated. Also, recipients with thinner external oblique and transversus abdominis muscles spent a longer time in the ICU postoperatively

Conclusion(s): A significant difference can be expected in the abdominal muscle thickness of LDLT recipients with cirrhosis and healthy donors. A moderate negative linear correlation exists between CTP score and thickness of transversus abdominis muscle. Lastly, patients found to be sarcopenic on measurement of external oblique and/or transversus abdominis thickness tend to have a longer postoperative ICU stay.

35AP02-7 Assessment for predictors of liver transplantation outcome

C. Barreiros¹, J. Sanahuia¹, R. Mellado-Artigas¹, E. Rivas¹, A. Blasi¹. A. Hessheimer²

¹Hospital Clínic de Barcelona, Anaesthesiology and Critical Care, Barcelona, Spain, ²Hospital Universitario La Paz, General and Digestive Surgery, Madrid, Spain

Background and Goal of Study: Multiple factors are related to liver transplantation (LT) outcomes. Among them, the most related are the type of donor, patients' comorbidities, and intraoperative course. We aim to assess which predictors are associated with poor outcomes at 90 days after LT.

Materials and Methods: Single center retrospective study of all consecutive patients undergoing LT from 2008-2018. Exclusion criteria were acute liver failure, living donor and multiple organ transplant. Data related to the type of donor (dead brain donor or donation after circulatory death), surgery and recipient characteristics that reported to be related to allograft failure were collected. We defined graft failure as graft cirrhosis, need for re-LT, and/or allograft-associated death between day 7 and day 90 after LT.

Results and Discussion: 622 patients were included in the analysis and 30 patients fulfilled the criteria for graft failure. After comparing donor type, age, body mass index, Child-Pugh and MELD at LT time, and baseline hemoglobin in the receptor, warm and cold ischemia time, post-reperfusion syndrome and number of red blood cell packages in the intraoperative setting, only the number of RBC administered during the intraoperative period was significantly associated with the incidence of graft failure (p=0.008).

Conclusion(s): Transfusional rate during the liver transplant seems to be the most important risk factor for graft failure between day 7 and 90 after LT. Despite the limitations of our study, anesthesiologists should focus on the development of both hemoglobin level optimization and intraoperative bleeding reduction strategies in order to avoid RBC transfusion.

Urgent liver transplant due to fulminant liver failure of unknown etiology, with acute leukemia diagnosed in the immediate postoperative period

M.J. Marono¹, E. Ganuza Martínez¹, A. Guereca Gala¹, A. Zabal Maeztu¹, M.C. Ruano Suarez¹, G. Ojinaga García¹ ¹Hospital Universitario de Cruces, Anestesiología y Reanimación, Barakaldo, Spain

Background: Acute liver failure is a life-threatening situation; its treatment is based on support measures, treatment of the etiological cause and, in many cases, liver transplantation. However, liver transplantation is contraindicated in terminal situations or extrahepatic cancer.

A fulminant liver failure secondary to acute leukemia diagnosed late in the postoperative period of urgent transplantation is described.

Case Report: 14-year-old patient admitted to our critical care unit due to acute liver failure (MELD 36) of unknown cause with rapid clinical and analytical deterioration developing encephalopathy and severe coagulopathy. An urgent liver transplant was performed 48 hours after admission.

Progressive cytopenia and hyperferrtinemia are observed in the postoperative period. Given these findings, bone marrow analysis was performed in which blast infiltration compatible with acute lymphoblastic leukemia was observed.

Given this finding, a multidisciplinary meeting is held to decide on the initiation of high-dose corticosteroid therapy during admission to the critical care unit, for subsequent treatment with chemotherapy after postoperative recovery. The patient is progressing favorably with a survival of more than 5 years at present. Discussion: In the face of acute liver failure we must look for the different etiological causes. Hematological diseases are a common cause of liver disorders, without normally being life-threatening. However, in the event of liver failure of unknown etiology. we must consider this possibility, since it represents a variation in treatment and a possible contraindication for liver transplantation. In this case, the patient did not show compatible symptoms before the transplant, so an urgent transplant was performed due to liver failure of unknown etiology.

Catalá, Muriel, Ocqueteau T., Mauricio, & Sarmiento M., Mauricio. (2017). Leucemia linfoblástica aguda con grave alteración hepática como manifestación inicial. Presentación de dos casos y revisión de la literatura. Revista médica de Chile, 145(6), 804-807. https://dx.doi.org/10.4067/s0034-98872017000600804 Learning points:

- In the face of acute liver failure we must look for the different etiological cause.
- We must think about hematological diseases in the diagnosis of acute liver failure of unknown etiology.

35AP02-10

The impact of preoperative anemia in liver transplant patients on blood product requirement, intraoperative blood loss and ICU length of stay

I.-A. Tutoveanu¹, M. Olita^{1,2}, E. Scarlatescu^{1,2}, D. Tomescu^{1,2} ¹Fundeni Clinical Institute, Department of Anaesthesiology and Intensive Care III, Bucharest, Romania, 2University of Medicine and Pharmacy Carol Davila, Department of Anaesthesiology and Intensive Care III, Bucharest, Romania

Background and Goal of Study: In cirrhotic patients anemia is frequent, but often neglected disease. In different surgical fields, preoperative anemia was identified as an independent risk factor for post-operative morbidity and mortality, however this topic was less studied in cirrhotic patients undergoing liver transplantation (LTx). The study objectives were to assess the incidence and impact of pre-operative anemia in LTx patients.

Materials and Methods: 300 liver cirrhosis patients undergoing LTx were enrolled. The collected data included: recipient characteristics, preoperative complete blood counts, intraoperative bleeding and transfusion requirements, ICU length of stay (LOS). Results and Discussion: Patients included had mean (±SD) age 49.8 (±11.9) years and mean (±SD) MELD score 18.4 (±7.1) points. According to WHO criteria, 83.7% of patients had preoperative anemia, with 38.7%, 43.7% and 1.3% of patients having mild, moderate and respectively severe anemia. The severity of anemia increased with the severity of the liver disease as assessed by MELD score. Ferritin levels, mean corpuscular volume and hemoglobin were not different between anemic and non-anemic patients. Compared to patients without anemia, cirrhotic patients with anemia had higher red cell distribution width (median(IQR) 16.9(3.7) vs 14.7(2), p<0.001), lower blood iron levels (median(IQR) 85.5(105.9) vs 130.4(77.2), p=0.008), higher intraoperative blood loss and transfusion requirements (median(IQR) 4250(5425) vs 2500(3175)ml; 4(6) vs 1(3) U RBCs, p<0.001), and longer ICU LOS (median(IQR) 6(3) vs 5(2) days, p<0.001).

Conclusion(s): Diagnosis and correction of pre-operative anemia in LTx candidates may reduce intraoperative transfusion requirements and the duration of ICU stay, leading to cost savings for the health service.

Hemolysis in microwave ablation of small liver tumors: preliminary results from an ongoing RCT

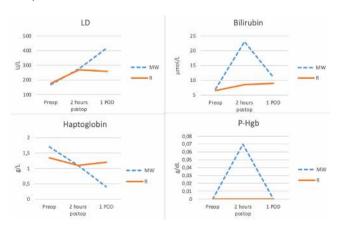

K. Lappen^{1,2}, I. Schrøder Hansen^{3,2,4}, S. Halvorsen^{4,2}, A. Avdem Fretland^{4,5}, H. Lang Orrem⁴, A. Espinoza⁴ ¹Oslo University Hospital, Rikshospitalet, Department of Research and Development, Oslo, Norway, 2University of Oslo, Institute of Clinical Medicine, Oslo, Norway, ³Oslo University Hospital, Rikshospitalet, Department of HPB Surgery, Oslo, Norway, 4Oslo University Hospital. Rikshospitalet, Intervention Center, Oslo, Norway, 5Oslo University Hospital, Rikshospitalet, Department of HPB Curgery, Oslo, Norway

Background and Goal of Study: Thermal ablation is a minimal invasive treatment of liver tumors, and can be done through radiofrequency (RF) or microwave (MW) ablation. It is well known that hemolysis can occur after ablation in both methods, previously associated with long ablation time of large hepatic tumors and hemangiomas. We here explore the extent of hemolysis after shorter ablation procedures on solid liver tumor metastasis.

Materials and Methods: We included patients from the New Comet study, an RCT comparing laparoscopic resection to thermal ablation of colorectal cancer liver metastasis less than 3cm in size (Clinicaltrials.govID: NCT05129787). 35 patients have been included in the MW-ablation arm, and 39 in the laparoscopic resection arm (R) as a control group.

The hemolysis markers LD, Bilirubin, Haptoglobin and plasma-Hemoglobin (p-Hgb) were analyzed preoperatively, 2 hours postoperatively and on the first postoperative day (1POD). Wattminutes (minutes of ablation X watt) were calculated to test for correlations with each hemolysis marker in the ablation group. We used the Mann-Whitney U test for group comparisons and Spearman's rank correlation test for assessing correlations.

Results and Discussion: Mean tumor size was 14.6 mm (R) and 13.2 mm (MW). We found significantly more hemolysis (p<0.05) in all four markers in the MW group compared to the control group (figure 1), and the extent of the hemolysis correlated with the energy delivered (wattminutes) (range 0.48-0.80, all p-values < 0.05).

Conclusion(s): MW ablation can result in a transient hemolysis even in the treatment of small liver tumors. The amount of energy delivered correlated with the degree of hemolysis. The clinical impact of these findings will be investigated in patient follow-ups.

35AP02-12

Septic versus vasoplegic shock in liver transplant surgery

M. Grao Roca¹, S. González-Suárez¹, H. Serrano¹ ¹University Hospital Vall d'Hebron, Department of Anesthesia, Barcelona, Spain

Background: During liver transplant surgery, hemodynamic instability usually appears during the graft reperfusion phase. However, it can occur at any phase of the procedure as hemorrhagic shock, cardiogenic shock, septic shock or vasoplegic syndrome (VS), and the differential diagnosis can be difficult.

Case Report: A 60-year-old male, Child C, MELD 28, underwent a second liver transplant due to recurrent hepatitis C and hepatocarcinoma. The dissection phase was difficult and required transfusion of 5 units of red blood cells and 14 units of fresh frozen plasma. The rest of the surgery was uneventful until the end of the neohepatic phase when, without active bleeding, the patient developed hypotension (MAP 45 mmHg, CVP 3 mmHg, PAP 10 mmHg, PCP 6 mmHg, CI 4.7 L/min/m², SVR 622 dyn-s-cm-⁵, HR 97 bpm) that required noradrenaline to achieve a MAP of 60 mmHg.

Postoperatively, the patient suffered hemorrhagic shock due to bleeding from the donor hepatic artery, requiring emergency surgery and numerous transfusions. Intraoperatively, an abscess was identified in the donor hepatic artery (WBC 32,000/µL).

Cultures and liver biopsies were obtained. Subsequently, a prosthetic graft was placed in the donor's hepatic artery due to the absence of arterial flow (arterial thrombosis). The patient progressed to hyperdynamic shock secondary to septicemia caused by Pseudomona aeruginosa of abdominal origin (hepatic infectious arteritis), leading to death.

Discussion: During surgery, the patient had distinctive signs of VS, such as MAP <50 mmHg, PCP ≤10 mmHg, CVP <5 mmHg, CI >2.5 L/min/m². SVR <800 dvn·s·cm-⁵. and elevated HR (1). However, positive cultures from liver biopsies, peritoneal fluid and blood confirmed septic shock as a probable diagnosis. Cardiogenic shock was ruled out because of preserved ventricular function. Anaphylactic shock was considered unlikely, as the vasoplegia was not temporally related to drug administration or transfusions.

References: 1. Clinton TL, et al. Ann Thorac Surg 2000;69:1198-204.

Learning Points: It should be considered that, although VS in liver transplant surgery has been associated with various factors such as surgical trauma, ischemia-reperfusion injury and systemic inflammatory response, its diagnosis is infrequent and typically of exclusion. The occurrence of deep vasoplegia requires early exclusion of septic shock to adjust antibiotic treatment and improve prognosis.

Features of anesthetic management and perioperative intensive care of pediatric liver transplantation

A. Sezina¹, A. Yakimchuk², P. Prilutsky³, A. Dzyadzko⁴, A. Shcherba⁵, O. Rummo⁶

¹State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Head of the Department of Anesthesiology and Resuscitation No. 4 (with recovery room), Minsk, Belarus, 2State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Department of Anesthesiology and Resuscitation (with recovery room), Minsk, Belarus, 3State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Head of the Department of Anesthesiology and Resuscitation No. 2. Minsk. Belarus. 4State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Head of the Department of Anesthesiology, Resuscitation and Intensive Care, Doctor of Medical Sciences, Professor, Minsk, Belarus, ⁵State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Deputy Director for Surgical Work, Doctor of Medical Sciences, Professor, Minsk, Belarus, 6State Institution Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Director of the State Institution "Minsk Scientific and Practical Center for Surgery, Transplantation and Hematology, Doctor of Medical Sciences, Minsk, Belarus

Background and Goal of Study: Liver transplantation is currently the only effective method for treating liver failure in children at the decompensated stage. Improving surgical techniques, anesthesiological support, and perioperative management have led to a significant increase in survival rates among pediatric patients. even those weighing less than 10 kilograms.

This study aims to analyze the specific aspects of anesthesiological management and perioperative care for pediatric liver transplantation performed in Belarus.

Materials and Methods: We used data from a retrospective analysis of 118 pediatric patients who underwent liver transplantation between 2009 and 2024. The age of patients ranged from 5 months to 17 years, with an average age of 1.5 years. The severity of the disease was assessed using the PELD-score.

We perform between 7 and 13 liver transplants for children each year, with biliary atresia, acute fulminant hepatitis, and hepatoblastoma being the most common indications.

Results and Discussion: When analyzing 118 pediatric liver transplants, we found that improving surgical techniques, such as using a reduced graft and split-transplant techniques, can help avoid the large-for-size syndrome.

This can lead to the development of complications like intraabdominal hypertension and compartment syndrome, as well as impaired venous outflow and graft dysfunction. Cava-portal transposition (n=6) can help revascularize the graft in cases of portal vein thrombosis.

Pediatric liver transplants have several features: high PELD score, high proportion of children under 3 years old (up to 50%), many urgent operations, and a high incidence of infections with multidrug-resistant bacteria (MDR), these operations are performed in a multidisciplinary adult hospital.

We develop an individualized management for each child based on their age, weight, disease status, functional impairments, and infectious status.

Conclusion(s): As a result of this approach, we obtained data on survival rate for children is 87.5% and the three-vear survival rate is 80.5%. The hospital mortality rate is 11.1%. The most common complications in the early postoperative period included renal dysfunction requiring renal replacement therapy (15.6%), neurological complications (12.5%), respiratory complications (9.4%). sepsis (9.5%), toxicity from calcineurin inhibitors (9.4%), cardiovascular complications (6.3%) and pulmonary embolism (PE) (3.1%).

Drugs and Pharmacology

Effects of intranasal insulin on Postoperative Delirium in elderly patients with type 2 diabetes mellitus: a secondary analysis of a randomized clinical trial

X. Hao1. W. Mi1. M. Sun1 ¹Chinese PLA General Hospital, Anesthesiology, Beijing,

Background and Goal of Study: Postoperative delirium (POD) is prevalent among older patients with type 2 diabetes mellitus (T2DM). Our previous study showed that intranasal insulin was a potential therapy to prevent POD in older patients¹. Therefore, a secondary analysis was employed to investigate the effects of intranasal insulin on POD in older patients with T2DM.

Materials and Methods: In the previous clinical trial, 128 patients undergoing elective orthopedic or pancreatic surgery with general anesthesia were randomised to intranasal administration of 40 IU insulin (Group I) or equal volume of normal saline (Group S), respectively, once daily from 5 minutes before anesthesia induction until 3 days postoperatively¹. For the current study, 50 diabetic patients (22 and 28 participants in Group S and Group I, respectively) were included. The primary outcome was POD incidence within the 3-day postoperative period in different groups. The secondary outcomes were the perioperative score changes of the Mini-Mental State Examination (MMSE) and Montreal Cognitive Assessment-Basic (MoCA-B), postoperative levels of interleukin-6 (IL-6), tumor necrosis factor α (TNF- α), S100- β , and Creactive protein (CRP) in different groups. Statistical differences between groups were determined using Student's t-test or Fisher's exact test for quantitative data or categorical data, respectively. P values < 0.05 were regarded as statistically significant.

Results and Discussion: As shown in table 1, Insulin treatment significantly decreased the incidence of POD in Group I than in Group S (P=0.042), increased postoperative MMSE (P=0.045) and MoCA-B (P=0.027) scores in group I than in group S. And the postoperative serum levels of CRP (P=0.058) and IL-6 (P=0.061) in Group I were lower than in Group S.

	POD	Baseline MMSE	Postope- rative MMSE	Baseline MoCA-B	Postope- rative MoCA-B	Serum TNF-α (pg/ml)	Serum S100-β (ng/ml)	Serum CRP (mg/dl)	Serum IL-6 (pg/ml)
Group S	8 (36.4%)	27.4 (1.9)	27.1 (2.4)	23.5 (2.4)	23.4 (3.0)	62.61 (14.72)	5.00 (1.45)	8.3 (7.2)	38.4 (9.5)
Group I	3 (10.7%)	27.4 (1.6)	28.1 (1.2)	24.0 (2.3)	25.0 (2.3)	63.11 (13.68)	5.03 (1.37)	4.8 (5.2)	33.0 (10.0)
P value	0.042*	0.917	0.045*	0.458	0.028*	0.902	0.955	0.058	0.061

Table 1.

Conclusion(s): Intranasal insulin therapy holds promise as a potential treatment for POD in elderly patients with T2DM. This study provided the basement for conducting a large-sample size study to further validate these results.

Effect of an intravenous bolus of LIDOCAINE on the estimated median effective concentration (EC50) of PROPOFOL during target-controlled intravenous anesthesia (TCIVA: Schnider model) for performing gastroscopy: a prospective. randomized, double-blind study

L. Jaubert¹, J.N. Mattys¹, O. Duranteau¹, T. Tuna¹, C. Boudart1

¹Université Libre de Bruxelles, Faculté de Médecine, Brussels, Belgium

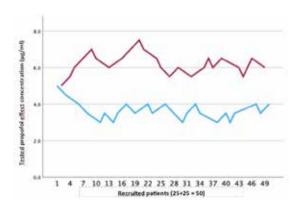

Background and Goal of Study: Gastroscopy often requires sedation to enhance patient comfort and improve examination quality. Propofol is the preferred sedative, but adjuncts like lidocaine may reduce its adverse effects.

This study evaluates the impact of an intravenous lidocaine bolus on the estimated median effective concentration of propofol during target-controlled intravenous anesthesia in gastroscopy.

Materials and Methods: This single-centre, prospective, randomized, double-blind, placebo-controlled study involved 50 adults scheduled for propofol sedation during gastroscopy. Participants were randomized into two groups: the lidocaine group received 1.5 mg/kg of intravenous lidocaine, while the placebo group received saline. Propofol concentration was adjusted based on the success of gastroscope insertion.

The primary endpoint was the median effective concentration of propofol, with secondary endpoints including total propofol consumption, side effects, and recovery time.

Demographic characteristics	Lidocaïne group	Placebo group	P-value
Age (years)	43.12 ± 13.55	39.6 ± 11.39	0.33
Gender (M/F)	11/14	13/12	0.57
Weight (kg)	70.04 ± 12.04	72.84 ± 13.98	0.46
Height (cm)	168.92 ± 9.38	169.36 ± 12.04	0.89
IMC (kg/m²)	24.48 ± 3.36	25.31 ± 3.61	0.40
ASA score (I/II)	5/20	4/21	0.72

Results and Discussion: The median effective concentration of propofol was 3.5 µg/mL [3.2; 3.8] in the lidocaine group versus $6.3 \,\mu\text{g/mL}$ [4.8; 7.9] in the placebo group (p < 0.01). The lidocaine group demonstrated lower total propofol consumption, fewer instances of desaturation and hypotension, reduced burst suppression episodes, less injection pain and cough, and quicker recovery times. No serious adverse events occurred.

Conclusions: An intravenous lidocaine bolus effectively reduces peak propofol concentration and its side effects, while also decreasing total propofol consumption and providing faster recovery wich seems advantageous for ambulatory anesthesia.

41AP01-3

Clinically significant recurarisation in the postanaesthesia care unit after robotic surgery with antagonism of rocuronium with sugammadex controlled by neuromuscular monitoring. A case report

T. Krönauer¹, F. Girrbach¹, P. Simon¹ ¹University Hospital Augsburg, Anaesthesiology and Operative Intensive Care Medicine, Faculty of Medicine, University of Augsburg, Augsburg, Germany

Background: When the patent on sugammadex expired in 2023, it seemed that the problems of residual neuromuscular blockade had been overcome. However, once the use of drugs increases, there is an inevitable risk that very rare, not yet widely recognised, side effects will come to light, especially if imprudence rises[1-3]. Case Report: A 41-year-old female patient with no relevant comorbidities except obesity and hypothyroidism underwent robotassisted, laparoscopic surgery for 8 hours. Anaesthesia was induced with sufentanil, propofol, and rocuronium, followed by TIVA. Rocuronium was administered continuously via perfusor and stopped 30min before the end of surgery. At a TOF count of 2, antagonisation was performed with 200 mg sugammadex (2.4 mg/kg), resulting in a TOF ratio >90% and uneventful extubation. 45 min after admission to the PACU, the patient became somnolent and desaturated to an oxygen saturation of 60%. Oxygen was administered and an oropharyngeal tube was placed, which led to a rise of saturation to 95%. The patient's systolic blood pressure rose to 220 mmHg and a shallow breathing pattern was noticed. Immediate TOF count of 2 confirmed the suspected recurarisation. After an additional dose of sugammadex (200mg), the patient stabilised rapidly and was asymptomatic without oxygen few minutes later. In a debriefing, she stated that she could not remember the incident and gave written consent to publication of the case.

Discussion: After high doses of rocuronium, a sufficient TOF ratio for extubation may be achieved with sugammadex, but many receptors might still be blocked, as a reduction in muscle strength starts if >70% of the nicotinic acetylcholine receptors of the motor endplate are occupied. A small amount of rocuronium molecules redistributing from peripheral compartments after sugammadex has been excreted could be sufficient to reestablish a higher degree of neuromuscular blockade[3].

Although the pharmacological causes may be different from traditional recurarisation after antagonisation with acetylcholinesterase inhibitors, the potential for varying degrees from unrecognised events to life-threatening hypoxia remains[1-3].

References:

- 1. Dubois BFH, BJA 2023
- 2. Todd MM, Anesthesiology 2023
- 3. Hunter JM, BJA 2024

Learning Points: Adequate dosing of blocking agents and their antagonists as well as focussed attention and pharmacological knowledge remains mandatory.

We recommend prolonged monitoring of patients antagonised with sugammadex.

41AP01-4

The dilemma of choosing safe anaesthetic medicines for a patient with Brugada syndrome needing vitrectomy! If the same patient needs a laparotomy, what pharmacological agents should vou choose?

S. Naithilath¹, M. Davies²

¹Milton Keynes University Hospital, Anaesthesia-Consultant, Milton Keynes, United Kingdom, ²Milton Keynes University Hospital, Cardiology-Consultant, Milton Kevnes, United Kingdom

Background: Brugada syndrome accounts for approximately 40% of cases of sudden cardiac death (polymorphic VT or VF) in patients with structurally normal heart1.

Case Report: 63 year old man with Brugada syndrome, hypertension and hypercholesterolemia was booked for vitrectomy. He denies any cardiac symptoms or family history of SCD. His 12 lead ECG shows typical Type 1 pattern that is diagnostic of Brugada syndrome. TTE shows normal LV, EF 60-65%, dilated LA and mild AR. Abnormal Holter with dominant rhythm sinus, 3000 episodes of bradycardia (lowest 27/min) and occasional ventricular ectopic. Procedure was done under a sub-tenon's block with Lignocaine and adrenaline. Patient had 4 hour ECG monitoring in Recovery and was discharged next morning.

Discussion: Propofol and Bupivacaine are on the Red list (avoid) for patients with Brugada syndrome². Lignocaine, Amiodarone, Tramadol, Metoclopramide and Ketamine are on the orange list (preferably avoid)2. Limited evidence is available about anaesthesia for patient with Brugada syndrome. Isoprenaline is the only recommended pharmacological option (should be readily available) and an aim to increase heart rate by 20%1. No definite recommendation for preference between general or regional anaesthesia. Discuss with Cardiology and ITU. If GA is given, then post-operative monitoring for at least 36 hours (5 half- lives of medicines). Monitoring: Continuous 5 lead ECG, BIS, Temp, neuromuscular monitoring, BP (+/-Arterial) and SPO2. Team briefing and preparation. Caution with Vagotonic manoeuvres (e.g pneumoperitoneum, neck surgery) bradycardia precipitates VT/VF. Avoid hyperthermia3.

If GA is necessary (e.g. laparotomy), safer drugs are Thiopentone, Fentanyl, Sevoflurane, NDMR, Paracetamol, NSAIDs, Dexamethasone, Ondansetron and Sugammadex.

References:

- 1. Levy D et al 2018, Anaesthesia for patients with hereditary arrhythmias part 1 Brugada syndrome, BJA 18(6) p 159-165
- 2. Webpage BrugadaDrugs.org (Department of Cardiology, University of Amsterdam) available at

www.brugadadrugs.org

3. Martorano P et al, 2022, Anaesthesia for Brugada syndrome, The Orphan anaesthesia (German Society of Anaesthesiology/ ICM)

Learning Points: Anaesthetists should be aware of Brugada syndrome; "safer" anaesthetic medications, important role of Isoprenaline and peri-operative monitoring for Brugada syndrome. Red and Orange list of drugs for patients with Brugada syndrome has anaesthetic medications in them.

Poisoning with calcium channel blockers and beta blockers drugs

B. Özkan¹, N. Turgut¹, K. Demir¹ ¹Prof. Dr. Cemil Taşcıoğlu City Hospital, Anestesiology and Reanimation, Şişli, Turkey

Background: The patient who was old 22 years, was diagnosed with bipolar disorder and had a five month pregnancy five month ago, afterwards she didn't go for a check up.

Case Report: The patient was found at home beside two boxes of beta blockers and two boxes of calcium channel blokers as empty. She was confused, hypotension (systolic blood pressure :70-74mmhg, diastolic blood pressure :30-32 mmhg) and bradhicardia (40-42 heart rate and this is the nodal rhytym), restricted diuresis when she brought to hospital.

Gynecological examination did not show the pregnancy. The patient was intervened with activated carbon, 0.2 ml/kg calcium chloride, 0.03 mg/kg glukagon, inotrop drugs (adrenalin and noradrenalin), insulin and dextrose.

Appropriate average arterial pressure and pulse can not sustain despite all treatments. The patient was consultated with cardiology department. Transvenous pacemaker was planned and inserted

The patient was taken to Intensive Care Unit and hemodynamic stabilization was restored. Dialysis was performed in the Intensive Care Unit. Durind these treatments, the patient's hemodynamic, vital signs, all system examination, especially neurologic, improved over time.

The pacemaker was controlled by cardiolog. Pacemaker was removed three days later when the patient's hemodynamics improve. At the finally the patient was discharged from Intensive Care Unit to service.

Discussion: We must quickly assess the patient's response to treatment in order to reach vital physiological values as soon as possible. The protocols should be applied carefully on poisoning of beta blockers and calcium channel blocker drugs.

We intend to emphasize the importance of applying mechanical support treatment (transvenous pacemaker, dialysis, ECMO etc) in time when there is no response.

Reference:

https://dergipark.org.tr/en/download/article-file/2243554 Learning Points: Poisoning, calcium channel drug, blocker beta blocker drug, transvenous pacemaker, dialysis.

41AP01-7 Effect of donepezil on the onset and duration time of neuromuscular blocking agent

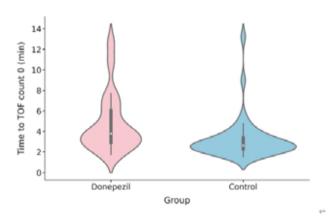

S.W. Jeong¹, S.H. Lee¹, S. Park¹, E.-A Jang¹ ¹Chonnam University Hwasun Hospital, Anesthesiology & Pain Medicine, Hwasun, Korea, Republic of

Background and Goal of Study: Donepezil, an acetylcholinesterase inhibitor, is prescribed to enhance memory and cognitive function in dementia patients, aiming to increase acetylcholine levels and slow disease progression. This drug's mechanism suggests potential interactions with nondepolarizing neuromuscular blocker used during anesthesia. This study examines the influence of donepezil on the action of nondepolarizing neuromuscular blockers, hypothesizing that donepezil administration will prolong the onset and reduce the duration of blocker effects.

Materials and Methods: This study was designed as a prospective, matched case-control, observational study approved by the IRB of author's hospital (CNUHH-2021-033) and registered at the CRIS of the Korean NIH(https://cris.nih.go.kr; KCT0005979). The study enrolled 20 dementia patients taking donepezil (Group D) and 40 controls (Control group). Anesthesia was induced and maintained with TIVA TCI. Neuromuscular blockade was monitored by electromyography with TwitchView, assessing the depth by TOF every 15 seconds and the PTC every 6 minutes. Rocuronium (0.9 mg/kg) was administered intravenously. Primary outcome was the time to TOF count 0 after rocuronium administration. Secondary outcomes included recovery times to TOF counts

Results and Discussion: Group D had an average donepezil dose of 5 mg over a 24-month duration. The time to TOF count 0 was significantly longer in Group D, with a mean of 3.61 minutes, compared to the control group's 2.63 minutes (P= 0.006). Recovery to TOF count 1 was notably quicker in Group D, averaging 31 minutes, versus 50.24 minutes (P<0.001) in the control group. Recovery to TOF count 4 also showed a significant difference between Group D averaging 53.67 minutes and the control group averaging 71.05 minutes (P = 0.002).

Figure 1. Violin plots of onset times for neuromuscular blockade #

This figure illustrates the time to reach a train-of-four (TOF) count of 0 following the administration of rocuronium, which measures the onset of neuromuscular blockade. The donepezil group shows a significantly longer time to TOF count 0, indicating a delayed onset compared to the control group (p = 0.006).

Conclusion: The study indicates that donepezil affects the pharmacodynamics of rocuronium by prolonging its onset time and shortening recovery duration. These findings suggest the need for careful dose adjustment of neuromuscular blockers in the anesthetic management of dementia patients taking donepezil to ensure safe and effective anesthesia.

Comparison of hypotensive events during general anesthesia induction with remimazolam vs. propofol: a retrospective study

A. Hashimoto¹, Y. Fujiwara² ¹Meitetsu Hospital, Anesthesia, Nagoya, Japan, ²Fujita Health University, Bantane Hospital, School of Medicine, Anesthesiology and Pain Medicine, Nagoya, Japan

Background and Goal of Study: Remimazolam is a novel shortacting benzodiazepine general anesthetic. It is said to have advantages over traditional drugs like propofol, such as less impact on hemodynamics and reduced respiratory suppression. In this study, we retrospectively investigated the use of remimazolam in our hospital and examined whether the occurrence of hypotension during the induction of general anesthesia differed between remimazolam and propofol.

Materials and Methods: After obtaining approval from the hospital's ethics committee, data were extracted for patients who underwent general anesthesia in our hospital between October 1, 2023, and March 31, 2024. Patients under the age of 18, those who were induced with anesthetics other than remimazolam or propofol, and those who experienced anaphylactic shock or other forms of shock during anesthesia induction were excluded. Hypotensive events during anesthesia induction were defined as either a mean blood pressure below 60 mmHg or the use of vasopressors. Basic patient information, the occurrence of hypotensive events, induction anesthetic, history of hypertension, and history of diabetes were extracted from electronic medical records and anesthesia records. Logistic regression analysis was used to evaluate whether the type of induction anesthetic was related to the occurrence of hypotensive events.

Results and Discussion: Among 498 patients, hypotensive events occurred in 197 cases. Remimazolam was used in 258 cases. The incidence rates of hypotension with remimazolam and propofol were 38.0% and 41.4%, respectively, with no significant difference observed. Logistic regression analysis, including variables such as the type of induction anesthetic, age, ASA-PS, history of hypertension, and history of diabetes, revealed no factors significantly associated with the occurrence of hypotension. Patients who were administered remimazolam were significantly older and had a significantly higher incidence of hypertension and diabetes.

Conclusion(s): The occurrence of hypotensive events during the induction of general anesthesia was not related to the type of anesthetic used, whether remimazolam or propofol.

41AP01-10

The effects of topical pharyngeal anaesthesia on patient tolerance and recovery time following gastroscopy under sedation

S. Dickson¹, D. Cappellari¹, A. Wu¹ ¹Eastern Health, Anaesthesia, Melbourne, Australia

Background and Goal of Study: In Australia, elective gastroscopies typically involve intravenous sedation, sometimes supplemented with topical pharyngeal anaesthesia (TPA). Previous studies have produced mixed results regarding the benefits of TPA. This study aimed to evaluate patient tolerance and recovery experience by objectively measuring the procedural smoothness and recovery time, comparing between patients who received TPA and those who did not.

Materials and Methods: A prospective cross-sectional study was conducted between November 2021 and March 2024. Informed consent was obtained from a convenient sample of adult patients undergoing elective gastroscopy, baseline patient and anaesthetic data, procedural smoothness and recovery time were then recorded. Procedural smoothness was measured by the incidence and severity of desaturations, body movement, and procedural interruptions; and recovery time was measured by 1) the time spent in the post-anaesthetic care unit (PACU) until eating and/or drinking (E+D); and 2) until PACU discharge. Descriptive statistics and the Student's T Test were used to compare between the two

Results and Discussion: Of the 70 included patients, 39 (56%) received TPA, baseline characteristics were comparable between the groups. Propofol was the mainstay of sedation, adjunct medications included midazolam, alfentanil and fentanyl. Desaturation occurred in seven patients: four significant (<90%) and three mild (<95%). All desaturations, except one significant event, occurred in the group without TPA. Coughing, the most common form of body movement, was noted in 14 procedures (20%), slightly more frequent in patients not receiving TPA. Recovery times were longer in the TPA group, with patients taking an average of 47minutes to E+D compared to 39 minutes without TPA (p = 0.02), and 74 minutes to discharge compared to 58 minutes without TPA (p

Conclusion(s): The addition of TPA appeared to improve patient tolerance during gastroscopy by enhancing the procedural smoothness However, it significantly delayed patient recovery and discharge, leading to increased demands on hospital resources and higher costs. Given that this study was conducted in a small hospital with a limited sample size, the generalisability of these results is uncertain. As such, larger-scale studies are necessary to validate these findings.

Hemodynamic effect of remimazolam compared with sevoflurane in thoracic surgery

<u>S. Hagihira</u>¹, S. Aihara¹, R. Uno², O. Uchida¹, T. Kamibayashi¹

¹Kansai Medical University, Department of Anesthesiology, Hirakata, Japan, ²Kansai Medical University Medical Center, Department of Anesthesiology, Moriguchi, Japan

Background and Goal of Study: Remimazolam is a short acting benzodiazepine. It is known that benzodiazepines had little effect on hemodynamics. Here we retrospectively compared the hemodynamic effect of remimazolam with that of sevoflurane during general anesthesia with epidural anesthesia undergoing video assisted thoracoscopic surgery (VATS).

Materials and Methods: After approval of our local ethical committee (#2021071), we enrolled 174 patients who had undergone VATS for lung cancer. Remimazolam group (RM; 2020/10-2021/05) was 86 cases and sevoflurane group was 88 cases (SV; 2020/01-2020/06). After arrival in the operating room, epidural catheter was placed at T5/6 or T6/7. In RM group, anesthesia was induced with remimazolam infusion at 1.5-2.5 mg/kg/hr. In SV group, anesthesia was induced with propofol 1.0-1.2 mg/kg. After that 3-4 mcg/kg of fentanyl and 0.6 mg/kg of rocuronium was administered and a proper size of double-lumen endobronchial tube was intubated and arterial catheter was placed at either side of radial artery and arterial blood pressure was continuously monitored.

In RM group, anesthesia was maintained by remimazolam. Infusion rate was adjusted by observing raw EEG waveform on the BIS monitor. In sevoflurane group, anesthesia was maintained with sevoflurane at expired concentration of 1.1-1.3%.

For epidural analgesia, 1% lidocaine (7-9 mL) was given initially, followed by 0.25% levobupivacaine (7-9 mL) 30 minutes later. Levobupivacaine (5-7 mL) was then administered every 50-70 minutes.

If systolic blood pressure dropped below 70-80 mmHg, either ephedrine (4 mg) or phenylephrine (0.1 mg) was given, with the choice left to the anesthesiologist. We compared the frequency of intraoperative vasopressor use (per hour) between the two groups. Statistical analyses included Student's t-test for parametric data and the Mann-Whitney U test for non-parametric data.

Results and Discussion: We excluded 4 cases in SV group and 3 cases in RM group, as they required dopamine infusion. Demographic data were similar and no significant difference was found. Frequency of vasopressor use was 0 [0, 0.97] in RM group and was significantly less compared with 1.55 [0.65, 2.90] in SV group (median [25th, 75th]). 48 cases (57.8%) in RM group were vasopressor free while 8 cases (9.5%) in SV group.

Conclusion(s): Decrease of blood pressure was much less in remimazolam anesthesia compared with that in sevoflurane anesthesia even with thoracic epidural anesthesia.

41AP02-1

Case report: efficacy of capsaicin 8% (Qutenza) in the treatment of acute intercostal neuropathic pain post-removal of thoracic drainage tube

R. Arroyo Garrido¹, M.L. Corbella Galindo¹, <u>A. Pineda Sánchez-Migallón</u>¹, C. Martínez Borrego¹, G. Martín Merino¹, J. Olarra Nuel¹ ¹Hospital Universitario de Fuenlabrada, Anesthesiology, Fuenlabrada, Spain

Background: Intercostal neuropathic pain (INP) following the removal of an endothoracic tube is a common problem that can delay discharge and increase patient morbidity. Effective pain management is crucial, particularly in cases refractory to conventional therapies

This report illustrates the successful use of Qutenza (capsaicin 8%) applied perilesionally in a patient with severe INP, achieving immediate analgesia, discontinuation of systemic analgesics, and timely discharge.

Case report: A 73-year-old woman was admitted to the internal medicine unit with disabling right chest pain. Two weeks earlier, she underwent surgery for a rib fracture and hemothorax, which required the placement and subsequent removal of an endothoracic drainage tube. Despite treatment with NSAIDs, opioids, and anticonvulsants, her pain persisted at 10/10 on the Numerical Rating Scale (NRS), severely impairing her quality of life and delaying discharge. The acute pain unit proposed perilesional application of Qutenza. After preparing the area with topical lidocaine 4%, the capsaicin patch was applied to the affected intercostal region. Within 24 hours, a significant pain relief (1/10 NRS), enabling the discontinuation of systemic analgesics, was reported allowing her to be discharged home.

Discussion: This case demonstrates the efficacy of Qutenza in managing refractory INP. The rapid onset of analgesia aligns with evidence suggesting capsaicin patches are a viable alternative to systemic therapies. Although guidelines often recommend topical treatments as second-line options, recent studies have shown that capsaicin patches can outperform oral agents such as pregabalin in localized neuropathic pain (1).

Emerging algorithms for treating localized neuropathic pain increasingly propose topical analgesics, including capsaicin patches, as first-line options, particularly for patients who cannot tolerate systemic therapies (2).

References:

1. Haanpää M, Cruccu G, Nurmikko TJ, McBride WT, Docu Axelarad A, et al. Capsaicin 8% patch versus oral pregabalin in patients with peripheral neuropathic pain. Eur J Pain. 2016;20:316-28.

2. Allegri M, Baron R, Hans G, Correa-Illanes G, Rojals VM, et al. A pharmacological treatment algorithm for localized neuropathic pain. Curr Med Res Opin. 2016;32:377-84.

Learning points: Perilesional application of capsaicin should be considered a viable and effective option for managing post-operative acute neuropathic pain, especially in refractory cases.

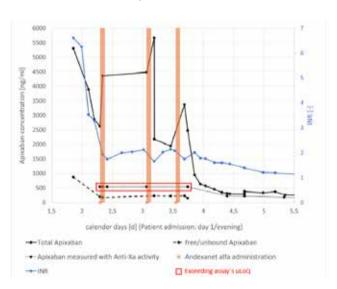

Concentration-time course of Apixaban after a massive overdose and repetitive treatment with Andexanet alfa – a case report

J.M. Rosenberger¹, R. Kraus¹, A. Dejaco¹, M. Paal², R. Burkhardt³, M. Kees¹

¹University Hospital Regensburg, Anaesthesiology, Regensburg, Germany, ²LMU University Hospital, Institute of Laboratory Medicine, Munich, Germany, 3University Hospital Regensburg, Institute of Laboratory Medicine, Regensburg, Germany

Background: Ondexxya^R (Andexanet alfa) is used to antagonise direct Xa inhibitors, e.g. apixaban, but has a shorter effective halflife (1). We report a case of massive apixaban poisoning and lifethreatening intraabdominal hemorrhage.

Case report: A man in his 50s presented with self-inflicted stab wounds and hemorrhagic shock. He was on apixaban for atrial fibrillation. Surgical exploration revealed intraabdominal bleeding. Coagulation parameters suggested relevant apixaban activity. Conventional procoagulatory treatment was applied (PPSB, fresh frozen plasma, platelets), but bleeding persisted, necessitating abdominal packing. An automated chromogenic anti-Xa-assay showed supratherapeutic levels exceeding the uLoQ (>541.3 ng/ mL). Ondexxya^R was administered (800mg bolus + 960mg/2h). Clinical signs of bleeding decreased only temporarily, so Ondexxya^R was repeated after 18h. A third dosage of Ondexxya^R was given prior to depacking. Post-treatment analysis by isotope dilution LC-MS/MS revealed initial apixaban plasma concentrations of 5302 ng/mL (~20 to 80 fold therapeutic range) (2). Concentrations fell below 500 ng/mL only by day 4. Administration of Ondexxya^R were immediately followed by a transient increase in total apixaban concentrations and a drop of INR. No effect could be detected on unbound apixaban concentrations or elimination.

Discussion: Ondexxya^R appears to be effective also in massive overdosing, but may necessitate repeated administration. Combination with eliminatory strategies (e.g. plasmapheresis) might be reasonable.

References:

1. Connolly SJ. Crowther M. et al. Full Study Report of Andexanet Alfa for Bleeding Associated with Factor Xa Inhibitors. N Engl J Med 2019;380(14):1326-35. PMID: 30730782.

2. Byon W, Sweeney K, et al. Population Pharmacokinetics, Pharmacodynamics, and Exploratory Exposure-Response Analyses of Apixaban in Subjects Treated for Venous Thromboembolism. CPT Pharmacometrics Syst Pharmacol 2017:6(5):340-9. PMID: 28547774.

Learning points: Andexanet alfa can stabilize bleeding in massive apixaban overdose but may require repeated dosing and adjunctive therapies.

Suicide attempts can include "synergistic" strategies.

41AP02-3 Remifentanil - a case of profuse sweating

C. Martins¹, M.M. Pereira Campos Mugeiro¹, I. Portela¹, N. Carrilo-Alfonso¹, S. Gestosa¹, A. Lares¹ ¹Unidade Local de Saúde do Algarve, Serviço de Anestesiologia, Faro, Portugal

Background: Diaphoresis during general anaesthesia (GA) is uncommon and the differential diagnosis can be challenging as multiple factors may play a role.1 Adverse drug reaction may be a potential cause. In this case report we present diaphoresis as a possible adverse reaction to remifentanil during total intravenous GA.

Case report: An 83-year-old male, ASA IV, was scheduled for total gastrectomy for adenocarcinoma. Past history included hypertension, dyslipidemia and moderate aortic stenosis. No allergy history. Total intravenous GA was chosen with Propofol and Remifentanil, titrated to bispectral analysis values between 40-60 and hemodynamic stability. Induction with orotracheal intubation was uneventful. After 30 minutes, the patient began to sweat profusely. In a systematic ABCDE approach, there were no ventilatory changes, the patient was hemodynamically stable with isochoric and isoreactive pupils, normoglycemic, apyretic and with no skin alterations. Depth of anaesthesia and infusion systems were adequate. Remifentanil was suspended and 15 minutes after, the profuse sweating stopped.

Discussion: Diaphoresis seldom occurs during GA and the differential diagnosis comprises several factors such as thermal overheating through excessive draping, metabolic or respiratory disturbances (thyrotoxicosis, hypoglycaemia, pheochromocytoma, hypoxia or hypercarbia), autonomic dysfunction and inadequate depth of anaesthesia.1 In this case, after exclusion of other causes using an ABCDE systematic approach, an adverse drug reaction was suspected as the diaphoresis ceased after suspending remifentanil perfusion. Remifentanil is an ultrashortacting synthetic opioid receptor agonist indicated for intravenous administration as an analgesic agent during the induction and maintenance of GA. Although the most common side effects during GA are bradycardia and hypotension, diaphoresis has been described when used for monitored anaesthetic care.2

References:

- 2. Lauwers M, et al. The safety and effectiveness of remifentanil as an adjunct sedative for regional anesthesia. Anesth Analg. 1999;88(1):134-140

Learning points:

- An ABCDE systematic approach to intraoperative complications is important for diagnosis.
- Diaphoresis is rare under GA and has been described as a Remifentanil adverse reaction.

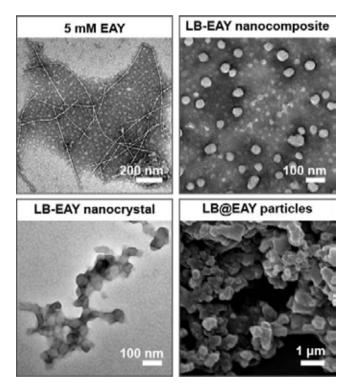

41AP02-4

Levobupivacaine interacting with a self-assembling peptide to form a slow-releasing formulation for long-acting analgesia

S. Liu1, J. Liu1, W. Wu1, F. Qiu1, W. Zhang1 West China Hospital, Sichuan University, Department of Anaesthesiology, Chengdu, China

Background and Goal of Study: Moderate to severe postoperative pain usually lasts 48-72 hours 1. Thus, there is a high need for long-acting analgesia in clinic. Local anaesthetics (LAs) were commonly used in the management of pain due to their fast-onset, low toxicity and non-addictiveness. To achieve long-term analgesia, slow-releasing formulations of LAs have been extensively studied.

Materials and Methods: We designed a self-assembling peptide EAY which was negatively charged as the carrier of levobupivacaine (LB). Thioflavine (ThT)-binding test, and transmission electron microscopy (TEM) were applied to characterise EAY. EAY was further used to encapsulate LB to prepare formulation in a bottom-up strategy. The morphology of LB@EAY particles was observed under scanning electronic microscope (SEM) and the releasing profile of drug particles in vitro was studied using the dialysis method. In addition, the analgesia efficacy of formulations was evaluated in rat sciatic nerve block (SNB) model.

Results and Discussion: EAY at the concentration of 5 mM could self-assemble into nanofiber in solution. EAY could interact with LB in solution to form nanoparticles through charge attraction, which could further form nanocrystal by alkalizing pH. LB@EAY formulation showed milky suspension and was composed of uniform nanoparticles. In the SNB model, each rat received a single injection of 0.2 ml of drugs. The nerve block duration for 4% LB@ EAY formulation lasted for 20.25 ± 7.42 hr. which was significantly longer than that for 0.75% LB hydrochloride (4.00 ± 1.11 hr) and 1.33% bupivacaine liposome (4.67 ± 1.51 hr). In addition, local injury scores for 4% LB@EAY including inflammatory cell infiltration, myocytotoxicity and axonal degeneration at 4 and 14 days after injection were similar to those for 0.75% LB hydrochloride. indicating the safety of formulation.

Conclusion(s): The self-assembling peptide EAY could high efficiently encapsulate LB to form stable slow-releasing formulation with long-acting nerve block.

Induction of general anesthesia during elective surgery in adults: A randomized, double-blind, phase 3 study of HSK3486 vs propofol (HSK3486-309)

A.W. Gelb¹, W.L. Daley², S. Bialka³, S.S. Nedeljkovic⁴, R. Badenes⁵, T.J. Gan⁶

¹University of California San Francisco, Department of Anesthesia and Perioperative Care. San Francisco. United States, ²Haisco-USA Pharmaceuticals, Inc., Department of Research and Development (R&D) and Medical Affairs, Global Clinical Operations, Bridgewater, United States, ³Medical University of Silesia, Department of Anaesthesiology and Intensive Care, Katowice, Poland. 4Brigham and Women's Hospital, Department of Anesthesiology, Perioperative and Pain Medicine, Boston. United States, 5Hospital Clinic Universitari, Department of Anesthesiology, Surgical-Trauma Intensive Care and Pain Clinic, Valencia, Spain, 6The University of Texas MD Anderson Cancer Center, Division of Anesthesiology and Perioperative Medicine, Critical Care and Pain Medicine, Houston, United States

Background and Goal of Study: HSK3486 is a phenol-derivative, nonbarbiturate, injectable emulsion for IV anesthesia with fast onset and rapid, stable recovery. HSK3486 is in clinical development in Europe and the US, and approved for induction of general anesthesia in adults in China. The primary objective of HSK3486-309 (phase 3 study in Poland, Spain, and the US; NCT05486416) was to investigate the noninferiority of HSK3486 vs propofol in successful induction of general anesthesia.

Materials and Methods: The primary endpoint of HSK3486-309 (multicenter, randomized [2:1], double-blind, propofol-controlled study) was successful induction defined as Modified Observer's Assessment of Alertness/Sedation score ≤1 after study drug administration, ≤1 top-up dose, and no rescue drug use. Success rate differences and 95% CIs were calculated using Farrington-Manning, with a -8% noninferiority margin. Key secondary endpoints were injection-site pain on the Numerical Rating Scale (NRS) and a composite of successful induction with maintained anesthesia depth, without substantial cardiac and respiratory events. Subgroup analyses of the American Society of Anesthesiologists physical status classification I-II and III-IV, ages <65 and ≥65 years, and body mass index <35 and ≥35 kg/m² were also conducted. Safety endpoints included adverse events, abnormal vital signs, and electrocardiogram findings.

Results and Discussion:Of 465 randomized participants, 445 were anesthetized and included in the efficacy analyses (HSK3486, n=300; propofol, n=145). Successful induction was

patients

achieved in 298 (99.3%) participants with HSK3486 and 143 (98.6%) with propofol. The difference in success rates was 0.7% (95% CI. -2.62% to 4.04%: P<.001). HSK3486 was noninferior to propofol for successful induction.

HSK3486 and propofol had similar induction success rates in all subgroups, with 100% successful induction in the ≥65 years sub-

At least mild pain (NRS ≥1) during injection was reported by 19% of HSK3486 participants and 59% of propofol participants (P<.001). The proportion with successful induction for the composite endpoint was 27% with HSK3486 and 31% with propofol (P=.425). HSK3486 and propofol were well tolerated.

Conclusion(s):HSK3486 was noninferior to propofol for successful induction, meeting the primary endpoint of this study. HSK3486 was associated with significantly less pain on injection vs propofol. HSK3486 and propofol had similar success rates for induction in subgroups.

41AP02-6 Intrahospital oral benzodiazepine use in surgical

J.G. Verhoeven¹, R. Geensen¹, J.M. Hendriks², N. Hunfeld^{3,4}, J. Jeekel¹, M. Klimek⁵ ¹Erasmus University Medical Center, Neuroscience, Rotterdam, Netherlands, ²Erasmus University Medical Center, Surgery, Rotterdam, Netherlands, 3Erasmus University Medical Center, Hospital Pharmacy, Rotterdam. Netherlands, 4Erasmus University Medical Center, Intensive Care, Rotterdam, Netherlands, 5Erasmus University Medical Center, Anesthesiology, Rotterdam, Netherlands

Background and Goal of Study: Oral benzodiazepines used for treatment of insomnia and anxiety are widely used in the general population. Data regarding benzodiazepine use during hospitalization is scarce, especially in the surgical department. The goal of this study was to determine the prevalence of intrahospital oral benzodiazepine use in the surgical population of a tertiary care center.

Materials and Methods: A retrospective cohort study was conducted using routinely collected healthcare data in Erasmus University Medical Center in Rotterdam, the Netherlands. Main outcome measure was prevalence of oral benzodiazepines usage during hospitalization at surgical wards. Secondary outcomes were benzodiazepine consumption in Defined Daily Doses (DDD)1 and adjusted odds ratios for sex, and readmission to a surgical ward.

Results and Discussion: 10,896 patients representing 14,928 admissions were included in this cohort, corresponding to all adult surgical patients admitted between September 2018 and September 2022. Median age was 62 (50-72) and 8,761 out of 14928 (58.9%) were male. Prevalence of benzodiazepine administrations in the surgical department was 21.6%. Temazepam (33%), oxazepam (24%), zopiclone (19%) and lorazepam (13%) were prescribed most often. Median number of tablets given during hospital stay was 3 (interquartile range 1-7). The most consumed benzodiazepines during the study period (in DDD) were temazepam (4032), zopiclone (3991), lorazepam (1221) and oxazepam (968). Female patients were more likely to have been administered a benzodiazepine, with an adjusted odds ratio (OR) of 1.09 (95% confidence interval 1.00 to 1.19). Benzodiazepine administration during admission was positively associated with higher 30-day surgical readmission, with an adjusted OR of 1.37 (1.22 to 1.54).

Conclusion(s): 21.6% of surgical patients uses an oral benzodiazepine during hospital stay. Oral benzodiazepine use is associated with the female sex and surgical readmission.

41AP02-8 Intrathecal fluorescein in suspected cerebrospinal fluid leak

J.C. Santos¹, B. Moreira¹, P. Vaz Salvador¹, L. Gomes¹ ¹ULS Entre o Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal

Background: Cerebrospinal fluid (CSF) leaks can occur spontaneously or as a consequence of skull base tumors, trauma, or surgery. In most cases, surgical treatment is essential, with high success rates. Accurate confirmation of the leak and its precise location is crucial. However, even after imaging studies, the exact site often remains uncertain. Intrathecal fluorescein (IF) stains the CSF with a fluorescent green color and can be useful for detecting CSF leaks. Although historical concerns regarding its safety have limited its use, recent studies have shown that low doses of IF are safe and effective.

Case Report: A 31-year-old woman, ASA II, with a history of nasal surgery complicated by a CSF fistula, repaired using fibrin glue. Years later, she underwent resection of an ethmoidal meningocele in the context of bacterial meningitis. One month after surgery, she presented with complaints suggestive of CSF rhinorrhea. Imaging studies were inconclusive in identifying or excluding the presence of a CSF fistula. The patient was thus scheduled for nasal endoscopic surgery to exploration.

TIVA was performed with neuromuscular relaxation and orotracheal intubation, under standard ASA monitoring, BIS™, TOF, and INVOS™, without complications. The patient was placed in the left lateral decubitus, and a lumbar puncture was performed using a 25G Quincke needle. 10mLs of CSF were aspirated, mixed with 25mg of fluorescein, and administered into the subarachnoid

The entire nasal cavity was examined, including during a Valsalva maneuver, without confirming contrast leakage and ruling out the presence of a fistula. It was concluded that there was no indication to proceed with surgery. The patient experienced an episode of urinary retention after the procedure, which resolved with catheterization. No further complications were reported.

Discussion: This clinical case aims to support the use of IF as a simple and safe technique for the detection of CSF fistulas. Despite its off-label use, it represents a valuable tool, to guide and avoid surgical procedures. When recommendations are followed, the side effects with this technique are minimal.

References:

Karan Jolly et al., The efficacy and safety of intrathecal fluorescein. Safe intrathecal fluorescein-Rev Esp Anestesiol

Learning points: The identification and localization of CSF fistulas can be challenging and IF is useful in their detection. When recommendations are followed, the administration is safe.

41AP02-9

To stay or not to stay: a quality improvement project evaluating the effect of Prilocaine on unplanned admissions in day surgery

J. Bailey¹, E. Teh¹

¹Lister Hospital, Anaesthetics, Stevenage, United Kingdom

Background and Goal of Study: Results from our previous audit identified a concerning rate of unplanned admissions following day-case procedures at our institution where the only available intrathecal agent was Bupivacaine. We hypothesised that the use of short-acting intrathecal agents, such as Prilocaine, could reduce the incidence of these admissions. Prilocaine was subsequently introduced to the anaesthetic formulary, and a re-audit was carried out.

Materials and Methods: We conducted a retrospective analysis of all patients who received spinal anaesthesia as their primary anaesthetic modality at Lister Hospital between August 2023 and April 2024. Only Prilocaine and Bupivicaine were available as intrathecal agents during this period. Patient records were reviewed to identify unplanned hospital admissions, the intrathecal agent used, and any anaesthesia-related causes. These data were compared to our previous audit.

Results and Discussion: Of the 486 patients who received spinal anaesthesia as a primary anaesthetic modality, 74 were planned day cases. Prilocaine was used in 42 (56.8%) cases, and Bupivacaine in 32 (43.2%). Eleven (14.9%) patients required unplanned admissions, of which 3 (4.0%) were attributable to anaesthesiarelated causes. Two cases were associated with the use of Bupivacaine, and one with Prilocaine. Compared to our previous audit, we observed a 1.2% reduction in unplanned admissions

Our findings align with larger studies highlighting Prilocaine's potential to accelerate patient recovery and discharge, but our results do not show as clear a benefit as expected. In light of these findings, we are in the process of developing clear guidance for using Prilocaine in this setting and intend to conduct educational sessions to improve confidence around its use. Additionally we are designing a standardised discharge protocol, that may help to minimise inappropriate transfers to the ward and identify any issues earlier in a patient's recovery. These are both alongside further training for our clinical staff.

Conclusion: Our study aimed to reduce unplanned admissions following day-case surgery by introducing Prilocaine as an intrathecal agent. While we observed a modest reduction in unplanned admissions, further fine-tuning is necessary. To achieve this, we are implementing several strategies to enhance the use of Prilocaine and improve patient outcomes. A subsequent audit will assess the impact of these interventions.

41AP02-10

The use of neuromuscular blocking agents and its reversal in adult, pediatric and pregnant patients in Italy: a survey of current management

L. Brugiaferri¹, M. Ciuffreda², E. Pisello², A. Federici¹, C. Piangatelli², D. Galante³

¹Università Politecnica delle Marche, Department of Anesthesia, Resuscitation, Intensive Care and Pain Management, Ancona, Italy, 2 Ospedale E. Profili - AST Ancona, Department of Anesthesia, Resuscitation. Intensive Care and Pain Management, Fabriano, Italy, ³Ospedale Tatarella - ASL Foggia, Department of Anesthesia, Resuscitation, Intensive Care and Pain Management, Cerignola, Italy

Background and Goal of Study: Despite the existence of national and international guidelines in management of myoresolution, there is a persistent heterogeneity in the use of neuromuscular blocking agents by Italian anesthesiologists. The aim of this article is to show the results of an Italian survey conducted to obtain information on the current management of myoresolution in Italy. Materials and Methods: A digital questionnaire was created and spread in different ways (as link via social networks or by word of mouth) to obtain data among specialists and residents in Anesthesia during a period between February 2023 and February 2024. The questions were about the type of patient, neuromuscular blocking agents used, frequency of use and type of neuromuscular monitoring, TOF ratio value considered safe to assess recovery from myoresolution, use of reversals with side effects related, incidence of postoperative residual curarization (PORC). All the information obtained has been stratified by age, geographical location and type of workplace (public or private centre). Moreover, data were collected anonymously and were analyzed considering the values in percentages.

Results and Discussion: The questionnaire was completed by 287 anesthesiologists. Rocuronium is the most widely used neuromuscular blocking agent in adult, pediatric and pregnant patients. Neuromuscular monitoring is used most frequently in relation to the type of patient (ASA \geq 2) and the type of procedure (major surgery) in both adults and children. In pregnant women, anesthesiologists who never use it predominate. Sugammadex is the most widely used reversal in both adults, pregnant women and children. Neuromuscular monitoring systems are little used while the clinical manifestations would seem to guide the possible additional doses of neuromuscular blocking agents or to evaluate recovery from neuromuscular blockade. This is one of the aspects that can explain why the incidence of PORC is not so low. Conclusions: This survey highlight what is the current Italian experience regarding the myoresolution in pediatric and adult patients. The data obtained show that clinical practice in the management of correct myoresolution is still not standardized. The immediate consequence is the real risk of incomplete neuromuscular recovery. A routine use of neuromuscular monitoring systems should be pursued to manage both neuromuscular blocking agents and their reversals in a more rational and conscious way.

41AP02-11

Comparison of Remimazolam PK/PD models in maintaining moderate sedation during knee and hip arthroplasty: a randomized study

R. Serzans¹, <u>S. Kazune^{2,3}</u>, I. Golubovska^{3,4} ¹Riga Stradiņš University, Faculty of Medicine, Riga, Latvia, ²Riga Stradinš University, Department of Anaesthesiology and Intensive Care, Riga, Latvia, 3Hospital of Traumatology and Orthopaedics, Anaesthesiology and Intensive Care. Riga, Latvia, 4University of Latvia, Faculty of Medicine and Life Sciences, Riga, Latvia

Background and Goal of Study: Various PK/PD models based on different populations are available for Remimazolam precision dosing using infusion. This study compared three published models (Schmith, Schüttler, Masui) in achieving moderate sedation (MOAA/S 2-3) during knee or hip arthroplasty under spinal anesthesia. Primary endpoints were time in target sedation range, target adjustments, remimazolam consumption (ml/kg/h), and mean target effect-site concentration (Ce) for achieving target sedation, EC50. Secondary endpoints were correlation between calculated Ce and MOAA/S and Patient State Index (PSI).

Materials and Methods: Twenty-four patients meeting criteria were included (Figure 1). Remimazolam was administered using target-controlled infusion, guided by one of three models. Initial target Ce was set at 0.2-0.4 µg/mL over 10 minutes (0.2 mg/mL concentration). MOAA/S, PSI, and physiological parameters were evaluated every 5 minutes, with target Ce adjusted accordingly in steps of ≥0.05 µg/mL for moderate sedation.

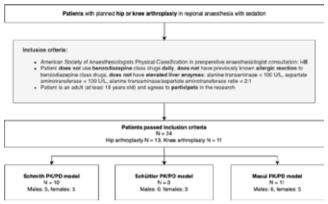

Figure 1. Study design.

Results and Discussion: Schmith model ensured the most time in target range (61%[45-77%]), followed by Schüttler (65%[33-97%]) and Masui (59%[41-78%]). Schüttler model required the fewest target adjustments (4[2-6]), while Masui and Schmith required 5[3-6]. Consumption was lowest with Masui model (0.209 mg/kg/h[0.163-0.294]). All differences were insignificant (p>0.05). Average Ce during sedation depth of MOAA/S 2-3 significantly differed between models (p<0.05): Schmith 0.186 mg/ mL[0.177-0.195], Schüttler 0.226 mg/mL[0.208-0.243], Masui 0.199 mg/mL[0.191-0.207]. Determined EC50 values: Schmith = 0.131[0.045-0.170], Schüttler = 0.175[0.021-0.228], and Masui = 0.116. Negative correlations were found between Ce and MOAA/S: Schmith (r=-0.329,p<0.05), Schüttler (r=-0.354,p<0.05), and Masui (r=-0.364,p<0.05). The correlation between Ce and PSI was moderate in Schüttler (r=-0.403,p<0.05), weak in Masui (r=-0.247,p<0.05).

Conclusions: Remimazolam PK/PD models demonstrated similar performance in maintaining sedation, each with specific strengths. PK/PD model calculated Ce correlated with clinical and measured sedation depth.

41AP02-12

Apnea during moderate to deep sedation using continuous infusion of remimazolam compared to propofol and dexmedetomidine

J. Lee¹, Y.K. Ko¹, Y.H. Kim¹

¹Chungnam National University Hospital, Anesthesiology and Pain Medicine, Jung-gu, Korea, Republic of

Background and Goal of Study: Remimazolam's rapid onset and offset make it an innovative sedative for use during regional anesthesia. However, its respiratory safety profile is not well understood. We compared the continuous infusion of remimazolam with commonly used sedatives, propofol and dexmedetomidine, after regional anesthesia.

Materials and Methods: This retrospective study included patients aged over 17, American Society of Anesthesiology (ASA) physical status 1 to 3, who underwent orthopedic surgery under regional anesthesia (neuraxial or brachial plexus blockade) and sedation with continuous infusion of dexmedetomidine, propofol, or remimazolam from February to December 2021.

Patients were designated as group R (remimazolam), P (propofol). or D (dexmedetomidine) according to the primary sedative used. Group R: remimazolam: 3 mg/kg/hr over 2 minutes followed by 0.5 mg/kg/hr continuous infusion

Group P: propofol: administered using target-controlled infusion (Schnider model), starting with 2-3 µg/mL

Group D: dexmedetomidine: 1 µg/kg infused over 10 minutes followed by 0.4-1 µg/kg/hr continuous infusion

Supplementary oxygen was routinely administered via a simple facial mask at a rate of equal to or above 5 L/min with side port expired CO₂ monitoring before the beginning of the sedation.

Apnea event was defined as expired CO₂<1 mmHg over consecu-

Several parameters related to apnea event including incidence (per group), total apnea time, number of event (per case), apnea index (apnea event per hour), and time of the first apnea event (onset time) were assessed.

Additionally, desaturation defined as SpO₂<94% over consecutive 30 seconds was assessed.

Results and Discussion: The apnea and desaturation events were summarized in Table. The incidence of apnea over 10 seconds was 63.9%, 67.3%, and 48.5% in group R, P, and D, respectively (overall, p<0.001). The incidence of desaturation over 30 seconds was 19.9%, 20.9%, and 10.9% in group R, P, and D, respectively (overall, p=0.022).

Several statistical measures were implemented to minimize potential biases in this study, but some limitations remain. The intervention threshold for apneic events was not predetermined, varying with the attending physician, potentially biasing outcomes such as total apnea time, apnea events per case, and desaturation events.

However, bias in the overall apnea incidence should be minimal, as no preventive measures were selectively applied in advance. The level of sedation was unreported, possibly causing an imbalance in sedation depth between groups. Despite this, sedations adhered to institutional protocol, suggesting significant variations, especially at initiation, were unlikely, and the protocol aimed for at least moderate sedation.

	Remimazolam	Propofol	Dexmedeto-				
	(R)	(P)	midine (D)	Overall P	D vs P	D vs R	R vs P
	(n=191)	(n=278)	(n=165)		p*	p*	p*
Apnea incidence (incidence per group)							
0	69 (36.1)	91 (32.7)	85 (51.5)	<0.001	<0.001	< 0.007	<0.508
1-2	51 (26.7)	82 (29.5)	42 (25.5)	NA	NA	NA	NA
>2	71 (37.2)	105 (37.8)	38 (23.0)	NA	NA	NA	NA
Total apnea time (seconds)	39.0 (0.0, 115.5)	40.5 (0.0, 185.0)	0.0 (0.0, 61.0)	<0.001	<0.001	<0.104	<0.018
Apnea event (per case)	1.0 (0.0, 4.0)	2.0 (0.0, 5.0)	0.0 (0.0, 2.0)	<0.001	0.011	0.194	0.173
Apnea index (event per hr)	1.0 (0.0, 3.3)	1.5 (0.0, 5.0)	0.0 (0.0, 1.7)	<0.001	<0.001	0.247	0.004
Apnea onset (min)	8.9 (4.6, 15.7)	9.5 (5.1, 18.8)	18.6 (10.5, 29.1)	<0.001	0.001	0.001	0.774
Desaturation event (incidence)	38 (19.9)	58 (20.9)	18 (10.9)	0.022	0.032	0.044	0.890

Conclusion: The findings of the current study demonstrated a considerable incidence of apneic events during moderate to deep sedation with remimazolam infusion. Although these events did not result in severe adverse events, it is important not to underestimate the risk of apnea, and close monitoring is strongly advised.

41AP03-1 Successful use of terlipressin to treat refractory shock after adrenal vein ligation in pheochromocytoma surgery

J. Elmawieh¹, A. Voicu¹ Gustave Roussy Cancer Campus, Anesthesiology, Villejuif, France

Background: Severe hypotension after adrenal vein ligation in pheochromocytoma surgery can be extremely severe and catecholamine-resistant [1]. Underlying mechanisms are sudden catecholamine deficiency in combination with a down-regulation of catecholamine receptors caused by chronic elevation of catecholamines. Chronic elevation of catecholamines may also suppress vasopressin synthesis.

Case Report: A 36-year-old female patient with a medical history of a 14x10 cm right adrenal paraganglioma (pheochromocytoma) metastatic to liver and secreting metanephrine (>100x normal levels) and normetanephrine (>40x normal levels) underwent open surgery after 2 weeks of pharmacological preparation with prazosin. Intraoperative tachycardia events were treated with landiolol and hypertensive events (systolic blood pressure >180 mmHg) with a continuous infusion of urapidil. Adrenal vein ligation was anticipated by stopping urapidil and maintaining adequate systolic blood pressure (>140 mmHg). After ligation, a severe drop in blood pressure was noted with a systolic blood pressure of approximately 40 mmHg for 10 minutes despite a high dose of noradrenaline exogenous infusion (up to 2 mg/hr) and fluid load. Terlipressin 0.5 mg was administered and resulted in a rapid correction of blood pressure and a decrease of noradrenaline support up (to 0.1 mg/hr) in just a few minutes.

Discussion: Terlipressin is a long-acting vasopressin analog with a partial selectivity for vasopressin V1a receptor. Several case reports described vasopressin use in a refractory shock after pheochromocytoma resection, but this is the first case report describing terlipressin use in this setting. Terlipressin is used with multiple-dose regimens in refractory septic shock [2] with a usual dose of 1 mg each 4 to 6 hours but this high dose can be associated with side effects and complications, such as mesenteric and digital ischemia. A low dose of terlipressin (bolus 0.5 mg or low continuous dose 1-2 mcg/kg/hr) can be sufficient to reverse hypotension and minimize side effects.

- 2. Terlipressin for septic shock patients: a meta-analysis of randomized controlled study. Zhu Y et al. J Intensive Care (2019) Learning Points: Terlipressin can be used in severe hypotension refractory to catecholamines after pheochromocytoma resection. Low-dose terlipressin is to be used to minimize potential side effects.

41AP03-2

Opioid resistance in a patient with prolonged cessation of oral naltrexone use: a case report

G. Sanine de Carvalho1, M. Garbin Ruiz1, J. Victor Alvachian Andrade¹, B. Gonçalves Miron¹, C. Haddad Silveira¹, G. Giroldo Badessa¹ ¹São Camilo University Center, Anesthesiology, São Paulo, Brazil

Background: The suspension of medications like Naltrexone is critical in anesthesiology. The case presented here illustrates a situation that deviates from established protocols1 and in which the interpretation is similar to other published reports².

Case Report: A 37-year-old woman underwent total thyroidectomy with general anesthesia and electrophysiological monitoring. Her history included chronic headaches treated with simple analgesics and recent use of Naltrexone for weight loss, discontinued 30 days pre-surgery. Upon admission, She presented with anxiety, managed with Midazolam, and received Sufentanil, Lidocaine, Propofol, Succinylcholine, and Ketamine for induction. During the surgery, the patient experienced increased heart rate, blood pressure, tremors, and a rise in Bispectral Index values, which required analgesic rescue. This pattern repeated, necessitating high doses of opioids (Sufentanil 0.7 mcg/kg, Remifentanil 1.5 mg) and adjuvants (Ketamine 0.55 mg/kg, Clonidine 1 mg/kg, Lidocaine 1.38 mg/kg). At the end of the procedure, extubation occurred without complications, 15 minutes after discontinuing Propofol.

Postoperatively, she experienced severe pain (7/10), treated with morphine, ketorolac, and dipyrone, yielding partial relief. Later, she disclosed prior use of high-dose Naltrexone (64 mg/day) and Bupropion (720 mg/day) for five months before stopping.

Discussion: The findings suggest prolonged Naltrexone effects, including opioid resistance persisting after its cessation. This resistance may result from extended use and high dosing, highlighting the need for revised perioperative management protocols in patients discontinuing Naltrexone.

"Perioperative Naltrexone Management: A Scoping Review by the Perioperative Pain and Addiction Interdisciplinary Network." Anesthesiology 141 (2): 388–99. https://doi. org/10.1097/aln.0000000000005040.

2. Tesson, B, A Bigot-Viale, J P Vigue, M Pierrot, and J C Granry. 1999. "Interactions between Naltrexone, an Opioid Antagonist, and Opioids Administered during General Anesthesia." Annales Françaises d'Anesthesie et de Reanimation 18 (2): 230-32. https://pubmed.ncbi.nlm.nih.gov/10207596/.

Learning Points: This case highlights the importance of suspending Naltrexone in perioperative management and the need for more evidence, particularly regarding its prolonged use.

41AP03-3 When ondansetron hits different: a rare extrapyramidal reaction

C. Silva Dias¹, J.B. Santos Fraga¹, F. Santos¹, J. Gaspar¹, F. Faria1

¹Instituto Português de Oncologia do Porto Francisco Gentil, Anaesthesiology and Intensive Care, Porto, **Portugal**

Background: Ondansetron, a 5-HT3 receptor antagonist, is widely used for managing nausea and vomiting in perioperative settings and chemotherapy. Common neurological side effects include fatigue, headache, and malaise. Extrapyramidal reactions are rare and mostly associated with metoclopramide. Reports of ondansetron-induced reactions are limited to a few outdated

Case Report: A 77-year-old male with stage IV small cell lung cancer (no cerebral metastases) experienced altered mental status and facial paresis minutes after ondansetron administration, initially suspected to be an acute vascular event. Angio-CT was normal, and symptoms resolved within 1.5 hours.

Days later, similar symptoms recurred, again linked to ondansetron. Severe hyponatremia complicated the case, but symptoms resolved minutes after biperiden administration, implicating ondansetron despite other confounding factors. Recognizing this rare adverse reaction required thorough evaluation and exclusion of life-threatening conditions.

Discussion: Nausea and vomiting are common in oncology, with ondansetron frequently used due to its safety and efficacy. Extrapyramidal reactions to ondansetron are rarely reported, but they can range from mild impairment of movements to altered mental status states, with airway compromise, sustaining a threat to life.(1)(2)

This case presented with altered mental status and facial paresis, mimicking vascular or cardiac events. Severe hyponatremia was initially considered as the cause, but detailed analysis of drug timing implicated ondansetron. Biperiden, an anticholinergic used for extrapyramidal symptoms, effectively reversed the reaction. Accurate drug history and high clinical suspicion were critical to diagnosis. Oncologic patients are often fragile, with multiple comorbidities and aggressive treatments. Every administered drug must be carefully assessed to minimize risks.

References:

- 1. Ritter MJ, Goodman BP, Sprung J, Wijdicks EFM. Ondansetron-induced multifocal encephalopathy. Mayo Clin Proc. 2003;78(9):1150-2.
- 2. Kumar N, Hu WTL. Extrapyramidal reaction to ondansetron and propofol. Mov Disord. 2009;24(2):312-3.

Learning Points: Ondansetron adverse reactions can mimic lifethreatening conditions; prompt and accurate investigations are essential.

In complex cases, a detailed drug history and high index of suspicion aid diagnosis.

Awareness of this rare reaction can avoid unnecessary diagnostics and inappropriate treatments.

41AP03-4

Optimizing sedation in endoscopic retrograde cholangiopancreatography: validation of a pharmacodynamic response surface model

C.-L. Huang¹, J.-Y. Liou¹, C.-K. Ting¹, W.-K. Chang¹ ¹Taipei Veterans General Hospital, Anesthesiology, Taipei, Taiwan

Background and Goal of Study: Endoscopic Retrograde Cholangiopancreatography (ERCP) requires precise sedation to ensure patient comfort and safety while maintaining rapid recovery. Advances in anesthetic monitoring, particularly the use of raw EEG, have improved our understanding of anesthesia depth. The interaction of anesthetic agents, however, remains challenging due to inter- and intraindividual variability. An existing NLMAZ response surface model has been validated for predicting patient responses to sedation with a triple-drug combination of midazolam, alfentanil, and propofol during endoscopic procedures. This study aimed to validate the Non-Linear Mixed Amount with Zero Amount (NLMAZ) response surface model for predicting sedation depth in patients undergoing Endoscopic Retrograde Cholangiopancreatography (ERCP), to explore the pharmacodynamics of multidrug anesthesia regimens.

Materials and Methods: Patients undergoing ERCP in Taipei Veterans General Hospital during January 2023 to March, 2024 under intravenous sedation were included. Sedation depth was assessed using the Modified Observer's Assessment of Alertness/ Sedation (MOAA/S) score and effect-site concentrations calculated from pharmacokinetic models. Custom MATLAB scripts analyzed EEG data for frequency power changes to correlate sedation depth with drug combinations.

Results and Discussion: Patient recruitment faced challenges and seven patients undergoing ERCP were included. The NLMAZ model achieved a prediction accuracy of 70% for MOAA/S <2, consistent with previous validation studies (76%-83%). EEG power analysis demonstrated characteristic changes during sedation, including increased alpha and delta activity. Positional effects, such as reduced alpha power in prone positioning, were noted, likely due to altered cerebral perfusion or CSF distribution.

The NLMAZ model effectively predicted anesthetic depth with acceptable accuracy in ERCP, demonstrating its applicability to clinical sedation management. However, individual variability and procedural factors such as positioning influenced the model's predictive accuracy.

Conclusion(s): The NLMAZ model is a valuable tool for optimizing sedation in ERCP. While effective, further studies with larger datasets are needed to refine predictions and explore the impact of positional and physiological factors on sedation depth.

41AP03-5 HX20304: a novel non-opioid compound with potent analgesic effects

X. Xie1, C. Deng1, S. Liu1, P. Gao1, W. Zhang1 ¹West China Hospital of Sichuan University, Department of Anesthesiology, Chengdu, China

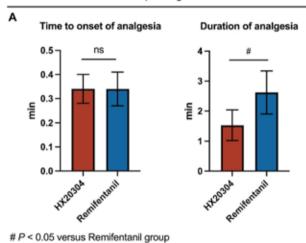

Background and Goal of Study: It is necessary to develop new powerful analgesics because of the global opioid crisis. The purpose of this study is to determine the potent analgesic effects of a novel non-opioid compound.

Materials and Methods: We obtained the non-opioid compound HX20304 based on previous studies. With remifentanil as the positive control, the tail clip test using an alligator clip was applied to determine the strong analgesic effect of HX20304, and plantar incision and spared nerve injury (SNI) models were used to demonstrate the effects of HX20304 in other pain.

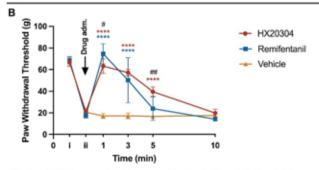

Using naloxone antagonism test to explore the relationship between HX20304 and opioid receptors. Mann-Whitney U test and two-way ANOVA analysis were applied with P<0.05 for signifi-

Results and Discussion: HX20304 exhibited strong analgesic effects in tail clip test, plantar incision, and SNI models, comparable to remifentanil. Using naloxone did not antagonize the analgesic effect. Based on these, we obtained a novel compound exhibiting potent analgesic effects without acting on opioid receptors.

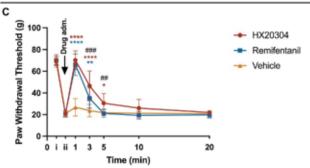

Analgesia in plantar incision 1 hour

**** P < 0.0001 versus Vehicle group; ## P < 0.01, and # P < 0.05 versus Remifentanil group; i, baseline; ii, modeling

Analgesia in SNI-induced neuropathic pain 14 days

**** P < 0.0001, ** P < 0.01, and * P < 0.05 versus Vehicle group; ### P < 0.001, and ## P < 0.01 versus Remifentanil group; i, baseline; ii, modeling

Antagonism of the analgesic effect by naloxone				
Drug/Compound	Antagonistic rate (%)			
Remifentanil	100			
HX20304	0			

Conclusion(s): HX20304 is a novel analgesic compound with the following characteristics: (1) non-opioid structure; (2) strong analgesic effects comparable to opioids; (3) no acting on opioid receptors. Further research will be done on the analgesic target and mechanism of HX20304.

41AP03-6

A rare cases of methaemoglobinaemia in cancer patients: clinical cases

A. Abildayeva¹, E. Seidaliyeva¹, B. Aliyeva¹, R. Zhumabiyev¹, N. Abdukhalilov1

¹Kazakh Research Institute of Oncology and Radiology, Anesthesiology and Intensive Care, Almaty, Kazakhstan

Background: Methemoglobinemia is a serious disorder characterized by impaired oxygen binding to iron in hemoglobin, followed by impaired oxygen delivery to body tissues. Various benzocainecontaining drugs can cause acquired methemoglobinemia. It is important for healthcare professionals to be aware of the signs and symptoms of methemoglobinemia and have a high index of suspicion for patients with unexplained cyanosis or impaired oxygen delivery.

Case report: The presented clinical cases describe methemoglobinemia associated with the use of the antacid Almagel A (magnesium hydroxide + benzocaine) in a 32-year-old woman with laryngopharyngeal cancer and a 45-year-old woman diagnosed with left kidney cancer, who were hospitalized at the Kazakh Research Institute of Oncology and Radiology.

Patients were transferred to the intensive care unit with symptoms of respiratory failure, such as cyanosis, fatigue, headaches, tachypnea and decreased saturation (SPO2) to 74-78% by pulse oximetry. Instrumental and laboratory study parameters were normal.

Arterial blood gas analysis showed an increase in the methemoglobin fraction (FMetHb) - 24-49% and a decrease in the oxyhemoglobin fraction (FO2Hb) 74-47%.

Patients were prescribed antidote therapy - methylene blue 1% at a rate of 1 mg / kg in the form of infusion. Arterial blood gas analysis (FMetHb, FO2Hb), saturation and skin color were monitored.

As a result, against the background of methylene blue infusion, patients showed clinical improvement with the disappearance of cyanosis, normalization of the FMetHb and FO2Hb in arterial blood.

Discussion: The presented clinical cases indicate that the use of over-the-counter drug magnesium hydroxide + benzocaine in patients can lead to serious adverse effects, such as methemoglobinemia and may cause life-threatening conditions, especially in patients with severe diseases.

References:

1. Iolascon A., Bianchi P., Andolfo I., Russo R., Barcellini W., Fermo E., Toldi G., Ghirardello S., Rees D., Van Wijk R., Kattamis A., Gallagher P.G., Roy N., Taher A., Mohty R., Kulozik A., De Franceschi L., Gambale A., De Montalembert M., Luca Forni G., Harteveld C.L., Prchal J. Recommenda-tions for diagnosis and treatment of methaemoglobinaemia // Am. J. He-matol. - 2021. -Vol. 2021

Learning points: These clinical cases demonstrate the difficulties of diagnosing methaemoglobinaemia and the effectiveness of using methylene blue as an antidote drug in treatment.

41AP03-7

Enhanced propofol toxicity via energy metabolism shift by circumventing the Crabtree effect: analysis of myoblasts and myotubes

Y. Kammura¹, Y. Mizuta¹, W. Li¹, T. Akahoshi², K. Yamaura¹ ¹Kvushu Universitv. Graduate School of Medicine. Department of Anesthesiology & Critical Care Medicine, Fukuoka, Japan, 2Kyushu University, Graduate School of Medicine, Department of Advanced Emergency and Disaster Medicine, Fukuoka, Japan

Background and Goal of Study: Propofol infusion syndrome (PRIS) predominantly affects pediatric patients and is associated with mitochondrial dysfunction; however, its underlying mechanisms remain unclear. In perioperative sedation, factors such as insulin resistance, fasting, reduced physical activity, and catecholamine release can limit glycolysis, shifting energy production to oxidative phosphorylation (OXPHOS). Skeletal muscle cells typically rely on glycolysis under glucose-rich conditions (Crabtree effect), but culturing cells in galactose medium suppresses glycolysis and forces reliance on OXPHOS as the primary energy source.

This study evaluated how such metabolic shifts affect propofol toxicity in skeletal muscle cells.

Materials and Methods: L6 myoblasts and myotubes were cultured in glucose and galactose medium to circumvent the Crabtree effect, shifting metabolism from glycolysis to OXPHOS. Propofol toxicity was assessed by measuring cell viability, lactate dehydrogenase (LDH) release, ATP production, and wound healing via scratch assay (n=3). Dexmedetomidine was tested under similar conditions to compare effects on cell viability and wound healing. Statistical analysis used ANOVA, with p<0.05 considered significant.

Results and Discussion: In galactose medium, propofol exposure significantly reduced cell viability (87.94% ± 2.55, p<0.05) at lower concentrations than in glucose medium, with increased LDH release, reduced ATP production, and impaired wound healing $(23.02 \pm 0.12\% \text{ to } 10.45 \pm 0.86\%, p<0.001)$. These effects were more pronounced in myoblasts compared to myotubes. In contrast, dexmedetomidine maintained cell viability and promoted wound healing regardless of the metabolic state. Skeletal muscle, which accounts for approximately 70% of systemic glucose utilization, is thought to be highly sensitive to metabolic disruptions, suggesting a potential role in the pathophysiology of PRIS. Particularly in pediatric patients with active muscle development, skeletal muscle metabolism may contribute significantly to PRIS susceptibility.

Conclusion(s): Propofol showed greater toxicity in myoblasts than in myotubes, with toxicity significantly enhanced under OX-PHOS-dependent conditions. These results highlight the importance of further investigation into skeletal muscle metabolism and its role in the pathophysiology of PRIS, particularly in pediatric populations.

41AP03-9

Anesthetic management of pheochromocytoma surgery. Case series

I. Zaragoza García¹, C. Luis Garcia¹, A. Fernández Castiñeira¹, M. Puyada Jáuregui¹, C.C. Llaja1, L. Trillo Urrutia1 ¹Hospital del Mar, Anestesiologia i Reanimació, Barcelona, Spain

Background: Pheochromocytoma is a catecholamine-producing tumour that can be treated with laparoscopic adrenalectomy. There is a risk of hypertensive crises due to the release of catecholamines. Patients typically present with arterial hypotension following resection due to relative vasodilatation and the residual effect of antihypertensive drugs.

Case report: Patient 1(P1): 36-year-old male with neurofibromatosis, diagnosed due to metanephrines determination. Premedication (PM): nifedipine.

P2: 55-year-old female with hypertension.

PM: doxazosin, nifedipine, propranolol. P3: 73-year-old male with palpitations and tremors.

PM: nifedipine. P4: 60-year-old female with a history of essential hypertension and hyperhidrosis. PM: doxazosin and propranolol. P5: 39-year-old male with a weight loss and hypertension.

PM: doxazosin, atenolol, nifedipine. P6: 56-year-old female with chest discomfort and hypertension.

PM: doxazosin, nifedipine, bisoprolol. P7: 58-year-old female with headache and hypertension.

PM: nifedipine, propranolol. Upon entering the operating room, it was observed that each patient exhibited hemodynamic stability. An epidural catheter was placed for post-operative analgesia, and general anaesthesia was performed.

The hemodynamic parameters were monitored by the Vigileo-FloTrac system, while nociception was assessed by nociceptor index (NOL) levels in patients 6 and 7. The NOL proved an effective method of distinguishing between haemodynamic changes resulting from catecholamine release or nociceptive stimulation. All patients received clevidipine infusion at the outset of the surgical procedure, which proved effective in reducing hypertensive peaks within minutes.

Following tumour excision, clevidipine was discontinued in all patients. Arterial hypotension occurred in all patients but was rapidly resolved with fluid therapy comprising objective infusion rates and intermittent boluses of phenylephrine. No patients required vasopressor infusion.

Discussion: Clevidipine is an intravenous calcium antagonist with rapid onset and a short half-life, which could be an optimal antihypertensive agent in the treatment of pheocromocytoma¹

References:

1.Luis C et al. Clevidipine for hypertension treatment in pheochromocytoma surgery. Rev Esp Anestesiol Reanim 2018 Apr:65(4):225-228

Learning points: It is essential to control haemodynamic parameters in pheochromocytoma surgery, with the use of fast and reversible drugs, with monitoring to ensure proper administration

Conclusion(s): Cefazolin 2g before incision and 1g after 2 hours provided optimal coverage for the initial surgery phase. However, additional doses, depending on surgery duration and patient characteristics (e.g., eGFR), are crucial to maintain adequate concentrations until closure. Increasing the sample size could provide more significant data.

Pharmacokinetics and pharmacodynamics of cefazolin: clinical implications for antibiotic prophylaxis in urologic and thoracic surgery preliminary results

E. Giusiano¹, S. Zuccolin¹, G. Menegatti², E. Ceraolo³, A. D'Avolio². G. Montrucchio^{1,3} ¹University of Turin, Department of Surgical Sciences,

Turin, Italy, 2University of Turin, Department of Medical Sciences, Laboratory of Clinical Pharmacology and Pharmacogenetics, Amedeo di Savoia Hospital, Turin, Italy, 3 Città della Salute e della Scienza, Department of Anesthesia, Intensive Care and Emergency, Turin, Italy

Background and Goal of Study: Surgical site infections (SSIs) are frequent healthcare-associated infections, causing significant morbidity, mortality, and costs. Antibiotic prophylaxis (AP), particularly with cefazolin, is vital for prevention. However, doubts persist about timing of administration, dosage, and redosing

This study aimed to: evaluate AP through a pharmacokinetic/ pharmacodynamic (PK/PD) approach, measuring cefazolin plasma concentrations and comparing them with minimum inhibitory concentration (MIC) values of pathogens responsible for SSI and with literature cut-offs associated with a higher infection risk; correlate drug levels to clinical variables and SSI occurrence.

Materials and Methods: A single-center prospective observational study has been conducted at a University Hospital in Italy since October 2023, involving urological and non-cardiac thoracic surgeries. Cefazolin was administered as per best clinical practice (2g within 1 hour before incision and 1g redosing after 2 hours).

Blood samples were collected at specific time points and concentrations measured using UHPLC-MS/MS. Clinical and outcome data on SSI were collected. Univariate analyses were performed using T-tests (after Shapiro-Wilk normality checks) and Chisquare or Fisher's exact tests.

Results and Discussion: Twenty-nine patients were included (59% thoracic, 41% urological), with a mean (SD): age 67.8 (8.0) years, body mass index (BMI) 24.8 (4.0) kg/m², eGFR 66.6 (28.0) ml/min. No superficial SSIs were found, but 3 cases of organ/ space SSIs occurred. The average total cefazolin plasma concentration at closure (T4) was 98.23 mg/L (19.65 mg/L free fraction). Free T4 was below 4 mg/L (EUCAST MIC for S. aureus1) in only one case, but below 16 mg/L in 10 cases. Total T4 was below 104 mg/L (best available literature option²) in 18 cases.

An interval between redosing administration and surgery completion exceeding 2 hours and eGFR >50 ml/min correlated with significantly lower T4, unlike BMI ≥25 kg/m².

Ex Vivo optimization of donor lungs with inhaled sevoflurane during normothermic ex vivo lung perfusion (VITALISE)

S. Yang¹, A. Gentile¹, M. Jabaudon², M. Struys¹, H. Leuvenink³, G. Nieuwenhuijs-Moeke¹ ¹University Medical Center Groningen, Department of Anesthesiology, Groningen, Netherlands, ²University Hospital Clermont-Ferrand, Department of Perioperative Medicine, Clermont-Ferrand, France, 3University Medical Center Groningen, Department of Surgery, Groningen, Netherlands

Background: Volatile anesthetics interfere with many processes underlying IRI and exerts lung protective properties. Multiple points of engagement are involved, including prevention of opening of mitochondrial permeability transition pores, preservation of glycocalyx, and direct effects on circulating immune. Ex vivo lung perfusion (EVLP) facilitates evaluation of grafts and extension of preservation time, and provides a therapeutic window of oppor-

We hypothesize that ventilation of donor lungs with sevoflurane during EVLP reduces injury and improves the quality of the transplanted lungs.

Methods: Thirty two lungs were randomized to 4 groups (n=8/ group) ventilated with sevoflurane 0%,2%,4%,6% Cet during EVLP in a slaughterhouse sheep model. Lungs were, flushed, and preserved cold storage for 3h, after which 4h EVLP was initi-

When a temperature of 32°c was reached ventilation was started. Functional measurements were recorded. Perfusate and tissue samples were collected.

Results: A steady state of the different target Cet sevoflurane was reached after 10 minutes (Figure 1).

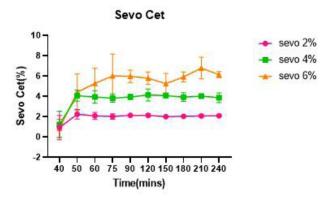

Figure 1.

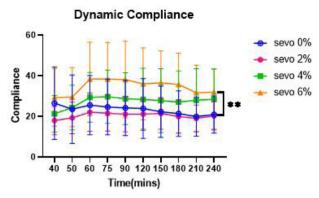

Figure 2.

The Sevo-6% group showed increase dynamic compliance (p=0.006) compared to Sevo-0% group (Figure 2).

After correcting the data to eliminate the effects of individual differences, Sevo-2%,4%,6% groups showed better compliance over time (p<0.0001). Sevo-6% group showed better oxygenation ability compared to Sevo-0% group (p=0.049).

Wet weight/dry weight ratio and post-pre EVLP lung weight indicated no differences between groups. Sevo-4% group showed highest potassium levels in the perfusate (0% vs 4%: 4.33 vs 4.52,p=0.008) and Sevo-2% group showed lowest lactate levels in the perfusate (0% vs 2%: 0.93 vs 0.89,p=0.003).

Conclusion(s): Ventilating lungs with sevoflurane during EVLP showed better compliance and oxygenation ability, especially the Sevo-6% group, while no differences on edema.

Acute restraint stress, not laparotomy, induces an increase in blood-brain barrier permeability in young mice

A. Mori¹, M. Yamagishi², R. Wang³, Y. Mitsumoto⁴, K. Nishiwaki5

¹Nagoya University Graduate School of Medicine. Department of Perioperative Management System, Nagoya, Japan, 2Nagoya University, School of Medicine, Nagoya, Japan, 3Tosei General Hospital, Initial clinical trainee, Seto, Japan, 4Hokuriku University, Department of Clinical Pharmacy, Faculty of Pharmaceutical Sciences, Kanazawa, Japan, 5Nagoya University Graduate School of Medicine, Department of Anesthesiology, Nagoya, Japan

Background and Goal of Study: Postoperative delirium (POD) develops as a direct result of surgical stress, preexisting vulnerability factors, such as advanced age, and additional factors, such as psychological stress. One potential mechanism underlying POD is blood-brain barrier (BBB) dysfunction as animal models exhibit such dysfunction. Here, we investigated the effects of acute restraint stress and laparotomy on BBB permeability in young mice. Materials and Methods: All experiments were performed according to the institutional guidelines and approved by the Animal Care Committee of Nagoya University. Male C57BL/6NJ mice, 10-11 weeks of age, were divided randomly into three groups (n = 9-12/group): control, restraint stress, and abdominal surgery under isoflurane anesthesia (iso/surgery). Fluorescein sodium salt (NaFl, 200 mg/kg), a tracer of BBB permeability, was administered subcutaneously, followed by restraint stress or iso/surgery 15 min later. Restraint stress utilized ventilated cylinder tubes that were placed vertically with the mouse head upward.

Stressed mice were left for 30 min and then returned to their home cages. Anesthesia was induced in the iso/surgery group in an anesthesia box for 5 min and then maintained at 1.5%-1.7% isoflurane using masks for 25 min, during which laparotomy was performed.

After shaving and cleaning the abdominal region, a 2.0-cm midline incision was made, the small intestine was manipulated for 1 min, and the incision was sutured. Thirty minutes after restraint stress or iso/surgery, the mice were euthanized and immediately perfused with saline. The frontal cortex was collected, weighed, homogenized in 20% trichloroacetic acid, and kept on ice for 30 min. Samples were centrifuged at 18,000×g at 4 °C for 15 min, and the fluorescence of the supernatant was measured using a fluorometer. NaFI contents in the frontal cortex were calculated as µg/g tissue wet weight. Differences between groups were evaluated using a two-tailed t-test. Differences were considered statistically significant at p < 0.05.

Results and Discussion: Although acute restraint stress caused a significant increase in the NaFI concentration in the frontal cortex, no changes were observed in the iso/surgery group. This suggests that psychological stress may play a greater role in the development of POD than surgical stress.

Conclusion(s): We demonstrated that acute restraint stress, but not laparotomy, increased BBB permeability in young mice.

Randomized controlled trial comparing the impact of deep versus moderate/superficial NMB on surgical conditions and muscle trauma during hip arthroplasty by direct anterior approach using minimally invasive surgery under opioid free anesthesia

I. Morais¹, J. Mulier², S. Saxena^{3,4}, M. Gisselbaek^{5,6}, J. Berger-Estilita^{7,8}, J. Vanlommel⁹ ¹CARP- Anesthesiology clinic of Ribeirão preto. Anesthesiology, Ribeirão Preto - SP, Brazil, 2UGhent. Anesthesiology, Ghent, Belgium, 3UMons, Research Institute for Health Sciences and Technology, University of Mons, Department of Surgery, Mons, Belgium, 4Helora, Mons, Department of Anesthesiology, Mons, Belgium, ⁵Geneva University Hospitals and Faculty of Medicine. Geneva, Switzerland., Department of Anesthesiology. Geneve, Switzerland, 'University of Geneva, Unit of Development and Research in Medical Education, Geneva, Switzerland, 7University of Bern, Institute for Medical Education, Bern, Switzerland, 8University of Porto, Centre for Health Technology and Services Research, Faculty of Medicine, Porto, Portugal, 9AZ Sint Jan Brugge, dep of Orthopedics, Brugge, Belgium

Background & goal of the study: The anterior approach for hip arthroplasty requires sufficient muscle relaxation to minimize trauma and ensure optimal surgical access. Inadequate relaxation can lead to muscle tears and contusions, increasing postoperative pain and inflammation.

This study evaluates whether clinical deep neuromuscular block (NMB) provides better surgical conditions than moderate NMB during hip arthroplasty.

Methods: This randomized controlled trial with blinded surgeons included 80 patients undergoing anterior approach hip arthroplasty. Patients were randomized into clinical deep NMB (posttetanic count < 6) or moderate/superficial NMB. Neuromuscular transmission monitoring verified block depth. All patients received opioid-free anesthesia using low-dose dexmedetomidine. lidocaine, and ketamine. Analgesia Nociception Index (ANI) monitoring was used to guide drugs administration to maintain low sympathetic stress.

Postoperative analgesia included paracetamol, NSAIDs, and rescue opioids. Surgical exposure, assessed using the adapted Leiden 5-point scale, postoperative pain, and muscle integrity were evaluated. CK and CRP levels were measured 24 hours postoperatively.

Results & Discussion: Deep NMB significantly improved exposure during incision (p=0.001), prosthesis insertion (p=0.008), and closure (p=0.001). No differences were observed in postoperative opioid consumption (p=0.66) or pain scores. CRP levels, nearly normal (20.18 & 18.54) and much lower than the 60 mg/ ml typically seen after opioid anesthesia with high-dose steroids (1), indicated minimal inflammatory reactions. This was attributed to the anti-inflammatory effects of the opioid-free protocol guided by ANI monitoring. Muscle tears and contusions were more frequent in the moderate NMB group (p=0.001) confirmed by a higher CK (476 vs. 298; p=0.016). No difference was found in postoperative Qo15 questionnaire results.

Conclusion: Deep NMB enhances surgical exposure and reduces intraoperative muscle damage without increasing postoperative pain or inflammatory markers. These findings support its use in anterior hip arthroplasty to minimize trauma and improve outcomes. The opioid-free anesthesia protocol effectively controlled inflammation, further optimizing perioperative care.

Lidocaine pre-treatment suppresses the acute restraint stress-induced increase in blood-brain barrier permeability in mice

M. Yamagishi¹, A. Mori², R. Wang³, Y. Mitsumoto⁴, K. Nishiwaki5

¹Nagoya University, School of Medicine, Nagoya, Japan, ²Nagoya University Graduate School of Medicine, Department of Perioperative Management System, Nagoya, Japan, ³Tosei General Hospital, Initial clinical trainee, Seto, Japan, 4Hokuriku University, Department of Clinical Pharmacy, Faculty of Pharmaceutical Sciences, Kanazawa, Japan, 5Nagoya University Graduate School of Medicine, Department of Anesthesiology, Nagoya, Japan

Background and Goal of Study: Several lines of evidence suggest that psychological stress can lead to increased blood-brain barrier (BBB) permeability. Additionally, vascular endothelial growth factor (VEGF) is a vascular permeability factor that promotes angiogenesis and increases BBB permeability. We have previously demonstrated in vitro that lidocaine suppresses VEGFinduced angiogenesis by inhibiting VEGF receptor-2 phosphorylation. Here, we investigated the effect of lidocaine pre-treatment on acute restraint stress-induced increases in BBB permeability in mice.

Materials and Methods: All experiments were performed according to the institutional guidelines and approved by the Animal Care Committee of Nagoya University. Male C57BL/6NJ mice, 10-11 weeks of age, were divided randomly into four groups (n=11-12/group): subcutaneous (s.c.) saline-administered control, saline s.c. + restraint stress, lidocaine 25 mg/kg s.c. + restraint stress, and lidocaine 50 mg/kg s.c. + restraint stress. Fluorescein sodium salt (NaFI; 200 mg/kg s.c.), a tracer of BBB permeability, was administered simultaneously with saline or lidocaine, followed by restraint stress 15 min later. Restraint stress utilized ventilated cylinder tubes that were placed vertically with the mouse head upward. Stressed mice were left for 30 min and then returned to their home cages. Thirty minutes after stress, the mice were euthanized and immediately perfused with saline. The frontal cortex was collected, weighed, homogenized in 20% trichloroacetic acid, and kept on ice for 30 min. Samples were centrifuged at 18,000×g at 4 °C for 15 min, and the fluorescence of the supernatant was measured using a fluorometer. NaFl contents in the frontal cortex was calculated as µg/g of tissue wet weight. Differences between the groups were evaluated using a two-tailed t-test or one-way ANOVA followed by Dunnett's test. Differences were considered statistically significant at p < 0.05.

Results and Discussion: Acute restraint stress increased NaFl concentration in mice's frontal cortex by approximately 15%. Both lidocaine doses showed a control level for NaFl concentration.

These results suggest that lidocaine pre-treatment can suppress the psychological stress-induced BBB permeability increase in mice.

Conclusion(s): We demonstrated that acute restraint stress increased BBB permeability in mice, which was suppressed by systemic lidocaine pre-treatment.

41AP04-5

The impact of local anesthetics on wound closure in cultured A549 human epithelial lung cells

I. Rajmilevich¹, Y. Lior¹

¹Tel Aviv Medical Center, Anesthesiology, Tel Aviv, Israel

Background and Goal of Study: Wound healing is a critical physiological process involving hemostasis, inflammation, proliferation, and tissue remodelling. Surgical wounds, though necessary for therapeutic interventions, are prone to complications, which impose significant healthcare burdens. Local anesthetics, commonly used during surgery for pain control, may affect wound healing.

This study investigates the effect of lidocaine and bupivacaine on wound closure in vitro using A549 human epithelial lung cells.

Materials and Methods: A549 cells were cultured to confluence and subjected to scratch assays to simulate wounds. Cells were exposed to lidocaine (2,4 and 8 μ g/mL) or bupivacaine (1,2 and 4 μ g/mL) under two conditions: 24-hour continuous exposure and 1-hour exposure followed by fresh medium replacement. Wound closure was monitored via microscopy over 24 hours, and cell-free areas were quantified using FIJI software. Statistical analyses were performed to compare wound closure rates among different groups, with significance set at p < 0.05.

Results and Discussion: Continuous exposure to both lidocaine and bupivacaine resulted in significant inhibition of wound closure, with larger wound areas after 24 hours compared to controls. Short-term lidocaine exposure (1 hour) showed no significant effect on wound closure, while bupivacaine exhibited a concentration-dependent delay in wound healing. Short term bupivacaine exposure at 4 μ g/mL caused an increase in wound size over time.

These findings align with previous studies indicating local anesthetics may interfere with cellular processes critical for wound healing. Lidocaine's transient anti-inflammatory effects may explain its differing outcomes between short and prolonged exposures.

A549 cells were grown to confluence and scratched using a pipetie top. Examplary figures from time T=0 and T=24 of the various assessed conditions.

Conclusion(s): Local anesthetics, particularly bupivacaine, demonstrate inhibitory effects on wound healing in vitro, with pronounced impacts during prolonged exposure. Lidocaine appears less detrimental in short-term applications. These results suggest the need for cautious use of local anesthetics in surgical settings and highlight the importance of further in vivo research to elucidate mechanisms and clinical implications.

Effect of respiratory acid-base balance on the rocuronium induced neuromuscular blockade and sugammadex induced reversal in the rat phrenic nerve hemidiaphragm

Y. Kim¹, J.-M. Choi², <u>C. Park</u>¹, H.J. Kwak¹, J.-Y. Kim³, H.-S. Yang⁴

¹Gachon University/Gil Medical Center, Department Anesthesia and Pain Medicine, Incheon, Korea, Republic of, ²University of Ulsan/ Asan Medical Center, Department Anesthesia and Pain Medicine, Seoul, Korea, Republic of, ³Ajou University / Ajou University Hospital, Department of Anesthesia and Pain Medicine, Suwon, Korea, Republic of, ⁴Hallym University / Chuncheon Sacred Heart Hospital, Department Anesthesia and Pain Medicine, Chuncheon, Korea, Republic of

Background and Goal of Study: In this study, we used an ex-vivo model to investigate the effect of respiratory acid-base balance on the rocuronium-induced neuromuscular blockade and the recovery pattern of sugammadex, both the train-of-four ratio (TOFr) and first twitch tension of TOF (T1) and determined their relationship

Materials and Methods: This ex-vivo study protocol was approved by the Ethics Committee of the Laboratory of Animal Research of the Asan Institute of Life Science (Seoul, Korea) on July 1, 2024 (Protocol No. 2017-13-114). Tissue specimens of the phrenic nerve-hemidiaphragm were obtained from 30 adult SD rats (male, weight 300g). Each specimen was immersed in an organ bath filled with Krebs buffer solution and stimulated with the TOF pattern using indirect supramaximal stimulation at 20-second intervals. After a 30-minute stabilization period, rocuronium loading and booster doses were serially administered at 10-minute intervals in each sample until > 95% depression of T1 was confirmed. Specimens were randomly allocated to the control (95% O2 + 5% CO2), respiratory acidosis (97.5% O2 + 2.5% CO2) and alkalosis (91% O2 + 9% CO2) group and sugammadex concentration 1:1 equimolar dose of rocuronium to produce >95% T1 depressions. Recovery from neuromuscular blockade was monitored using T1 and the TOF ratio simultaneously until the recovery of T1 to > 95% and the TOF ratio to > 0.9.

Results and Discussion: Dose-response curve of T1% and TOFr in acidosis group was shifted to left (p<0.0001) comparing those in alkalosis group. However, There are no differences between those in control and alkalosis group (p=0.026). Recovery progression pattern of sugammadex induced reversal of T1 and TOFr are quite different among these three groups (p=0.0001). However, the regression curve obtained from TOFr was not fit well (p=0.0428). Total dose of rocuronium and sugammadex is different between control vs respiratory acidosis (p=0.0318 in ROC, p=0.0315 in SGX), and between respiratory acidosis vs alkalosis (p=0.0007 in ROC, p=0.0007 in SGX)

Conclusion(s): We suspect that respiratory acid-base changes will be affected the rocuronium induced relaxation and reversal of sugammadex. But it will be needed further suty.

Effect of intravenous magnesium sulphate on neostigmine or sugammadex reversal of rocuronium-induced neuromuscular block - a randomized electrophysiological study

C. Rocha Baltazar Tasso de Figueiredo¹, S. Grape^{1,2}, M. Verdonck³, S. Brull⁴, C. Czarnetzki^{5,6,7} ¹Hospital of Sion, Department of Anaesthesia and Intensive Care, Sion, Switzerland, 2University of Lausanne UNIL. Faculty for Biology and Medecine. Lausanne, Switzerland, 3Ghent University, Department of Business Informatics and Operations Management, Ghent, Belgium, 4Mayo Clinic College of Medicine and Science, Department of Anesthesiology and Perioperative Medicine, Jacksonville, United States, 5Geneva University Hospitals, Division of Anaesthesiology, Department of Anaesthesiology, Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland, 6Università della Svizzera italiana, Faculty of biomedical sciences, Lugano, Switzerland, 7University of Geneva, Faculty of Medicine, Geneva, Switzerland

Background and Goal of Study: Magnesium potentiates the effects of neuromuscular blocking agents by decreasing acetylcholine release from the presynaptic nerve terminal. Its administration after recovery can result in a recurrence of neuromuscular block (NMB). Rocuronium-induced NMB can be antagonized by neostigmine, an anticholinesterase agent, or sugammadex, a selective relaxant binding agent.

The primary aim of this study was to investigate the effect of magnesium on neostigmine- or sugammadex-induced recovery of rocuronium NMB.

Materials and Methods: This double-blind, two-center, IRB-approved randomized study of 48 patients (ASA I-II), aged 18-65 yrs. undergoing elective surgery and patients stratified by sex. Neuromuscular monitoring used normalized acceleromyography (TOF-Watch SX®, Ireland) at the thumb and recorded Train-of-Four (TOF) stimulation q 15 sec. Neuromuscular block was induced with rocuronium 0.6 mg/kg. At the re-appearance of 2 twitches of TOF, patients received either glycopyrrolate (10 µg/ kg) plus neostigmine (50 µg/kg), or sugammadex (2 mg/kg) in a double-blinded manner. Ten minutes after achieving a normalized TOF ratio of 0.9, patients received 60 mg/kg IV magnesium over 5 min. Primary outcome (recurrence of NMB) was defined as 2 consecutive normalized TOF ratio <0.9. Monitoring continued until a normalized TOF ratio of 0.9 returned. Analysis according to group assignment (A or B) was kept blinded and performed with Python v3 and the SciPy statistical library (v1.14.1). Fisher's Exact test evaluated the association between treatment groups (Groups A or B) and recurrence of NMB (a decrease in TOF ratio <0.90).

Results and Discussion: Data were analysed in 45 patients. In group A (n=23), administration of magnesium resulted in recurrence of block in 10 (43.5%) of patients. In group B, 21 of 22 (95.5%) patients experienced recurrence of block. There was a significant association between treatment group (A or B) and TOF ratio decrease; odds ratio of 27.3 (p-value of 0.0002).

Conclusion(s): These findings indicate that magnesium distinctly affects the potentiation of rocuronium residual neuromuscular block reversed with neostigmine versus sugammadex. Further studies are needed to validate these outcomes and improve clinical protocols, particularly for obstetric patients receiving general anesthesia for delivery, where magnesium use is common.

41AP04-8

Predictors of prolonging neuromuscular effects after administration of rocuronium

T. Sugiura¹, S. Isono², T. Suzuki¹, A. Ide¹, J. Okazaki¹ ¹Kimitsu Central Hospital, Anesthesia, Kisarazu, Japan, ²Chiba University, Division of Respiratory Molecular Medicine, Medical Mycology Research Center, Chiba, Japan

Background and Goal of Study: Postoperative residual muscle paralysis is one of major causes of postoperative severe hypoxemia and re-intubation. Anesthesiologists occasionally decide not to administer neuromuscular (NM) reversal agent solely based on the dose and duration of NM agent and the clinical assessments, resulting in severe residual muscle paralysis. No previous study systematically determined the risk factors of prolonging NM blocking effects. This prospective observational study aimed to identify predictors of prolonging NM blocking effect and to assess predictability of the clinical model.

Materials and Methods: The study was approved by our institutional ethical committee and written informed consent from each participant was waved due to non-invasive nature of the observational study.100 adult patients (20-92 ys, 59 males, BMI 15-35 kg/m2) undergoing general anesthesia with rocuronium (Rb) participated in the study. Train of four count (TOFC) was measured every 12 seconds to determine spontaneous TOFC 1 recovery period after initial Rb administration (0.6-0.9mg/kg) (RP1: primary variable) and after additional 10 mg Rb (RP2). Multiple linear regression with backward step-wise method explaining RP1 and RP2 was performed using 10 preselected variables (age, sex, ASA-PS, BMI, albumin, [GTP, total bilirubin, GFR, anesthetics, Rb dose per BW).

Results and Discussion: There was a large variation in RP1 and RP2 among the participants (means±SD, RP1: 48±18, RP2: 32±14 minutes). Independent predictors of prolonging RP1 were identified as higher age (p<0.001), greater BMI (p=0.005) and larger Rb1 dose/BW (p<0.001) (R2=0.302) whereas those of longer RP2 were higher age (p=0.028), lower GFR (p=0.037) and larger Rb2 dose/BW (p=0.017) (R2=0.217). Thus, our results suggest that Rb effects are likely to be underestimated by anesthesiologists in patients with higher age, obesity and renal dysfunction and when larger dose of Rb was administered. The identified predictors are in agreements with reported features of patients with recurarization in the previous literatures. More importantly, the models determined in this study only predict 30 and 22% of the TOFC1 recovery time.

Conclusion(s): Recovery time from rocuronium-induced NM paralysis is unable to be accurately predicted solely based on preoperative patient information, and NM monitoring is necessary to confirm full-recovery of NM function.

Development of rapidly metabolized etomidate derivatives with improved safety and anesthetic performance

Y. Zhao^{1,2}, B. Ke^{1,2}

¹Sichuan University, Department of Anesthesiology, West China Hospital, Chengdu, China, 2Sichuan University, Laboratory of Anesthesia and Critical Care Medicine, National-Local Joint Engineering Research Centre of Translational Medicine of Anesthesiology. Chengdu, China

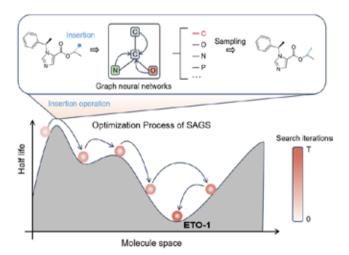

Background and Goal of Study: Since its introduction in the 1970s, Etomidate has been widely used in clinical general anesthesia because of its minimal hemodynamic effects. However, its significant adrenal suppression poses a major limitation to its clinical utility. To address these challenges, AI (SAGS) was used to obtain new molecules with faster metabolism and reduced adrenal inhibition, paving the way for safer and more effective anesthetics.

Materials and Methods:

- 1. Based on SAGS, the structure of etomidate was iteratively refined to shorten its half-life, yielding a lead compound.
- 2. A series of derivatives were synthesized. In vitro and in vivo evaluations were conducted to screen a candidate compound with good anesthetic activity and fast metabolism.
- 3. The anesthetic activity and safety profile of candidate compound were evaluated systematically.

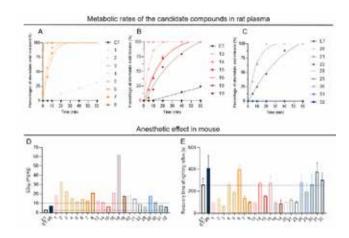

Results and Discussion:

1. Based on Al screening, we found an optimized etomidate derivative as a lead compound.

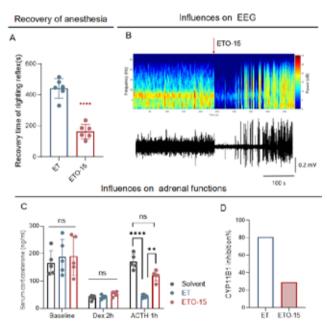

Al screening process

2. In vitro and in vivo results suggest ETO-15, exhibited rapid metabolism and a shorter recovery time, making it a candidate compound.

3. ETO-15 showed better anesthetic activity, a faster recovery time and a weaker inhibition of adrenal function, marking it as a promising candidate in clinical applications.

Conclusions: In the study, we identified a promising compound ETO-15 with a good anesthetic effect and a weaker inhibition of adrenal function, laying the groundwork for subsequent advancements in this field.

Effects of sevoflurane concentration and gender on the pathology of malignant hyperthermia in a mouse model

H. Miyoshi¹, T. Ikeda¹, K. Mukaida¹, K. Kido¹, S. Narasaki¹, Y. Tsutsumi1

¹Hiroshima University, Anesthesiology and Critical Care, Hiroshima, Japan

Background and Goal of Study: Malignant hyperthermia (MH) is caused by inhaled anesthetics. However, it is unknown whether the concentration of inhaled anesthetics affect the onset of MH. We investigated the effect of sex difference and sevoflurane concentration on the onset of MH in RYR1[R2509C] mutant mice (MH model mice).

Materials and Methods: MH model mice were anesthetized with intravenous anesthetics, followed by tracheal intubation and mechanical ventilation. Rectal temperature and heart rate were monitored. Sevoflurane were administered at 1 MAC (2.5%) to male and female MH model mice, and following parameters were compared; time to onset of MH, time to peak temperature, peak temperature, time to maximum heart rate, maximum heart rate, time to death. The onset of MH was defined as when the body temperature exceeded 38°C. Subsequently, sevoflurane were administered at 0.5 MAC (0.5 MAC group) or 1 MAC (1 MAC group) to male MH model mice to examine the effects of the difference of sevoflurane concentration. Data are presented as medians [interguartile range], and statistical analysis was performed using the Mann-Whitney U test, with P < 0.05 considered significant.

Results and Discussion: Male MH model mice (n = 6) showed significantly shorter time to onset of MH, peak temperature, maximum heart rate, and death. The time to onset of MH was 11.5 [10.3-14.3] minutes in male mice and 26.5 [21.5-29.3] minutes in female mice (n = 6) (P=0.01). In the experiments on two different concentration of sevoflurane, the maximum body temperature in 0.5 MAC group (n = 5) was significantly higher than that of 1 MAC group (n = 6) (44.8 [44.6-45.1] °C vs 42.5 [42.3-42.6] °C, P=0.014). The time to onset of MH was 27.0 [22.8-31.3] minutes in 0.5 MAC group, which was significantly slower compared to that of 1 MAC group (P=0.025). No significant differences were observed in other evaluation items.

Conclusion(s): Male MH model mice developed MH more rapidly than females. Lower concentration of sevoflurane showed longer time to onset of MH and greater increase in peak temperature. It is necessary to remind that the exposure to high concentrations of sevoflurane can causes more rapid and more severe symptoms of MH.

41AP04-12

The diagnosis of malignant hyperthermia using cultured skeletal muscle does not differ depending on the location of the muscle biopsy

H. Miyoshi¹, T. Ikeda¹, K. Mukaida¹, S. Otsuki¹, S. Narasaki1, Y. Tsutsumi1 ¹Hiroshima University, Anesthesiology and Critical Care, Hiroshima, Japan

Background and Goal of Study: The gold standard for the diagnosis of malignant hyperthermia (MH) is a skeletal muscle contracture test performed using the rectus femoris muscle, specifically the Ca-induced Ca release (CICR) test in Japan. Previously, we reported the usefulness of a diagnostic method using cultured skeletal muscle as an alternative to the CICR test. In this study, we investigated the influence of the muscle sample collection site on the measurement results of this diagnostic method.

Materials and Methods: We retrospectively analyzed data from patients who underwent a CICR test and a diagnostic assay using cultured skeletal muscle for patients suspected of MH susceptibility. Patients were classified into two groups, CICR-positive and CICR-negative, based on the CICR test results. The reactivity (EC50: 50% effective concentration) of cultured skeletal muscle to caffeine (Caf) and 4-chloro-m-cresol (4CmC) was compared between the two collection sites (biceps brachii and rectus femoris). Data are presented as medians (interquartile range), and statistical analysis was performed using the Mann-Whitney U test, with P < 0.05 considered significant.

Results and Discussion: A total of 96 patients underwent both CICR testing and cultured skeletal muscle analysis. Muscle biopsies were performed in the biceps brachii (n=49), rectus femoris (n=37), and other (n=10) muscles. In the CICR-positive group, the EC50 for Caf was 2.9 [2.5-3.3] mM in the biceps brachii (n=33) and 2.9 [2.3-3.3] mM in the rectus femoris (n=24) (P=0.56). The EC50 for 4CmC was 126 [93-153] uM and 137 [112-170] uM in the biceps brachii and rectus femoris, respectively (p=0.33). In the CICR-negative group, the EC50 for Caf was 4.9 [4.4-5.8] mM in biceps brachii (n=16) and 4.9 [4.5-5.0] mM in rectus femoris (n=13) (p=0.68). The EC50 for 4CmC was 243 [220-290] µM and 256 [225-297] µM in biceps brachii and rectus femoris, respectively (p=0.72). Differences in cultured skeletal muscle analysis due to the site of collection have been unknown until now, but the results of this study show that there is no significant difference in the reactivity of Caf or 4CmC between rectus femoris and biceps brachii.

Conclusion(s): The results of functional analysis using cultured skeletal muscle for MH diagnosis are not affected by the site of muscle collection. Collecting muscle tissue from a minimally invasive site will reduce the physical damage on patients.

Anesthetic management of a patient with Alpha-Gal Syndrome: are all medications labeled as safe truly risk-free? - A case report

P. Silva¹, M. Silva¹, I. Simões¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Alpha-gal syndrome results from a hypersensitivity reaction to the carbohydrate galactose
⊓-1,3-galactose (alpha gal) found on the surface of cells of most mammals. The production of IgE antibodies against alpha-gal can cause drug related immediate and red meat delayed-onset anaphylactic reactions.1 Drugs used during the perioperative period can be potential triggers for these reactions, making a thorough anesthetic assessment essential in such cases.

Case Report: A 70-year-old man with alpha-gal syndrome was scheduled for the elective excision of submandibular metastasis from cutaneous squamous cell carcinoma, along with ipsilateral cervical lymphadenectomy. To ensure optimal planning, a detailed evaluation was conducted with the hospital's pharmaceutical team to identify safe medications and surgical materials. Although some literature suggested etomidate as a safe intravenous anesthetic2, the similar emulsion composition of propofol and etomidate raised concerns, as propofol is considered potentially unsafe. A detailed investigation revealed that the etomidate formulation available at our institution contained potential anaphylactic triggers. Lubricants and ointments were also avoided due to the presence of glycerin and/or lanolin in their composition. We will later describe all the drugs used and studied. No allergic reactions occurred in the perioperative period.

Discussion: Managing patients with multiple allergies poses a significant challenge for physicians, particularly when the allergen may be present as an excipient in various drugs. Compounding the complexity is the fact that the same excipient may have different sources (e.g. animal or plant-based), and this information is not always disclosed on medication labels, often necessitating direct communication with the manufacturer for clarification. Therefore, collaboration with pharmacists is essential as well as the review of all excipients in the medications planned for use.

Learning Points: This case report highlights the importance of multidisciplinary collaboration and analytical reasoning in research evaluation in anesthesiology.

41AP05-2

Remimazolam for procedural sedation: a large multicenter observational retrospective cohort

A. Goval^{1,2}, D. Schroeder³, M. Teixeira⁴ ¹Mayo Clinic, Alix School of Medicine, Rochester, United States, ²Mayo Clinic, Medical Scientist Training Program, Rochester, United States, 3 Mayo Clinic, Department of Biostatistics, Rochester, United States, 4Mayo Clinic, Department of Anesthesiology and Perioperative Medicine, Rochester, United States

Background and Goal of Study: Remimazolam is a novel and reversible benzodiazepine sedative-hypnotic with ultrafast onset and rapid metabolism. The remimazolam literature typically involves a small number of patients undergoing a specific procedure. Here we report the safety and efficacy of remimazolam in over 8,000 patients across three Mayo Clinic sites undergoing a wide variety of procedures.

Materials and Methods: Patients aged 1-100 who received remimazolam at one of three Mayo Clinic sites between June 2021 and February 2024 were retrospectively identified. Demographics, case summaries, anesthetic management including drug and dose administration, and Richmond Agitation Sedation Scale (RASS) scores were abstracted for each patient. Data analysis was conducted in SAS and Python.

Results and Discussion: Our dataset consisted of 8,756 patients (61% male). Of these, 24% underwent surgical and 76% underwent NORA procedures. Most of our patients were ASA 3 or above (1: 1%, 2: 10%, 3: 60%, 4: 28%, 5: 1%). 45% were during MAC anesthesia cases, 35% during general cases without airway, 12% during GETA cases, and 8% during regional or bedside sedation cases. Most were cardiovascular procedures (2112 cardioversions), followed by GI procedures, bronchoscopes, tube insertions, and brain stimulator placements. Remimazolam was most often co-administered with propofol (60% of cases), vasopressors (34%), flumazenil for reversal (14%), and dexmedetomidine (7%). The mean time to return to baseline RASS score was 13 minutes, and mean PACU time was 31 minutes. There were 15 reported allergies to remimazolam, of which two had positive tryptase. There were 11 deaths within 4 hours of remimazolam administration who underwent a secondary in-depth analysis.

Conclusion(s): Remimazolam appears to be a safe and effective anesthetic agent for use in MAC, local, and general anesthesia across a variety of procedures, including in emergent ASA patients (ASA 4-5), to achieve brief periods of moderate sedation, anxiolysis, or deepened sedation in conjunction with other anesthetics. Our PACU and return to baseline RASS times are shorter than those reported in the literature following midazolam or propofol use, indicating that remimazolam may accelerate recovery. The deaths within 4 hours of remimazolam administration from our dataset were unlikely to be directly associated with remimazolam administration. We had two cases of possible anaphylactic reactions to remimazolam.

41AP05-3 Metronidazole toxicity in a 71-year-old female after two months of treatment

U. Brennan¹, E. Quinlan¹, S. Hakak¹ University Hospital Waterford, Anaesthesiology, Waterford, Ireland

Background: Neurotoxicity associated with metronidazole is a rare complication and only a small number of case reports are documented in the literature. In cases of metronidazole toxicity, bilateral dentate nuclei often demonstrate hyperintensity on T2weighted MR images.

Case Report: We present a 71-year-old female who underwent emergency Hartmann's procedure secondary to a newly diagnosed sigmoid tumour. Her hospital course was complicated by multiple ICU admissions requiring two months (63 days) of metronidazole treatment.

In ICU, the patient had an acute drop in GCS, dysarthria and choreiform seizure like activity of her upper limbs. FAST calls and multiple CT brains showed no acute findings. MRI brain showed abnormal T2/FLAIR high signal within the splenium of corpus callosum, bilateral dentate nuclei, right pons and subcortical white matter in the bilateral frontal and parietal lobes. There was associated restricted diffusion in the fronto-parietal subcortical white matter, corpus callosum and at the grey-white matter interface in the occipital lobes. Lumbar puncture ruled out infective cause. Metronidazole was stopped and her GCS slowly improved.

Discussion: This case demonstrates the serious consequences of a rare side effect of metronidazole. Neurotoxicity mimicked a stroke and meningitis, among many other differentials. Metronidazole neurotoxicity most commonly occurs after prolonged exposure to the drug, however can also occur at low doses. The mainstay of treatment is immediate cessation of metronidazole, and providing supportive care to the patient. Symptoms may take weeks to improve, but in most patients symptoms eventually resolve.

References:

- 1. Patel L, et al. 'Acute metronidazole-induced neurotoxicity: An update on MRI findings.' Clinical Radiology, Volume 75, Issue 3,
- 2. D. Quickfall, N. Daneman, A.A. Dmytriw, D.N. Juurlink, 'Metronidazole-induced neurotoxicity.' CMAJ Oct 2021, 193 (42) E1630; DOI: 10.1503/cmaj.20167
- 3. Guglielmo, B.J. 'Metronidazole neurotoxicity: Suspicions confirmed', Clinical Infectious Diseases, 72(12), pp. 2101-2102. doi:10.1093/cid/ciaa400.

Learning points:

- It's important to be aware of the potential neurological complications associated with prolonged use of metronidazole.
- · Recognition of the symptoms and cessation of treatment are crucial in the management of neurotoxicity.
- Most patients will fully recover from their symptoms, however this can often be over a prolonged period

41AP05-4

Reversal of rocuronium-induced fixed pupillary dilation by sugammadex, in an ICU patient after

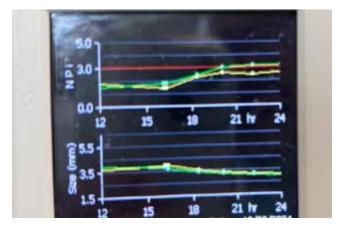

A. Sarigiannis¹, P. Pappas², C. Balakera¹, K. Nikitakis¹, M. Trimandyli¹, P. Kouki¹

¹General Hospital of Nikaia "Agios Panteleimon", Anaesthesiology Department, Athens, Greece, 2General Hospital of Nikaia "Agios Panteleimon", Intensive Care Unit Department, Athens, Greece

Background: It is literature reported that rocuronium administration can cause mydriasis, especially in ICU, intubated patients due to COVID. Though not clear, blood brain barrier impairment can

Case Report: A 66yr female ICU patient (70 kg) was transferred to operating theatre for 2ndexploratory laparotomy. She was in ICU for 2 weeks, after being operated for right colectomy and HIPEC due to metastatic ovarian cancer. During transfer to the OR the patient was intubated, with remifentanil, midazolam and low noradrenaline infusion (1 µg/kg/h). During induction fentanyl (150 µg), propofol (40mg) and rocuronium (70 mg) were administered (10 mg of rocuronium were given 60 min later). Anaesthesia was preserved with sevoflurane and low dose of noradrenaline continued intraoperatively. The patient received 8mg morphine for postoperative analgesia. Before induction of anaesthesia both pupils were equal in size and reactive to light (special eye patches were used for protection). Postoperatively pupils were checked, and there was bilateral mydriasis (Size R 4.33, L 4.82) and non-reactive to light (NPi R 0.8, L 0.7). It was suspected that rocuronium caused this side effect and it was decided to administer sugammadex (200mg). There was an immediate improvement in light reflex but laggish in pupils' size. Full eye-recovery was gradual, within 24hours.

Discussion: Intraoperative use of rocuronium in an ICU non-COVID patient caused pupils' mydriasis and depression of light reflex. Reverse of this rare side effect was imminently achieved with sugammadex administration and consequently, other serious CNS causes were excluded

Reference:

M. Winant, et al. BJA 2024 Mar;132(3):627-629

Learning points: Administration of rocuronium in an ICU patient caused mydriasis and depression of light reflex. Use of sugammadex reversed this rare side effect.

41AP05-6

Clinically relevant concentrations of dexmedetomidine affect wound healing dosedependently and time-dependently in vitro

A. Nahman¹, J. Toukan¹, N. Muhanna², I. Matot¹, Y. Lior¹ ¹Tel-Aviv Medical Center, Anesthesia, Intensive Care and Pain Medicine, Tel Aviv Yafo, Israel, 2Tel-Aviv Medical Center, Head and Neck Surgery Unit, Tel Aviv Yafo, Israel

Background and Goal of Study: Dexmedetomidine is a selective alpha 2 agonist commonly used for anxiolysis, sedation, and analgesia in operating theaters and ICUs, in both adults and pediatric patients, with measured serum concentrations ranging between 0.2 and 20 ng/ml.

Additionally to its sedative and analgesic qualities, several works have suggested improved wound healing. However, these reports examined only specific patient populations and lacked mechanistic aspects. Thus, the effect of dexmedetomidine on wound healing remains poorly understood.

This study aimed to investigate the effect of clinically-relavant dexmedetomidine concentration on wound healing in an in vitro model.

Materials and Methods: A459 human epithelial cells were cultured to 100% confluence, scratched using a pipette tip, followed by media replacement to media with (test) or without (control) dexmedetomidine in clinically relevant concentrations. In a second setting, cells were exposed to =dexmedetomidine for times ranging from 30 to 90 minutes to assess the effect of short-period exposure. Wound healing was studied using serial photography, image analysis was done with the Fiji software and statistical analysis with Prism GraphPad software...

Results and Discussion: Our results showed that dexmedetomidine exposure interfered with scratch closure in a dose-dependent manner - dose increase from 0.02 ng/ml to 2 ng/ml resulted in increasing inhibition of scratch closure in A459 cells, up to complete lack of closure and expansion of the scratch area as compared to controls. Additionally, gradual increase of exposure time from 30 minutes to 90 minutes resulted in a similar inhibition of wound healing rate.

Conclusion(s): In contrast to our hypothesis, our results suggest an inhibitory effect of dexmedetomidine on in-vitro wound healing. These results might be of clinical importance given the growing use of dexmedetomidine in the operating room, emergency departments, and intensive care units. Future research should further characterize the effect of dexmedetomidine on wound healing in cell cultures and to elucidate the participating molecular mechanisms.

41AP05-7

IV Methocarbamol use for pain control in patients undergoing open liver resection

S. Pham¹, S. Bradley¹, A. Kwater¹, J.-A. Oliver¹, H. Huang¹, G. Ovsak1

¹The University of Texas MD Anderson Cancer Center, Anesthesiology, Houston, United States

Background: Muscle cramps occur in 29-88% of patient with liver disease and is only made worse when they undergo open liver resection (1). While epidural placement remains the gold standard for pain control in open abdominal cases, this has gone out of favor in many institutions due to the large hemodynamic shifts that can occur in patients undergoing a liver resection. There has been a large interest in multimodal pain control and enhance recovery after surgery (ERAS) amongst the hepatobiliary community. One of the medications rising in popularity is methocarbamol, a muscle relaxant with a relatively safe drug profile. However the affects of methocarbamol on patients undergoing liver resections have not been well studied.

Case Report: The patient is a 74-year-old female diagnosed with cholangiocarcinoma. She underwent a open liver resection. Pain control was achieved intraoperatively with multimodal combination of acetaminophen, hydromorphone, celebrex, and methocarbamol with bilateral quadratus lumborum 1 block using exparel and 0.25% bupivacaine mixture. The case proceeded uneventfully and the patient was extubated awake and taken to the Post Anesthesia Care Unit (PACU). Shortly after arriving, she complained of pain and another dose of 500mg IV methocarbamol was given. Previous dose was five hours prior. The patient quickly became obtunded and an emergency response was called. She was intubated and an arterial blood gas obtained was consistent with respiratory acidosis. The patient was eventually extubated several hours later.. The rest of her post operative recovery was uneventful.

Discussion: The use of methocarbamol for liver surgical pain control has not been well studied. While the mechanism of action is not known, it's effect is thought to be localized to the central nervous system rather than a direct effect on skeletal muscles. It has been looked at in cirrhotic patients and was shown to be safe to use in those chronic liver conditions, however this has not been looked at in patients with acute injuries. Side effects include drowsiness, headache, and potential respiratory depression when combined with other sedatives. It should be used carefully in elderly patients undergoing liver resections, but otherwise has been shown to be affective for pain control.

References:

1. DOI: 10.1097/MEG.000000000001310, (2) PMID: 18711953 Learning points: Efficacy and safety of IV methocarbamol use in patients undergoing open liver resection

41AP05-8

Rocuronium-Induced anaphylactic shock with reversal after the use of sugammadex: a case report

I. Ferreira¹, <u>D. Vasconcelos</u>¹, Â. Mota¹, C. Oliveira¹, H. Machado¹

¹Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Porto, Portugal

Background: Anaphylaxis is a rare but life-threatening condition in the perioperative setting, often occurring during general anesthesia (GA) induction due to the successive administration of multiple drugs, making identification of the causative agent challenging. Among these, rocuronium is most frequently implicated. The use of its antidote, sugamadex, appears to positively impact the reversal of this condition. We present a case illustrating this. Case Report: A 54 yo male, ASA II, was scheduled for laparoscopic bilateral inguinal hernia repair as outpatient surgery. His medical history included hypertension (treated with enalapril) and smoking. He reported an allergy to ibuprofen (hives) and a previous uncomplicated orthopedic surgery under GA. GA was induced with 50ug of fentanyl, 80mg of lidocaine, 160mg of propofol, 20mg of ketamine and 100mg of rocuronium followed by orotracheal intubation. Four minutes later, the patient developed severe hypotension (SBP < 60 mmHg), tachycardia, and bronchospasm, unresponsive to ephedrine ev (total of 20mg) and phenylephrine ev (total of 0,2mg). Anaphylactic shock was suspected, and treatment with adrenaline ev (3 bolus of 0,1mg), 200mg of hydrocortisone ev, 2mg of clemastine ev, IV fluids, and bronchodilators was initiated. Despite these measures, hypotension persisted, requiring norepinephrine infusion, with minimal effect. Suspecting rocuronium's role in anaphylactic shock, 400 mg of sugammadex was administered, resulting in rapid blood pressure normalization. The patient's hemodynamic and respiratory status improved, and he was extubated and transferred to an intermediate care unit for monitoring. On day two, he was discharged and referred to outpatient immunoallergology. Elevated tryptase levels and positive Prick tests exclusively for rocuronium identified it as the trigger for the anaphylaxis, with a recommendation for its future avoidance.

Discussion: Anaphylactic shock was attributed to rocuronium, a rare but life-threatening complication of GA that requires prompt recognition and intervention, even in patients with no previous issues. If suspected, the administration of sugammadex may be crucial for stabilizing the patient.

References:

McDonnell NJ. et al; Sugammadex in the management of rocuronium-induced anaphylaxis; Br J Anaesth. 2011.

Learning points: In suspected rocuronium-induced anaphylaxis, the administration of sugammadex may be effective in treatment and aid in identifying the causative agent.

41AP05-9

Does somatostatin modulate the effects of dobutamine on hepatic blood flow?

T.-G. Eggermont¹, J. Van Limmen¹, F. Gryspeerdt², S. De Hert¹, L. De Baerdemaeker¹, P. Wyffels¹ ¹UZ Ghent, Anesthesia, Ghent, Belgium, ²UZ Ghent, General Surgery, Ghent, Belgium

Background and goal: Somatostatin (SOMATO) acts as a portal inflow regulator, influencing hepatic blood flow (HBF). Dobutamine (DOBU), a widely used inodilator, is known to enhance overall intestinal blood flow. However, the effect of dobutamine on HBF in patients treated with SOMATO has not been previously studied. This study aims to evaluate the interaction between dobutamine and SOMATO on HBF.

Methods and materials: After ethical committee approval, patients scheduled for pancreaticoduodenectomy were included in the study. All patients received total intravenous anesthesia via target-controlled infusion of propofol (Schnider model) and remifentanil (Minto model). SOMATO was administered based on surgical requirements. Hemodynamic variables were monitored and recorded using Pulsioflex™. HBF was measured using ultrasound transit time technology (Medi-Stim AS). Baseline measurements (T1) were taken before initiating DOBU at a dose of 2 mcg/kg/min (T2), which was then increased to 5 mcg/kg/ min (T3), maintaining a minimum interval of 10 minutes between measurements. Hemodynamic parameters, indexed hepatic arterial flow (HAFi), and indexed portal vein flow (PVFi) were recorded simultaneously. Patients were categorized into group S (receiving SOMATO) and group C (control). Data analysis was performed using linear mixed modeling.

Results: A total of 30 patients were included. At baseline HAFi was higher and PVFi was lower in SOMATO treated patients. DOBU dose-dependently increased cardiac index and heart rate. The predicted increase in PVFi was 92 ml.min⁻¹.m⁻² (+/- 18 ml.min⁻¹.m⁻²) at T3 (p < 0.05) and the predicted decrease in HAFi was 60 ml.min⁻¹.m⁻² (+/- 18 ml.min⁻¹.m⁻²) at T3 (p < 0.05), both were independent of SOMATO use. The net effect on total HBFi remained similar.

Conclusion: The effects of DOBU in incremental dosages on HBF was similar in both somatostatin-treated and non-treated patients.

41AP05-10

SGLT-2 inhibitors may not be associated with an increased risk of perioperative adverse events

T. Tenge^{1,2}, S. Roth¹, E. Ahrens², L.J. Wachtendorf², G. Chen². M.S. Schaefer^{1,2} ¹University Hospital Düsseldorf, Department of Anesthesiology, Düsseldorf, Germany, 2Beth Israel Deaconess Medical Center, Department of Anesthesia, Critical Care and Pain Medicine; Center for Anesthesia Research Excellence (CARE), Boston, United States

Sodium-glucose-cotransporter-2 (SGLT-2) inhibitors are antidiabetic drugs increasingly prescribed due to their beneficial effects on cardiovascular mortality. A serious side effect is SGLT-2-inhibitor-associated ketoacidosis which may be perpetuated during perioperative care. Data guiding anesthesiologists on the perioperative risk and safety of SGLT-2 inhibitors are sparse. We hypothesized that preoperative SGLT-2 inhibitor use is associated with higher risks of perioperative adverse events.

This retrospective cohort study included adult patients with diagnosed type 2 diabetes, heart failure and/or chronic kidney disease undergoing surgery between 2020 and 2024 at a tertiary healthcare-center in New England, United States. SGLT-2 inhibitor use within two weeks prior to surgery was identified through prescription records and anesthesia reports. The primary outcome was 30-day adverse postoperative events including major complications, readmission, and death. Secondary outcomes included the components of the primary outcome. In exploratory analysis, we investigated effects of SGLT-2 inhibitors on perioperative arterial blood gas analysis pH values. For statistical analyses, inverse-probability-weighted regression adjustment (IPWRA) including covariates related to patient and procedural characteristics was performed.

Among 21,158 patients, 1,383 (6.5%) used SGLT-2 inhibitors preoperatively, with an increasing trend (3.0% in 2020, 11.1% in 2024. p<0.001). Adverse postoperative events occurred in 13.8% of patients, 11.1% in SGLT-2 inhibitor users versus 14.0% in non-users (odds ratio [OR], 0.76; 95% CI 0.64 to 0.91; p=0.002). This association was not significant following IPWRA (average treatment effect [ATE], -1.73%; 95% CI -3.77 to 0.31; p=0.09). Secondary analyses suggested marginally lower 30-day mortality in SGLT-2 inhibitor users (ATE, -1.12%; 95% CI -1.90 to -0.35; p=0.004). Patients using SGLT-2 inhibitors had lower pH upon first intraoperative arterial blood gas analyses (-0.01; 95% CI -0.02 to -0.01; p=0.004) but comparable incidences of perioperative acidosis with pH<7.3 (adjusted OR, 0.99; 95% CI 0.75 to 1.32; p=0.97).

While surgical patients using SGLT-2 inhibitors had a measurable but clinically irrelevant lower pH, comparable risks of major postoperative adverse events and perioperative acidosis were observed. Future research should explore the lower 30-day mortality and assess perioperative safety and strategies in different populations.

41AP05-12

Intravenous dexmedetomidine prolongs the duration of spinal anesthesia sensory block: a systematic review with meta-analysis

M.L.G. Rivas^{1,2}, C.S. Govêia², C.G. Fávero³, C.A.M.d. Silva³, K.H.R.d. Costa², F.M.L. Dias²

¹University of Brasilia, Anesthesiology, Brasília, Brazil, ²The University of Brasilia, Anesthesiology, Brasília, Brazil, ³Brasília University Hospital, anesthesiology, Brasília, Brazil

Background and Goal of Study: Dexmedetomidine (DEX), as an adjuvant for regional anesthesia, promotes sedation, enhances analgesia, and is believed to extend the duration of the sensory block induced by spinal anesthesia. This study aims to analyze the effect of intravenously administered DEX on the duration of the sensory block in spinal anesthesia.

Materials and Methods: A systematic review and meta-analysis of randomized clinical trials (RCT) was conducted using PubMed, LILACS, and Google Scholar databases, according to PRISMA guidelines. The eligibility criteria included RCT published in English, until August 2024, that evaluated the effect of intravenously administered DEX on the duration of the sensory block of spinal anesthesia compared to intravenous saline infusion, based on PI-COS strategy. The weighted mean difference (WMD) was used for continuous variables, and relative risk (RR) for dichotomous variables, with 95% confidence intervals (95% CI). The primary outcome was sensory block duration, and secondary outcomes included the duration of the motor block and postoperative analgesia, bradycardia, and arterial hypotension. A subgroup analysis was performed for bolus versus continuous infusion administration. Rayyan and RevMan 5.4 softwares were used.

Results and Discussion: From 1,552 results, 17 trials were selected, including 627 patients in the control group and 626 in the intervention group. DEX bolus dose and continuous infusion increased the sensory block duration with a WMD of 54.85 minutes $(95\% \text{ CI } [39.13-70.57], I^2 = 99\%, p < 0.00001), which was not ob$ served with exclusive use in continuous infusion (95% CI [-22.52 to 184.34], $I^2 = 100\%$, p = 0.13). Intravenous DEX prolonged the motor block duration with a WMD of 73.10 minutes (95% CI [49.42-96.78], $I^2 = 99\%$, p < 0.00001) and analgesia length with a WMD of 91.59 minutes (95% CI [72.03-111.15], I2 = 99%, p < 0.00001). DEX also increased the incidence of bradycardia (RR = 4.18, 95% CI [2.53-6.90], $I^2 = 0\%$, p < 0.00001), but there was no significant change in arterial hypotension (RR = 1.71, 95% CI [0.99-2.95], $I^2 = 14\%$, p = 0.31).

Conclusion(s): Intravenous DEX administration prolongs sensory and motor block durations of spinal anesthesia and provides postoperative analgesia. There is an increased risk of bradycardia, but not of hypotension.

Use of oxygen insufflation via laryngectomy to prolong apnoeic time for the repair of tracheoesophageal fistula in an adult patient

Y.M. Gn1

Singapore General Hospital, Department of Anaesthesia. Singapore, Singapore

Background: The repair of a tracheoesophageal fistula (TEF) through a laryngectomy stoma is an uncommon procedure which poses unique anesthesia challenges. We describe the use of total intravenous anesthesia (TIVA) and oxygen insufflation to provide tubeless anesthesia.

Case Report: A 57 year old male with a laryngectomy was listed for a TEF repair. The otolaryngologist requested for tubeless anesthesia to maximise view of the TEF, and paralysis of the patient to minimise coughing intraoperatively.

We decided to use TIVA to provide anesthesia with paralytics, while placing a 10Fr suction catheter attached to high oxygen flow (10L/min) above the carina through the laryngectomy for apnoeic insufflation, with bag-mask ventilation (BMV) on standby. We observed apnoeic periods for up to 12 minutes. We postulate that this method could potentially permit a longer apnoeic time. albeit not demonstrated here as we prophylactically placed the patient back on BMV before desaturation could occur, before returning to oxygen insufflation again for surgery to continue. The surgery duration lasted 2 hours without desaturation.

Discussion: This simple set up successfully provided tubeless anesthesia, while minimising additional logistical requirement (ie. with jet ventilator) or surgical disruption (ie.with only intermittent mask ventilation).

Limitations include mucosal dessication which may be mitigated by using humified gas for long cases. Barotrauma is a possible although endobronchial insufflation with gas flow of up to 45L/ min has been safely tolerated in the literature¹. Airway soiling is mitigated by placing the patient in Trendelenburg position.

A similar case report utilised oxygen insufflation successfully for the same operation, but the patient was maintained on spontaneous ventilation intraoperatively2. Here, we describe its feasibility in apnoeic patients with equally good results.

References:

- 1. Watson RJ, Szarko R, Mackenzie CF, et al. Continuous endobronchial insufflation during internal mammary artery harvest. Anesth Analg. 1992;75(2):219-225.
- 2. Joynt GM, Chui PT, Mainland P, et al. Total intravenous anesthesia and endotracheal oxygen insufflation for repair of tracheoesophageal fistula in an adult: Anesthesia & Analgesia. 1996;82(3):661-663.

Learning Points: TIVA with oxygen insufflation via the larvngectomy stoma can prolong apnoeic time while providing tubeless anesthesia, thereby minimising surgical interruption for BMV in a TEF repair.

42AP01-3

An innovative technique for extraluminal bronchial blocker application in One-Lung Ventilation for children under two years of age

Y.-C. Wang¹, H.-H. Huang¹, C.-H. Huang¹, W.-T. Hung², W.-M. Hsu²

¹Natoinal Taiwan University Hospital, Anesthesiology, Taipei, Taiwan, ²National Taiwan University Hospital, Surgery, Taipei, Taiwan

Background and Goal of Study: One-lung ventilation (OLV) is a crucial and challenging technique in pediatric video-assisted thoracoscopic surgery (VATS). The right upper lobe bronchus in infant is notably short, making it challenging to achieve an adequate seal with the extraluminal bronchial blocker. We developed a modified approach that combines extraluminal bronchial blocker placement with single-lumen endobronchial intubation to enhance the efficacy of right-side OLV.

Materials and Methods: We reviewed patients under 2 years of age who underwent elective VATS at National Taiwan University Children's Hospital between September 2019 and August 2024. In the standard extraluminal bronchial blocker placement, the blocker's balloon was positioned to occlude the main bronchus on the operative side. For the modified extraluminal bronchial blocker technique, the balloon was adjusted to occlude the Murphy eve. increasing the likelihood of achieving successful one-lung ventilation (OLV) (Figure). This modified technique was introduced for right-sided OLV beginning in April 2023. We conducted a historical cohort comparison to assess whether this modification improved the success rate of OLV.

extraluminal bronchial blocker

Modified extraluminal bronchial blocker

Results and Discussion: A total of 61 patients were included in the analysis, with 40 treated before and 21 treated after the introduction of the modified extraluminal bronchial blocker technique for right-sided OLV. Age, body weight, and carina-to-bronchus distance were similar between the two groups. After April 2023, there was an increase in segmentectomies, and extubation times were shorter in this later group. The incidence of suboptimal operative fields, use of artificial capnothorax, and intraoperative blocker adjustments are presented in the Table.

	Before April 2023		After April 2023	
	L (N=26)	R (N=14)	L (N=11)	R (N=10)
Artificial pneumothorax	4	3	0	1
Suboptimal operation field	4	5	0	1
Intraoperative blocker adjustment	4	3	2	3
Unsatisfactory OLV	8 (30.8%)	7 (50%)	2 (18.2%)	3 (30%)

The modified extraluminal bronchial blocker placement reduced the incidence of unsatisfactory right-sided OLV by 20%.

Conclusion(s): Modified extraluminal bronchial blocker placement is feasible in pediatric patients under 2 years of age and reduces the incidence of perioperative unsatisfactory OLV.

Background and Goal of Study: Traditional intubation manikins are often expensive and lack anatomical fidelity, particularly in the lower airway, making them suboptimal for teaching lung isolation techniques and double-lumen tube placement. Three-dimensional (3D) printing of tracheobronchial models offers a cost-effective, anatomically accurate alternative for hands-on training, enabling life-sized visualization and practice.

Materials and Methods: In collaboration with the 3D Lab at Hospital de Sant Pau, we designed transparent tracheobronchial models using preoperative computed tomography (CT) scans of male and female anatomy, printed in polylactic acid plastic (PLA).

These models allowed visualization and practice with bronchial blockers (e.g., Cook Arndt®, Cook Cohen®, EZ-blocker®, Univent™) and facilitated training in the placement of right- and left-sided double-lumen tubes.

Workshops were organized annually for residents in anesthesia, pulmonology, thoracic surgery, and intensive care, as well as for anesthesiologists on our team. Each session concluded with a satisfaction survey to evaluate its effectiveness.

Results and Discussion: Participants (grouped in six) rotated through three scenarios:

- Identifying airway structures using a complete 3D airway model with a bronchoscope.
- 2. Practicing right- and left-sided double-lumen tube placement using 3D tracheobronchial models and a bronchoscope.
- 3. Practicing the placement of various bronchial blockers available in daily practice using the 3D models and a bronchoscope. Post-session satisfaction surveys assessed organization, methodology, schedule, teaching, and materials on a 0–4 scale (0 = strongly disagree, 4 = excellent). All categories received an average score of 4, indicating excellent satisfaction.

The 3D models provided an effective and realistic hands-on learning experience, helping participants master techniques for double-lumen tube and bronchial blocker placement through the use of patient-specific models.

Conclusion: 3D printing is increasingly relevant in medicine, particularly for airway management in thoracic surgery. These tracheobronchial models offer a valuable, realistic tool for improving expertise, supporting continuous learning, and training future anesthesiologists in lung isolation techniques.

The efficacy of right displacement of trachea on double lumen tube intubation under fiberscope

Y.C. Wang¹, C.-K. Ting¹

¹Taipei Veterans General Hospital, Anesthesiology, Taipei, Taiwan

Background and Goal of Study: The malpositioning of left-sided double-lumen endobronchial tubes (DLTs) may lead to prolonged intubation time, hypoxia, and an increased risk of airway injury, posing significant threats to patient safety. Over the years, various blind maneuvers have been employed to assist in the placement of DLTs into the left bronchus, including right tracheal displacement and head-turn maneuver. This study aims to evaluate the practical effectiveness of these maneuvers under visualized quidance.

Materials and Methods: Patients undergoing thoracic surgery requiring one-lung ventilation between March 2024 and December 2024 were enrolled in this study. A total of 16 patients participated, with each undergoing the right tracheal displacement maneuver. The primary outcome was the degree of horizontal displacement of the left main bronchus as observed on the screen. The secondary outcome was whether the left main bronchus crossed the screen's midline from the left side due to the maneuver.

Results and Discussion: The average horizontal displacement of the left main bronchus to the right, as observed on the screen during right tracheal displacement, was 6.43%. Fisher's Exact Test revealed a statistically significant association (p=0.018) between the maneuver and displacement exceeding 10% of the screen. As a secondary outcome, one patient (16.66%) showed the left main bronchus crossing the midline from the left side of the screen.

Table 1 Demo	graphy
Case number	N=16
Age	61.9±9.8
Height	163.2±8.9
Weight	65.8±14.5
BMI	24.5±3.7

	Thrust Delta > 10%	Thrust Delta <= 10%	Marginal Row Totals
Pre-Push	0	16	16
Post-Push	6	10	16
Marginal Column Totals	6	26	32(Grand Total)
Statistic value is 0.0177.	The result is signific	ant at p < 0.05	

Conclusion(s): The right tracheal displacement effectively shifted the left main bronchus into a clearer visual field on the screen, facilitating the placement of the double-lumen tube into the left bronchus.

Hypoxemia during rapid sequence induction and intubation (RSII) in morbidly obese patients: a randomized controlled trial comparing a non-muscle relaxant volatile RSII with intravenous RSII

Q. Huang¹, Y. Hua¹, G. Chen¹, T. Zhu¹ ¹Sichuan University; West China Hospital of Sichuan University, Department of Anesthesiology, Chendu, China

Background and Goal of Study: Morbidly obese patients undergoing bariatric surgery are prone to hypoxemia during rapid sequence induction and intubation (RSII). Alternative RSII methods that preserve peripheral oxygen saturation (SpO₂) during the peri-intubation period are required. We hypothesised that volatile RSII combined with airway nerve blocks would be associated with a lower incidence of hypoxemia than traditional intravenous RSII in morbidly obese patients.

Materials and Methods: Forty-two patients aged 18 to 65 years with body mass index>35 kg/m2 undergoing bariatric surgery were randomly allocated.

Intervention: Intravenous RSII (propofol and rocuronium, Group RSII) or airway nerve block followed by volatile RSII (sevoflurane inhalation along with bolus propofol, Group Block).

All patients received videolaryngoscope-assisted endotracheal intubation. The primary outcome was the incidence of desaturation (SpO₂<92%) before and during intubation.

Secondary outcomes included:

A. The peri-intubation lowest SpO_a;

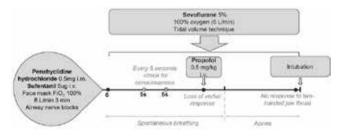

B. Intubation difficulty scale (IDS) scores, first-pass success rates, and intubation time;

C. Peri-intubation hemodynamic parameters.

Results and Discussion: Group Block had a significantly lower incidence of desaturation [4.8% (1/21) vs. 66.7% (14/21); absolute difference, 62%: 95% confidence interval, 34 to 78%: P<0.0001]. and a superior lowest SpO₂ (97% (92 to 98.5%) vs. 88% (80 to 92%), P=0.002). IDS scores in Group Block were slightly higher than those in Group RSII (0.71±0.64 vs. 0.24±0.54, P=0.013).

First-pass success rates were 100% in both groups, and the average intubation time in both groups was comparable (52.2±12.7s vs. 47.4±4.8s, P=0.14). There was a great decrease in rate pressure product in Group Block compared with Group RSII (10949.8±2408.0 vs. 15242.5±3176.9, P<0.01).

Conclusion(s): A combination of airway nerve blocks, sevoflurane, and propofol is a suitable method for RSII that improves hypoxemia and provides good intubation conditions in morbidly obese patients.

The Airway Terminology and Outcome Measures (ATOM) project to develop a core outcome set for airway management research: identification of candidate outcomes

A. Fuchs¹, B. Cornwell², K. Haynes³, A. Mohamed⁴, V. Tanna⁵, J. Hansel⁶, ATOM COS Steering Comittee ¹University of Bern, Inselspital, Bern University Hospital, Department of Anaesthesiology and Pain Medicine, Bern. Switzerland, ²Royal United Hospitals Bath NHS Trust, Bath, United Kingdom, 3Guv's and St Thomas's NHS Foundation Trust, London, United Kingdom, ⁴Manchester Royal Infirmary Hospital, Manchester Foundation Trust, Manchester, United Kingdom, 5Wythenshawe Hospital, Manchester Foundation Trust, Manchester, United Kingdom. 6The University of Manchester. Division of Immunology, Immunity to Infection and Respiratory Medicine, Manchester, United Kingdom

Background and Goal: Airway management comprises various procedures for respiratory support. Heterogeneity in outcome reporting across airway management studies hinders evidence synthesis and translation into clinical practice. The Airway Terminology and Outcome Measures (ATOM) project aims to define a core outcome set (COMET 3146) for airway management research by selecting a consensus-based standardised minimum collection of outcomes.

Materials and Methods: We searched MEDLINE, Embase, the Cochrane Central Register of Controlled Trials and ClinicalTrials. gov on 16/11/2023, with search terms used in a systematic review by Ahmad et al. [1] for published and ongoing studies from 2019. We added these to extend the existing database [1] containing studies from 2006 until 2019. We included RCTs and prospective observational studies of adult patients (≥18y) undergoing airway management. Two blinded reviewers screened eligible records in Covidence. We extracted outcomes from 100 random studies. with a 3:1 ratio of interventional to observational studies. Outcomes were considered for final inclusion if used in at least two studies and grouped into domains.

Results and Discussion: 60,023 records were screened and 2,863 were deemed relevant following exclusions, yielding a total of 4,368 studies incorporating those from the previously published review. From the 100 randomly selected studies, 669 outcomes were identified with 480 instruments. Following deduplication and data clean-up, 137 unique outcomes were identified, of which 64 were reported in at least two studies and were included in the final list of candidate outcomes. The most frequently reported outcomes are given in Table 1.

Domain	Outcome	Number of Studies	
Procedural Effectiveness	Time to intubation	44	
	Number of attempts	43	
	Glottic view	24	
Physiology	Ventilation	42	
-	Blood pressure	22	
	Heart rate	13	
Adverse Events	Complications	20	
	Oropharyngeal trauma	19	
	Hypoxaemia	19	
Patient Reported Outcomes	Sore throat	22	
Other	Hoarseness	10	
	Predictors of difficulty	11	

Table 1. Domains with most frequent outcomes.

Conclusion(s): We produced a list of the most frequent outcomes reported in a sample of airway management studies. These will inform a modified Delphi consensus process, where key stakeholders, including patients, clinicians and researchers, will be invited to prioritise them. We aim to identify up to ten agreed core outcomes, with suggested instruments, to be reported in all future airway management studies.

Germany

Pre-hospital post-cardiac-arrest-anaesthesia for reintubation of an extraglottic airway to an endotracheal tube - a multicentre observational study

G. Jansen¹, L. Eugen², A. Hoyer³, Y. Keller⁴, B. Strickmann⁵, J. Hinkelbein¹ ¹Johannes Wesling Klinikum Minden, Anaesthesiology, Minden, Germany, ²Studieninstitut Westfalen-Lippe, Medizin und Rettungswesen, Bielefeld, Germanv. ³University of Bielefeld, Biostatistics, Bielefeld, Germany, ⁴City of Dresden, Department of Public Order and Security; Fire and Disaster Control Office; Integrated Regional Control Centre, Dresden, Germany, 5District of Gütersloh, Emergency Medical Service, Gütersloh,

Background and Goal of Study: Following return of spontaneous circulation (ROSC) in out-of-hospital circulatory arrest (OHCA), post-cardiac-arrest-anesthesia (PCA) is often required, especially if an extraglottic airway (EGA) is to be replaced with an endotracheal tube. The present study examines characteristics, complications and effects of PCA in pre-hospital post-resuscitation-care

Materials and Methods: All emergency interventions between 2019-2021 in Dresden, Gütersloh, and Lippe were analyzed for adult patients with OHCA, unconsciousness, and ROSC to hospital admission. Primary endpoint was the achievement of target parameters of post-resuscitation-care (systolic blood pressure≥100mmHg, etCO2:35-45mmHg, SpO2:94-98%) by the application of PCA. Secondary outcome was rate of re-arrest, as well as additional narcotics used. Propensity-score-analysis was used for evaluation.

Results and Discussion: A total of 391,305 emergency operations with 2.298 OHCA (incidence 0.58%: 95%CI:0.54-0.63) with ROSC were observed until hospital admission in 706 patients (30.7%; w=34.3%; age=68±14 years). PCA for replacing an EGA with an ETI was administered to 152 (31.5%; 95%CI: 27.4-35.9) patients. 44 patients has to be excluded due to incomplete datasets for the propensity-score-matching.

The remaining 106 patients received PCA with Midazolam: n=53(76.9%), Propofol: n=24(34.8%), (S-)Ketamine: n=7(10.1%); Fentanyl: n=40(58.0%), Morphine: n=1(1.4%), Cis-Atracurium: n=7(10.3%) and/or Rocuronium: n=13(18.8%)).

Re-Arrest occurred in n=23(21.7%; PCA: n=7(30.4%) vs. No-PCA: n=16(69.6%)).

Propensity-score-analysis showed that guideline-recommended ventilatory targets (odds ratio (OR): 6.50, 95%CI: 1.47-28.80; p=0.0137) were achieved significantly more often with PCA than without PCA.

However, no evidence of an increased chance of reaching oxygenation targets (OR: 1.20, 95%Cl: 0.37-3,93; p=0.7633) was found. While there was no evidence for an influence on the rate of hypotension at the end of the treatment (OR:1.29: 95%CI:0.48-3.45; p=0,6180), there was evidence for reduced odds for a re-arrest in patients receiving PCA (OR:0.31; 95%CI:0.10-0.94, 0.033). Conclusion(s): Application of PCA for replacement of an EGA with an ETI allows for early achievement of ventilation targets of post-resuscitation-care with no evidence of adverse haemodynamic effects or re-arrest.

42AP01-9

Gastric ultrasound - shining a light on fasting times

T. Melo¹, F.m.M.G.v. Guedes¹, J. Moreira¹ ¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Aspiration of gastric contents is a rare but potentially disastrous anesthetic complication(1). Perioperative fasting guidelines aim to reduce the risk of aspiration in elective and healthy patients, but they may not be enough to patients with certain comorbidities.

Gastric ultrasound is a tool to ensure patient safety when the recommended

fasting times are unreliable or when there are barriers in communication.

Case Report: A 62-year-old woman was scheduled for hallux valgus surgery. Medical history included deafness, grade II obesity, hiatal hernia, gastroesophageal reflux disease (GERD), and depression.

Despite adhearence to a six-hour fasting period for solids, a gastric ultrasound was performed due to her risk factors, revealling both solid and liquid content in the dorsal decubitus position, prompting the postponement of the surgery, and thereby avoiding the patient's exposure to unwaranted risk.

The situation was explained to the patient and her family, and tailored fasting recommendations were provided for a next surgical appointment.

Discussion: Gastric ultrasound is a bedside, non-invasive and reproducible tool that improves patient safety (2).

This case aligns with the rising body of literature that suggests that regular fasting times may not always provide a low aspiration risk in certain patient populations, and inidividualized, more conservative fasting instructions, as well as ultrasound verification, may be necessary to insure patient safety. Considering that gastric pH is the most important factor for pneumonitis, any solid content found in the gastric antrum represents an unacceptable risk in the context of elective surgery for a benign condition

1. Cook, T. M., Woodall, N., & Frerk, C. (2011). The NAP4 report: Major complications of airway management in the UK. London: The Royal College of Anaesthetists.

2. Baettig, S. J., Filipovic, M. G., Hebeisen, M., Meierhans, R., & Ganter, M. T. (2023). Pre-operative gastric ultrasound in patients at risk of pulmonary aspiration: a prospective observational cohort study. Anaesthesia, 78(11), 1327-1337.

Learning Points: Gastric ultrasound is an increasingly accessible tool for assessing aspiration risk in patients with comorbidities, and an improvement in patient safety.

The presence of risk factors for delayed gastric emptying may warrant the implementation of tailored dietary, pharmacological, and behavioral measures to ensure the lowest possible risk of aspiration.

42AP01-11

Pulmonary aspiration during induction of anaesthesia in patients who gastric contents in two patients taking semaglutide for weight loss

M. Somri¹, J. Hossein², S.A. Avraham², A. Salim², F. Shehade², F. Somri³

¹Technion - Israel Institute of Technology, Anesthesia, Haifa, Israel, ²Bnai Zion Medical Center, Anesthesia, Haifa, Israel, 3Università degli Studi G.D'Annunzio Chieti Pescara, Medicine, Pescara, Italy

Background: Semaglutide is a new weight loss treatment that has received substantial media attention in recent years. Anaesthetists must be aware of a potentially dangerous side effect of the drug: decreased gastric emptying. This is caused by effects on gastric smooth muscle, mediated by the vagal afferent nerves. This is especially relevant in the peri-operative setting where pulmonary aspiration of gastric contents is a recognised complication (1,2). Here, we report two cases of peri-operativer regurgitation of gastric contents in patients taking semaglutide.

Case Report: Case 1: A 70-year-old male (BMI 35) with multiple comorbidities presented for elective ERCP. Despite 12-hour fasting and using rapid sequence induction, gastric regurgitation occurred during intubation. Oxygen saturation dropped to 83% but stabilized after appropriate interventions. The procedure was completed successfully and the patient was discharged after one

Case 2: A 25-year-old female (BMI 32) on semaglutide for weight loss presented for breast abscess drainage. Despite 8-hour fasting, regurgitation occurred upon LMA removal, requiring emergency intubation. The patient recovered without complications. Both cases highlight potential gastric motility issues in patients using semaglutide, suggesting the need for additional precautions during anesthetic management.

Discussion: Since 2021, semaglutide has gained recognition as a `celebrity weight loss.

A patient taking semaglutide may have a full stomach despite compliance with routine pre-operative fasting guidelines. We consider how to manage patients receiving glucagon-like peptide-1 agonist therapy in the peri-operative period, including identifying those at high risk of regurgitation.

References:

1. Frias JP, Davies MJ, Rosenstock J, et al. Tirzepatide versus semaglutide once weekly in patients with type 2 diabetes. New England Journal of Medicine 2021; 385: 503-515.

2. Somri F, Somri M, Gaitini L, Kharouba J, Gómez-Ríos MÁ. Exploring a novel scavenger for inhalational induction in pediatric anesthesia. A promising approach. J Clin Anesth 2024;94:111375

Learning Points: We are not the first group to suggest a connection between semaglutide and peri-operative aspiration Precautions such as rapid sequence induction and tracheal intubation can be used, but gastric ultrasound may also be useful in the pre-operative environment to help identify patients at high risk of aspiration.

42AP02-1

From skin to airway: employing ultrasonography in the prediction of difficult laryngoscopy and ventilation

G. Mitos¹, A. Marchi¹, S. Soteriades¹, E. Kiourtzieva¹, G. Thoma¹, E. Argyriadou¹

¹Aristotle University of Thessaloniki, Department of Anesthesiology and Intensive Care, Thessaloniki, Greece

Background and Goal of Study: Predicting difficult laryngoscopy (DL) and ventilation (DV) is a key objective of preoperative evaluation. Traditional clinical indices (modified Mallampati score, thyromental distance, upper lip bite test) have been extensively used, albeit with variable reliability. Recently, ultrasound (US) has emerged as a promising modality for airway assessment. This study aims to evaluate the predictive reliability of specific US indicators for DL and DV.

Materials and Methods: A prospective observational study was conducted in adult patients scheduled for elective surgery under general anesthesia at <a>IHEPA General University Hospital in Thessaloniki, Greece. Preoperative airway evaluation with traditional clinical indices was combined with the following US measurements: thyromental distance (TMD) in neutral head position. TMD at maximal head extension, vocal cord commissure-to-skin distance (VCCSD) and epiglottis-to-skin distance (ESD). Data were analyzed for correlation with DL and DV as binary outcomes. DL was defined as a score of 3 or 4 on the Cormack-Lehane scale and DV as a score of 3 or 4 on the Han scale. Predictive performance of US parameters was computed using receiver operating characteristic (ROC) curve analysis. US measurements were performed by a single trained operator. In all cases, mask ventilation and intubation were performed by a second skilled operator.

Results and Discussion: A total of 230 patients were included in the study, 74 (32.2 %) of whom were female. The median BMI was 25.3 (range: 15.0-46.9) and the median age was 44 (range: 18-94). Our analysis determined that the most reliable predictor of DI was VCCSD (AUC 0.812) with a cut-off value >7.9 mm (86.8% sensitivity, 52.0% specificity). VCCSD was also the most reliable predictor of DV (AUC 0,786) with the same cut-off value (>7.9 mm, 80.0% sensitivity, 44.1% specificity). Due to its high sensitivity but low specificity, VCCSD should be used in conjunction with established clinical indicators.

Conclusion(s): The integration of ultrasonography into preoperative airway evaluation could enhance difficult airway prediction and patient safety. Further studies are warranted to validate these findings so that ultrasonographic airway indicators can be incorporated into airway management algorithms.

Botulinum toxin masseter injection in progressive bulbar paralysis: Anesthetic management

P. Carrão¹, C. Silva², <u>J. Branquinho</u>², A. Guedes² ¹Unidade Local de Saúde Viseu Dão-Lafões, Medicina Intensiva, Viseu, Portugal, ²Unidade Local de Saúde Viseu Dão-Lafões, Anestesiologia, Viseu, Portugal

Background: Motor neuron diseases (MNDs) are rare neurological disorders affecting upper motor neurons (UMNs) and/or lower motor neurons (LMNs). Progressive bulbar palsy (PBP) is an MND characterized by progressive LMN involvement in the brainstem, impairing the motor neuron signals to facial, lingual, and pharyngeal muscles. Patients with MNDs present significant anesthetic challenges, including potential difficult airway management.

Case Report: A 70v old female with 4v diagnose of PBP scheduled for radical mastectomy presented decreased pulmonary function, facial expression loss, dysphagia, anarthria in the anaesthesiology apointment. On airway observation the interincisor distance was <1cm. The case was brought to multidisciplinary discussion involving the anaesthesiology, neurology and the surgical teams, which led to urgent scheduling of botulinum toxin masseter injection and 3 weeks surgery postponement to allow maximum toxin effect. On the surgery day the patient interincisor distance had improved to 2-3cm. The airway approach was carefully planned and uneventful fiberoptic tracheal intubation was performed under sedation (dexmedetomidine, cetamine) and spontaneous ventilation. Total intravenous anaesthesia was perfomed with propofol infusion, one single bolus of fentanil at surgical incision without NMB. Mechanical ventilation was weaned cautiously at the end of the surgery and adequate ventilation and neurological recovery were rapidly achieved allowing extubation and safe transference to PACU and the ICU care previously arranged wasn't necessary. The patient preoperative neurologic baseline status was unchanged, who went home 5days later.

Discussion: PBP presents significant challenges in anesthetic management due to bulbar dysfunction, respiratory compromise, and sensitivity to anesthetic agents. Early and thorough preoperative evaluation is vital for identifying risks, optimizing the patient's condition, and developing a safe perioperative strategy. In this case, botulinum toxin facilitated improved airway access, highlighting its role in managing trismus secondary to MNDs.

References:

Arora RD, Khan YS. Motor Neuron Disease. Treasure Island (FL): StatPearls Publishing; 2024 Jan-. Available from: https://www.ncbi.nlm.nih.gov/books/NBK560774/

Learning points: This case emphasizes the importance of individualized planning and a multidisciplinary team approach to managing MND patients and the usefulness of botulinum toxin masseter injection.

42AP02-4

Evaluation of third generation video laryngeal mask for airway management in general anaesthesia

M. Kalina¹, J. Jobánek¹, M. Hanauer¹
¹Děčín Hospital, Department of Anaesthesia, Resuscitation and Intensive Care, Děčín, Czech Republic

Background and Goal of Study: Blind insertion technique is used commonly for laryngeal mask insertion nowadays. But, suboptimal alignment of laryngeal mask using the blind insertion technique is reported in up to 60% of cases. The new video laryngeal mask SaCoVLM was recently invented. This new technology combines laryngeal mask and video camera and promise improvement in insertion technique. Therefore we evaluated the new third generation of video laryngeal mask SaCo VLM in terms of successful insertion rate.

Materials and Methods: In this pilot study, the population were patients without predicted difficult airway undergoing elective surgery in general anaesthesia. In these patients third generation of video laryngeal mask SaCo VLM was used to manage airway. The mask was inserted after induction to general anaesthesia. Our primary outcome was insertion first attempt success rate. Secondary outcomes were number of insertion attempts needed for successful ventilation, total insertion success rate and the time needed to start successful ventilation.

Results and Discussion: Total of 30 patients were enrolled in the study. There was no significant difference in demography of the study population. The insertion first attempt success rate was 90%. In two cases two insertion attempts were needed for successful ventilation. In one case laryngeal mask size 4 was switched with size 5. Then successful ventilation was achieved. The mean time needed for successful ventilation was 12 seconds. Conclusion(s): SaCoVLM, the new third generation video laryngeal mask is a promising new technology to manage airway during general anaesthesia with high first attempt success rate and high overall insertion success rate.

A non-invasive technique of anterior ethmoid nerve block during nasotracheal intubation

C.-C. Huang¹, K.-Y. Lu¹, W. Lan¹ ¹MacKay Memorial Hospital, Anesthesiology, Taipei, Taiwan

Background and Goal of Study: The anterior ethmoid nerve (AEN), a branch of the nasociliary nerve from the ophthalmic division of the trigeminal nerve, innervates the superior nasal meatus and anterior nasal septum. During nasal intubation, AEN stimulation often triggers abrupt hemodynamic changes via brainstem reflex pathways. To minimize discomfort and maintain stable hemodynamics, we evaluated a non-invasive anterior ethmoid nerve block (AENB) during nasotracheal intubation.

Materials and Methods: Patients undergoing oral or otolaryngological surgery with nasotracheal intubation between January 1, 2024, and October 31, 2024, at Mackay Memorial Hospital were included. AENB patients were matched with non-AENB controls based on propensity scores calculated from age, sex, and ASA classification.

Anesthesia followed a standardized protocol. In the AENB group, 2-3 mL of 2% lidocaine was sprayed into the superior nasal meatus using a syringe with an intravenous catheter, targeting the AEN's origin. If resistance occurred, the syringe was withdrawn until the solution was fully delivered. This ensured precise anesthetic delivery.

Hemodynamic data were analyzed to assess AENB effectiveness. The primary outcome was heart rate change within 20 minutes post-induction, and the secondary outcome was blood pressure change within the same period.

Results and Discussion: A total of 40 patients were included during the retrospective review of cases. Heart rate changes were significantly lower in the AENB group compared to controls (28.6% vs. 49.8%; 95% CI: [-0.3078, -0.1172]; P < 0.01). However, the change in blood pressure did not show statistically significant results (39.8% vs. 7.6%; 95% CI: [-0.2160, 0.8588]; P = 0.2335).

Conclusion(s): AENB significantly reduces heart rate changes, indicating its effectiveness in minimizing stimulation during nasotracheal intubation. This non-invasive technique stabilizes hemodynamic responses and may benefit other procedures involving nasal instrumentation. Further studies with larger populations are needed to confirm these findings and explore broader applications.

42AP02-7

A comparative evaluation of four different periglottic airway devices with preformed shape: A prospective, randomized, comparative, clinical, controlled study

E. Dimitriou¹, S. Antoniou¹, M. Spyraki¹, T. Beskou¹, A. Zotou¹, D. Aretha¹

¹University Hospital of Patras, Anesthesiology and ICU, Patras, Greece

Background and Goal of Study: Correct placement of secondgeneration supraglottic airway devices is crucial for patient safety and efficient airway management. A less-than-optimal anatomical and functional positioning, can cause clinical malfunction. The aim of this study was to evaluate 4 most popular periglottic airway devices (I-Gel[™], LM Protector[™] LM Fastrach[™], LM Proseal[™]) as regards to ventilation sufficiency and perfection of installation/ anatomical application to the larynx (evaluation with flexible video-bronchoscope).

Materials and Methods: 240 adult patients ASA (I-II) were randomly separated in 4 groups (60 patients in each group) for an elective surgical procedure under general anesthesia. The primary outcome of our study was the adequacy of ventilation which was evaluated with volume leak percent and differences between inspired and expired tidal volume (ΔTV), while secondary outcomes included time for SAD insertion, oropharyngeal leak pressure, perfection of anatomical application to the larynx and complication rate.

Results and Discussion: There were no statistically significant differences in patients baseline and airway characteristics among the 4 groups. Data related to LMA insertion, ventilation sufficiency and complications are presented in Table 1 and Figure 1.

	lgel	Protector	Fastrach	Proseal	P-value

Data are presented as means (SD), medians (interquartile range 25-75, IQR), or as numbers and percentages (%). *******Differences between SADs

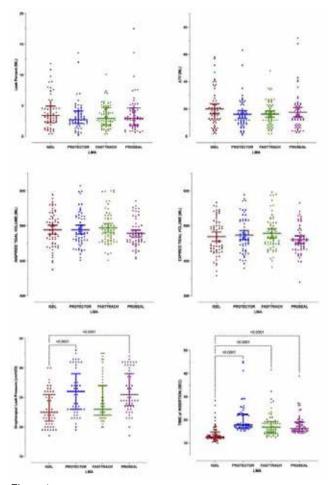

Figure 1:

Conclusion(s): There were no statistically significant differences among the 4 SADs as far as it concerns the ventilation sufficiency and the anatomical application to the larynx. I-Gel™ revealed faster insertion time and lower complication rate. Oropharyngeal leak pressure was significantly higher in LM Protector™ and LM ProsealTM.

42AP02-8

Challenges in airway management during tracheal resection: a case report

J. Borrell Vega¹, M.J. Arguis¹, M.J. Carretero¹, S. Italiano¹, S. Martínez-Otero¹, M. López-Baamonde^{1,2} ¹Hospital Clínic Barcelona, Department of Anaesthesiology, Barcelona, Spain, ²University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer- IDIBAPS, Barcelona, Spain

Background: Tracheal malignant lesions are rare and surgical resection presents multiple challenges concerning airway management.1 The anesthetic approach and perioperative management of a large tracheal tumour resection involving six rings near the carina are described.

Case Report: A previously healthy 55-year-old woman was scheduled for resection of a hypervascularised high-grade adenoid carcinoma located 15 mm from the carina, involving six rings and occupying 60% of the tracheal lumen. Awake intubation with fibro bronchoscope was chosen, with cold saline and tranexamic acid applied locally before inserting an 8 cm endotracheal tube past the tumour (Pic1).

In anticipation of the potential need for ECMO due to bleeding from the lesion, incapability of ventilation or surgical potential complications, a multidisciplinary team (anaesthesiology, thoracic and cardiac surgeons) decided to place femoral introducer sheaths to perform a fast guidewire exchange if needed.

During tracheal resection, in-field ventilation of the left bronchus was performed, with brief apnea periods for suturing while maintaining oxygen saturation >90%. Blood loss was minimal, the surgery proceeded without complications and extubation occurred in the OR. Multimodal analgesia, including intravenous and epidural drugs, was administered.

Discussion: Multidisciplinary collaboration is essential for complex airway surgeries to minimize complications. 1When performing direct airway surgery, if a potential difficulty in the patient's oxygenation is anticipated, vascular introducer sheath placement may be considered to ensure easy quick access in case ECMO becomes necessary. Multimodal analgesia, including loco-regional techniques, is vital for pain control, rehabilitation, and preventing pulmonary complications.

Reference:

1. doi:10.1016/j.thorsurg.2024.09.00.

Learning points: Tracheal resection for intraluminal lesions poses significant risks to airway integrity. Proactive planning is crucial to maintain oxygenation, with ECMO as a feasible solution. Collaboration among surgical and anaesthesiology teams is essential for planning complex airway surgeries to minimise complications.

42AP02-9

Hereditary angioedema in a young patient: treading the extubation pathway

D.F. Papadaki¹, E. Ischaki¹, E. Margioula¹, K. Chatzistavrou¹, S. Kokkoris¹ ¹General Hospital of Athens Evaggelismos - Polykliniki, Intensive Care Unit, Athens, Greece

Background: We report a case of a 20 y.o. female patient with previously undiagnosed hereditary angioedema (HAE) who presented with severe acute laryngeal edema, requiring emergency tracheostomy after initial intubation.

Case Report: The patient presented to the emergency room with facial and neck swelling. Her medical history included morbid obesity, depression while receiving oral contraceptives. Despite normal initial direct laryngoscopy (DL), the patient developed acute dyspnea and severe laryngeal edema unresponsive to corticosteroids or adrenaline, resulting in a peri-arrest state and emergency intubation with a 6.0 OT tube. The patient was transferred to the ICU, where HAE was suspected based on her clinical presentation and medical history provided by her parents, and treated accordingly. Due to an acute respiratory deterioration, bronchial toilet was necessary, raising the dilemma of whether to replace the OT tube with a larger size or perform an emergency tracheostomy. Since the former was deemed precarious, a tracheostomy was performed. Despite multiple C1 inhibitor administrations and transient improvement in laryngeal swelling, tracheostoma removal was not possible due to recurrent swelling with each airway maneuver. Her hospitalization proceeded without complications, the diagnosis was confirmed, and she was discharged with the plan to remove the stoma in due time.

Discussion: HAE is a rare cause of laryngeal edema. Nonetheless, diagnosis is necessary as usual approaches, like corticosteroids, are ineffective. Awake intubation with flexible fiber-optic bronchoscope should be employed when possible. There are very few extubation protocols reported in literature for these patients. which mainly include performing a cuff-leak test or DL.1 On the contrary, in our case even performing a DL to assess the degree of laryngeal edema was a potential trigger.

- 1. Floyd E, et al. An extubation protocol for angioedema. OTO Open. 2017 Feb 3;1(1):2473974X17691230.
- 2. Moellman JJ, et al. A consensus parameter for the evaluation and management of angioedema in the emergency department. Acad Emerg Med. 2014 Apr;21(4):469-84.

Learning points: Differentiating laryngeal edema in the emergency setting is challenging but crucial for appropriate treatment. This case highlights that airway management and extubation in such patients can be as difficult as intubation, while further research is needed in establishing appropriate protocols.

42AP02-10

PrediSuisse: Automatized Assessment of difficult airway using three different models of videolaryngoscope with the help of facial recognition techniques and neural network

P. Flückiger¹, G. Casso², G.L. Salvodelli³, O. Voegtlin¹, J. Didier¹, P. Schoettker¹

¹University Hospital Lausanne (CHUV), Department of Anesthesiology, Lausanne, Switzerland, ²Istituto CardioCentro EOC, Department of Anesthesiology and Intensive Care, Lugano, Switzerland, 3Geneva University Hospitals and Faculty of Medicine, Division of Anaesthesia, Department of Anesthesiology, Clinical Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland

Background: Airway management is crucial in every anesthetic procedure with alteration of consciousness. Intubation difficulties are mostly unanticipated and may have disastrous consequences. Accurate preoperative assessment is fundamental to identify patients at risk before anesthesia. Predicting airway difficulties remains a challenging task and there is a lack of consensus on the best method to achieve it. Furthermore, due to the widespread clinical application of recently introduced videolaryngoscopes (VL), we should reconsider traditional predictive methods that are not validated for these tools.

This study aims to predict and classify airway difficulty with VL, using facial recognition techniques and a neural network.

Methods: "PrediSuisse" is a multicentric research project (NCT06453525) including 1800 patients undergoing elective general anesthesia in Switzerland, aimed at predicting the difficult airway using videos of the patients' face processed by an automated smartphone application. Videos of the patients' face will be recorded with an iPhone 15 showing four pre-established facial and head motions during the routine pre-anesthesia consultation. The first phase of the study will consist of training a convolutional neural network (CNN) with these videos. Intubation difficulty will be defined by a panel of 3 airway experts reviewing the recorded images of the intubation acquired by three different models of VL in addition to the subjective assessment of the operator and informative description from the software. The performance of the "PrediSuisse" algorithm will finally be tested on a validating set of patients using inferential statistics (t-tests, ANOVA, and regres-

Secondarily, we aim to identify new morphological features that may be related to difficult tracheal intubation when using three different models of VL with various shapes of blade (MacIntosh, hyperangulated or channeled).

Results: The first patient enrollment will be in early 12/2024. We plan to collect the training set from the first 500 patients in the three participating institutions until early 03/2025, allowing the training of the algorithm. Preliminary results will be presented in

Conclusions: This is the first study aimed at generating a fully automatic software to predict difficult airway using recordings of the intubation process acquired by three different VL with specific blades on a European population.

42AP02-11

Diagnosis of newly developed glottis edema (GE) during gastroscope (GC) removal

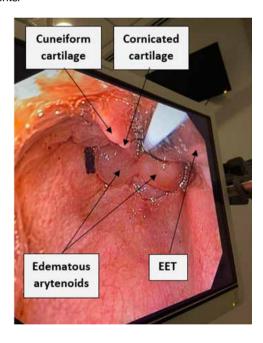

B. Apaolaza¹, A.M. Pola Jiménez¹, C. Salvador Vidal¹, N. Lopetegui Puertas¹, M. Sanz¹, M.J. Salvador Bravo¹ ¹Hospital Universitario de Navarra, Anestesiologia, Pamplona, Spain

Background: Laryngeal injury is usual after endotracheal intubation and, although it is uncommon, it could result in an emergency cricothyrotomy. Therefore, it is essential to assess proper condition of the airway (AW) before extubation.

Case Report: We present an 87-y-o male that was scheduled for an endoscopic extraction of pyloric lithiasis. In the preoperative anesthesia consultation, no predictors of a difficult AW were acknowledged. Following standard general anesthesia induction, the laryngoscope (LC) was inserted and an endotracheal tube (EET) was placed on the first attempt without incidents.

While removing the LC, no sign of laryngeal injury was detected. They performed the procedure and during the removal of the GC a newly developed GE was observed.

Thus, we transferred the patient intubated to the PACU for administration of dexamethasone 4mg/8h. After 24 hours, a cuff leak test (CLT) was performed and the patient was extubated without incidents.

Discussion: Laryngeal injury is common after endotracheal intubation, presenting with varying degrees of edema and limited vocal cord movement that could result in an AW that is neither ventilable nor intubable, where the only life-saving option is a cricothyrotomy. Consequently, if a potential glottic impairment is suspected, it is essential to assess its condition before extubation. In order to do this, we have several tests and the most used ones are CLT, laryngeal ultrasound and video laryngoscope (VL). The first two tests are rapid and non-invasive. However, with the third test, we can assess the AW directly since it is an invasive test.(1) In our case, the gastroscope served the function of the VL without adding the risk of another invasive test: since, we were able to fully visualize the glottis and it had a direct effect on our actions, as we decided not to extubate the patient.

References:

1. Li M, Yan Y, Li P, Zhang L. The difficult removal of tracheal tube after general anesthesia: A case report, 2022/10/7.

Learning points: Routine airway assessment during the removal of the GC is a simple, inexpensive and rapid measure that helps assessing the proper condition of the airway for extubation.

42AP02-12 Novel right lung isolation in bronchus suis

M. Puskac¹, M. Antonoff², D. Thakar¹ ¹The University of Texas MD Anderson Cancer Center, The Department of Anesthesiology and Perioperative Medicine, Houston, United States, ²The University of Texas MD Anderson Cancer Center, The Department of Thoracic & Cardiovascular Surgery, Houston, United States

Background: Bronchus Suis is an anatomical variant of the right main stem bronchus (RMS) seen in 0.1-2% of the population.1 In this variant the RMS typically arises from the right lateral tracheal wall within 2cm of the main carina.1

Case Report: A 66-year-old presented for right upper lobectomy for lung cancer. The patient had undergone CT-imaging and bronchoscopy demonstrating her right upper lobe (RUL) arising from the right lateral trachea above the main carina. The lobectomy required right lung isolation.

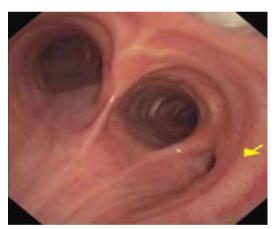

Fig.1 Bronchus suis.

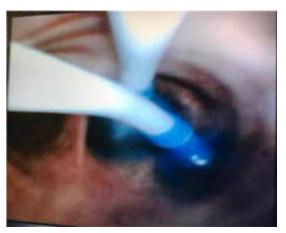

Fig.2 Vivasight view of bronchial blockers in the bronchus intermedius and the right upper lobe.

After induction, a CMAC was used to place a 9.0fr Fuji Uniblocker through the glottis, at a depth of 25cm. After the patient was intubated with the Fuii Uniblocker, an 8.0 Vivasight SLT was placed next to the blocker at a depth of 20cm. Once the Vivasight tube was in place, the Vivasight monitor was used to place the indwelling Fuji Uniblocker in the right bronchus intermedius.

The balloon was inflated to isolate the right middle and lower lobes. Another 9.0fr Fuji Uniblocker was placed through the Vivasight tube and into the bronchus suis, then inflated to deflate the RUL.

Discussion: The Vivasight tube allows for continuous monitoring of the blockers. The Fuji Uniblocker's angled and rigid design allow for ease of placement with the Vivasight camera and no bronchoscope.

Learning points: This represents a novel technique, in that no bronchoscope was required for placement, and there was continuous visualization of the blockers.

42AP03-1 Soft palate perforation during orotracheal intubation facilitated by the C-MAC videolaryngoscope

M.J. Puerta Ordóñez¹, E. Rodriguez Matarranz¹, A. Martinez Serrano¹, J.R. Rodriguez Fraile¹ ¹Hospital Universitario de Guadalajara, Anestesiologia, Reanimacion y Tratamiento del Dolor, Guadalajara, Spain

Background: We report a case in which soft palate was perforated during an endotracheal intubation, a difficult airway guided by the C-MAC videolaryngoscope.

There are few records of this type of iatrogenic intubation and its consequences.

Case Report: 51-year-old man, hypertensive, type III obesity with truncal profile. Predictors of difficult airway: poor cervical mobility, body mass index 35, beard, protruding teeth, snorer. We performed general anaesthesia, using a videolaryngoscope and a styletted endotracheal tube. Cormack - lehane I/IV. Technical difficulty in inserting the tube into the pharyngeal cavity due to patient's anatomical characteristics.

After intubation we visualised blood around the tube, and following removing the videolaryngoscope blade we observed soft palate perforation, the tube having passed through it.

Spontaneous cessation of bleeding and assessment by otolaryngologist, deciding on conservative treatment. Uneventful extubation. Subsequent telephone follow-up of the patient: the defect closed spontaneously postoperatively within 10 days.

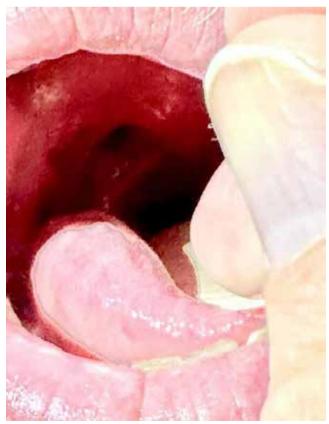

Discussion: The use of a rigid stylet and focus the attention on the C-MAC monitor could probably have been contributory factors to this complication [1].

References:

- 1. Pham Q et al. Soft Palate Injuries During Orotracheal Intubation With th Videolaryngoscope. The Annals of Otology, Rhinology, and Layngology. 2017.
- 2. Long WL et al. Palatopharyngeal wall perforation during glidescope intubation. Anesthesia and Intensive care. 2008.

Learning points: Soft palate perforation during orotracheal intubation is very unlikely, but may be increased by the use of rigid stylet and lack of display of the oral cavity [2]. In case of resistance to inserting the tube, check the structures to avoid injury. Oral mucosa perforation with well-defined borders is usually resolved with conservative treatment.

B. Silva¹, J. Machado Nogueira¹, I. Pestana², C. Mexêdo² ¹Unidade Local de Saúde da Região de Aveiro, Anesthesiology, Aveiro, Portugal, ²Unidade Local de Saúde de Santo António, Anesthesiology, Porto, Portugal

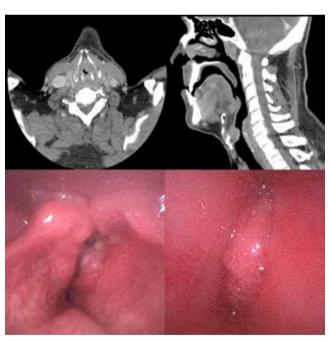

Background: Identifying a difficult airway is crucial for anesthetic planning but even when identified, it can be even more difficult than predicted and raise challenges between the challenge.

Case Report: Male, 50 years old, admitted due to dysphonia and dyspnea for median efforts for study and biopsy throw to suspension microlaryngoscopy (SML). Nasendoscopy previously performed by ORL team showed ulcerovegetative lesion with starting point in left vocal cord, conditioning homolateral hemilarynx paralysis. CT scan the day before surgery showed marked stenosis of the larynx with airway patency.

Awake tracheal intubation using flexible bronchoscopy (ATI:FB) with MLT tube was performed, under high-flow nasal oxygen, sedation with remifentanil, lidocaine topicalization and cooperating patient in spontaneous ventilation. ATI:FB was successful with second operator.

During the procedure, it was visualized the lesion among marked distortion of the larynx, a very small glottis collapsing during respiratory movements. The major difficulty was in subglottic passage. During SML was verified transglottic neoplasm with high risk of airway loss, resulting in tracheostomy.

After tracheostoma, laryngectomy tube was placed for ventilation and direct visualization of the subglottis was achieved with the fibrescope, confirming severe obstruction and eminent airway loss. Tracheostomy tube was placed for airway maintenance.

Discussion: High-flow nasal oxygen, as a pillar of the sTOP technique, was particularly essential on this case, not only to maintain blood oxygenation but to allow some permeability in the airway, and assist the ATI:FB.1 Difficult airway is dynamic, such as diagnosis, depending on physiological factors such as disease progression or edema, and can rapidly aggravate, as in this case, complicating airway and future disease management.

42AP03-3

The role of airway ultrasound in the management of a predicted difficult airway

A.R. Rocha¹, <u>A. Carneiro</u>¹, S. Maia¹, G. Norte¹, M. Sá¹, S. Caramelo¹

¹Unidade Local de Saúde Trás-os-Montes e Alto Douro, Anesthesiology, Vila Real, Portugal

Background: Managing a difficult airway in urgent or life-threatening situations can be a significant challenge. Traditional airway evaluation methods often have limitations, especially in patients with history of cervical surgery. Ultrasound (US) has emerged as a promising tool for airway assessment due to its accessibility, safety and non-invasive nature.

Case Report: A 71-year-old male was proposed for an urgent exploratory laparotomy for suspected colon ischemia. He was hemodynamically unstable, requiring vasopressor support, and had a Glasgow Coma Scale score of 9. His medical history included vertebromedullary trauma in the cervicothoracic region nine years prior, resulting in paraparesis at the D4 level and a post-tracheostomy status due to prolonged mechanical ventilation. He also had chronic pulmonary disease and required home non-invasive ventilation with cough assist for difficulty clearing secretions. Physical examination revealed limited cervical mobility and edentulism. An US examination was performed for airway assessment. Using a linear probe in a transverse orientation, we measured the following parameters: in the thyrohyoid view, the distance from the skin to the epiglottis (DSE) was 1.9 cm; and in the suprasternal view, the tracheal diameter was 9.6 mm. Intubation equipment was prepared: a size 7 orotracheal tube with a stylet and a videolaryngoscope. A rapid sequence induction was performed due to aspiration risk, and successful tracheal intubation was achieved on the first attempt without complications. Post-surgery, the patient was transferred to the ICU on mechanical ventilation due to multi-organ dysfunction, extubated 12-24 hours later, and discharged home after 21 days.

Discussion: US can offer a fast and valuable enhancement to traditional airway evaluation, especially in urgent cases. Studies suggest that a DSE >2.48–2.54 cm is a reliable indicator for difficult laryngoscopy. In cases of possible tracheal stenosis following tracheostomy, US can assist in selecting the appropriate tube size. This case highlights the potential of US to enhance airway management.

- 2. Fernandez-Vaquero et al. (2023). Preoperative airway ultrasound in the sniffing position. Braz J Anesthesiol., 73(5), 539-547

Learning points: Ultrasound can be a valuable resource for optimizing airway management, especially in difficult scenarios.

42AP03-4

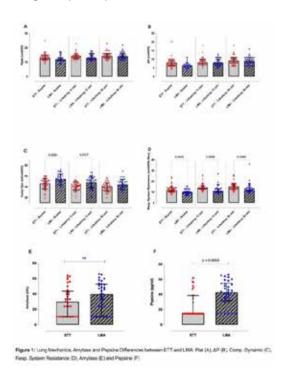

Comparison of laryngeal mask airway Protector™ with endotracheal tube: Evaluation of respiratory mechanical parameters in controlled mechanical ventilation and prevalence of pulmonary microaspiration. A prospective, randomized. comparative, controlled clinical study

S. Antoniou¹, E. Dimitriou¹, N. Drakos², A.-L. de Lastic³, D. Georgakopoulou³, D. Aretha¹

General University Hospital of Patras, Department of Anesthesiology and Intensive care, Patras, Greece. ²General University of Patras, Department of General Surgery, Patras, Greece, 3University of Patras Medical School, Laboratory of Immunohematology, Division of Hematology, Department of Internal Medicine, Patras, Greece

Background and Goal of Study: Supraglottic airway devices are a valuable alternative to endotracheal intubation to maintain airway. The aim of this study is to compare laryngeal mask airway (LMA) Protector™ with the endotracheal tube, regarding to the respiratory mechanical parameters and the prevalence of aspiration.

Materials and Methods: 85 adult patients ASA (I-II) were scheduled to receive endotracheal tube (ETT group, N.=44) or (LMA) Protector™, N=41) for airway management during urology procedures. Assessments included intraoperative lung mechanics (Peak inspiratoty pressure, Dynamic Compliance, Plateau Pressure) in suspine and in lithotomy position, insertion time, success first pass rate, hemodynamics data, and pharyngolaryngeal complications. Assessment of aspiration risk was evaluated by detecting and quantifying pepsin and amylase in bronchoalveolar lavage samples of patients.

Results and Discussion: From 168 consecutive pts 85 pts (44 in ETT and 41 in LMA group) enrolled in the study and included in the analysis. There were no statistically significant differences in pts baseline and airway characteristics between groups. C_{the}was significantly higher while Resistance was lower in the LMA group, at different time points. Pepsine levels was significantly higher in the LMA group while amylase levels were similar between groups. Data related to devices insertion, ventilation sufficiency and complications are presented in Table 1 and Figure 1. Hemodynamics were similar between the two groups.

	ETT (44 pts)	LMA Protector (41 pts)	P-value
Time of intubation or LMA insertion (sec), median (IQR)	31.10 (29.0-35.7)	20.4 (18.7-22.9)	<0.0001
Success First Pass (Yes), no (%)	44 (100)	32 (78.05)	0.001
Leak Fraction at 30 min (%), median (IQR)	1.94 (0.00-3.85)	0.0 (0.0-1.86)	0.041
Peak Inspiration Pressure at 30 min (cmH2O), median (IQR)	19.00 (17.25-21.75)	18.00 (16.00-21.00)	>0.99
Complications, n (%)			
Cough	9 (20.45)	2 (4.88)	0.05
Blood in the device	1 (2.27)	18 (19.51)	0.01

Data are presented as means (SD), medians (interquartile range 25-75, IQR), or as numbers and percentages (%).

Conclusion(s): LMA Protector revealed better ventilation effectiveness, but higher Pepsine levels compared to ETT. Blood was more often in LMA.

42AP03-5

Navigating the airway labyrinth: Innovative awake intubation strategies in complex facial ameloblastoma

M. Blesa¹, J. Fernández-Ruiz¹, J. Llopis Lorente¹, S. Eltayeb-Ferrer¹, P. Charco-Mora², M.P. Argente-Navarro³

¹Hospital Universitario y Politécnico La Fe, Anesthesiology, Valencia, Spain, 2 Hospital Universitario y Politécnico La Fe, Specialist Practitioner, Valencia, Spain, 3Hospital Universitario y Politécnico La Fe, Head of Anaesthesiology and Resuscitation Department. Director of Anaesthesia, Resuscitation and Surgical Block, Valencia, Spain

Background: Awake tracheal intubation (ATI) is the gold standard for managing anticipated difficult airways. The modified "sprayas-you-go" (SAYGO) technique, using an epidural multiperforated catheter, efficiently delivers topical anesthetic to minimize hemodynamic responses. Smaller diameter orifices enable reduced flow of local anesthetic, potentially decreasing airway irritation compared to traditional bolus injections (1). This approach was applied in the management of a patient with a facial ameloblastoma, characterized by extensive local invasion and severe airway compromise. Adhering to the ASA 2022 guidelines (2), awake flexible bronchoscopic intubation was performed via the nasal route, incorporating precise airway topicalization.

Case Report: To ensure airway patency, the use of sedative agents was avoided during the procedure. Anterior nasal nerves, the pterygopalatine ganglion, and the nasopharynx were anesthetized using cotton pledgets soaked in a solution of tetracaine (1%) and adrenaline (0,01%) applied to the preselected nostril under nasofibroscopic guidance. Fibroscopy was performed with the endotracheal tube preloaded on the scope, advancing until

a direct view of the carina was obtained. The SAYGO technique was employed to anesthetize the remaining structures. After confirming adequate bilateral lung ventilation, general anesthesia was initiated.

Discussion: Maintaining spontaneous ventilation during awake fiberoptic intubation is crucial to avoid the high-risk "cannot intubate-cannot oxygenate" scenario (2). Advanced airway management requires a multifaceted approach combining meticulous pre-procedural planning, precise technical execution, and comprehensive patient-specific risk assessment. Anesthesiologists must deploy refined topicalization techniques and strategically select airway devices that optimize both surgical access and patient respiratory mechanics.

References:

1. Journal of clinical monitoring and computing, 37(1), 55–62. 2. Anesthesiology, 136(1), 31–81.

Learning points:

SAYGO technique optimizes airway topicalization with minimal irritation.

Spontaneous ventilation prevents critical intubation risks.

42AP03-6

Recurrent airway obstruction and failed extubation: A challenging case of nasopharyngeal mass and oropharyngeal lipoma

T. Barros¹, <u>F. Santos</u>¹, S. Bento¹, R. Fonseca¹, E. Valente¹¹Local Health Unit of the Leiria Region, Anesthesiology Department, Leiria, Portugal

Background: Extubation is a critical phase in the management of anesthetized patients, carrying significant risks of complications. Failed extubation is a potentially life-threatening event arising from multiple factors. While often due to pulmonary or cardiovascular causes, upper airway obstruction can present a unique challenge, particularly when associated with anatomical abnormalities. We present a case of recurrent extubation failure caused by probable superior airway obstruction.

Case Report: A 53-year-old male, ASA II, presented with two months of progressive symptoms, including headaches, diplopia, left hemifacial paresthesia, positional dyspnea, dysphonia, dysphagia and weight loss. Imaging studies revealed a large nasopharyngeal tumor with extensive skull base destruction, carotid canal invasion, sphenoidal sinus involvement and left venous sinus encroachment. The airway was partially compromised, with obliteration of the nasopharyngeal airway space but preserved oropharyngeal and hypopharyngeal air columns. Additionally, a large midline tongue lipoma was identified. The patient underwent an endonasal biopsy under general anesthesia. Two extubation attempts failed due to immediate post-extubation respiratory insufficiency, bronchospasm and superior airway obstruction. Reintubation was required and the patient was admitted to the intensive care unit. A tracheostomy was performed two days later. Discussion: This case highlights the challenges associated with airway management in patients with complex head and neck pathology. The combination of a large nasopharyngeal mass, oropharvngeal lipoma, and potential post-operatively edema created a dynamic and unpredictable airway. While the exact mechanism of recurrent obstruction is unclear, it is likely multifactorial. Our case emphasizes the importance of a thorough preoperative evaluation and multidisciplinary planning to identify potential complications and optimize outcomes.

References:

1. Benham-Hermetz J, Mitchell V. Safe tracheal extubation after general anaesthesia. *BJA Education*, 21(12): 446e454 (2021). doi: 10.1016/j.bjae.2021.07.003

Learning points: Extubation failure should prompt immediate assessment of potential anatomical and physiological contributors. Multimodal imaging and airway risk assessment are essential in patients with upper airway masses. Multidisciplinary collaboration ensures tailored management for complex airway cases, minimizing perioperative risks.

42AP03-7

Orotracheal intubation in a patient with anticipated difficult airway due to laryngeal cancer: A case using videolaryngoscopy and bougie

L.E. Romero Cardozo¹, A.N. Leguizamon Guerra¹, Á.A. Roncancio Fernandez², M.C. Bautista González² ¹Universidad Nacional de Colombia, Department of surgery, Anaesthesiology unit, Bogota, DC, Colombia, ²Hospital Universitario Nacional de Colombia. Anaesthesiology department, Bogotá, Colombia

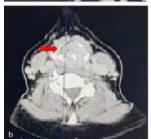

Background: Airway management in patients with laryngeal cancer is challenging. Awake tracheal intubation with a fibrolaryngoscope or videolaryngoscope is recomended in cases of anticipated difficult airway (1).

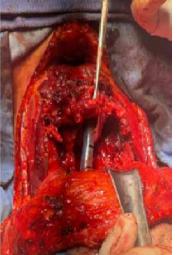

The bougie is usually considered as a rescue device, its use remains limited and is infrequently employed on the first attempt.

Case Report: A 63-year-old woman with stage T3N0M0 laryngeal carcinoma and 90% glottic lumen obstruction was deemed unsuitable for tracheostomy due to potential interference with the surgical access site. Minimal sedoanalgesia was administered to maintain spontaneous ventilation.

Videolaryngoscopy enabled the successful passage of a bougie through the glottis, followed by the insertion of an orotracheal tube through the obstruction. The airway was ultimately secured through tracheostomy at the conclusion of the surgery, without complications.

Discussion: In addition to the standard recommended strategies. a bougie was selected due to its smaller diameter, which facilitated passage through the glottic lumen. Currently, there are no specific guidelines for airway management in cases of obstruction, such as tumors, when endotracheal intubation is preferred as the initial approach.

However, studies suggest that using a bougie during the first intubation attempt may improve success rates, although its application remains limited (2,3).

Learning points: Employing a bougie on the first intubation attempt, particularly in patients with difficult airways due to obstruction, may enhance intubation success and reduce complications.

42AP03-8

Airway obstruction from capsule aspiration: timely intervention by a passing anesthesiologist

P. Vaz-Salvador¹, J. Santos¹, I. Pita², A. Fonte¹, I. Cardoso¹ ¹ULS Entre Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal, ²ULS Entre Douro e Vouga, Gastroenterology, Santa Maria da Feira, Portugal

Background: Airway obstruction is a leading cause of inadvertent death in children and also poses significant risks to the geriatric population (1). The progressive decline in laryngeal protective reflexes with aging makes elderly patients more vulnerable to lifethreatening events (2).

Case Report: A 92-year-old male patient, hypocoagulated due to atrial fibrillation and hospitalized for digestive bleeding (of unknown etiology but stabilized), was found by the Anesthesiology team in the Gastroenterology Unit. He was sitting at the edge of his bed, leaning forward, conscious but persistently coughing ineffectively. The immediate suspicion was airway obstruction, confirmed by visualization on the monitor of the videocapsule in the distal trachea and carina. The diagnosis of endoscopic capsule aspiration was confirmed. Airway clearance maneuvers were initiated, consisting of 5 back blows followed by 5 abdominal compressions. The patient was encouraged to cough throughout the process. The maneuvers were effective, and the capsule was expelled through the mouth after the fifth abdominal compression. The capsule was then safely placed in the duodenum under direct vision via upper digestive endoscopy with propofol sedation, without further incident.

Discussion: The algorithm for managing airway obstruction by a foreign body, commonly used in out-of-hospital settings, is also applicable in the hospital environment. Anesthesiologists can play a crucial role in managing such medical emergencies within the hospital setting.

Learning Points:

- 1. Early Recognition of Airway Obstruction: Timely recognition of airway obstruction and prompt intervention are critical, especially in elderly patients with diminished reflexes.
- 2. Effective Use of Airway Clearance Maneuvers: Back blows and abdominal compressions can be life-saving techniques when managing airway obstruction from a foreign body, even in the hospital setting.
- 3. Role of Anesthesiologists in Emergencies: Anesthesiologists are vital in managing airway emergencies, utilizing their expertise in airway management to address acute situations effectively.
- 4. Safety Protocols for Endoscopic Procedures: Direct visualization and careful handling during endoscopic procedures ensure safety when placing foreign bodies like videocapsules in the digestive tract.

Taping technique in shoulder arthroscopy to minimize cervical edema and prevent airway complications during extubation

C. Urmann¹, J.C.D. Zanin¹, V. Corradi¹, A.K.W. Hsu¹, T.M. Taglietti¹, V.R.M. Pacheco¹ ¹Universidade Regional Integrada, Medicina, Erechim, Brazil

Background: This case report discusses an innovative taping technique for a patient undergoing shoulder arthroscopy. The aim is to generate tissue compression between the shoulder and neck to minimize the outflow of arthroscopic fluid and cervical edema, while increasing airway protection during extubation, as the surgery may involve complications related to extubation due to cervical edema.

Case Report: Anesthesia protocol and orotracheal intubation were performed. The patient was positioned in the lateral decubitus position. Antisepsis of the shoulder was done, and a sterile micropore tape, 100 mm wide, was placed on the skin, laterally to the sternum, at the sixth costal arch anteriorly, over the pectoralis major muscle and sternocleidomastoid muscle, laterally on the cervical area (taking care not to compress the jugular vessels), over the trapezius muscle medial to the clavicle, and along the posterior cervical region in the scapular line, extending to the sixth costal arch posteriorly. Sterile fields were positioned, and punctures for the video trocar placement for joint repair were made.

Measurements were taken of the cervical circumference 1 cm below the thyroid cartilage, the brachial circumference 10 cm below the acromion, and the airway pressure – all measurements were taken after the anesthetic block and at the end of the surgery, to verify variations at different time points.

Discussion: After 60 minutes of arthroscopy, there was no increase in airway pressure. The cervical circumference increased by 0.5 cm, and the brachial circumference increased by 5 cm.

References:

MEMON M, Kay J, GHOLAMI A, SIMUNOVIC N, AYENI O.R. (2018). Fluid Extravasation in Shoulder Arthroscopic Surgery: A Systematic Review. Orthop J Sports Med. 2018;6(5):2325967118771616

Learning Points: The technique was effective and promising, reducing fluid extravasation to the cervical region, not increasing airway pressure, and increasing fluid extravasation to the brachial region, thereby protecting the airway during extubation. Further clinical studies are necessary.

Comparative evaluation of i-gel insertion techniques: a crossover Manikin study on duration and ease of insertion in two operator positions

H. Clift¹, S. Selvaraj¹, P. Gaur¹, R.S. Chaggar¹

'London North West University Healthcare NHS Trust,
Anaesthetics, London, United Kingdom

Background and Goal of Study: The i-gel is a second-generation supraglottic airway device (SAD) designed for use in a variety of airway management settings. Conventionally, the i-gel is inserted with the operator standing behind the patients' head, however it can also be inserted from the side of the patient, which may improve functional residual capacity when the patient is in a semi-recumbent position and provide better visualisation of the oropharynx allowing airway manipulation.

The primary outcome of the study was to compare participant's ease of insertion between the two techniques. Secondary outcomes assessed the number of attempts and time taken to successful insertion.

Materials Methods: All study participants were healthcare professionals with varying levels of experience inserting SAD's. A manikin with standard airway anatomy was used in two set up positions. Each participant completed the study inserting a size 3 igel in the two positions; both from behind the head (conventional) and side of the manikin. Attempts were timed, and the number of attempts required for successful insertion were recorded. A pre and post i-gel insertion survey was completed to ascertain participants' comfort level completing both techniques, before and after the study.

Results and Discussion: 30 participants completed the study. 58.6% of participants recognised inserting the i-gel from the side of the patient as an accepted technique. The average insertion time was 4.57 seconds when completed from the conventional position, compared to 3.97 seconds from the side. All participants successfully inserted the i-gel on their first attempt. 37.9% of participants reported feeling more comfortable inserting the i-gel from the side after completing the study, 6.9% indicated discomfort with this approach. There was little change in comfort levels in the conventional group pre- and post-insertion.

Conclusion: I-gel insertion from the side of the manikin was faster compared with the conventional position; with a third of participants feeling more comfortable with the technique following the manikin study.

Increased awareness and teaching of the i-gel side insertion method may aid its implementation into routine clinical practice as a fast and effective alternative technique. This may be useful in emergency situations including trauma, difficult patient positioning and obstructed access to the patient's head.

Laryngospasm triggered by awake tracheal intubation in a patient with a large neck mass: a case report

M. Xie1, Y. Liang1, J. You1, Q. Zhou1, J. Huang1 ¹Sichuan Provincial People's Hospital, School of Medicine, University of Electronic Science and Technology of China, Anesthesiology, Chengdu, China

Background: Awake tracheal intubation is needed for a general anesthesia patient with a predicted difficult airway. In this case, the patient experienced laryngospasm during the awake fibreoptic nasal tracheal intubation.

Case Report: A 60-year-old man (ASA II, BMI 21.9) scheduled for neck lumpectomy (81 mm×62 mm mass) with no asthma history, held 5 mL of 2% lidocaine orally for 5 minutes and received 8 L/ min of 100% oxygen via face mask. He received IV penehyclidine 0.5 mg, midazolam 1 mg, and sufentanil 5 µg, along with infusions of dexmedetomidine (0.7 µg/kg/h) and remifentanil (0.05 µg/kg/ min), as well as lidocaine cream and ephedrine for local anesthesia and nasal vasoconstriction. The cricothyroid puncture was not done due to difficulty locating the cricoid by hand palpation because of the patient's large neck mass. As the fibreoptic bronchoscope approached the vocal folds, the patient suddenly coughed, followed by laryngospasm and oxygen saturation to 85%. We provided oxygen under mask pressure and the wheezing subsided. The patient was then positioned sitting up while continuing oxygen, and the laryngospasm was relieved. We conducted an ultrasound-guided cricothyroid puncture and superior laryngeal nerve block, administered inhaled salbutamol and 10 mg IV dexamethasone. Reintubation was successful, and the bronchoscope passed through the glottis without causing laryngospasm.

Discussion: During awake tracheal intubation, patients might face hemodynamic changes, coughing, and decreased oxygen saturation, but laryngospasm is rare. Patients without cricothyroid puncture or larynx nerve block often only experience an irritating cough. Reyes Marquez's study found that patients with laryngeal neuropathy, gastroesophageal reflux, or those lying supine were more prone to laryngospasm.[1] In this case, the large neck mass could have impaired laryngeal nerve function, exacerbating and potentially triggering laryngospasm.

References:

1. Reyes Marquez Altemir, Carmen Gorriz Gil, Virginia Matallama, et al. Phenotypic characterization of laryngospasm: the utility of laryngeal neurophysiological studies. Journal of Voice. 2024 Nov;38(6):1471-1477.

Learning Points: Optimize local anesthesia for the nose, throat, and airway during awake tracheal intubation. Be alert for laryngospasm in patients with chronic cough, asthma, gastroesophageal reflux, or possible laryngeal nerve damage.

42AP03-12

Management of distal tracheal injury after general anesthesia

J. Maia¹, F.F. da Costa Rosa¹, P. Santos^{1,2}, C. Granja^{1,2} ¹Unidade Local de Saúde São João, Anaesthesiology, Porto, Portugal, ²Faculdade de Medicina, Universidade do Porto, Porto, Portugal

Background: Rett syndrome is associated with restrictive pulmonary syndrome, leading to complications like aerophagia and pneumomediastinum. We report a case of a 41-year-old female with Rett syndrome undergoing general anesthesia for dental

Case Report: After an uneventful anesthetic induction and the initiation of mechanical ventilation with protective ventilation parameters, there was a progressive increase in airway pressures, reaching the maximum defined pressure of 40 cmH2O, with a gradual reduction in the tidal volume. The surgery was completed in 15 min, leaving no time to identify the cause of the condition. The patient resumed spontaneous ventilation with a normal respiratory pattern, allowing for extubation without apparent complications. In the Post-Anesthesia Care Unit, the patient developed subcutaneous emphysema and respiratory distress. The Computed Tomography scan revealed pneumomediastinum and raised suspicion of a distal tracheal laceration, later confirmed by bronchoscopy. The multidisciplinary team opted for a conservative approach due to the high surgical risk and the infeasibility of prosthesis placement as determined by the pneumology team. The patient received conservative management with left main bronchus selective intubation (6.0 mm single lumen tube) and mechanical ventilation until spontaneous healing, achieving successful extubation after 19 days.

Discussion: Regardless of the susceptibility to barotrauma in this case, managing distal tracheal lacerations requires positioning the distal end of the endotracheal tube (ETT) and its cuff below the injury. An alternative approach could involve intubating each bronchus with separate tubes and alternating between ventilation and CPAP. It is important to note that other devices, such as double lumen tubes, may not be suitable for managing these injuries, as they increase the risk of trauma and fail to meet the aforementioned requirements.

References:

Schultz, Rebecca J., et al. "Rett syndrome: Genetics, clinical features, and diagnosis". UpToDate, 2024; Boutros, Jacques, et al. "Multidisciplinary management of tracheobronchial injury". European Respiratory Review 31.163 (2022).

Learning Points:

- 1. In distal tracheal lacerations, it is essential to position the distal end of the ETT and its cuff below the injury site.
- 2. Conservative management, including selective intubation and mechanical ventilation, can support spontaneous healing and lead to successful recovery.

42AP04-1

Non-invasive resolution of perioperative airway obstruction in a patient with a giant anterior mediastinal mass

L. Qian¹, B. Xianq¹

¹West China Hospital of Sichuan University, Department of Anaesthesiology, Chengdu, China

Background: This case report highlights a critical airway obstruction in a patient with a mediastinal tumour following anaesthesia induction, underscoring the unpredictability of airway management despite normal preoperative imaging. It illustrates the potential effectiveness of non-invasive positional adjustments in managing airway emergencies.

Case Report: A 23-year-old male with a mediastinal tumour underwent preoperative evaluation, showing no symptoms and tolerating the supine position. CT imaging identified a 12 cm irregular anterior mediastinal mass without airway narrowing. Post-anaesthetic induction, the patient experienced significant ventilatory difficulties, indicated by increased airway resistance. After ruling out anaphylaxis and laryngospasm, immediate endotracheal intubation was performed, but airway pressures remained elevated at 41 mmHg. Despite appropriate tube placement confirmed via fibreoptic bronchoscopy, the patient's oxygen saturation dropped sharply to 31%, heart rate to 42 bpm, and ventilation became increasingly challenging. Repositioning to the left lateral decubitus position led to a swift reduction in airway pressure to 23 mmHg, oxygen saturation rose to 97%, and heart rate and blood pressure normalized.

Discussion: This case illustrates the unpredictable airway management challenges posed by mediastinal tumours, despite the absence of preoperative symptoms or imaging suggesting airway compression. The patient's reaction indicates that the tumour's airway impact was dynamic, contingent on positioning and anaesthetic effects (1). Anaesthesiologists must maintain vigilance for airway crises in seemingly stable individuals, as rapid deterioration can occur. Readiness for alternative strategies, including immediate repositioning and auxiliary airway management techniques, is essential. This case emphasizes the critical need for comprehensive preoperative assessment and ongoing intraoperative alertness.

References:

1. Erdös G, Tzanova I. Perioperative anaesthetic management of mediastinal mass in adults. Eur J Anaesthesiol. 2009;26(8):627-32

Learning points: This case highlights the potential for acute airway obstruction following anaesthesia induction in asymptomatic mediastinal tumour patients, highlighting the limitations of preoperative imaging. It stresses the significance of intraoperative positional modifications in reducing airway compression and the necessity for anaesthetists to be equipped for airway emergencies.

42AP04-2

Successful management of post-intubation tracheal laceration after a routine endotracheal intubation

N. Alçada¹, B. Moreira¹, L. Gomes¹ ¹Unidade Local de Saúde Entre Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal

Background: Post-intubation tracheal laceration (PITL) is an extremely rare, potentially fatal event, with a mortality rate around 22%.1 Diagnosis is based on clinical signs and imaging and it is confirmed by bronchoscopy.1 Decision between conservative and surgical treatment is based on clinical and endoscopic findings.^{1,2} In this report we present a case of PITL after an uneventful intu-

Case Report: A 59 yo, ASA II, female, was admitted for elective laparoscopic cholecystectomy. ASA standard, depth of anesthesia and neuromuscular blockade monitoring was used. Total intravenous anesthesia was conducted. Intubation was uneventful, with a 7.0mm endotracheal tube (ET), without stylet. Surgery proceeded without complications. Neuromuscular blockade was reversed and the patient extubated uneventfully. The patient was transferred to post-anesthesia care unit and later discharged to general ward, without any adverse event. In her room, after efforts to urinate, the patient felt a sharp pain and tinnitus and developed dyspnea, dry cough and facial edema. Subcutaneous emphysema was later palpated. CT-Scan showed bilateral emphysema, pneumomediastinum and a laceration on the posterior tracheal wall. Bronchoscopy confirmed tracheal laceration. The patient did not meet criteria for urgent surgery and was managed conservatively. At postoperative day 10, imaging showed little remaining emphysema and signs of resolved tracheal laceration. Bronchoscopy showed resolution of tracheal laceration. The patient was discharged with complete resolution of symptoms.

Discussion: Overinflation of the cuff and sudden movement of the tube are the two most common causes of PITL.2 In this case, neither tube nor head were moved during surgery. Cuff pressure was not measured and it is impossible to discard or confirm overinflation as the cause for this PITL. Direct tracheal laceration is less likely in this case, since stylet was not used and intubation was simple. We hypothesize that a sensitive pars membranosa, was possibly rendered more susceptible to laceration by the ET cuff. Increased intrathoracic pressure due to strain to initiate voiding, might have been the determining factor for laceration.

References:

- 1. Eur J Cardiothorac Surg. 2009;35(6):1056-1062.
- 2. Ann Thorac Surg. 2000;69(1):216-220.

Learning points:

- Cuff pressure should be measured after every intubation.
- Onset of symptoms after maneuvers that increase intrathoracic pressure should alert for possible PITL.

42AP04-3

Awake intubation in the face of a massive goiter: navigating the airway challenge

E. Pinheiro Tavares¹, M. Abreu Pires¹, A.M. Araújo¹ ¹Centro Hospitalar Universitário de Santo António. Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva Emergência e Urgência, Porto, Portugal

Background: The authors aim to demonstrate the effectiveness and safety of awake tracheal intubation (ATI) in the management of a predicted difficult airway, a technique that remains under-

Case Report: An 87-year-old man presented to the emergency department with progressive dyspnea. Medical background included heart failure of ischemic etiology, smoking, hypertension and right-sided multinodular goiter (Figure 1).

Examination noted stridor, worsening with left lateral decubitus position, and mild tachypnea. A right hemithyroidectomy was proposed. High-flow nasal oxygen (HFNO) was initiated upon the patient's arrival. A remifentanil infusion and 10% lidocaine spray for topicalization were used prior to flexible fiberoptic intubation via the oral route. Due to the patient's lack of cooperation, a propofol infusion was initiated. The procedure was successfully completed, and a size 5 microlaryngoscopy tube was placed. General anesthesia was then induced.

The surgery proceeded uneventfully, and the patient was extubated to HFNO, followed by progressive weaning to a nasal cannula. He was discharged on the fifth postoperative day without dyspnea or any complications.

Figure 1.

Discussion: In this case, managing a predictably difficult airway was mandatory since postponing the procedure was not an option. Progressive airway compromise and patient's inability to tolerate apnea prompted ATI as the procedure of choice. Ultrasound evaluation of the airway revealed significant anatomical distortion. making alternative approaches to airway management technically challenging. The sedation regimen chosen may also be debatable, as propofol, when combined with remifentanil, can increase the risk of respiratory depression. However, ensuring the patient's ability to tolerate airway instrumentation was a key consideration.

References:

1. Ahmad I, El-Boghdadly K, et al. Difficult Airway Society guidelines for awake tracheal intubation (ATI) in adults. Anaesthesia 2020;75(4):509-528.

Learning points: HFNO and patient's tolerability are key to the success of fiberoptic intubation. Head and neck imaging are a valuable tool for airway approach planning.

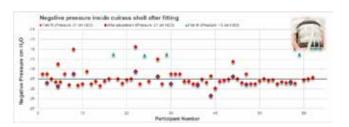

42AP04-4

Biphasic cuirass ventilation in healthy volunteers: a prospective observational study on mounting time and optimal seal

A.-L. Lihn¹, J.F. Schmidt¹, M.S. Kristensen¹ ¹University Hospital of Copenhagen, Department of Anaesthesia, Centre of Head and Orthopedics, Rigshospitalet, Copenhagen, Denmark

Background and Goal of Study: Biphasic Cuirass Ventilation (BCV) consists of a shell mounted on the anterior part of the upper body followed by application of extra-thoracic alternating negative and positive pressure has shown great potential in laryngeal surgery.^{1,2} Knowledge of the technical aspects of modern BCV is sparse and this study investigates the time required for fitting a cuirass shell to visible ventilation and obtaining an airtight seal which is required for optimal function of BCV.

Materials and Methods: Sixty-two healthy volunteers (24 males, 38 females, age 41±7yrs, height 173±10cm and weight 73±14kg) were videorecorded during cuirass shell mounting and fitting, followed by initiation of BCV. Fitting time of the cuirass shell was defined as time from initial contact with the shell to visible thoracic movement (mean±SD seconds (range)). Additionally, the correspondence between the preset negative pressure on the ventilator (-15 and -21 cm H₂O for 4 and 58 participants, respectively) and the actual pressure inside the shell was measured. Optimal seal was defined by measured pressure matching set pressure within ±2 cm H₂O. If the pressure difference was larger or if the cuirass shell had visible leak, readjustments were performed.

Results and Discussion: Among the 62 participants, 51 were fitted optimally on the first attempt (mean pressure 21±2 cm H2O, Time 91±21s (65-163). 11 participants required a readjustment to obtain an airtight seal, 5 was due to visible leak and 6 due to suboptimal pressure. For these 11 participants the total time for an airtight seal was 126±28s (98-176). For all 62 participants the total time to obtain optimal fit was 97±26s (65-176). This finding was 5s faster than in a previous study which did not evaluate the fit of the cuirass but compared cuirass mounting-time to intubationtime (177s).3

Conclusion(s): Fitting a cuirass shell and obtaining an airtight seal followed by biphasic ventilation is a relatively quick procedure with a high success rate. BCV may have a place as ventilatory support not only in the elective, but also in acute settings.

Videolaryngoscopic awake intubation in the sitting position: a case report

C. C. Duarte¹, <u>S. Lourenço</u>¹, M. Veiga², J. Galacho³, J. Pinho⁴

¹Unidade Local de Saúde Santa Maria, Anesthesiology, Lisboa, Portugal, ²Unidade Local de Saúde do Médio Tejo, Anesthesiology, Tomar, Portugal, ³Paincare - Clinica de Tratamentos de Dor, Anesthesiology, Lisboa, Portugal, ⁴Instituto Português de Oncologia de Lisboa Francisco Gentil, Anesthesiology, Lisboa, Portugal

Background: Management of complex airways is a core aspect of anesthesiology and critical care. Ensuring successful outcomes often requires skillful adaptation of techniques to the specificities presented by the clinical case. In this case report, we aim to explore an approach that may be considered for awake tracheal intubation using videolaryngoscopy when the patient is unable to tolerate the supine position.

Case Report: A 58-year-old patient with a known vocal cord neoplasm presented to the emergency department with dyspnea, stridor and inability to tolerate the supine position. Nasal fiberoptic laryngoscopy by Otolaryngology confirmed the laryngeal tumor as the cause, and an indication for urgent tracheostomy was placed. After multidisciplinary discussion, a primary strategy of awake tracheal intubation in the operating room followed by tracheostomy under general anesthesia was chosen.

Upper airway topicalization was obtained with lidocaine spray and nebulized lidocaine with adrenaline and dexamethasone. Intravenous fentanyl was cautiously administered to reduce anxiety and tachypnea. While administering supplemental oxygen via a nasal cannula, a second anesthetist used a MacGrath videolaryngoscope to intubate the trachea with a styletted 5.0 microlaryngeal tube, in a "face-to-face" position. General anesthesia was induced after capnography confirmation of tracheal placement, and tracheostomy and postoperative recovery were uneventful. The patient reported the intubation as only moderately uncomfortable.

Discussion: This case demonstrates that managing complex airways frequently requires adaptation to the clinical scenario and available resources. "Face-to-face" videolaryngoscopic awake intubation may be a valuable alternative for patients with laryngeal tumors unable to tolerate the supine position.

Learning points:

- Clinical evaluation of the patient and a comprehensive understanding of airway management alternatives enabled the development of a patient-tailored plan.
- Adequate oxygenation and airway topicalization are essential to the success of an awake intubation.
- Backup plans must be in place in case the initial approach proves unsuccessful.

42AP04-6

Pulmonary aspiration in the immediate period after stroke, are we even aware of that?

G. Araújo¹, <u>S. Faria</u>¹, C. Barreto¹¹Unidade Local de Saúde Gaia Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: A key risk of the airway approach is pulmonary aspiration of gastric contents. There are strategies described for prevention in patients at risk.¹

Stroke can lead to gastroparesis, which is underexplored in the immediate period after the event.²

Case Report: An 81-year-old male, ASA IVE, was admitted to the Emergency Department at 1pm due to a stroke confirmed by cerebral angiography. He underwent immediate endovascular revascularisation under analgesia, with no complications.

At 6.30pm, acute ischaemia of the right lower limb was detected, requiring emergency right femoral artery thrombectomy, with no criteria for admission to a level three care unit.

On arrival at the operating room at 7pm, the Glasgow Coma Scale was 7. Balanced general anaesthesia was performed with proper monitoring. Rapid sequence induction was made, with 2.2 µg/ Kg of fentanyl, 1 mg/Kg of lidocaine, 1 mg/Kg of propofol and 1 mg/Kg of rocuronium. After administration of the muscle relaxant, massive vomiting of food content occurred. The patient was placed in the lateral decubitus position and the regurgitated contents aspirated. He was then repositioned to Trendelenburg and conventional laryngoscopy was used for orotracheal intubation. Endotracheal aspiration was carried out, with drainage of the

contents, before the patient was placed on controlled ventilation. Subsequently, a nasogastric tube was placed and 1 litre of gastric content was aspirated.

The procedure was performed without complications, and the patient was extubated uneventfully. On the third post-operative day, right-sided pneumonia was diagnosed. In the following days, his neurological condition deteriorated and he died on the 11th day after the stroke.

Discussion: There must be an awareness to the immediate consequences of stroke, such as gastroparesis, and preventive measures should be developed in these at-risk patients to ensure a safe approach to the airway, especially in emergent procedures under spontaneous ventilation.

Gastric ultrasound prior to induction of anaesthesia can help to detect gastric contents and aid the decision-making in a patient with need of urgent airway protection.

References:

- 1. Anesthesiology. 2021;135:284-291.
- 2. Am J Gastroenterol. 2006;101:1655-65.

Learning points: Developing an airway approach plan and adopting preventive strategies for pulmonary aspiration are critical to prevent complications in the immediate post-stroke period, regardless of the preoperative fasting status.

42AP04-7

Practicability and effectivity of the Air-Q3Gsp supraglottic device: a renewed secondgeneration self-pressurizing laryngeal mask

P. Mesa¹, Á. Salas Ortega¹, G. Iturriaga Oliver¹, F. Sánchez Prieto¹, D. Portilla Huerta¹ ¹Hospital Universitario Puerto Real, Unidad Bloque Quirúrgico, Cádiz, Spain

Background and Goal of Study: 2nd generation LMA had an internal gastric tube what expanded their use. The possibility of drainage gastric secretion, the improvement of materials and the new geometric design enabled a better sealing pressure making them a reliable airway management system. AirQ has released he Air-Q 3G sp, a self-pressurized with gastric access and a endotracheal tube ramp that makes the insertion simplier. The principle of the self-pressurizing is that the fresh gas flows into the cuff of the self-pressurizing SGD and seals it keeping the seal between P_{IP} and the PEEP. The aim of this study is to evaluate the practicability and the effectiveness of the AirQ3G SP

Materials and Methods: Observational study analyzes patient's weight, height, Body Mass Index, AirQ3G SP sizes, number of attempts for insertion, achieving sealing pressure, required inspiratory pressures, proper positioning of the laryngeal mask and patient comfort. All our patients received general anesthesia. Seal pressure achieved was calculated immediately after placing on the laryngeal mask lowering fresh gas flow to 3 lpm; patient was ventilated manually with closing the APL valve stopping when noise through mouth was heard. P was set for a tidal volume of approximately 6 ml/kg always; PEEP 4-5 cm H2O. Mechanical ventilation mode was PVC, alternating with VCV to verify a Driving pressure below 13 cm H2O. Correct placement of the mask was verified using pressure/volume loops and leak volume. Fibroscopy was performed recording the POGO. Patients were asked about any discomfort. Results were collected in Excel data table. Results and Discussion: Patients recruited December 1st 18 (final n: 32 patients) BMI > 25 77,7% BMI>30 22,2% Median pressure: Leak 31cmH₂O. PIP 10 cmH₂O. PEEP 4 cmH₂O. Insertion at first: 94.4% POGO100:100% of patients. Sore throat:0

Conclusion: The preliminary data shows that AirQ3Gsp is a safe. suitable and feasible device for general and/or combined anesthesia in obese patients. The SGD is remarkably easy to insert, ensuring proper placement, making possible intubation through it if becomes necessary. The AirQ3Gsp provides security to the airway thanks to its superior seal pressure; also it seems the AirQ3Gsp cause less sore throat thanks to a lower cuff pressure. The low inspiratory pressure required, combined with the optimal driving pressure measured, provides confidence in operating within a lung-protective ventilation scenario.

42AP04-8

Airway management of cervical abscess with hemorrhage: a case report

M. Neto Martins¹, C. Martins¹, P. Santana Ramos¹ ¹ULS São João, Anesthesiology, Porto, Portugal

Background: Airway hemorrhage is a critical and potentially catastrophic event, contributing significantly to morbidity and mortality during airway management. (1) This case illustrates a successful strategy in managing a patient with a large upper airway

Case Report: A 57-year-old male. ASA II, with a recent history of acute tonsillitis complicated by peritonsillar abscess drainage. presented for urgent hematoma evacuation and exploratory cervicotomy due to a deep cervical abscess. Despite the absence of respiratory distress, trismus complicated the airway assessment. Cervical CT revealed significant leftward deviation and extensive local edema. Awake flexible fiberoptic bronchoscopy was performed in the presence of the surgical team to maintain spontaneous ventilation after 1 mg of midazolam and topical airway anesthesia. During the procedure, the patient experienced respiratory difficulty, attributed to localized muscle tone loss. However, prompt and effective nasofibroscopy ensured successful airway management without further complications.

At the beginning of surgery, multiple large clots were identified in the oropharynx following the use of a mouth opener. Postoperatively, the patient required mechanical ventilation for suspected necrotizing fasciitis. He was extubated after 13 days without complications and later discharged.

Discussion: Proactive planning and systematic algorithms were key to patient safety. Awake intubation ensured ventilation, while thorough airway assessment, preoxygenation, fiberoptic expertise, and surgical team support contributed to successful management

References:

1. Kristensen, M.S., McGuire, B. Managing and securing the bleeding upper airway: a narrative review. *Can J Anesth/J Can Anesth* **67**,128–140 (2020). https://doi.org/10.1007/s12630-019-01479-5

Learning points: Proactive planning and the use of systematic algorithms are essential for patient safety. Awake intubation plays a critical role in maintaining spontaneous ventilation until the airway is secured. Key factors for success include thorough airway assessment, proficiency in fiberoptic techniques, adequate preoxygenation, and collaboration with the surgical team.

42AP04-9

Airway management challenges in a patient with advanced head and neck cancer: a case report

M.-L. Coutinho¹, <u>M. Brito Coimbra</u>¹, I. Simões¹¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Patients with head and neck malignancies who have undergone radiotherapy present significant airway management challenges due to anatomical distortion. These patients are at high risk of obstruction, complicating diagnostic and therapeutic procedures. Pre-procedural planning and a multidisciplinary approach are essential.

Case Report: A 62-year-old male with a history of neck radiotherapy was recently diagnosed with invasive esophageal squamous cell carcinoma. He was scheduled for flexible bronchoscopy to evaluate potential tracheal invasion. Pre-procedural evaluation included endoscopy revealing a friable esophageal lesion causing luminal stenosis, and cervical CT showed an esophageal mass with glottic deviation.

The patient presented with hoarseness but no stridor or respiratory distress. The procedure was performed under deep sedation with spontaneous ventilation, using ASA standard monitoring and BIS. Sedation was induced with alfentanil and propofol, and topical lidocaine was applied.

Early desaturation required placement of a supraglottic airway. Despite high peak inspiratory pressures and irregular expired CO₂, oxygen saturation remained adequate, allowing bronchoscopy to proceed.

Findings included a distorted epiglottis and posterior tracheal compression without invasion or fistula. Post-procedure, the patient exhibited delayed awakening and stridor. Blood gas analysis revealed $PaCO_2$ 141 mmHg. Non-invasive ventilation was started, and otolaryngology evaluation showed a narrow glottic cleft and bilateral immobility of the vocal cords.

After awakening, informed consent was obtained for tracheostomy. Orotracheal intubation via fiberoptic bronchoscopy was performed using a 6.5 mm endotracheal tube to ensure safe trans-

port to the operating room, where tracheostomy was completed. The patient recovered well and was discharged on the sixth post-operative day.

Discussion: This case highlights the challenges of managing airways in patients with head and neck malignancies. Despite being asymptomatic, the patient developed rapid airway compromise requiring advanced techniques. Proactive evaluation, imaging, and a multidisciplinary team are critical to managing high-risk cases.

Learning Points: Airway management in patients with malignancy and radiotherapy requires proactive evaluation, advanced tools, and multidisciplinary collaboration. Contingency planning is key, as even asymptomatic patients may develop critical obstruction.

Effect of pre-curving endotracheal tube in number of intubation attempts and use of intubation aids: a multi-site prospective service evaluation project

S. Rosas¹, A. Punton¹, L. Scurkova¹, C. Urquhart¹, J. Jawaheer¹

¹Queen Elizabeth University Hospital, Department of Anaesthesia and Critical Care Medicine, Glasgow, United Kingdom

Background and Goal of Study: Use of intubation aids such as stylets increases risk of airway trauma and limiting number of attempts is recommended to reduce trauma risk [1,2]. Pre-curving the endotracheal tube (ETT) has been suggested to improve first pass success [3] but evidence of its effectiveness is lacking. We aimed to assess the effect of pre-curving the ETT on use of intubation aids and number of intubations attempts in clinical practice.

Materials and Methods: This project received ethical approval from Caldicott Guardian. We tested ETT ability to pre-curve by placing Murphy's eye in 15mm adaptor for 5 minutes and allowing them to stand for 1 minute and then prospectively collected data on predicted difficulty of intubation, whether ETT was precurved, type of laryngoscope used, type of ETT used, type of intubation aids used and number of intubation attempts between 10th – 23rd June 2024 across all three hospitals in Glasgow South sector.

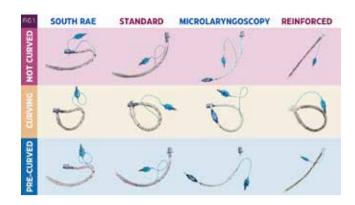

Results and Discussion: All ETT with exception of reinforced ETT were deemed to be pre-curvable (Figure 1) so we excluded reinforced ETT from our analysis. Of 136 patients who received intubation, only 7 (5.1%) had predicted difficult intubation and in 94.1% of cases videolaryngoscope was used.

ETT was pre-curved in 69.1% of cases. No intubation aids were used in 93.6% of intubations with pre-curved ETT, compared to only 50.0% in non-curved ETT group (p<0.001).

In pre-curved ETT group, 95.7% of intubations only required one attempt, compared to 69.0% of first pass success in the non-curved ETT group (p<0.001).

We use an estimated 3400 stylets and 1480 bougies per year at a cost of £14996 per year. Pre-curving our ETT would save £13147 per year and reduce use of single use plastics.

Conclusion(s): Pre-curving ETT significantly reduced need for intubation aids and number of intubation attempts, and would result in significant cost savings and reduced utilisation of single use plastics.

42AP04-11 Combined technique for managing a difficult airway: a case report

P. Vieito¹, E. Tavares¹, C. Mateus¹, I. Madeira¹, H. Machado¹

¹Unidade Local de Saúde de Santo António. Departamento de Anestesiologia, Porto, Portugal

Background: According to the Difficult Airway Society guidelines, awake tracheal intubation is the gold standard in airway management for a predicted difficult airway, as airway-related complications in anaesthetized patients can be life-threatening.

Case report: A 58-year-old male with a history of larvngeal carcinoma treated with radiation presented in the emergency department with orthopnea, dysphagia and severe cervical pain due to a suspected thyroid cancer with extensive cervical adenopathy. CT scan documented a large anterior cervical mass with left tracheal deviation and narrowed airway (Fig 1).

Due to dysphasia, a surgical percutaneous gastrostomy was requested, which could not be performed under local anesthesia because of his obesity. Airway assessment revealed a Mallampati score III, severely limited neck extension, a large goiter and dyspnea in supine position.

Additionally, the cricothyroid membrane was inaccessible due to the enlarged goiter and airway sonography was not tolerated due to pain.

In the operating room, the patient was positioned at a 45° angle and high-flow oxygen therapy was started at 30 L/min. Airway was topicalised with lidocaine spray and remifentanil infusion was started. Oral fiberoptic intubation was performed to maintain nasal high-flow oxygen.

Fiberoptic technique was uneventful but a resistance to tracheal tube advancement was noted. A combined technique with videolaryngoscopy (VL) was performed revealing a large displaced epiglottis and narrow oropharyngeal space impeding tube progression.

With the displacement of the tongue and elevation of the epiglottis with the VL, successful intubation was achieved and capnography confirmed.

Total intravenous anesthesia was induced.

Fig 1.

Discussion: This case highlights the importance of careful airway assessment and the use of awake tracheal intubation in patients with multiple risk factors for difficult airway management. Successful intubation was facilitated by high-flow oxygen therapy and a combined technique for real-time visualization.

Learning points:

- -Thorough airway assessment is essential for strategy definition.
- -Combined airway techniques enhance intubation performance.

42AP04-12

Systematic review & meta-analysis of videolaryngoscopy vs. direct laryngoscopy in paediatric tracheal intubation: adverse events and safety outcomes

A.C. Lusardi¹, G. Koepp-Medina², A. Fuchs², R. Bonfiglio¹, B. Di Fonzo¹, N. Disma¹, Bern and Genoa Airway Group ¹IRCCS Istituto Giannina Gaslini, Unit for Research in Anaesthesia, Genoa, Italy, 2Bern University Hospital, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background and Goal of Study: Pediatric intubation can be challenging due to specific anatomical and physiological characteristics, which may increase the risk of failure, oesophageal intubation, hypoxia, airway trauma, and cardiac arrest. Videolaryngoscopy (VL) represents a technological advancement over direct laryngoscopy (DL), and has been suggested as a new standard. This systematic review and meta-analysis evaluates the efficacy and safety of VL compared to DL in pediatric patients.

Materials and Methods: We systematically searched MEDLINE, Embase, Cochrane Central Register of Controlled Trials, CINAHL, Web of Science Core Collection, and Scopus on 5 February 2024. The review adhered to Cochrane methodology and included randomized controlled trials (RCTs) comparing VL and DL for tracheal intubation in paediatric patients (<16 years). PROSPERO Registration number: CRD42024498524.

No significant differences were found between VL and DL in failed intubation (RR: 0.8, 95% Cl: 0.53–1.2, p=0.26), oesophageal intubation (RR: 0.49, 95% Cl: 0.16–1.54, p=0.18), or complications (RR: 1.2, 95% Cl: 0.55–2.62, p=0.61).

Subgroup analysis in patients under 1 year of age showed a trend towards fewer failed intubations with VL (RR: 0.71, p=0.07), which was statistically significant for oesophageal intubation (RR: 0.16, p<0.01).

Conclusion(s): These findings suggest that VL and DL have comparable outcomes for pediatric tracheal intubation. Videolaryngoscopy significantly reduces the relative risk for oesophageal intubation in small children (<1y). There is significant heterogeneity in the definitions of failed intubation and reported complications across different RCT. Standardization of outcomes and terminology is needed to reduce this variability and make studies more comparable.

42AP05-1

The role of bedside echocardiography in the diagnosis of pulmonary complications

J. Magalhães Pereira¹, <u>G. Bem</u>¹, T. Barbosa¹, C. Bispo¹, J. Fernandes¹

¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Negative pressure pulmonary edema (NPPE) is a form of noncardiogenic pulmonary edema that results from the generation of high negative intrathoracic pressure needed to overcome upper airway obstruction. NPPE is potentially lifethreatening situation developing rapidly in otherwise healthy young people. We describe the use of lung ultrasound (LUS), a tool that has been gaining increasing importance in clinical practice, in a case of NPPE.

Case Report: We present the case of a 17-year-old male patient, ASA II, who underwent emergent surgery for testicular torsion. His medical history included controlled asthma. The procedure, under general anesthesia, was uneventful. During extubation, the patient exhibited reflexive biting of tracheal tube, managed with propofol. He was subsequently extubated without complications. While in the recovery room, the patient developed upper airway obstruction, reversed with jaw thrust maneuvers. Pulmonary auscultation revealed no adventitious sounds. In minutes, patient's condition progressively worsened, presenting with respiratory distress, desaturation to SpO2 82%, and crackles on auscultation. LUS revealed predominant B-lines pattern in all four pulmonary quadrants, suggesting a diagnosis of pulmonary edema. After differential diagnosis of acute onset perioperative pulmonary edema, NPPE was assumed and treatment with furosemide and positive pressure ventilation was initiated, resulting in gradual clinical improvement. The patient was transferred to the pediatric intensive care unit and managed with high-flow nasal oxygen therapy. On the fourth post-operative day he was discharged with full clinical recovery.

Discussion: This case highlights the critical role of bedside echography in the prompt diagnosis and management of post operative pulmonary complications. LUS offers numerous advantages, such as high diagnostic yield, rapid and noninvasive diagnosis, portability, real-time guidance of therapeutic decisions, dynamic assessments, and cost-effectiveness. Therefore is becoming a fundamental skill for anesthesiologists.

References:

1. Caballero-Lozada AF, et al. Bedside ultrasound for early diagnosis and follow-up of postoperative negative pressure pulmonary oedema: case reports and literature review. Anaesthesiology Intensive Therapy. 2019

Learning points: NPPE is a potentially life-threatening that develops rapidly in otherwise healthy young persons. LUS can help promptly diagnose PPCs as NPPE.

42AP05-2

Lung and chest wall compliance measured with the non-invasive PEEP step method during laparoscopic surgery

A.G. Abdulhussein¹, O. Stenqvist¹, S. Lindgren¹
¹Sahlgrenska University Hospital, Institute of Clinical
Studies, Sahlgrenska Academy, Department of
Anaesthesia and Intensive Care, Göteborg, Sweden

Background and Goal of Study: Abdominal surgery is increasingly performed by laparoscopic surgery with insufflation of carbon dioxide in the abdomen, with pressures up to 20 cmH2O, which presses the diaphragm cranially, resulting in a decrease in lung volume.

The purpose of the study was to outline the changes in lung and chest wall compliance (CL, CCW) using a new non-invasive method for separate lung and thoracic mechanics, the PEEP step method (PSM) [1, 2].

Materials and Methods: Eighteen patients undergoing laparoscopic intestinal surgical procedures were included in this observational study. Measurements of lung and chest wall compliance were performed with PSM through a two-step PEEP increase where the end-expiratory lung volume change (ΔΕΕLV) was measured spirometrically after induction (BL), after pneumoperitoneum, and after exsufflation.

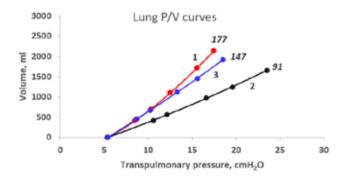

Fig. 1. Pressure/volume curves calculated with the two-step PEEP method. Curve numbers: CL, ml/cmH2O. Red curve: after induction. Black: after CO₂ insufflation with 16 cm H₂O. Blue: after exsufflation.

Results and Discussion: Results: CCW and CL decreased during CO2 insufflation in all patients, CCW from 136±43 to 95±25, CL from 110±31 to 66±14 ml/cmH2O. Transpulmonary driving pressure increased by 50%, from 3,7±0,8 to 6,1±1,1 cmH2O, but the increase was not due to overstretching but to the decrease in lung volume. The PSM software calculated that the optimal PEEP level was 10 cmH2O higher than clinically used, 17 vs. 7 cmH2O. After CO2 exsufflation and supine positioning, CCW and CL recovered to near baseline levels.

Conclusion(s): Lung mechanics and EELV were significantly affected during CO2 insufflation during laparoscopic surgery. The PEEP step method indicates that PEEP should be significantly higher to preserve lung volume during laparoscopic surgery. By measuring before weaning, it's possible to see if lung mechanics have been restored, or if a recruitment manoeuvre may be desirable

- 42AP05-3 **Breathing through thyroidectomy complications**

C. Vasconcelos¹, S. Conceição¹, S. Cruz¹, S. Cadilha¹ ¹Unidade Local de Saúde de São José, Anestesiologia, Lisboa, Portugal

Background: Bilateral recurrent laryngeal nerve injury and cervical hematoma are major complications of thyroid surgery that can significantly challenge airway management and threaten the patient's life. We present a case involving both complications following extubation, leading to imminent compromise of the airway.1 Case Report: A 78-year-old woman, ASA III, underwent an elective total thyroidectomy due to a substernal multinodular goiter. Airway assessment revealed a Mallampati score II and a rightward tracheal deviation on CT. Following induction and successful mask ventilation, intubation was uneventful with videolaryngoscopy. During surgery, iatrogenic bilateral recurrent laryngeal nerve injury occurred, with complete sectioning of the left nerve and uncertain injury to the right. Due to possible airway compromise, the team anticipated a challenging extubation and discussed the airway plan, which was known by all members: use a tube exchanger to assess vocal cord mobility with videolaryngoscopy; extubate if appropriate; and reintubate if needed: Plan A videolaryngoscopy and Plan B surgical airway. After reversing muscle blockade, the left vocal cord showed paresis, the right exhibited slight movement, and both had edema. With spontaneous ventilation and a mobile cord, the tube exchanger was removed, and the patient emerged from anesthesia. However, after a few minutes, she developed an important inspiratory stridor and SpO2 dropped to 89%. Reintubation was promptly decided and Plan A was successful. Immediately after intubation, significant cervical swelling was noted, leading the surgical team to review hemostasis. Postoperatively, the patient was transferred intubated to the ICU, where she was extubated two days later, but required reintubation the next day due to stridor. Following discussion with the otolaryngologist, an elective tracheostomy was performed for persistent stridor and bilateral vocal cord paresis seen on nasofibroscopy. The patient was discharged and continued physiotherapy and speech therapy at home. Seven months later, significant improvement allowed for tracheostomy removal.

Discussion: This case highlights the importance of a multidisciplinary approach and clear strategy definition with effective team briefing. Rapid decision-making and expertise were crucial in identifying and addressing airway compromise. It also underscores the dynamic characteristic of the airway, requiring close monitoring and adaptability in management.

42AP05-4

Lung mechanics during anesthesia for laparoscopic robot-assisted surgery

A.G. Abdulhussein¹, S. Hammarskjöld¹, O. Stenqvist¹, S. Lindgren¹

¹Sahlgrenska University Hospital, Institute of Clinical Studies, Sahlgrenska Academy, Department of Anaesthesia and Intensive Care, Göteborg, Sweden

Background and Goal of Study: The aim of the study was to measure lung mechanics during anesthesia for robot-assisted surgery using the PEEP step method (PSM).

Currently, there is no simple bedside method to evaluate lung mechanics separately from chest wall mechanics or lung volume changes during CO₂ insufflation and positional changes.

There are also no studies on the individualization of ventilator settings during robot-assisted surgery.

Materials and Methods: Fourteen gynecological and urological patients participated in this observational study. Data for calculating lung and chest wall compliance were collected using a laptop connected to the ventilator.

The Lungbarometry™ software calculates lung compliance (CL) and transpulmonary driving pressure (PL) during a two-step PEEP increase where end-expiratory lung volume change (ΔΕΕLV) was measured by spirometry after induction (BL), after pneumoperitoneum and Trendelenburg position, and before awakening.

Additionally, ΔEELV was measured during CO2 insufflation, CO2 exsufflation, and during tilting.

Results and Discussion: Patients were circulatory and respiratory stable. CL was significantly affected during CO₂ insufflation and tilting down in all patients (BL 133 ± 28 vs. 71 ± 24 ml/cmH_oO, p <0.001). PL increased (+4.6 ± 2.1 cmH2O, p<0.001 vs. BL). After CO₂ exsufflation and returning to the flat position, CL recov-

ered compared to baseline (133 \pm 28 vs. 141 \pm 34 ml/cmH2O, p = 0.491). The decrease in EELV during CO, insufflation and headdown tilting did not recover before awakening (Fig. 1).

The Lungbarometry program suggested an optimal PEEP level that was twice as high as the clinical routine level.

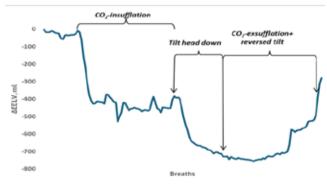

Fig. 1

EELV changes during abdominal CO₂ insufflation + head-down tilting and exsufflation before tilt head-up. Volume changes were measured as the cumulative difference in expiratory tidal volume. Conclusion(s): PSM could be used as a simple bedside tool to measure lung mechanics during surgery. Lung mechanics and EELV were significantly affected during surgery. Our measurement method indicates that a higher PEEP would be beneficial for this type of procedure to preserve lung volume.

42AP05-5

Unexpected Tracheoesophageal Fistula diagnosis under intubated general anesthesia in a post-esophagectomy cancer patient

H. Chen¹, M.-H. Hung¹ ¹National Taiwan University Hospital, Department of Anesthesiology, Taipei, Taiwan

Background: Tracheoesophageal fistula (TEF) is a rare but serious complication associated with esophageal malignancies. During general anesthesia, TEF can cause significant ventilatory challenges, including circuit leaks and contamination risks, necessitating immediate recognition and specialized anesthetic management.

Case Report: A 67-year-old man with esophageal cancer, who had an Ivor Lewis esophagectomy two years earlier, presented for esophageal dilation due to recurrent anastomotic strictures. After induction of anesthesia and tracheal intubation, bilateral breath sounds were confirmed. Anesthesia was maintained with low-flow sevoflurane using end-tidal control mode. At a fresh gas flow of 0.5 L/min, the ventilator bellows stopped functioning despite normal readings from the breathing circuit and capnography. Injecting additional air into the endotracheal tube's pilot balloon and increasing the fresh gas flow temporarily restored function. However, during esophagoscopy, the leak recurred, prompting suspicion of a TEF. The anesthetic plan was switched to total intravenous anesthesia (TIVA) to prevent volatile agent contamination. The fistula, located 2 cm above the carina, was confirmed via esophagoscopy and bronchoscopy.

bserved using a suction catheter passed throu escohageal fistula located 2 cm above the cari

Discussion: This case underscores the importance of suspecting TEF in patients with esophageal cancer when unexplained ventilation issues occur under positive pressure ventilation. Early recognition allows interventions that can prevent severe respiratory complications. Key management strategies include positioning the endotracheal tube cuff distal to the fistula to maintain ventilation and reduce leakage, switching to TIVA, and utilizing bronchoscopy and esophagoscopy for precise fistula localization. Minimizing postoperative positive pressure ventilation may reduce the risk of anastomotic breakdown.

Reference:

Parker, R.J. et al. BJA, 100(1):139-140

Learning Points: Suspect TEF in esophageal cancer patients with unexplained circuit leaks. Early diagnosis and tailored ventilation are vital to prevent complications, requiring close anesthesiology-surgery collaboration for optimal outcomes.

42AP05-6

Emergent airway challenge in the intraoperative setting: resolving an acute false passage in a patient with a tracheostomy

D. Revuelta¹, G. Urquijo¹, M.A. Perelló¹, Á. Barranco de Santiago¹ ¹Hospital Clínic de Barcelona, Anaesthesiology and Critical Care, Barcelona, Spain

Background: Mechanical ventilation in patients with tracheostomy is often regarded as simple because of the direct access to the airway1. However, there are situations that can be challenging, for example, when a new false passage of the tracheostomy occurs. We present a case where emergent rescue maneuvers were necessary due to difficulties in ventilating a patient through the tracheostomy.

Case Report: A 63 year-old patient started with acute pharyngeal cellulitis and abscess formation extending to mediastinum. In this setting, an emergency cricothyroidotomy was performed. Two days later, he underwent an elective tracheostomy. During the hospital admission, the patient worsened. A thoracic CT scan was performed, showing evidence of mediastinitis aggravation. Therefore, urgent surgery was indicated to perform surgical debridement. The procedure was performed under total endovenous anaesthesia, connecting the patient to the ventilator through the traqueostomy. After that, a bronchial blocker was inserted under fiberoptic visualization in the main right bronchus. One lung ventilation was started and the surgery proceeded without incidents, through a right thoracotomy approach. However, at the end of the procedure, the patient started desaturation and hypotension, and a sudden increase in the peak pressure with a flat capnography trace was evidenced. We deflate the bronchial blocker but, despite of that, these signs maintained and we could not evidence lung ventilation. An emergent fiberoptic view revealed a false passage and, in that moment, we saw a new purulent wound in the anterior cervical region.

Emergency endotracheal intubation was performed in the lateral decubitus position using hyperangulated videolaryngoscopy, revealing glottic edema and periglottic swelling with a narrow passage. Therefore, a 6.5 mm endotracheal tube was introduced. Periods of bilateral lung ventilation were alternated with periods of apnea, and the thoracotomy was closed without incidents.

Discussion: False passages are a recognized but infrequent complication during the intraoperative period2, but it can be lifethreatening. Early detection through clinical signs and monitoring is crucial, with an immediate communication to the surgical team that an unanticipated difficult airway has been declared. In this clinical scenario where there is no patient's oxygenation, emergent measures must be taken.

42AP05-8

Pilot clinical trial to determine the safety of endotracheal intubation with the aid of the 'Airway Shield™' intubation mask in patients undergoing elective surgery

J. Alonso Babarro¹, N. Moracho Pascual², R. Sancho Carrancho³

¹The Prince Charles Hospital, Adult Intensive Care Services, Queensland, Australia, ²Airway Medical Research Group, Clinical Research and Medical Communication, Santander, Spain, 3 Marqués de Valdecilla University Hospital, Anaesthesiology Department, Santander, Spain

Background and Goal of Study: Despite recent advances in laryngoscopy, including video laryngoscopy and channelled laryngoscopes, endotracheal intubation (ETI) is often challenging and it is associated with both major and minor complications. The Airway Shield™ is a novel medical device (a mouthpiece canula made of flexible plastic) designed to guide the endotracheal tube (ETT), which follows the laryngoscope blade previously introduced through the device. In addition, the Airway Shield™ protects the patient from the risk of trauma, and the clinician from the aerosols generated during the ETI. In this study, we determined whether the Airway Shield™ is safe and effective to assist in performing ETI with video laryngoscope in surgical patients.

Materials and Methods: Twenty patients undergoing elective surgery under general anaesthesia were recruited for a single-center trial at the Marqués de Valdecilla University Hospital. Five anaesthesiologists performed ETI using the Airway Shield™ in each of the patients. Intubation time and success rate were measured for each attempt. Participants were surveyed at the end of the study to evaluate the ease of intubation using the Airway Shield $^{\mathsf{TM}}$.

Results and Discussion: Of the 20 intubations, 19 were successfully performed with the Airway Shield. Of these, 17 ETIs were successfully completed on the first pass and the remaining 2 on the second pass. The average intubation time was 32.9 seconds. There were no reported complications, neither accidental extubations during the removal of the device. Participants scored the ease of intubation with Airway Shield on a scale of 0-10, with a mean score of 7.6.

Conclusion(s): The Airway Shield device enables successful and safe intubation with short intubation times in patients in the operating rooms, and provides an easy to perform intubation technique as perceived by the operators. This pilot study will provide the basis for future studies involving more patients and more complex settings.

42AP05-9

Challenges in airway management of a child with severe esophageal caustic stricture and undiagnosed dynamic airway obstruction

S. Cabete¹, A. César², A. Casimiro³ ¹Centro Hospitalar Universitário de Santo António, Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal, ²Hospital D. Estefânia, Unidade Local de Saúde de São José, Serviço de Anestesiologia, Lisboa, Portugal, ³Hospital D. Estefânia, Unidade Local de Saúde de São José, Unidade de Pneumologia Pediátrica, Lisboa, Portugal

Background: who suffer caustic ingestion are at risk of airway seguelae.

Case Report: A 2-year-old African boy, 11kg, with oesophageal caustic stricture, was scheduled for an oesophageal dilation 9 months post-ingestion. He had sialorrhea, nocturnal cough and was fed via a gastrostomy.

After inhalation induction and insertion of an intravenous (IV) catheter, 0.2mg alfentanil and 20mg propofol were administered. Adequate facemask ventilation was confirmed, and 30mg of propofol were administered. Intubation with a 3.5mm tube with a stylet under direct laryngoscopy was uneventful: omega-shaped epiglottis, no identification of arytenoid cartilages, modified Cormack-Lehane 2a.

General anaesthesia was maintained with sevoflurane.

After intubation, bronchospasm occurred and was treated with inhaled bronchodilators.

The oesophageal opening was not identified endoscopically. Bronchoscopy revealed supraglottic fibrosis extending into the hypopharvnx. After spontaneous breathing recovered, the tracheal tube was removed for the remaining examination, which was interrupted by desaturation episodes requiring suction and facemask ventilation. Intermittent airway obstruction due to a laryngeal mass (Fig A) and tracheomalacia (Fig B) was diagnosed. Next, an obstructive breathing pattern and delayed recovery of consciousness were noted. Recovery was achieved following facemask ventilation.

Subsequent nasopharyngolaryngoscopy (Fig C) revealed left cord hypomobility.

Discussion: Late airway complications from caustic ingestion are unpredictable. With obstructive symptoms, there is a high risk of aspiration and hyperreactive airway responses.

Benign obstructive airway conditions can impair spontaneous breathing while under the effect of anaesthetic agents and contribute to a delayed recovery of consciousness due to hypercapnia.

Reference:

1. Payal YS, Sogal PS, Cs P. Corrosive poisoning and its implications on pediatric airways. *Korean J Anesthesiol*. 2023;76(6):643-644.

Learning Points: Difficult airway and high risk of respiratory complications should be expected in children with caustic injuries¹. A timely multidisciplinary evaluation is essential to ensure safe anaesthesia.

42AP05-10

Airway management challenges in a patient with Moebius syndrome: a case report

<u>D. Gao Nunes</u>¹, G. Reis¹, R. Pires¹¹*Unidade Local de Saúde São José, Anesthesiology, Lisboa, Portugal*

Background: Moebius syndrome is a rare, nonprogressive neurological disorder (prevalence 2-20/million births) characterized by facial paralysis and defective extraocular eye movements secondary to congenital paresis of the facial and abducens cranial nerves. These classic features are often accompanied by upper airway, thoracic and diaphragmatic hypotonia, and craniofacial abnormalities which complicate airway management. Affected infants typically present with an immobile, expressionless facies. This case highlights the perioperative difficulties in managing the airway of a patient with Moebius syndrome.

Case Report: An 18-year-old male with Moebius syndrome presented for a corneal suture. General anesthesia with a supraglottic airway device was the first plan of approach. Significant air leaks precluded effective ventilation despite attempts with different sized supraglottic devices. Bag-mask ventilation was difficult. Direct laryngoscopy was unsuccessful due to severe hypotonia, coupled with a lax, omega-shaped epiglottis and anterior glottis. Videolaryngoscopy with a hyperangulated blade and cricoid pressure facilitated successful intubation.

The procedure was uneventful. Challenges resumed at extubation phase. Neuromuscular blockade was reversed with sugammadex, and residual block excluded with quantitative peripheral nerve stimulation. After extubation, facial hypotonia obscured clinical indicators of consciousness and spontaneous ventilation in a desaturating patient. Nasopharyngeal tube placement and multiple secretion aspirations were required. The patient was transported with nasal oxygen and capnography to the postoperative care unit (PACU) for monitoring.

Discussion: This case underscores the complexity of airway management in Moebius syndrome. Facial and pharyngeal hypotonia complicate supraglottic device use and intubation. Videolaryngoscopy proved invaluable in overcoming anatomical challenges. Extubation required a high index of suspicion for inadequate ventilation, emphasizing the need for close monitoring.

Reference:

Orphan Anesthesia. (2024, DEC06). Moebius Syndrome. Available at: https://www.orphananesthesia.eu

Learning Points: Optimal perioperative management in patients with Moebius syndrome demands thorough preparation, alternative airway strategies, and vigilance during recovery. This case reinforces the role of videolaryngoscopy in syndromic airway scenarios and highlights the importance of tailored postoperative care.

42AP05-11

Managing subglottic stenosis safely: awake fiberoptic bronchoscopy with a narrow-bore endotracheal tube: a case report

A. Capdevila Feixas¹, S. Moreno-Jurico¹, I.M. Baltar¹, L. Gómez¹, M. Ubré¹, E. Rivas¹

¹Hospital Clínic Barcelona, Anaesthesiology, Resuscitation and Pain Treatment, Barcelona, Spain

Background: Benign subglottic stenosis presents significant challenges for airway management. This case report highlights the management of a patient with severe subglottic stenosis undergoing general anesthesia for abdominal surgery.

Case Report: We report the case of a 51-year-old male with subglottic stenosis (>50%, Cotton-Myer grade II) due to prolonged intubation after polytrauma at age 25 and refractory to surgical treatment. A detailed airway management strategy was devised by the anaesthesiology and otorhinolaryngology team. Awake fiberoptic bronchoscopy was successfully performed. An attempt to advance a size 5.0 endotracheal tube encountered resistance at the stenosis (Fig.1A-1B). A guidewire was introduced through the working channel of the bronchoscope (Fig.1C), enabling the insertion of a 4.4mm tube (Fig.1D). Flow-controlled ventilation (FCV) maintained normocapnia and oxygenation during surgery, with peak pressures of 19 and a PEEP of 5 cmH2O. The patient was extubated in theatre without complications.

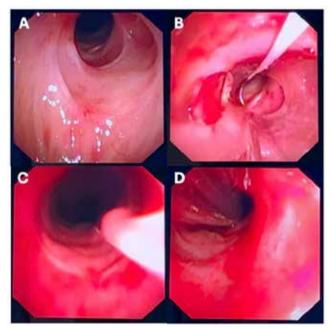

Fig.1. Awake Intubation Sequence

Discusion: The American Society of Anesthesiologists recommends awake intubation for anticipated difficult airways¹. However, in subglottic stenosis, awake intubation alone may fail due to resistance caused by the stricture. While there is limited evidence supporting a single awake technique, fiberoptic bronchoscopy enhances safety by allowing direct visualization of the stenosis. Combining FCV with narrow-bore tubes seems to ensure effective ventilation and oxygenation in severe airway narrowing². The use of a guidewire to intubate with a narrow-bore tube following fiberoptic bronchoscopy has not been documented but was successful and safe in this case as it allowed direct airway visualization.

References:

- 1. Jeffrey L, et al. Anesthesiology 2022;136:31-81;
- 2. Filauro M. et al. Acta Otorhinolaryngol Ital. 2022;42(2):189-93 Learning Points: Preoperative planning and multidisciplinary collaboration are critical for managing complex airways. Combining awake fiberoptic intubation with guidewire narrow-bore tube insertion and FCV ensures safe intubation and adequate oxygenation in patients with narrowed airways.

42AP05-12

The Aintree Intubation Catheter in an unexpected difficult airway: a case report

D. Padilla¹, E. Lopetegui Auzmendi¹, I. Hernández Zubelzu¹, A. Arregui Rodriguez¹, G. Etxeberria Larreina¹. T. Fernández de Casadevante Etxezarreta¹ ¹Donostia University Hospital, Anesthesiology and Resuscitation, San Sebastian, Spain

Background: The Aintree Intubation Catheter (AIC) is a bougie tube with a larger internal diameter (4.7 mm) than standard airway exchange catheter. In a context of unexpected difficult airway it allows placing a pediatric fiberoptic bronchoscope through its lumen to guide the exchange of a supraglottic device [(laryngeal mask (LM)] to an endotracheal tube (ETT) (1). Our Anesthesiology Department of Donostia University Hospital (DUH) found out recently the existence of de AIC and started to evaluate its utility in several patients.

Case Report: The patient is a 27 years old man. After recurrent episodes of acute epiglottitis, the patient is scheduled for resection of the lingual tonsil, lymphoid tissue of the base of the tongue, and mucosa of the epiglottis.

Due to the presence of several predictors of difficult airway (marked retrognathia, prominent teeth), the decision is made to attempt intubation with a Storz video laryngoscope: the epiglottis and abundant pharyngeal lymphoid tissue are visualized, obstructing the view of the glottis. The next attempt is made with a pediatric bronchoscope in the sleeping patient, but again, there is poor visualization of the laryngeal anatomy. The airway is successfully secured with an I-gel LM, size 4, with an acceptable fit. The AIC with a pediatric bronchoscope loaded into it is used successfully to exchange the laryngeal mask airway to a size 7 ETT. Between each intubation try, the patient is ventilated with a face mask or LM, maintaining oxygen saturation above 97%.

Discussion: In the DUH, after rescuing an unexpected airway with a LM, we normally use the "tube-over-tube" technique to exchange it for an ETT. This process can be technically challenging and has the potential risk of damaging the airway.

After testing the AIC in several patients and given this case, we consider that the visualization with the fiberscope allows for a more careful and safe exchange, potentially reducing the risk of airway trauma (1), as well as direct confirmation of the final placement of the ETT in the trachea. In addition, its usage is technically easy.

Retrograde intubation: case series at a tertiary care oncology set-up: time to revisit the technique?

M. Sharma¹, S. Jee Bharti¹, S. Bhatnagar¹, D.S. Mishra¹, R. Garg¹, N. Gupta¹

¹All India Institute of Medical Sciences, New Delhi, Department of Oncoanaesthesia and Palliative Medicine, New Delhi, India

Background: Retrograde intubation can be successfully used in awake, sedated, obtunded, or apneic patients who have either an anticipated or unanticipated difficult airway. The American Society of Anaesthesiologists (ASA) describes retrograde intubation as an alternative approach to difficult intubation in the non emergent pathway as per their difficulty airway algorithm. It also serves as a valuable skill when fibreoptic scope isn't available. We discuss two cases of difficult airway managed at a tertiary care onco-centre with retrograde intubation: One with conscious sedation with dexmedetomidine, and another with usage of airway blocks

Case Report: Case 1: C/o Ca buccal mucosa posted for CR+MND+PMMC flap. Mouth opening <1FB with limited neck extension due to post radiotherapy changes. Retrograde intubation done after airway topicalization with Mckenzie technique and dexmedetomidine infusion.

Case 2: C/o ameloblastoma lower alveolus posted for central arch segmental mandibulectomy= neck dissection+ free fibular flap. Retrograde intubation done after airway topicalization with Mckenzie technique and B/L Superior laryngeal + transtracheal blocks

Discussion: These two cases aim to emphasize the feasibility of awake retrograde intubation with both conscious sedation with dexmedetomidine and airway blocks. Awake retrograde intubation is avaluable assest in the armammetorium of an anaesthesiologist, especially in a resource limited setting without access to state of the art difficult airway equipments, including a fibreoptic scope.

References:

- 1. Dhara SS. Retrograde tracheal intubation. Anaesthesia. 2009; 64: 1094-1104
- 2. Reena RV (2018) Limited mouth opening: retrograde intubation revisited. Saudi J Anaesth 12(2):349-351.

Learning points:

- 1. Retrograde intubation is a feasible rescue airway management technique which can prove to be valuable especially in a resource limited setting.
- 2.Skill like Retrograde intubation should be a part of the difficult airway management algorithm, which will make it an integral part of teaching learning curriculum. It is advised that residents should undergo training of RI through audiovisual methods, in manikin simulators or cadavers . Familiarity with this simple and quick technique will lead to higher success rates even during emergency difficult airway scenarios.

42AP06-2

Frova as a rescue tool during awake videolaringoscopy: a case report

C. Fernandes Marques¹, A. Machado Borges², S. Farraposo¹, J. Melo Borges² ¹Unidade Local de Saúde de São José, Serviço de Anestesiologia, Lisboa, Portugal, ²Hospital do Divino Espirito Santo de Ponta Delgada, Serviço de Anestesiologia, Ponta Delgada, Portugal

Background: Managing a difficult airway (DA) can be challenging for anesthesiologists. Predicting complications, proper planning, and a multidisciplinary approach are essential for ensuring patient safety and successful intubation [2].

Fiberoptic bronchoscopy, the gold standard for DA management, may not be suitable in certain cases such as when nasal obstructions or important bleeding are present [1].

Moreover, recent guidelines emphasize the importance of combining techniques and tailoring airway strategies to approach the airway effectively [2].

This case presents a DA management approach using videolaryngoscopy and a Frova introducer following initial failures with fiberotic bronchoscopy.

Case Report: A 75-year-old female, ASA III, with hypertension, type 2 diabetes, and a multinodular goiter causing tracheal deviation, was scheduled for total thyroidectomy. Intubation attempts using videolaryngoscopy and awake nasal fiberoptic bronchoscopy failed due to significant nasal epistaxis, postponing the surgery. This was later attributed to a nasal polyp.

The patient was scheduled for its removal and orotracheal intubation with C-MAC® videolaryngoscope was successfully achieved under remifentanil infusion and topical airway anesthesia with lidocaine 10%.

The first two attempts with a 7.0 and 6.0 tube failed due to inability to progress through the glottic narrowing. The third attempt succeeded with the Frova introducer facilitating intubation by providing a guide for a 6.0 tube through the restricted airway. Thyroidectomy was later performed with fiberoptic-guided intubation, reflecting resolution of airway challenges after polyp re-

Discussion: This case highlights the Frova introducer key role in difficult airway management and its use in awake videolaryngoscopy, enabling successful intubation when other techniques

Multidisciplinary collaboration and planning were essential for the outcome. It highlights the importance of nasal obstructions and adapting airway management strategies for patient safety and procedural success.

1. Miller, R. D. (2020). Miller's Anesthesia (9th ed.). Elsevier. 2. American Society of Anesthesiologists. (2020). Practice Guidelines for Management of the Difficult Airway. Anesthesiology, 132(1), 1-33.

Learning points: Managing a DA demands preparation, teamwork, and flexibility. A clear, defined plan paired with effective collaboration can significantly improve patient outcomes.

42AP06-3

Airway management in a patient with Goldenhar syndrome and prior history of difficult intubation

R.M. da Costa Graça¹, M.T. Boneco¹, I. Rodrigues¹ ¹Unidade Local de Saúde de Santa Maria - ULSSM, Anestesiologia, Lisboa, Portugal

Background: Goldenhar syndrome (GS) is a rare congenital disorder characterized by hemifacial microsomia with ear, eye, and vertebral bodies anomalies. Cardiac, renal and respiratory involvement may occur. Challenges in airway management should be anticipated primarly due to mandibular hypoplasia and cervical spine malformation¹.

Case Report: A 15-year-old male patient with GS, ASA III, was admitted for unilateral ear reconstruction. Past medical history included multiple reconstructive surgeries and a prior history of difficult intubation. No other comorbidities were identified. On physical examination, predominant clinical features included severe mandibular hypoplasia. Mallampati score was class IV. An anticipated difficult airway was expected and preparations made accordingly. The chosen approach was an oral awake fiberoptic intubation (FOI) using a flexible bronchoscope, performed under sedation with airway topicalization with lidocaine spray, and maintaining spontaneous breathing. Additional airway and emergency equipment were available. Adequate preoxygenation was performed and supplemental oxygen was delivered via nasal cannula during intubation. FOI was successful on the second attempt. Anesthesia maintenance was achieved with sevoflurane. Surgery was uneventful, extubation was performed in the operating room without any complications and the patient discharged home the next day.

Discussion: This case highlights the complexities of anesthetic management of GS patients. The patient's previous history of difficult intubation and difficult airway predictors prompted meticulous planning. Opting for an oral awake FOI was a strategic choice, with adequate preoxygenation and continuous delivery of supplemental oxygen being crucial steps in maintaining oxygen saturation levels. Despite the challenges, the team's preparation allowed for successful intubation without adverse events and a smooth extubation without complications, reflecting the comprehensive planning and execution of the anesthetic strategy.

Reference:

1. Cakmakkaya, O.S. & Kolodzie, K. (2023). Anaesthesia recommendations for Goldenhar syndrome. Anästh Intensivmed, 64:S27-S38.

Learning Points: This case underscores the importance of tailored approaches in managing patients with complex craniofacial anomalies such as GS. Adequate preoperative assessment, planning, and use of awake FOI were pivotal in ensuring a safe and successful outcome.

42AP06-4

A novel approach combining an old technique to achieve one lung ventilation in pediatric patient

D. Kaur¹, S. Singh¹, P. Owusu-Agyemang¹, R. Kapoor¹, T. Idowu¹, J. Heir¹ ¹University of Texas MD Anderson Cancer Center, Anesthesiology, Houston, United States

Background: Achieving one lung ventilation(OLV) is vital for thoracic surgery, however double lumen tube placement(DLT) is not always feasible in young pediatric patients and bronchial blocker(BB) placement can be challenging due to difficulty in guiding distal airway trajectory assuring proper BB placement. We describe BB placement with External Tracheal Manipulation Maneuver(ETMM)1 prior to intubation with endotracheal tube(ETT), thereafter, confirming correct placement with fiberoptic bronchoscopy(FOB).

Case Report: 6 yo male hx of osteosarcoma presented for wedge resection of left upper lobe. Given the patient's size a BB was selected for OLV in lieu of DLT. However, BB(Arndt 5Fr) was placed prior to ETT placement via laryngoscopy and advanced to left mainstem bronchus utilizing ETMM, whereby the trachea is displaced to the right side externally while simultaneously advancing the BB. Airway then secured with 5.5MM cuffed ETT, correct placement of BB in left mainstem bronchus confirmed with 3.0mm pedi-FOB. Minor adjustments in depth of BB position could be done in controlled fashion without interference by BB as it was outside ETT, allowing FOB to move freely in small ETT. OLV achieved without issue, and no static or dynamic airway pressure perturbations were noted; at end of surgery, patient was extubated without any complications.

Discussion: Comparatively pediatric OLV can be more challenging due to physiological, anatomical differences, various pathologies, and size limitations of lung isolation devices. FOB can be onerous due to restricted tube sizes through which BB and scopes can appropriately fit, while providing adequate oxygenation and ventilation. Moreover, achieving OLV without traumatizing the pediatric airway, avoiding excessive airway pressures when devices are sharing the ETT such as FOB and BB is ideal. BB placement using ETMM followed by ETT placement is a useful technique as the FOB is given maximum room to maneuver in a secured airway via ETT to allow confirmation of correct placement. Moreover, since with this technique the BB is outside the ETT and once FOB is removed, maximum ETT diameter is available for ventilation, thus reducing airway pressures.

Reference:

1. JCardiothorac Vasc Anesth 2016 Aug;30(4):1061-3

Learning points: BB placement with ETMM can provide ideal OLV in pediatric patients, facilitating surgery potentially avoiding trauma with larger DLTs while affording maximum ETT diameter possibly reducing barotrauma.

42AP06-5

Case report: Difficult airway management in patient with submandibular adenocarcinoma

D. Farzaliyeva¹, S. Koruk¹, H. Kocoglu¹ ¹Istanbul Medeniyet University, Anesthesiology and Intensive Care, Istanbul, Turkey

Background: Patients with submandibular gland malignancies often present with either a slow or rapidly growing mass in the submandibular triangle of the neck, with or without pain. In this study. We reported a case of adenocarcinoma of the submandibular gland presenting with the upper-airway obstruction, which necessitated emergency tracheostomy.

Case Report: A 44-year-old male patient was referred from the Medical Oncology Clinic to the Otolaryngology Clinic due to increasing swelling in his neck with a 1 year progressive, painless submandibular swelling, which worsened. There was associated dysphagia to solid, muffled voice, weight loss, and features of upper-airway obstruction.

The physical examination showed a chronically ill middle-aged man in obvious respiratory distress. The neck examination revealed a huge left submandibular swelling that crossed the midline (110x10 cm).

We were concerned about impossible direct laryngoscopy because the massive tumor in the floor of the mouth compressed the base of the tongue against the posterior wall of the pharynx, restricting the space for inserting the laryngoscope blade. Therefore, we planned to perform awake nasal fiberoptic intubation to secure the airway.

Although the procedure was complicated by the massive tumor, successful intubation was achieved

Discussion: In cases of predicted or known difficult laryngoscopy, the FOB is ideal for navigating the airway and bypassing oropharyngeal lesions due to the insertion cord's thin diameter and high manoeuvrability.

Learning points:

Awake fiberoptic nasotracheal intubation, along with airway blocks and appropriate sedation, can be a viable option in patients with submandibular gland malignancies

42AP06-7

Comparison of clinical performance and complications of I-gel, Classic, and ProSeal laryngeal mask airways in endobronchial ultrasound-guided tracheobronchial needle aspiration

D. Güzelkaya¹, D. Unal², E.Z. Terzi², J. Ergil², S. Akcalı Duru³ ¹Ankara Etlik City Hospital, anesthesiology and reanimation, Çankaya/ Ankara, Turkey, ²Ankara Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey, ³Ankara Etlik City Hospital, CHEST DİSEASE, Ankara, Turkey

Background and Goal of Study: This study compared the Classic, Proseal laryngeal mask airways (LMA) and I-gel, in patients undergoing endobronchial ultrasound-guided tracheobronchial needle aspiration (EBUS-TBNA) for clinical performance and complications.

Materials and Methods: Patients (n:183) undergoing EBUS-TBNA were assigned to Classic LMA, Proseal LMA and I-gel groups for airway management. Predictors of difficult airway, ease of insertion of the supraglottic airway devices (SAD), airway pressures, ease of fiberoptic scope (FO) advancement and complication rate were assessed

Results and Discussion: Groups were similar regarding patient characteristics and difficult airway predictors. More patients in the Classic LMA group needed airway opening maneuver (36.1%) for SAD insertion than the Proseal LMA (4.9%) and I-gel (16.4%) groups (p<0.001). Difficult glottis visualisation with FO was higher in Group Classic LMA (45.9%) than the Proseal LMA (13.1%) and I-gel (14.8%) groups (p<0.001). Very difficult FO insertion through the glottis was higher in Group Classic LMA (31.1%) than in the Proseal LMA (4.9%) and I-gel (4.9%) groups (p<0.001). Oropharyngeal leak pressure after insertion of SAD was lower in Group Classic LMA (24.48 mmHg) than Proseal LMA (27.25 mmHg) and the I-gel (27.05 mmHg) groups (p<0.001). The mean FO advancement attempt in Group Proseal LMA (1.34± 0.75) and I-gel (1.38±0.9) was lower than in Group Classic LMA (2.46±1.88) (p<0.001). The mean insertion time in Group I-gel (27.36±17.64 sec) was longer than in Group Classic LMA (20.18±13.24 sec) (p:0.029). The rate of minor dental, lip, and tongue injury, hiccups, laryngospasm, sore throat, and blood stain on SAD were similar between groups.

Conclusion(s): In EBUS-TBNA procedures under general anesthesia, glottis visualisation is limited with the use of Classic LMA compared to Proseal LMA and I-gel, FO passage through the vo-

cal cords requires more attempts and despite a better glottic seal, operators report that the procedure is more difficult with Classic LMA.

Mastering airway challenges: a critical case of emergency tracheostomy in a patient with laryngeal obstruction

C. Pinto¹, <u>J. Pereira</u>¹, M. Pereira¹, A. Nogueira¹, S. Pereira¹, L. Ormonde²

¹North Lisbon University Hospital Centre (CHULN), Department of Anesthesiology, Lisboa, Portugal, ²North Lisbon University Hospital Centre (CHULN), Department of Anesthesiology, Lisbon, Portugal

Background: Difficult airway management presents significant challenges in anesthetic practice, particularly in patients with complex anatomical or pathological conditions.^{1,2}

This case ocuses on a 64-year-old female patient with a history of laryngeal chondrosarcoma, presenting with respiratory distress and stridor.

Case Report: The patient was admitted to the ER exhibiting severe dyspnea and stridor. A prior CT scan revealed a laryngeal expansive lesion, compromising her airway.

Given the patient's condition, a meticulous preoperative plan was devised, for a careful airway assessment and management strategy. Awake intubation was attempted using fiberoptic bronchoscopy by the most experienced doctor, but the procedure was unsuccessful due to significant airway obstruction.

Consequently, an urgent tracheostomy was performed by the ENT team under local anesthesia and sedation using ketamine and midazolam. The procedure was completed swiftly and without complications, effectively securing the airway.

Discussion: This case underscores the complexity of managing patients with difficult airways, particularly in the context of malignancies that distort normal anatomy. ^{1,2} Awake intubation remains a preferred technique however, its success is contingent upon various factors, including the degree of airway obstruction and the operator's experience. The rapid conversion to tracheostomy highlights the importance of preparation and adaptability in emergency airway management. The use of local anesthesia and sedation can facilitate airway interventions while minimizing patient discomfort.

References:

1. Hohn A, Kauliņš T, Hinkelbein J, et al. Awake tracheotomy in a patient with stridor and dyspnoea caused by a sizeable malignant thyroid tumor: a case report and short review of the literature. Clin Case Rep. 2017 Oct 5;5(11):1891-1895; 2. Fusco P, Iuorio A, Della Valle M, Ferraro F. Awake tracheostomy in a patient with acute upper airway obstruction: an emergency application of an elective percutaneous procedure. Open Access Emerg Med. 2019;11:167-170.

Learning points: This case illustrates the critical aspects of managing difficult airways, including the necessity for thorough preoperative planning, the value of experienced personnel, and the readiness to perform emergency procedures such as tracheostomy. Effective communication and collaboration between specialties are essential in optimizing patient outcomes in challenging airway scenarios.

42AP06-10 Take my breath away

B. Silva¹, J. Nogueira¹, C. Bastos¹, O. Santos¹ ¹Unidade Local de Saúde da Região de Aveiro, Anesthesiololy, Aveiro, Portugal

Background: Approaching a difficult airway is a challenge inherent to the practice of anesthesiology, becoming particularly complex in an emergent context, especially while practicing in a peripheral hospital.

Case Report: Male, 56 years old, ASA score IIE, admitted to the emergency department of a peripheral hospital due to an acute peritonsillar abscess. The anesthesiology team was requested, having verified a conscious and cooperative patient, presenting with sialorrhea, dyspnea and dysphagia. Airway evaluation showed a mouth opening of 4 cm, Mallampati score IV and bulging of left parapharyngeal region. The absence of night ENT emergency service forced the patient to be transferred to a tertiary hospital, but first it was mandatory to ensure airway patency. Awake traqueal intubation (ATI) was performed. The process was explained to the patient and alternative plans were considered, such as fibroscopy and marking of cricothyroid membrane. Preoxygenation, topicalisation with lidocaine with head elevation and sedation with midazolam and dexmedetomidine were performed, followed by videolaryngoscopy with hyperangulated blade, which was successful on first attempt, but required aspiration of secretions. After confirmation of correct tube placement, anesthetic induction was performed.

Discussion: ATI is the technique of choice in predicted difficult airway. Multiple factors increase its success rate, such as supplemental oxygen, spontaneous ventilation, conscious sedation, patient cooperation and topical anesthesia. The performance of this technique in a peripheral hospital can be a rare event, causing anesthesiologists to have lesser contact and these skills may be lost over time. As the anesthesiologist is the airway expert, strengthening emergency teams with anesthesiologists becomes a priority, such as the adequate training of professionals in ATI. The availability of equipment for this practice is important, thus prior planning and adequate budgeting is mandatory.

References:

1. Ahmad et al, Difficult Airway Society guidelines for awake tracheal intubation (ATI) in adults. Anaesthesia 2020; (2) Myatra et al, Optimizing education in difficult airway management: meeting the challenge. Ambulatory anesthesia 2017

Learning points: Strengthening emergency teams with anesthesiologists trained in difficult airway management and supporting them in acquiring these skills; reinforce peripheral hospitals with the necessary equipment; ensure alternative plans.

42AP06-11

Qualitative assessment of possible pain and discomfort in awake biphasic cuirass ventilated patients: a prospective observational study

J.F. Schmidt¹, A.-L. Lihn¹, M.S. Kristensen¹ ¹Rigshospitalet, University Hospital of Copenhagen, Department of Anaesthesia, Centre of Head and Orthopaedics, Copenhagen, Denmark

Background and Goal of Study: Modern Extra-thoracic biphasic Cuirass Ventilation has recently been established for airway surgery with unlimited access to the airway.^{1,2} Before surgery, a frequent question from patients is if cuirass ventilation is associated with pain or discomfort, however, no study has described this. This study evaluated if awake cuirass ventilation is associated with pain or discomfort. This knowledge is required to give patients correct and appropriate pre-procedural information, or premedication, before initiating cuirass ventilation.

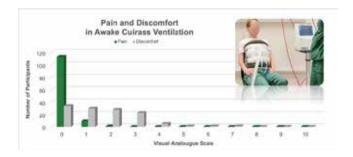

Materials and Methods: Healthy volunteers had awake cuirass ventilation.2 Following Ethics Committee approval participants gave written and oral consent and evaluated the level of possible pain or discomfort on a visual analogue scale from 0-10 where 0 represented no pain or discomfort, respectively and 10 represented worst imaginable pain or discomfort, respectively. Moreover, all participants rated their subjective perception of how effective the cuirass ventilation supported their ventilation with statements of no support =1, partly support =2 and cuirass overtook my ventilation =3. Results are presented as mean± standard deviation.

Results and Discussion: Participants where 43±8 years old. weighed 74±15 kg and were 174±10 cm tall. Sixty-seven identified as women and 56 as men. Ninety-two percent experienced no pain and 10 experienced very little pain i.e., VAS < 3 during cuirass ventilation with a mean VAS score of 0.1±0.3. Cuirass ventilation was generally not uncomfortable, with an overall VAS score of 1.6±1.4 and with only 7 out of 123 participants (6%), scoring above VAS 3. The subjective perception of ventilation support from cuirass ventilation was reported as full ventilation in 46%, partly ventilation in 50% and 4% did not feel any effect.

Conclusion(s): Awake cuirass ventilation is not painful, rarely uncomfortable, and supports ventilation in most awake patients. These results can be used to inform patients when using cuirass awake, or before airway surgery with cuirass ventilation, and to plan and choose ventilatory support.

Anesthetic approach with neuromonitoring tube and endobronchial blocker in uniportal VATS surgery

M. Neto Martins¹, J. Henriques², T. Barbosa¹ ¹Unidade Local de Saúde de São João, Serviço de Anestesiologia, Porto, Portugal, 2Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Porto, **Portugal**

Background: The resection of mediastinal lesions closely associated with the recurrent laryngeal nerve (RLN) requires intraoperative neuromonitoring (IONM) to prevent nerve damage. In thoracic surgeries, one lung ventilation (OLV) is conventionally achieved with a double-lumen tube (DLT)(1), however, the need for IONM creates a challenge in airway management. This case demonstrates an alternative approach combining a neuromonitoring electromyography endotracheal (EMG-ET) tube with an endobronchial blocker EZ Blocker in a non curarized patient to meet both surgical and anesthetic demands, ensuring patient safety.

Case Report: A 50-year-old female patient with a mediastinal cystic lesion, otherwise healthy, was scheduled for resection via uniportal left video-assisted thoracoscopic surgery (VATS). Due to the lesion's intimate contact with the left RL and the need for IONM, a EMG-ET tube was used instead of the DLT as per institutional practice. Following anesthetic induction, a EMG-ET tube was successfully placed and alignment confirmed via videolaryngoscopy. To achieve OLV, an EZ-Blocker was placed under direct bronchoscopic guidance, ensuring proper cuff inflation and effective lung isolation. Before surgical incision, the neuromuscular blockade was reversed with sugammadex. The surgery proceeded uneventfully, and the patient was extubated at the end of the procedure without complications.

Discussion: This case highlights an effective alternative for lung isolation during VATs when RLN monitoring is essential. The substitution of the DLT with a neuromonitoring tube combined with an EZ-Blocker and the absence of curarization met the surgical and anesthetic requirements while maintaining airway safety. Previous studies suggest that endobronchial blockers are a safe and efficient solution in situations where DLTs are less suitable(2). This case underscores the importance of tailored, evidence-based approaches to challenging clinical scenarios.

Reference:

1. DOI: 10.1016/1053-0770(92)90056-d; 2. DOI: 10.1186/s13019-018-0767-9.

Learning points: Combining a neuromonitoring endotraqueal tube with an endobronchial blocker is a safe and effective alternative to DLTs in VATs procedures requiring RLN monitoring. Avoiding neuromuscular blockade enables optimal conditions for IONM, while careful airway management ensures patient safety and surgical success.

42AP07-1

An unexpected subglottic clot: a case of an unpredictable difficult airway

D. Vasconcelos¹, T. Silva¹, A. Pombo¹, C. Mexêdo¹ ¹Unidade Local de Saúde de Santo António, Departamento de Anestesiologia, Clínica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal

Background: Tracheostomy is a frequently necessary procedure in patients who require prolonged ventilatory support. There complications, such as local bleeding, which sometimes require surgical revision or even replacement of the cannula in the operating room. Airway management in these cases can be challenging. Case Report: We report a case of a 51-year-old man with a persistent tracheostomy bleeding. The patient had been admitted to the Intensive Care Unit 10 days previously following a haemorrhagic stroke, which required a tracheostomy due to his altered mental status and subsequent need of airway protection. For the tracheostomy surgical revision the surgeons needed to extract the cannula, so it was crucial to secure the airway with an endotracheal tube (ETT). The patient was admitted to the operating room, sedated and connected to a ventilator through the tracheostomy cannula. The anaesthetic team decided to intubate via fibreoptic bronchoscopy, which revealed a massive clot in a subglottic position (above the tracheostomy cannula), occupying the entire tracheal lumen, making it impossible to pass the ETT. The team immediately reported the finding and placed a Frova introducer connected to an oxygen source through the cannula to ensure not to lose access to the airway. The surgical team externalized the cannula to access the clot and remove it through the tracheostoma. As the clot was being removed the ETT was advanced. Only after confirming the correct placement of the ETT, the Frova was removed.

Discussion: In this case, the anaesthetic team decided to use fibreoptic bronchoscopy for intubation, considering the risk of losing access to the airway. This proved to be a wise approach, as intubation using either direct or videolaryngoscopy would likely result in dislodgment of the clot into the lower airways, posing a risk of obstruction and potentially catastrophic consequences. It was also decided to use a Frova as a backup, providing a secondary route to the airway. This not only serves as a guide for a potential new cannula but also allows for oxygenation during the procedure.

Reference:

Hyzy, R.C. (2023) Tracheostomy: Postoperative care, maintenance, and complications in adults, UpToDate.

Learning points: This case highlights the importance of considering the intubation technique for tracheostomy revision. It is of paramount importance to consider fibreoptic bronchoscopy for intubation in patients with persistent tracheostomy bleeding.

42AP07-2

Does growth hormone cause obstructive sleep apnea and expected difficult airway without facial feature changes in patients with growth hormone secretory pituitary adenoma?

M. Wfa1, M. Riyadh2, W. El-Araby3, K. Soliman3 ¹Tanta University, Anesthesia and ICU, Tanta, Egypt, ²Ibn Sina Hospital, anesthesia and ICU, Kuwaitk, Kuwait, 3lbn Sina Hospital, anesthesia and ICU, Kuwait, Kuwait

Background: Obstructive sleep apnea (OSA) secondary to upper airway obstruction can affect up to 70% of acromegalic patients who are manifested by enlarged hands, feet and hypertrophy of the facial bones, especially the mandible. (1) Soft tissues of the nose, mouth, tongue, lips, laryngeal and pharyngeal soft tissues leading to a reduction in the size of the glottic opening, hypertrophy of the peri epiglottic folds, and calcinosis of the larvnx can all contribute to airway obstruction and respiratory disease.

Case Report: male patient aged 43 y old, BMI 40, achieved 4 criteria of STOP_BANG score . Medical history of hypothyroidism and gynecomastia. Surgical history of diagnostic upper GIT endoscope due to gastritis.

Vital data: normal, Air way: Mallampati II. Investigation: Euthyroid, prolactin level (high), IGF-1 400 ng/ml (high level). ECG: normal sinus rhythm.

Intraoperative: patients f monitored by 5 ASA monitoring, invasive arterial blood pressure monitoring and CVP . Preoxygenation for 3 minutes, anesthesia given we used c-mac for intubation, and we found that hypertrophy kissing tonsils and peri epiglottic folds, Cormack-Lehane Grade III, c-mac changed to D-mac and one trial taken, using armored tube size 7.5 cuffed, we used fiberoptic but there difficulty because the oozing which occurred from these hypertrophied fragile tonsillar tissue ,fiberoptic trial failed so we prepared set of percutaneous tracheostomy ready to protect the airway, we made a last attempt using D-mac and intubation done. we used fiberoptic to confirm the tube site and patency.

Armored metallic tube to regular one and shifted intubated after discussion with surgeons and family, stable hemodynamics to ICU.

Discussion: According to our study and the previous studies made, GH may affect only the airway without other features which appear in patients with acromegaly

References:

Pazarlı AC, Köseoğlu Hİ, Kutlutürk F, Gökçe E. Association of Acromegaly and Central Sleep Apnea Syndrome, Turkish Thoracic Journal, 2017 Nov 29:20(2):157-159.

Learning points: ENT consultation must be routine before surgeries in cases with high growth hormone level even without presence of acromegaly.

42AP07-4

Postoperative controlled ventilation in a patient with Montgomery's T-Tube in situ following laryngotracheal reconstruction

M. Rajasekaran¹, N. Senathi¹, G. Ganesan¹ ¹MGM healthcare, Anaesthesiology and surgical ICU, Chennai, India

Background: The Montgomery T-tube(MTT) poses many anaesthetic challenges, particularly with respect to the delivery of volatile agents and controlled ventilation. The Montgomery tube has the disadvantage of not having a suitable adaptor for standard catheter connector. There may be difficulty in maintaining controlled ventilation as the upper end of the intratracheal position of tube has to be occluded to prevent loss of inspired gas.

Case Report: A 75year old female with morbid obesity was admitted for laryngotracheal reconstruction, patient had a size 6 tracheostomy tube in situ. She required BIPAP support preoperatively. Surgeon planned to use MTT of size 14mm external diameter as tracheal stent. We established that the intratracheal lumen would allow the easy passage of a Portex tracheal tube (cuff removed) with a maximum ID of 6.5mm (ED 8.2 mm) prior to surgery. During surgery, once the MTT was placed, 6.5mm ID tracheal tube was inserted bougie aided under the guidance of video laryngoscope into the intratracheal lumen. The ET tube was fitting the MTT, the surgeon guided the ET tube and placed the tip of the tube proximal to the junction of T-tube. The extratracheal lumen was occluded and patient was mechanically ventilated for 24 h through the oral endotracheal tube. Patient was extubated after 24 hours with the surgeon holding the T-tube in place.

Discussion: Controlled ventilation through a MTT poses unique challenges due to leak from proximal end of the tube. There is insufficient literature regarding mechanical ventilation in patients with MTT in situ. Orotracheal intubation guided by videolaryngoscope with a bougie passing through the MTT proves to be practicable

Learning points: Controlled ventilation in a patient with MTT insitu can be achieved by orotracheal intubation.

Tea trolley training: a way of training your airway skills during your regular day shift

F. Torregrosa Torralba¹, E. Torres Palomares¹, <u>L. Serra</u>¹, X. Onrubia Fuertes¹, E. Martínez González¹, J.V. Llau Pitarch¹

¹Dr Peset Hospital, Anesthesiology, Valencia, Spain

Background and Goal of Study: The "Tea trolley training" is a learning method that originated at the Royal United Hospital in Bath. It arose from the interest in promoting the acquisition of knowledge during working hours while also providing a reward for the learner (1). The practice of technical skills through simulation systems enables greater integration of the knowledge acquired (2).

Materials and Methods: The method was used to train the SART-DP in airway management skills, with two instructors from GVAP, a simulation station with a model for intubation using an optical bronchoscope, and another with the ORSIM simulator. These devices were placed on a trolley, which also contained coffee and pastries at the bottom.

One of the instructors would take over the operating room, allowing the anesthesiologist to step out and participate in a learning session lasting between 10 and 15 minutes. The instructor would advise and guide the learner in solving cases. This was followed by a small reward in the form of a snack. Anonymous questionnaires were then distributed to assess the utility and satisfaction of the participants. Out of the 25 participants, 18 completed the questionnaire.

Results and Discussion: Responses were collected from 18 members of the SARTDP. 94.4% found this activity useful. They rated it 9.17 (out of 10) for whether participating in this experience could improve behaviors useful in a real-life case, and the same score for whether it helped them maintain technical skills with the devices. Satisfaction was rated 9.39, and conducting the training during working hours received a score of 8.44. The role of the instructor was rated 9.83, and the materials used were rated 9.44. Conclusion(s): Tea Trolley Training is an easy-to-implement learning method with a high degree of satisfaction among participants. It allows for widespread dissemination within the target population as it takes place during working hours, and promotes team building.

42AP07-6 An almost impossible airway in a massive goitre

A. Silva¹, <u>G. Araújo¹</u>, M. Paiva¹ ¹Unidade Local de Saúde Gaia Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: Massive goitre, with compression of adjacent airway structures, is an anaesthetic challenge.

Awake Fibreoptic Intubation (AFI) is the preferred technique for managing an anticipated difficult airway (DA).¹

Case Report: A 52-year-old male with mild heart failure, sleep apnoea, hyperthyroidism and metabolic syndrome presented for total thyroidectomy due to massive goitre. He had symptoms of dyspnoea. CT scan revealed probability of difficulty in airway approach. Nasopharyngoscopy showed total airway obstruction in resting state.

In the operating room, the patient was semi-recumbent with standard ASA and invasive blood pressure monitoring. AFI conditions were guaranteed. Initial intubation attempts by mouth and nose, with Flexible Fibreoptic Bronchoscopy (FFB), failed due to anatomical distortion.

A combined technique using videolaryngoscopy (VL) and nasal FFB was employed. The use of VL lifted the soft tissues and helped defining the correct pathway. On the second attempt, a 7.0 mm endotracheal tube was successfully positioned above the carina, and induction of anaesthesia carried out.

Three experienced pneumologists attempted multiple intubations. The entire process lasted for 90 minutes.

Surgery proceeded without major complications under balanced general anaesthesia. Postoperatively, extubation was not attempted and the patient was transferred to the ICU sedated and ventilated.

Discussion: Managing the airway in massive goitres is challenging due to anatomical distortions and in our case the impossibility of tracheostomy. This case highlights the importance of hybrid techniques, present in the ASA DA algorithm.²

Multidisciplinary collaboration, leadership and patience were crucial for the positive outcome, emphasising their importance in highly stressful situations.

References:

1. BJA Education, 2022, Volume 22, 298-305.

2. Anesthesiology 2022: 136:31-81.

Learning points:

Multidisciplinary preoperative planning, control of the situation while thinking in alternative solutions, is critical in DA management. The simultaneous use of VL and FFB can surpass some challenges and should be considered in similar scenarios.

42AP07-7

Subglotic stenosis: dilation with the new "Trachealator" device. a case report

M. Ibarguren¹, I. Agarrista Agirrezabala¹, E. Lopetegui Auzmendi¹, J. Ariño Larrañaga¹, A. Arregui Rodriguez¹, I. Hernandez Zubelzu¹ ¹Hospital Universitario Donostia, Anesthesiology, Donostia - San Sebastian, Spain

Background: Subglottic stenosis is the pathological narrowing of the airway between the vocal cords and the trachea. It can be of congenital origin (10%) or acquired (90%).

The main symptom is stridor, mainly biphasic, both during inspiration and expiration. When we talk about treatment, we will have non-surgical treatments and invasive treatments, among which is endoscopic dilation using an adapted balloon. The main drawback of this intervention is the impossibility of ventilating the patient during dilation.

With new technologies, new devices have been designed to alleviate this problem, among which we find the "Trachealator".

The "Trachealator" is a non-occlusive balloon dilatation for the airway made up of small balloons, which allow the dilation of the trachea while keeping the airway permeable at all times, allowing ventilation.

Case Report: A 64-year-old woman diagnosed with subglottic stenosis. Endoscopic treatment using the "Trachealator" device is decided upon. Anesthetic induction is performed without incident and a No. 4 ambu laryngeal mask is placed. The "Trachealator" device and a FBC are introduced through it for verification. Dilation is performed, maintaining ventilation.

Discussion: Regarding anesthetic management, some difficulties were encountered. The use of the "Trachealator" requires a specific adapter that allows simultaneous introduction of the balloon and the FBC through the laryngeal mask. During the procedure, when using the Aisys2 respirator, equipped with a concertinadriven mechanism, leaks were observed through the adapter that were not adequately compensated.

In conclusion, it would be advisable to design an adapter that minimizes leaks and allows optimal ventilation.

Learning points: Subglottic stenosis, new treatments and devices

42AP07-8

Perioperative management of a patient with Type 1 Hereditary Angioedema for urgent surgery

T. Afonso Lima¹, D. Caldas Pacheco¹, J.P. Ferreira¹, N. Andrade¹

¹Unidade Local de Saúde do Alto Minho, Serviço de Anestesiologia, Viana do Castelo, Portugal

Background: Hereditary Angioedema (HAE) is a rare, autosomal dominant disorder characterized by recurrent episodes of angioedema. The most common forms are caused by deficiency or dysfunction in C1 inhibitor. Triggers for acute attacks are common in the perioperative period namely some drugs, orotracheal intubation and others.

Case report: A 20-year-old man, ASA-PS II, with HAE type I, presented with a laceration of the 2nd and 3rd fingers of the right hand with tendinous section of the extensors. The patient was first diagnosed with HAE at the age of six, with recurring symptoms through is life and over the last year, an increased recurrence with three acute attacks that required emergency services. C1 inhibitor concentrate were administered. 1h before the procedure. After premedication with midazolam, an ultrasound and nerve-stimulator-guided axillary brachial plexus block was performed with ropivacaine 0,75%, 20ml. The procedure took less than 1h and after recovery in the Post-Anesthesia Care Unit the patient was transferred to a level 2 ICU where he remained uneventful for 24h.

Discussion: The rarity of HAE makes it challenging to Anesthesiologist and a careful perioperative planning is fundamental. Although there are no guidelines regarding perioperative management, prophylaxis with C1-INH is recommended to prevent acute attacks as is regional anesthesia. Other therapeutic options include starting or increasing doses of androgens or administration of fresh frozen plasma.

This case highlights keys aspects of HAE management for sur-

- the prophylactic use of C1 inhibitor and its availability during and after surgery;
- the avoidance or airway handling, as acute airway edema can be life-threatening, but as it can always supervene it's crucial to closely monitor and have equipment ready to secure the airway;
- the assurance of ICU monitoring for at least 24h with readily available C1 inhibitor

Additionally, education of patient on how to manage or seek care if an attack occurs after discharge is of paramount value.

Reference:

Rodrigues, C., et all (2018) Journal of the Portuguese Society of Anesthesiology, 27(1), 70-77 Conceição, L., et all (2014). Journal of the Portuguese Society of Anesthesiology, 22(1), 20-23

Learning Points: Increasing awareness of prophylaxis will allow providers to develop an perioperative plan; Preference for regional anesthesia to avoid airway handling; Careful observation after surgery to detect delayed manifestations

Transfixing haematoma after anterior cervical arthrodesis surgery

S. Gholamian Ovejero¹, J.R. Peiró Jesús¹,

H. Del Pino Soriano¹, A.C. Orozco Vinasco¹,

C. Crespo Gómez¹, R. González Velasco²

¹Hospital Universitario Severo Ochoa, Anestesiología y Reanimación, Leganés, Spain, ²Hospital Universitario Central de la Cruz Roja San José y Santa Adela, Anestesiología y Reanimación, Madrid, Spain

Background:Transfixing haematoma after anterior cervical surgery has an incidence of around 0.2-1.9%¹. Most events occur within 48 hours after surgery, reintubation is frequently required and deaths due to airway obstruction have been described.

Case report:A 76-year old man was admitted for discectomy and anterior cervical arthrodesis C3-C5. Seven hours after surgery, the patient had dyspnoea, difficulty breathing and stridor. A CT scan showed obstructive symptoms, as well as cervical haematoma with active bleeding and tracheal obstruction. Otorhinolaryngology was notified due to the possibility of requiring an emergency tracheostomy. The surgical staples were removed, 100% oxygen and 1 mg of midazolam were administered. Awake fibreoptic (FO) intubation was attempted, but without success. Therefore, a tracheostomy was performed, while the haematoma was evacuated. The patient was discharged after 24 hours in intensive care.

Discussion:ThThe possible mechanisms by which a haematoma can produce airway compromise are direct mechanical compression and airway oedema. Clinical findings are variable, from difficulty talking and breathing in the early stages, to dyspnoea, inspiratory stridor and cyanosis, with potential progression to respiratory failure. The primary objective is to establish patency of the airway by intubation (direct laryngoscopy, FO or surgical means). General guidelines include bringing the patient to the operating theatre, administering 100% oxygen and minimising the use of sedatives.

Awake FO intubation or direct laryngoscopy technique should be attempted. If the intubation fails, a haematoma evacuation is recommended, and an additional attempt at intubation is performed. Finally, if these measures fail, a surgical airway will need to be established either by cricothyroidotomy or surgical airway by a specialist.

Reference:

1.Palumbo MA et al.Airway compromise due to wound hematoma following anterior cervical spine surgery.Open Orthop J.2012;6:108-13.

Learning points: Transfixing haematoma is a potentially lethal complication associated with anterior cervical spine surgery. Early recognition and isolation of the airway is essential.

42AP07-10

The use of VivaSight Single Lumen with a enbronchial blocker in MIDCAB surgery – a feasibility study

K. Subrtova¹, M. Lips¹, J. Soltes¹, T. Brozek¹, P. Michalek¹ General University Hospital in Prague, Department do Anaesthesiology, Resuscitation and Intensive Care, Prague, Czech Republic

Background and Goal of Study: The VivaSight Single Lumen is a single-use endotracheal tube with an integrated camera for continuous airway visualization on the attached monitor. In this pilot study, we evaluated the feasibility of its use for intubation and endobronchial blocker placement in patients undergoing minimally invasive direct coronary artery bypass (MIDCAB) surgery.

Materials and Methods: Data from 32 patients scheduled for elective MIDCAB surgery between 2021 and 2024 were retrospectively analyzed. Airway management was performed using the VivaSight Single Lumen tube and an endobronchial blocker by 10 anesthesiologists of varying seniority. Outcomes included insertion success rate, quality of lung separation, surgical conditions, and respiratory complications. Ease of use and satisfaction were assessed via a questionnaire.

Results and Discussion: The VivaSight Single Lumen tube was successfully placed using direct laryngoscopy in 31 patients (96.9%). One failure (3.13%) occurred in a patient with a Cormack-Lehane score III and subglottic stenosis, who was eventually intubated with a fibrescope through an i-gel supraglottic device. The endobronchial blocker was successfully placed using the VivaSight visualization alone in 29 patients (93.5%); 2 cases (6.5%) required additional fiberoptic repositioning of the blocker due to obstructed view by sputum. Adequate lung collapse and optimal surgical conditions were achieved in all cases. No major intraoperative respiratory complications occurred, except for one patient (3.13%) temporarily requiring higher PEEP after resuming two-lung ventilation. Postoperative chest X-rays showed left-sided dystelectasis or atelectasis in 16 patients (50%), however, only 2 patients (6.3%) required CPAP or non-invasive ventilation, and 1 patient (3.13%) had a conservatively managed left-sided pneumothorax unrelated to central venous cannulation.

All 10 anaesthesiologists found the VivaSight Single Lumen tube easy or very easy to use and would prefer it over a standard endotracheal tube with a fiberscope.

Conclusion: Using the VivaSight Single Lumen tube for intubation and endobronchial blocker placement is feasible in MIDCAB surgery patients. A prospective randomized controlled study is planned to investigate this method further.

42AP07-11

Detection of predictors of difficult airway in pre-anesthetic evaluation and their correlation with difficult orotracheal intubation in oncology patients

G. Balieiro Moriggi Pimenta¹, P. Romero Domingues², G. Giroldo Badessa², C. Haddad Silveira², A. Mariane Vieira Lino Alfano², B. Gonçalves Miron² ¹Centro Universitário São Camilo, Anestesiology, São Paulo, Brazil, 2Centro Universitário São Camilo, Anestesiologia, São Paulo, Brazil

Background and Goal of Study: Difficult airway (VAD) is a clinical situation in which a trained physician has difficulty in performing endotracheal intubation, facial mask ventilation, or both. The Pre-Anesthetic Assessment (PAA) is crucial for theanesthetist to detect patients with risk factors for DA. Both the unpredictability linked to the diagnosis and the lack of careful airway assessment compromise the medical approach and contribute for DA being the leading cause of morbidity and mortality related to anesthesia. The aim of this study is to evaluate whether the predictors of difficult airway align with current practice during orotracheal intubation.

Materials and Methods: This study was conducted in an observational, cross-sectional and retrospective manner between January 2023 and December 2023, at a public healthcare hospital for oncological patients in São Paulo, Brazil. Data were collected from patients' electronic medical records: whether they had risk factors for AD identified in the pre-anesthetic evaluation and if they had been described as intubation/difficult airway in the intraoperative anesthetic record. The inclusion criteria were patients who underwent thyroidectomy and hysterectomy between January and December 2023. The exclusion criteria were patients who underwent other surgical procedures or who underwent the procedure outside the defined period. The DA predictors analyzed in the APA included age, sex, Mallampati classification, obesity, increased cervical circumference or retrognathism, and the presence of tumors or abscesses.

Results and Discussion: During the study period, 177 thyroidectomies and 217 hysterectomies were performed. Difficult intubation was described in 13 patients who underwent thyroidectomy (0.73%) and 16 who underwent hysterectomy (0.57%). Despite many patients having at least two predictors of difficulty, DA was identified in only 10 out of 29 reported cases, meaning that approximately 65.5% of DA cases went unrecognized.

Conclusion(s): Although risk factors are incorporated into evaluation scores, no score has yet demonstrated high specificity and sensitivity for diagnosis, making DA identification difficult and prone to error. Therefore, the development of new

tests or scores is essential, as they will enable the progressive integration of DA prediction into daily practice.

42AP07-12

Neonatal airway management in maternal fetal surgery case report

H.N. Günay¹, S. Arican¹, A. Ozkan Kaya², R. Yilmaz¹, A. Taylan¹

¹Necmettin Erbakan University Faculty of Medicine. Anesthesiology and Reanimation, Konya, Turkey, 2Konya City Hospital, Anesthesiology and Reanimation, Konya,

Background: Maternal-fetal surgery is a multidisciplinary surgery involving obstetrics and paediatric anaesthesia, involving both mother and fetus. In this case report, we aimed to present the surgical management of a fetus with ongoing placental circulation.

Case Report: Spinal anaesthesia was performed in a 29-week pregnant woman with no known disease. Tracheostomy was prepared for the fetus diagnosed with antenatal oronasal mass. After delivery, the placenta was not clamped and the fetus was placed on the table without separation from the placenta. Tracheostomy was decided for a fetus with a heart rate >100/min, no reflex response and the mass completely filled the oral cavity. Propofol, fentanyl, remifentanil infusion was administered to the mother to prevent maternal awareness and for anaesthesia and analgesia in the fetus. The fetus, whose tracheostomy was opened and separated from the placenta and who was not breathing spontaneously, was connected to a mechanical ventilator. The fetus was operated at the age of 4 days because of a rapidly growing oronasal mass. The mass was reported as an immature teratoma (epignatus).

Discussion: Ex-utero intrapartum (EXIT) procedures are performed close to term to ensure fetal lung maturity. Before the umbilical cord is clamped, the placental circulation continues while the surgical procedure is completed and the fetus is delivered at the end of the procedure. EXIT procedures, uteroplacental flow is maintained and surgery can be performed for 2 hours. (1) Morphine, fentanyl, remifentanil are used for maternal-fetal analgesia and sedation. Even if the fetus cannot perceive pain at the cortical level, it has the ability to receive information from nociceptive stimuli and form a response to pain and shape the development of the nervous system. (2)

This case, we report our experience in the airway management of a fetus with oral teratoma under spinal anaesthesia for maternalfetal surgery.

- 2. Brusseau R, Mizrahi-Arnaud A. Fetal anesthesia and pain management for intrauterine therapy. Clin Perinatol 2013; 40:429-42.14

Learning points: Mini surgical procedure can be performed on the fetus without separation of the placenta, in which case maternal anesthesia management

42AP08-1

Temporomandibular joint ankylosis in pediatrics: A challenge in airway management

A. Postiga¹, C. Pereira¹, R. Silva¹, F. Portugal¹ ¹Unidade Local Saude de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Intubation in a patient with temporomandibular joint (TMJ) ankylosis is a challenge for the anesthesiologist (1).

Case Report: A 12-year-old male patient proposed for temporomandibular arthroplasty due to TMJ ankylosis associated with mandibular microsomia (Image 1).

Image 1 - Facial dysmorphia with retrognathia

The case was discussed by a multidisciplinary team and the initial plan for approaching the airway was nasotracheal intubation guided by fibroscopy in an awake patient.

A surgical approach to the airway was established as a rescue plan - the cricothyroid membrane was identified.

An additional anesthesiologist was asked to help with the sedation, so that the anesthesiologist who was experienced in performing fiberscopy could concentrate solely on it. The importance of clear, concise and "closed-circuit" communication during the procedure was reinforced.

Sedation was made by one of the anesthesiologists, with ketamine and propofol in small boluses, titrated for loss of consciousness but maintenance of spontaneous ventilation. Fibroscopy was performed by the second anesthesiologist.

During the procedure, there was always effective communication between the whole team, with the main anesthesiologist communicating with the anesthesiologist who was performing the fiberscopy, informing him that spontaneous ventilation was being maintained and that peripheral oxygen saturation was adequate. The rest of the anesthetic-surgical procedure was uneventful.

Discussion: The presence of different anesthesiologists for sedation and for the fiberscopy technique was essential for the fluidity of the procedure. Communication between the two anesthesiologists allowed the second anesthesiologist to perform the technique smoothly and without altering his focus.

References:

1. Anesth Essays Res. 2018 Jan-Mar;12(1):282-284.

Learning points: This case demonstrates the importance of preparation and planning, making the most of the non-technical skills of the whole team when approaching a foreseeable VAD.

42AP08-2

Universal videolaryngoscopy for tracheal intubation in the operating room. The multicentre prospective before after videolar-surgery study protocol

S. Alonso Gómez¹, M. Taboada¹, M.d.I.Á. Orallo², N. Molins³, M. Bermúdez⁴, E. Mosquera⁵ ¹University Clinical Hospital of Santiago, Spain., Department of Anaesthesiology, University Clinical Hospital of Santiago, Spain., Santiago de Compostela, Spain, ²Hospital of Vigo, Department of Anaesthesiology. University Clinical Hospital of Vigo, Spain., Vigo, Spain, ³University Clinical Hospital of A Coruña, Spain., Department of Anaesthesiology, University Clinical Hospital of A Coruña, Spain., A Coruña, Spain, 4University Clinical Hospital Lucus Augusti, Lugo, Spain., Department of Anaesthesiology, University Clinical Hospital Lucus Augusti, Lugo, Spain., Lugo, Spain, 5University Clinical Hospital, Ferrol, Spain., Department of Anaesthesiology, University Clinical Hospital, Ferrol, Spain., Ferrol, Spain

Background and Goal of Study: Although evidence from various trials has demonstrated the advantages of videolaryngoscopy over direct laryngoscopy for intubation in the operating room, its effectiveness as a universal approach for tracheal intubation in real-world operating room settings remains uncertain.

Materials and Methods: We conducted a prospective, multicenter, quasi-experimental study to evaluate the effectiveness of universal videolaryngoscopy versus direct laryngoscopy for tracheal intubation in real operating room settings. During the non-interventional phase (June-December 2023), 35 anesthesiologists from 8 hospitals performed tracheal intubations for elective or urgent surgeries using the Macintosh direct laryngoscope as the first intubation option. During the interventional phase (March-September 2024), the same anesthesiologists performed tracheal intubations using a videolaryngoscope, which was provided to each of them, as the first intubation option. The primary outcome was the incidence of "easy intubation," defined as successful intubation on the first attempt, easy laryngoscopy (modified Cormack-Lehane grades I-IIa), and no need for adjuvant airway devices during intubation.

Results and Discussion: Among 5132 patients included, easy intubation was achieved in 2216 of 2567 patients (86.3%) during the interventional phase, compared to 1903 of 2568 patients (74.1%) in the non-interventional phase (absolute risk difference: 12.2 percentage points; 95% CI, 10-14; P < 0.001). Successful intubation on the first attempt was higher in the interventional phase (2351/2567; 91.6%) compared to the non-interventional phase (2203/2568; 85.8%; P < 0.001). Difficult laryngoscopy during tracheal intubation occurred in fewer patients during the interventional phase (186/2567; 7.2%) than in the non-interventional phase (441/2568; 17.2%; P < 0.001).

Conclusion(s): Among adult patients undergoing tracheal intubation in a real operating room setting, the use of universal videolaryngoscopy resulted in a higher incidence of patients with easy intubation, higher incidence of successful intubation on the first attempt and lower incidence of difficult laryngoscopy.

42AP08-3

Overcoming airway challenges - Managing a massive cervical lipoma with mediastinal extension via awake fibreoptic intubation

N. Leiria¹, M. Mariano Pereira¹, J. Crisóstomo¹, R. Pires¹ ¹Unidade Local de Saúde de São José, Anaesthesiology, Lisbon, Portugal

Background: Managing airways in patients with large compressive masses, particularly those extending into the mediastinum, is challenging due to anatomical and physiological changes. This case describes the anaesthetic approach for a large cervical lipoma with superior mediastinal extension causing substantial airway compression.

Case Report: An 80-year-old male patient, ASA III, presented with a voluminous cervical lipoma extending into the superior mediastinum, which caused rhinolalia but no dyspnoea, orthopnoea, or stridor. Preoperative evaluation highlighted severe pharyngeal airway narrowing and anterior displacement of adjacent structures. Elective excision was planned via cervicotomy with anterior mediastinotomy under general anaesthesia. Intraoperative advanced airway was achieved through awake fibreoptic intubation. The patient was sedated with midazolam (1mg) and dexmedetomidine (1ug/kg/min for 5 minutes, followed by 0,5ug/kg/min). Periglottic lidocaine 1% was administered for topical anaesthesia. A nasotracheal tube (6.5mm, reinforced) was successfully placed on the first attempt. Post-intubation, airway patency and ventilation were ensured throughout. Anaesthesia was maintained with propofol and remifentanil. The tumour was completely excised through cervicotomy, without complications. On the third postoperative day, extubation occurred uneventfully in the ICU. Residual supraglottic oedema was managed with corticosteroids. The patient was discharged one week later. Three weeks after surgery, a follow-up nasopharyngolaryngoscopy showed no abnormalities. **Discussion:** This case underscores the importance of thorough airway management, considering the anatomical and physiological signs of a difficult airway. Awake fibreoptic intubation remains the gold standard for anticipated difficult airways, especially in cases of anatomical distortion and physiological compromise¹. Besides technical expertise, appropriate sedation (to preserve ventilatory drive), and patient collaboration, thorough planning and coordinated care are vital to attaining optimal outcomes2.

Perioperative anesthetic considerations in a patient with acquired tracheoesophageal fistula undergoing laparoscopic intervention: a case report

G. Neto¹, M. Vieira Silva¹, G. Tenreiro¹, R. Rabiço¹, Ó. Camacho¹ ¹ULS Matosinhos, Anesthesiology Department, Matosinhos, Portugal

Background: Acquired tracheoesophageal fistula (TEF) is a rare pathological connection between the trachea and esophagus, often linked to esophageal malignancy.[1] The establishment of communication from the airway to the upper-gastrointestinal tract poses constant risk of gastric aspiration and implies a tailored airway management based on the fistula's size and location to mitigate complications.[1]

Case Report: This case report details the anesthetic management of a 78-year-old man, ASA IV, receiving palliative care for esophageal adenocarcinoma, two years after undergoing an Ivor-Lewis esophagectomy and chemo-radiotherapy. The patient's condition was further complicated by the development of a TEF, measuring 1.5cm in diameter, located 5cm above the carina, which exacerbated his dysphagia. Due to the failure of an esophageal prosthesis and percutaneous endoscopic jejunostomy, a laparoscopic jejunostomy was proposed. General anesthesia was induced in a semirecumbent position following preoxygenation. Induction involved the intravenous administration of 100ug of fentanyl, 50mg of lidocaine and 50mg of propofol followed immediately by 60mg of rocuronium for a rapid sequence intubation. The patient was intubated with a 7.5 endotracheal tube (ETT) guided with stylet, performed using a C-MAC®videolaryngoscope with a D-Blade. The ETT cuff was insufflated at a deeper tracheal position, with the 25cm mark at the labial commissure. Proper ETT positioning distal to the fistula was confirmed using a flexible-fiberscope, ensuring no bronchial intubation and clear visualization of the carina. Pressure controlled ventilation-volume guaranteed was selected as the ventilatory mode, using low tidal volumes with continuous monitoring of oxygenation and airway pressure. GA was maintained with 1-2% sevoflurane. The surgery lasted 2 hours and was uneventful. At the end, the patient was extubated in a semirecumbent position and admitted in the postanestheticcare-unit for further vigilance.

Discussion: Effective preoperative planning and precise ETT placement ensured a safe and uneventful surgical outcome.

Learning points: This case emphasizes the critical importance of tailored anesthetic and airway management in patients with TEF and highlights the need for a multidisciplinary approach in managing such cases to minimize complications.

Pediatric airway management in a child with achondroplasia and extensive submandibular tumor: a successful videolaryngoscopy case

V. Eckardt¹, <u>D. Mendes</u>¹, J. Pelicano Paulos²
¹Unidade Local de Saúde Lisboa Ocidental,
Anesthesiology, Lisboa, Portugal, ²Unidade Local de
Saúde São José, Anesthesiology, Lisboa, Portugal

Pediatric airway management can be challenging, especially in conditions like achondroplasia, a genetic disorder causing dwarfism in the limbs, linked to difficult airway management (1,2).

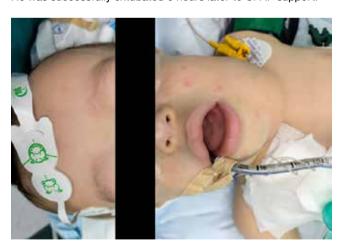

We describe a 2-year-old with fibromatosis, achondroplasia, foramen magnum stenosis and chronic respiratory insufficiency on nocturnal non-invasive ventilation, scheduled for excision of a submandibular tumor.

Preoperative planning involving a maxillofacial surgeon and an experienced anesthesiologist was essential. The patient presented with dysphagia for solids, snoring and progressive upper airway collapse.

Evaluation revealed macroglossia, good mouth opening, unrestricted neck mobility and CT scan with a mass measuring 66x50x75mm causing airway deviation but patent tracheal lumen. We decided for inhalational induction with sevoflurane, intravenous (IV) propofol and remifentanil maintenance and intubation via videolaryngoscopy.

Mask ventilation proved uncomplicated with an oropharyngeal airway. After securing IV access, propofol and remifentanil were administered, followed by rocuronium. Through C-MAC® videolaryngoscope with a pediatric D- blade, a glottic deviation by the mass was visualized, but vocal cords were clear (POGO 100%). A size 4 armored endotracheal tube was successfully placed on the first attempt.

The surgery was uneventful. Transfer to the pediatric intensive care unit was needed due to edema and risk of airway collapse. He was successfully extubated 6 hours later to CPAP support.

This case underscores the importance of thorough preoperative planning, teamwork and communication in managing pediatric airways, particularly in complex cases. Videolaryngoscopy proved effective in securing a challenging airway safely.

Perioperative and multidevice approach to the anticipated difficult airway

D. Paixão¹, S. Freitas², H. Salgado²
¹Instituto Português de Oncologia de Lisboa Francisco
Gentil, Anesthesiology, Lisbon, Portugal, ²Unidade Local
de Saúde de Braga, Anesthesiology, Braga, Portugal

Background: anticipated difficult airway is one of the most challenging areas in Anesthesiology. While awake intubation is crucial (1), the management of airway challenges during emergence and extubation remains underemphasized.

Case Report: an 82-year-old male with a history of obesity and valvular heart failure was scheduled for hemithyroidectomy due to a giant right goiter. Preoperative assessment revealed several risk factors for difficult airway, including Mallampati score of 4, upper lip bite test class III, and a short and enlarged neck with a cervical mass deforming airway anatomy and compressive symptoms. Significant left tracheal deviation was noticed in Chest CT. Nasofibrolaryngoscopy was not able to visualize any glottic structure due to compression of the hypopharynx.

The patient was preoxygenated with high flow nasal cannula (HFNC) and the location of the cricothyroid membrane was identified with ultrasound (2). Awake flexible bronchoscopic intubation was then performed and the airway was secured without complications. After the surgery, a staged extubation set was utilized and the patient was successfully extubated to HFNC. He was then transferred to an High Depedency Unit, the extubation set was removed after 24 hours and he was discharged from the hospital one week later.

Discussion: this case report emphasizes the complexity of managing an anticipated difficult airway. While the focus is frequently on awake bronchoscopic intubation, there are several other procedures and devices of uttermost importance to maintain adequate oxygenation, ventilation and airway patency. Respectively,

HFNC is fundamental to maximize safe apnea time; ultrasound identification of the cricothyroid membrane eases progression to rescue airway: and finally, the staged extubation set allows one to secure the airway should any complication arise and reintubation is needed.

References:

1. PMID: 31729018; (2) PMID: 27432055; (3) PMID: 37420175 Learning points: a comprehensive approach that spans the entire perioperative period and implicates mastery of different devices and techniques should be utilized in the management of the anticipated difficult airway.

42AP08-7 Universal use of videolaryngoscopy for double-lumen tubes: Subanalysis of the VIDEOLAR-SURGERY study

R. Iraburu¹, P. Mirón¹, C. Francisco¹, J.J. Amate², C. Díaz², J. Fernández¹

¹University Clinical Hospital of Santiago, Spain., Department of Anaesthesiology, University Clinical Hospital of Santiago, Spain., Santiago, Spain, 2Hospital of Vigo, Department of Anaesthesiology, University Clinical Hospital of Vigo, Spain., Vigo, Spain

Background and Goal of Study: Tracheal intubation with double-lumen tubes (DLTs) is considered challenging compared to standard endotracheal tubes due to the technical demands and anatomical considerations involved.

Materials and Methods: This is a subanalysis of a large prospective, multicenter, quasi-experimental study performed on 8 spanish hospitals to analyze the effectiveness of universal videolaryngoscopy against direct laryngoscopy for tracheal intubation in a real operating room setting (VIDEOLAR-SURGERY study).

Our primary aim was to compare whether using a videolaryngoscope as the initial device for intubation with a double-lumen tube (DLT) improves the rate of "easy intubation" compared to the Macintosh laryngoscope. Easy intubation was defined as successful intubation on the first attempt, easy laryngoscopy (modified Cormack-Lehane grades I-IIa), and no need for additional airway devices during the procedure.

In the non-interventional phase (June-December 2023), anesthesiologists performed tracheal intubations with DLT for elective or urgent surgical procedures using the standard Macintosh direct laryngoscope as the first intubation option. In the interventional phase (March-September 2024), the same anesthesiologists performed tracheal intubations with DLT using a videolaryngoscope as the first intubation option.

Results and Discussion: Among the 189 patients included, easy intubation was achieved in 73 of 95 patients (76.8%) during the non-interventional phase (phase 1), compared to 86 of 94 patients (91.5%) in the interventional phase (phase 2) (p = 0.005). Additionally, subjective difficulty decreased in the interventional phase, with 8 moderate difficult intubations (8.4%) in phase 1, compared to only 2 (2.1%) in phase 2 (p = 0.048).

Conclusion(s): The McGrath videolaryngoscope, used as the first-choice device for DLT intubation, significantly increased easy intubation rates and reduced moderate complexity perception among anesthesiologists. These findings support its systematic implementation in clinical practice to improve safety and efficiency during tracheal intubation with a DLT.

42AP08-8

Emergent airway management of patients with tracheobronchial stents. A Case Report

J.A. Cortés Vásquez¹, J.J. Morales Behaine², L.J. Pinzón Lozano¹, J.R. Beltrán Melgarejo¹ ¹National University of Colombia, Anesthesiology and Resuscitation, Bogotá, Colombia, 2Mayo Clinic, Anesthesiology, Rochester, United States

Background: The use of tracheal stents for treating central airway diseases has increased. However, these patients are at high risk for airway obstruction, especially after the procedure. The stents can complicate emergency airway interventions. To ensure patient safety, the medical team must create and communicate a clear plan for managing unexpected airway emergencies (1)

Case Report: An 86-year-old patient with a history of a cervical mass extending into the anterior mediastinum and infiltrating the anterior tracheal wall, underwent rigid bronchoscopy and tracheal stent placement for airway management. The procedure was uneventful. However, in the ICU, the patient developed respiratory distress, oxygen desaturation, and ventilatory failure requiring emergent intubation. During intubation, the tracheal stent was inadvertently dislodged distally. The stent was repositioned under general anesthesia in operating room under direct vision to ensure stent and Endotracheal tube through the stent to prevent airway lesions secondary a stent mobilization and assure the relocation, and the patient was successfully intubated through the stent to maintain adequate oxygenation in the ICU. Two weeks later, as extubation was not feasible, a transbronchial tracheostomy was performed to establish a secure airway

Discussion: Managing the airway in patients with tracheal stents is complex due to anatomical changes and the risk of complications like stent dislodgement or airway collapse. During emergent intubation, strategies must prioritize preventing airway obstruction from stent displacement. Alternative ventilation methods, such as ECMO, supraglottic devices (with spontaneous breathing) and low-frequency jet ventilation. The optimal ventilation strategy should be individualized, taking into account the stent's position and the underlying reason for stenosis (2.3)

References:

- 1.SaudiJAnaesth2018Oct-Dec;12(4):626-628
- 2. ShanghaiChest2022;6:13
- 3. BJAEduc2022 Apr;22(4):160-166

Learning points: The takeaway from this case is that intubation and extubation of a patient with a high-risk airway should not be undertaken unless physicians are fully prepared to manage potential complications.

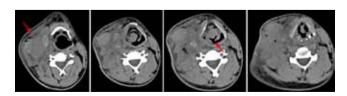

42AP08-9

Emergency front-of-neck access: the need to be prepared

A. Freire¹, M. Silva¹, J. Moralejo¹, J. Amaral¹
¹Unidade Local de Saúde do Alentejo Central,
Anesthesiology, Évora, Portugal

Background: In an anticipated difficult airway situation (ADA), guidelines suggest the performance of an awake tracheal intubation (1). Still, emergency front-of-neck access (eFONA), a rare but lifesaving procedure, might be needed and the scalpel-bougietube (SBT) is recommended as first-line technique (2). This case presents an eFONA situation in which an alternative to the SBT approach was conducted, highlighting the need for regular training in this technique.

Case Report: Male, 21 years old, ASA-PS IV, hospitalized for a diffuse large B cell lymphoma. Computed tomography of the neck showed multiple right laterocervical adenopathies causing marked deviation of the larynx and trachea towards the left without structural compression. Nasopharyngolaryngoscopy noted a neoformative lesion resting on the glottis with consequent obstruction of the airway but not yet causing respiratory difficulty. The patient was scheduled for surgical tracheostomy in five days but developed stridor and desaturation the next day. An attempt at awake videolaryngoscope-assisted orotracheal intubation was unsuccessful due to immediate active airway hemorrhage once the blade was introduced given the high friability of the glottic lesion. Due to lack of in-person otorhinolaryngology support, an emergent percutaneous cricothyroidotomy was performed with immediate resolution of the stridor and desaturation.

Discussion: In this case of ADA, the choice to maintain spontaneous ventilation was adequate (1). However, given the expected progression of airway compromise, the timing for tracheostomy can be argued on. Also, the SBT technique is the gold standard for

eFONA (2) and, in this case, a percutaneous technique was conducted due to operator's experience, underscoring the need for the anesthetist to be updated and comfortable in performing eFO-NA through regular training, considering its lifesaving nature (2). **References:** 1.

Anesthesiology. 2022; 136:31–81; 2. BJA Education. 2019; 19(8):246-253

Learning points: In an ADA, awake tracheal intubation is advised. eFONA is a rare but lifesaving procedure and the SBT technique is recommended. The anesthetist must undergo regular training in eFONA.

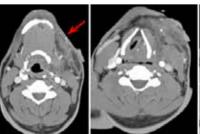

42AP08-10

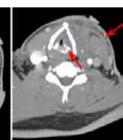

Can't intubate, can't oxygenate: eFONA as a core skill of the anesthetist

A. Freire¹, M. Silva¹, J. Moralejo¹, J. Amaral¹
¹Unidade Local de Saúde do Alentejo Central,
Anesthesiology, Évora, Portugal

Background: In "can't intubate, can't oxygenate" (CICO) situations, hypoxia is responsible for cardiac arrest and death or brain injury in survivors (1). Emergency front-of-neck access (eFONA) is the final step in rescuing the airway in such scenarios and surgical cricothyrotomy (SC) is recommended over tracheostomy (2). This case presents a CICO situation solved with a tracheostomy approach, noting SC as a core skill of the anesthetist.

Case Report: Male, 39 years old, ASA-PS VE, admitted to the Emergency Room for an anterior penetrating neck trauma after an accident with an angle grinder not affecting large vessels or causing visible active hemorrhage. Upon admission, the patient was alert with a left neck hematoma but no signs of respiratory difficulty and underwent cervical computed tomography. He then developed mild stridor with sudden loss of airway patency. Attempt at videolaryngoscopy-assisted orotracheal intubation under sedation was unsuccessful due to airway distortion. Facemask ventilation was ineffective and consequent severe and prolonged hypoxemia developed. A technically difficult percutaneous tracheostomy was performed, after which cardiorespiratory arrest on pulseless electrical activity developed, with reversal after two cycles of advanced life support. The patient underwent urgent vascular surgery and progressed favorably with preserved cognitive function.

Discussion: In this CICO case, because of operator inexperience in SC, an emergency percutaneous tracheostomy was performed. However, this technique is time-consuming, as seen in the case, and might injure major vascular structures (1), not being recommended as rescue oxygenation in CICO scenarios (2). Therefore, in the emergency setting, SC is a faster and more reli-

able approach to secure the airway (2) and the anesthetist must be ready to execute it.

References:

1. BJA Education. 2019; 19(8):246-253; 2. Trends in Anaesthesia and Critical Care. 2018: 22:45-55

Learning points: Although rare, CICO situations are associated with cardiac arrest and death. eFONA is the final step in airway management in CICO situations so surgical cricothyrotomy presents as a core skill of the anesthetist.

42AP08-11

Airway management in the context of cervical trauma in a pediatric patient

C. Fernandes¹, F.m.M.G.v. Guedes¹, M. Oliveria¹ ¹Unidade Local de Saúde de São João, Anesthesiology, Porto, Portugal

Background: Cervical trauma often anticipates difficult airway management, as invasive maneuvers may worsen injuries. Laryngotracheal injuries secondary to blunt cervical trauma occur in <1% of all trauma patients. In children, common causes include falls involving hyperextension of the neck, causing compression of the larynx and trachea against the spine.[1]

Case Report: A 35-month-old boy suffered a penetrating-blunt trauma to the anterior neck and was proposed for wound exploration and suturing. Presenting with hoarseness and stridor but no respiratory distress, ENT exam showed mild vocal cord edema and CT showed bilateral subcutaneous emphysema.

Spontaneous ventilation was maintained with boluses of ketamine and dexmedetomidine. Nasofibroscopy was performed post-induction showing no new injuries. The surgery was uneventful, and the patient discharged the following day.

Discussion: This case highlights the importance of considering airway trauma in cervical injuries. Hoarseness and stridor are nonspecific but can point to injury.[2] Subcutaneous emphysema meant possible airway trauma.

Without definitely ruling out laryngotracheal injury, sedoanalgesia allowed for spontaneous ventilation, as advancing a tube into the trachea risked aggravating existing injuries, a false lumen, or turning a partial laryngotracheal injury into a complete transection,[1] The management of airway injuries remains controversial, but endotracheal intubation using a fiberoptic scope or tracheostomy should always be considered as alternatives.[1,2]

Given that this was a minor surgical exploration with an estimated duration under 30 minutes, and considering the possibility of worsening an airway injury with a more invasive approach, this strategy provided an appropiate balance of risks and benefits.

References:

- 1. D. Chatterjee, R. Agarwal, L. Bajaj, S. N. Teng, and J. D. Prager, "Airway management in laryngotracheal injuries from blunt neck trauma in children," Paediatr Anaesth, vol. 26, no. 2, pp. 132-8, Feb 2016, doi: 10.1111/pan.12791.
- 2. M. Carratola and C. K. Hart, "Pediatric tracheal trauma," Semin Pediatr Surg, vol. 30, no. 3, p. 151057, Jun 2021, doi: 10.1016/j. sempedsurg.2021.151057.

Learning points:

Managing airway trauma remains complex, but intubation with fiberoptic scope or tracheostomy should be considered.[1,2] For the short duration of surgery and possible airway injury, this strategy allowed for patent airway and spontaneous breaathing

42AP09-1 The case of the missing airway

M. Puskac¹, E. Lai¹, K. Mitchell², W. Hofstetter², M. Antonoff², G. Mena¹

¹The University of Texas MD Anderson Cancer Center, Department of Anesthesiology and Perioperative Medicine, Houston, United States, ²The University of Texas MD Anderson Cancer Center, Department of Thoracic & Cardiovascular Surgery, Houston, United States

Background: Tracheal esophageal fistulas (TEF) pose many difficulties in anesthesia.1 Planning proper instrumentation of the airway, while preventing aspiration and insufflation of the mediastinum, are among some of these challenges.1 This TEF was challenging to manage because the entire posterior tracheal and anterior esophageal walls were missing.

Case report: A 29-year-old female with lymphoma and TEF during pregnancy presents for repair 6 weeks postpartum. She initially presented at 6 weeks gestation with a large mediastinal mass and underwent tracheal stenting. After treatment she had a 5cm TEF. Airway management included a rapid sequence induction, rigid bronchoscope insertion and jet ventilation. Stent was removed, and an exchange catheter was placed through the scope. The scope was removed over the catheter and an endotracheal tube (ETT) was placed over the catheter. The catheter was removed and fiberoptic visualization confirmed the ETT cuff distal to the TEF. After the airway was opened, ventilation was via cross-table ventilation distally. A loop was tied through the tip of the oral ETT and a clamp placed on the distal end of the loop. The oral ETT was retracted into the proximal airway during crosstable ventilation

After resection and the majority of anastomosis was completed, the oral ETT was guided into the distal airway and the cross-table

Discussion: TEFs can be life threatening due to the risk of aspiration and sepsis. TEFs of this size are rare and require meticulous management with limited information on techniques. Abnormal airway anatomy presents unique challenges in securing and protecting the airway.1,2

References:

- 1. Adate KU, et al. Airway manoeuvres during anaesthetic management of adult acquired tracheo-oesophageal fistula. Airway 2021;4:128-31.
- 2. Bibas BJ, et al. Surgery for intrathoracic tracheoesophageal and bronchoesophageal fistula. Ann Transl Med 2018;6(11):210.

Learning points: Understanding advanced airway strategies in these cases is vital to prevent further morbidity and mortality.^{1,2} There is limited information on large acquired TEF management, therefore it is crucial to share successful techniques.

42AP09-3

Prehospital definitive airway management during the first year of the swords of iron war

T. Talmy^{1,2,3}, R. Nadler¹, I. Radomislensky⁴, I. Sinai², Israel Trauma Group

¹Israel Defense Forces, Medical Corps, Ramat Gan, Israel, ²Tel-Aviv Sourasky Medical Center, Division of Anesthesia, Intensive Care & Pain Management, Tel Aviv, Israel, ³The Hebrew University of Jerusalem, Department of Military Medicine, Faculty of Medicine, Jerusalem, Israel, 4The Gertner Institute for Epidemiology and Health Policy Research, Israel National Center for Trauma & Emergency Medicine Research, Ramat Gan, Israel

Background and Goal of Study: Prehospital trauma protocols have increasingly prioritized hemorrhagic shock management over advanced airway interventions except in cases of life-threatening airway compromise or severely inadequate oxygenation. While endotracheal intubation (ETI) is the gold standard for advanced airway management, cricothyroidotomy (CRIC) is a common alternative with high reported success rates. This study evaluates the characteristics of military personnel requiring prehospital definitive airway management during the Swords of Iron War. Materials and Methods: Data were collected from the Israel Defense Forces Trauma Registry (October 2023 - October 2024) for patients undergoing either ETI or CRIC. Variables included injury mechanisms, vital signs, interventions, and provider-reported attempts and success rates. Profound shock was defined as systolic blood pressure (SBP) ≤ 90 mmHg or, if SBP was unrecorded or unmeasurable, mental status change or absence of a peripheral pulse. Hospital admission data were sourced from the Israeli National Trauma Registry.

Results and Discussion: A total of 137 patients were identified, with 96 (70%) undergoing ETI and 41 (30%) undergoing CRIC. The median age was 23 years (interguartile range 21-30), and 97% were male. Blast injuries (61%) and gunshot wounds (28%) were the most common mechanisms. Most patients (91%) were unresponsive upon initial assessment. Face and neck injuries were significantly more common among CRIC patients, and 37% of those undergoing CRIC had at least one failed ETI attempt. Self-reported cumulative success rates were 82% for ETI and 85% for CRIC. Profound shock was present in 81% of patients, with whole blood and freeze-dried plasma administered to 45% and 30%, respectively. Overall, 57 patients (42%) died before hospital arrival. Median transport time was 62 minutes, with no significant difference between the groups. Of 65 patients with inhospital data, 43 (66%) had an Injury Severity Score ≥ 25, and in-hospital mortality was 28%.

Conclusions: Military trauma patients requiring prehospital definitive airway management frequently present in profound hemorrhagic shock and exhibit high mortality rates. CRIC is often performed in the context of facial or neck injuries and following failed ETI attempts. Despite high reported success rates (>80%), the poor overall outcomes suggest these procedures are frequently employed as salvage interventions in critically decompensated patients.

42AP09-5

The association between video vs. direct laryngoscopy and the development of peri-intubation desaturations: a retrospective cohort study

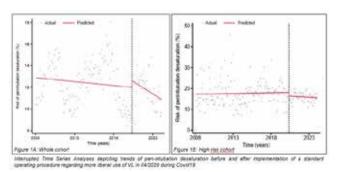

L.-M. Wichelhaus^{1,2}, B.-S. Paschold^{1,2}, L. Kaiser^{1,2}, T. Tenge^{1,3,2}, M.S. Schaefer^{1,3,2}, S.K. Ramachandran^{1,2} ¹Beth Israel Deaconess Medical Center, Department of Anesthesia, Critical Care and Pain Medicine, Boston, United States, 2Center for Anesthesia Research Excellence (CARE), Department of Anesthesia, Critical Care and Pain Medicine, Boston, United States, 3University Clinic Heinrich Heine University Düsseldorf, Department for Anesthesiology, Düsseldorf, Germany

Background: Video laryngoscopy (VL) can improve intubation success rates, reduce intubation attempts and time compared to direct laryngoscopy (DL) [1,2]. As a consequence, the use of VL has become increasingly frequent. However, it remains unclear whether this translates into improved rates of peri-induction hypoxemia at an institutional level. We hypothesized that a substantial shift to VL in our hospital during Covid19 reduced peri-intubation desaturations.

Methods: In this retrospective cohort study, we analyzed 190,758 patients from 2008 until 2024 who underwent surgery under general anesthesia with endotracheal intubation at BIDMC in Boston, USA. The primary exposure was the implementation of a standard operating procedure that triggered a strong increase in the frequency of VL use in 04/2020. The primary outcome was peri-intubation desaturation defined as hypoxemia <90% for >1 minute. Interrupted Time Series Analyses adjusted for a priori defined confounder models were applied.

Results: Between 2008 and 2024, 12.3% of patients had periintubation desaturations. Overall, 40.729 (20.0%) patients were intubated with VL. which rose from 4.2% in 2008 to 76.4% in 2024. In adjusted analyses, there was a steady decrease in peri-intubation desaturations throughout the whole study period which was significantly accelerated with a more liberal use of VL (Pre-intervention slope: coeff. -0.0004, p=0.024; post-intervention slope: coeff. -0.002, p<0.001; change in slope: coeff. -0.001, p<0.001) (Figure 1A).

In a pre-defined high-risk cohort no significant post-intervention effect could be seen (Pre-intervention slope: coeff. 0.0001, p=0.71; post-intervention slope: coeff. -0.001, p=0.21; change in slope: coeff. -0.001, p=0.23; intercept: coeff. -0.029, p=0.29) (Figure 1B).

Figures.

Conclusion: A more liberal use of VL was associated with a decrease in peri-intubation desaturations. In the high-risk cohort no post-intervention effect was noticed, which could be due to a more frequent use of VL for difficult cases. These findings should be confirmed through prospective trials.

The impact of the head position on the laryngeal mask airway leak in paediatric patients: prospective randomized control trial

H. Harazim^{1,2}, B. Kořínková¹, S. Pycz¹, J. Kalina³, J. Klučka¹, P. Štourač^{1,2}, Roman Kula, Dominik Fabián ¹University Hospital Brno, Masaryk University, Department of Paediatric Anaesthesiology an Resuscitation, Brno, Czech Republic, ²Medical Faculty, Masaryk University, Department of Simulation Medicine, Brno, Czech Republic, 3Masaryk University, Faculty of Science, Brno, Czech Republic

Background and Goal of Study: Horizontal alignment of the tragus and jugulum (sniffing position, SP) is the recommended head position for adult patient's laryngeal mask airway (LMA) insertion. Recent studies show that beyond sniffing position (BSP, 25% increase in head elevation) can lead to better larynx visualisation and easier airway management. However, here are no available data on head position for LMA placement in paediatric patients. This study aims to compare the incidence of first-try LMA insertion failure and the LMA leak between neutral (NP), sniffing and beyond sniffing head positions in paediatric patients.

Materials and Methods: The prospective randomized observational study was conducted with local Ethical Committee approval and informed consent was obtained. We included all paediatric patients (age 2-19 yrs) undergoing elective surgery with controlled ventilation during general anaesthesia with LMA and without predicted difficult airway management. The head position for the LMA insertion was randomized to NP, SP and BSP. The number of attempts to successful LM insertion was reported and after 5 minutes of artificial ventilation, the LMA leak volume and peak inspiratory pressure (PIP) needed for audible volume leak were measured in all three head positions. The LMA leak volume was defined as a mean of three consequent inspiration and expiration volume differences. Statistic analysis was performed by ANOVA test and Student t-test.

Results and Discussion: In the period of February 2022 to November 2024, we enrolled 163 patients. We did not demonstrate any significant difference in the first try LMA insertion failure incidence (3/51; 4/54; 5/58), nor did it demonstrate any significant difference in the LMA leak volume was 15, 15, 10 mL for NP, SP and BSP. PIP needed for audible volume leak median was 19, 18, and 19 cmH20 for NP, SP and BSP with no significant difference. Intracuff pressure applied in each LMA cuff was also analysed by Student t-test, showing no significant difference with intracuff pressure median of 60 cmH20 for each head position.

Conclusion(s): Different head positions in paediatric patients did not caused the difference in LMA leak volume and in first-time LMA insertion failure.

42AP09-7

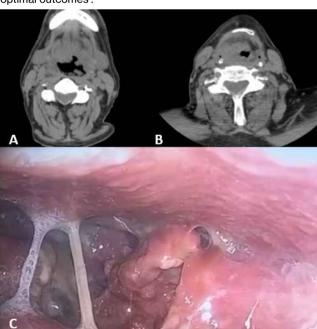

Awake intubation for tracheostomy in a patient with supraglottic carcinoma: a case report

P. Ribeiro Neto¹, C. Dantas de Oliveira¹, T.M. Cardoso¹, I. Pestana¹. C. Mexêdo¹. S. Duarte¹ ¹Unidade Local de Saúde de Santo António, Serviço de Anestesiologia, Porto, Portugal

Background: Managing difficult airways in patients with head and neck malignancies is challenging due to dysphagia, obstruction, and anatomical distortion. Preoperative strategies, including advanced oxygenation techniques and awake intubation, are crucial to prevent airway collapse and maintain oxygenation in high-risk cases.

Case report: Informed consent was obtained. A 58-year-old male with epilepsy, alcoholism, smoking, and supraglottic squamous cell carcinoma presented to the emergency department with total dysphagia. A percutaneous endoscopic gastrostomy (PEG) was proposed. After preoperative anesthesia assessment, otorhinolaryngology was consulted, indicating urgent tracheostomy due to a large supraglottic tumor involving the entire epiglottis, obstructing visualization of the vocal cords (image). Awake intubation via fibroscopy was planned. The patient was placed on highflow nasal oxygen (HFNO). Lidocaine airway topicalization was attempted but not tolerated due to dysphagia. Light sedation with remifentanil infusion was used. Nasal fiberoptic intubation with a 6.5 reinforced tube was accomplished, maintaining adequate oxygenation. The procedure enabled safe tracheostomy and gastrostomy without complications.

Discussion: This case highlights challenges in managing difficult airways in advanced head and neck malignancies. Multidisciplinary discussion and awake fiberoptic intubation are essential for securing the airway in cases of anatomical distortion and risk of collapse. HFNO aids oxygenation, reduces desaturation risks, and improves airway visualization. This case underscores the importance of advanced oxygenation methods and individualized anesthetic approaches for safe airway management, ensuring optimal outcomes1.

Reference:

1. Ahmad I, El-Boghdadly K, Bhagrath R, et al. Difficult Airway Society guidelines for awake tracheal intubation in adults. *Anaesthesia*. 2020;75(4):509–528.

Learning points:

- Detailed airway evaluation is crucial in head and neck tumors.
- HFNO aids in oxygenation and maintains airway patency.
- Awake Intubation ensures safe airway management.
- Adapted airway management improves outcomes.

42AP09-8

The improvement and availability of difficult airway equipment in the emergency department (ED) at Scunthorpe General Hospital – a quality improvement project (QIP)

<u>J. Jose</u>¹, P.K. Gunasekaran², N.H. Soe², S.A. Mangat², R.A. Manohar², T. Mahmood²

¹Northern Lincolnshire and Goole Foundation Trust -Scunthorpe General Hospital, Anaesthetics, Scunthorpe, United Kingdom, ²Northern Lincolnshire and Goole Foundation Trust, Anasthetics, Scunthorpe, United Kingdom

Background and Goal of Study: Difficult airway scenarios are commonly encountered in the emergency department. It is challenging to manage them without appropriate airway equipment. The aim of our QIP was to investigate whether the difficulty airway trolley in the emergency department is maintained according to the Difficulty Airway Society (DAS) guidelines.

Materials and Methods: Two random checks of the difficult airway trolley were conducted on the 26th of February and 25th of April 2024 as per the standards of DAS. The results were presented in the anaesthetic audit meeting. The shortfalls were identified and as a result, we liaised with the emergency department in creating a formal checklist of items which are essential to be stocked and monitored. A re-audit was carried out after 6 months. Results and Discussion: Outcome of the initial audits was that only 65% - 75% of contents were present. After implementing a formal checklist, the re-audit data showed that the compliance has improved to 96%. Difficult airway trolley was fully equipped except for the intubating LMA and Bronchoscope. The former was not available in the market and the latter could be borrowed from theatres when required. In addition, ED team agreed for regular checks of the trolley.

Conclusion(s): Our QIP showed an improvement in the compliance of Difficult airway trolley from 65-75% to 96% with implementation of a formal checklist and recording the replacement of an item/items when used.

42AP10-3

Airway management in a patient with Zenker's diverticulum and oesophageal foreign body

D. Ly Liu¹, N. De Luis-Cabezón¹, O. Romero Menchaca¹, I. Sanchez Castro², M.A. Fernandez-Vaquero³
¹Basurto University Hospital, Anaesthesiology and Intensive Care, Bilbao, Spain, ²Urduliz Hospital, Anaesthesiology and Intensive Care, Urduliz, Spain, ³Clinica Universidad de Navarra, Anaesthesiology and Intensive Care, Madrid, Spain

Background: A Zenker's diverticulum (ZD) is a posterior outpouching of the pharyngeal wall that occurs at the junction of the lower part of the throat and the upper portion of the oesophagus⁽¹⁾. Foreign body in the oesophagus can occur after accidental ingestion and its estimated annual incidence is 13 per 100,000 in adults⁽²⁾.

This combination in the emergency setting multiplies the risk and incidence of complications.

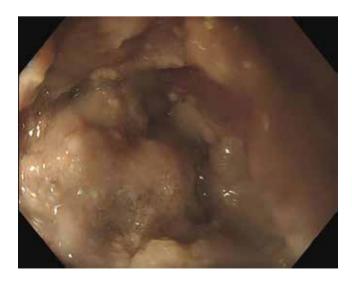

Case Report: An 81-year-old woman with ZD was admitted to the emergency department (ED) because 48 hours before, she swallowed a piece of food. She presented dysphagia, sialorrhea and regurgitation. A gastroscopy with topic anaesthesia was performed in the ED, but it was impossible to complete.

Partial exploration showed abundant liquid and solid content compatible with food impaction at 30 to 40 cm from the dental arch. Awake oral fibreoptic intubation with good tolerance in the OR was performed using nebulization of 4 ml of lidocaine 5% and SAYGO.

Once the airway was secured, general anaesthesia induction was followed. Gastroscopy could be performed, removing a piece of meat and the rest of oesophageal content. The patient was extubated and admitted to the PACU. She was successfully discharged the same day with no complications.

Discussion: Complications are potentially preventable. Deaths are highly prevalent with advanced age and are associated with neurologic, upper gastrointestinal and pulmonary conditions. It is of vital importance to minimize these risks.

As there are no specific anaesthesia protocols, anaesthesia and airway management must be individualized to improve each patient's safety.

References:

1. Dos Santos et al. Challenging Airway Management in Patients with Zenker's Diverticulum, Cureus 13(11): e19578: 2) Schaefer TJ. Trocinski D. Esophageal Foreign Body.In: StatPearls [Internet]. Treasure Island (FL): StatPearls Publishing; 2023 Jan 30.

Learning Points: The combination of Zenker's diverticulum and oesophageal foreign body in the emergency setting is challenging because of an increased risk of mortal complications. Thus, it is important to individualize anaesthesia management and ensure patient safety.

42AP10-4

Point-of-Care Ultrasound (POCUS) for complex airway management in hyoid bone and thyroid cartilage fractures

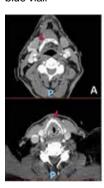

M.A. Fernández-Vaguero¹, C. Puga-Carrasco¹, M. Álvarez de Linera-Alperi², C. Zulueta-Santos² ¹Clinica Universidad de Navarra, Anesthesia and Intensive Care, Madrid, Spain, 2 Clinica Universidad de Navarra, Otorhinolanryngology, Madrid, Spain

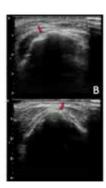

Background: Trauma to the airway may cause acutely life-threatening situation; the recognition and management of these patients can pose a challenge for the anesthesiologist.

Case Report: A 75-year-old male presented to the emergency department with speech difficulty following a strangulation assault during a robbery.

The on-call otolaryngologist ordered a cervical CT, revealing acute traumatic cervical injuries including a hyoid bone and thyroid cartilage fractures, and haematoma infiltration in the glottic plane. Fiberoptic bronchoscopy revealed: edema on the mucosa of the arytenoid cartilages and on both vocal cords, without apparent airway compromise and unaffected subglottic tracheal rings.

The patient was transferred to the Intensive Care Unit (ICU) for airway monitoring in the initial post-trauma hours, with intubation readiness in case of haematoma or edema worsening. Ultrasound was used to control the hematoma in the hvoid bone and thvroid cartilage. The trachea appeared centered with no apparent caliber reduction. Therefore, anticipating a difficult airway in this patient, early POCUS was performed by identifying cricothyroid membrane and marking, using a Tuohy needle and methylene blue vial.

Discussion: For patients with altered anatomy, especially in difficult airway scenarios, identifying the cricothyroid membrane (CTM) location is crucial. If conventional methods fail (palpation), ultrasonography can reliably identify the CTM, facilitating optimal patient positioning. In cases requiring emergency Front of Neck Access (eFONA), the pre-marked CTM location aids swift repositionina1.

- 3. Lin J et al. Diagnostics. 2023; 13. doi:10.3390/ diagnostics13091541.

Learning Points:

- 1. Ultrasonography has emerged as the fifth pillar of bedside physical examination, supplementing inspection, palpation, percussion, and auscultation2.
- 2. Point-Of-Care Ultrasound (POCUS) is now integral for targeted inquiries, focused differential diagnoses, and procedural guidance3, especially in difficult airway scenarios like trauma with altered anatomy.

42AP10-5

Retrograde scalpel Cricothyrotomy. An alternative technique of FONA (front of neck access)

T. Vrettos¹, D. Aretha¹, A. Zotou¹, S. Antoniou¹, A. Datsikas¹, G. Vogiatzis¹ ¹University of Patras Medical School, Anesthesia and ICU. Patras. Greece

Background and Goal of Study: Main drawback of applying FONA technique (front of neck access) is that is too operative for anesthetists. Goal of study is the development of an alternative tecniquue to FONA, as it is described by DAS, more familiar to anesthetists

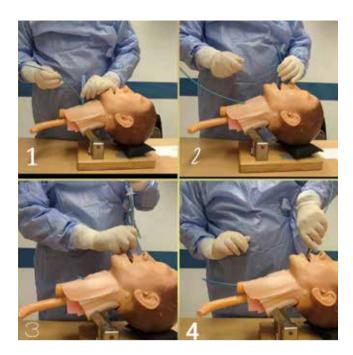

Materials and Methods: Scalpel No11. Bougie guide, endotracheal tube (ENT) No 7. Model. With scalpel No11 we make a small (2mm) direct vertical incision to the cricothyroid membrane of the model. We keep steady the blade and we insert the bougie catheter with the curved tip parallel to the blade at first and then we rotate it in cephalic (retrograde) direction. When the tip of the catheter reaches the pharvnx we hook it with our fingers and pull it out of the mouth. We intubate through the bougie. When the ENT passes the vocal cords the advancement of the endotracheal tube stops.

First we remove the bougie until the back tip reaches the skin. Second we pull the bougie again for only 1 cm max inside trachea. Third we advance the bougie to the final position. Advancement of ENT to final position follows

Results and Discussion: 20 trials were performed. All the trials were performed in model for airway management. Trial average was 45s", SD (8). All trials were successful. ENT advancement through a bougie is a process familiar and less stressful to anesthetists.

That is a major advantage of the method. So there is a high possibility for a less experienced physician to perform FONA on time if he implement a less stressful for him technique. It is also allowed to use wider ENT (more than 7.0), compared to ordinary FONA (6.0). Wider tube is critical for ventilation of patients with

Drawback of the method is that is needed quite well mouth opening and muscle relaxant because we have to hook the tip of the bougie inside the mouth with our fingers.

Conclusion(s): Retrograde scalpel Cricothyrotomy is an alternative high success rate technique to ordinary FONA, for unexpected intubation failure. It is useful for intraoperative implamentation mainly

42AP10-6 An unexpected presence of neurofibroma type 2 tumor in the airway

C. Vu¹. A. Muthukumar²

¹MD Anderson Cancer Center, Anesthesiology, Houston, United States, 2Henry Ford Hospital, Anesthesiology, Detroit, United States

Background: Neurofibromatosis (NF) is an inherited single-gene disorders, with an incidence of 1: 3,500 individuals at birth.1

A neurofibroma is a benign mass of the peripheral nerve or nerve root that consists of Schwann cells, fibroblasts, perineurial cells, and mast cells. NF type 1 presents with airway tumors, but NF type 2 rarely does.2

We present a case of NF type 2 in which the neurofibroma was unanticipated found in the hypopharyngeal during intubation.

Case Report: A 30-year-old male with history of NF type 2 and Schwannoma of orbit was scheduled for an orbitotomy with bone flap. Neither recent notes or MRI report mentioned there was a tumor in the airway. During intubation we saw a 3cm tumor in the right hypopharynx (Fig 1).

Even though the tumor hindered the airway, we were able to intubate the patient. A post operative MRI of the neck revealed the presence of a new hypopharyngeal neurofibroma consistent with our clinical finding (Fig 2).

Discussion: MRI is the gold standard in detecting newer lesions but since the clinical management remains same, often these patients are not routinely screened for new lesions.3 While mucosal neuromas are common, larger neuromas in the airway is always unanticipated when the patient does not have any symptoms like hoarseness or difficulty swallowing. In scenarios like this, following difficult airway algorithm is the main management.

Learning Points: The case underscores the importance of being prepared for unexpected airway obstruction. It also brings awareness of airway tumor incidence and patients with NF type 2.

42AP10-7 Late night case of emergent front-of-neck (eFONA) access

A. Avstreihs¹, J. Kravčuks²

¹Pauls Stradinš Clinical University Hospital, Anesthesiology and Intensive Care, Riga, Latvia, ²Pauls Stradinš Clinical University Hospital, Emergency Department, Riga, Latvia

Background: Emergent front-of-neck access (eFONA) is a rarely performed though life-saving procedure in CICO scenarios. This case represents the challenges of eFONA in clinical practice.

Case Report: A 65-year-old male transferred from the private healthcare facility to the hispital due to respiratory distress. On presentation, patient was unresponsive, GCS of 8, RR 26 x/min, breathing with accessory muscle involvement. SpO2 of 86% on 15 L/min oxygen. ABG showed severe respiratory acidosis. PMH: COPD, primary arterial hypertension and class III adiposity. The decision of tracheal intubation was made. After RSI, first intubation attempt was performed with standart geometry MAC4 blade. During direct laryngoscopy Cormack-Lehane IIIb view was noted. The attempt was unsuccessful. Patient desaturated to SpO2 of 65%. The second attempt was VL with hyperangulated blade which also failed. LM iGel #5 was successfully inserted and patient SpO2 raised to 85%. Third attempt was performed using hyperangulated blade and a bougie. During the third attempt the patient desaturated rapidly which lead to cardiac arrest. ROSC was obtained after 5 min of CPR. Ventilation continued through LM and SpO2 remained in low 80-ies. The decision to proceed to emergent front-of-neck access was made. For the first attempt cannula cricothyrotomy (QuickTrach) was utilized.

Due to the large neck circumference and adiposity, we failed to advance the cannula into the trachea. Second attempt was using scalpel-bougie-tube technique. After vertical cut, we managed to palpate the cricothyroid membrane and a 6.0 mm ETC was advanced through the bougie into the trachea.

Afterwads definitive tracheostomy was performed by ENT. The patient was transferred to ICU. He was weaned off the ventilator on day 9. On day 15 he was discharged from the hospital with no neurological deficit.

Discussion: 'Scalpel-bougie-tube' technique is recommended by DAS, whereas wide-bore catheter techniques are associated with high failure risk [1]. The case report clearly demonstrates the challenges of CICO situation.

References:

1. Price, T. M., & McCoy, E. P. (2019). Emergency front of neck access in airway management. BJA education, 19(8), 246-253. Learning Points: Scalpel cricothyroidotomy, using a 'scalpelbougie-tube' should be a first-line eFONA technique. Due to low incidence the obtaining of eFONA skills in real clinical situations is questionable, therefore extensive simulation-based training should be anticipated.

42AP10-8

Electromyographic single twitch stimulation to predict vocal cord opening after a small dose of succinvlcholine for facilitated mask ventilation

T.P. Weber¹, A.I. Georgevici¹, S.J. Werner¹, M. Klutzny¹, J. Herzog-Niescery¹ ¹Ruhr-University of Bochum, Anaesthesiology and Intensive Care, Bochum, Germany

Background and Goal of Study: Neuromuscular blocking drugs (NBDs) open the vocal cords and facilitate mask ventilation. However, NBDs also impede the return to spontaneous breathing by paralysis of the diaphragm, which is problematic in cannot ventilate cannot intubate situations. Thus, the current German S1 guideline on airway management recommends the use of short-acting NMDs such as succinylcholine in patients at risk, but neither a dose is defined, which ensures open vocal cords while diaphragmatic activity is maintained, nor a method is given that monitors the NBD effect on the vocal cords.

We evaluated if the neuromuscular block monitoring of the abductor digiti minimi muscle after electromyographic single twitch stimulation of the ulnar nerve correlates with vocal cord opening. The quantification of succinylcholine's effect on the vocal cords after 0.1 and 0.9 mg/kg IBW was the secondary endpoint.

Materials and Methods: Thirty adult patients scheduled for elective surgery were included. Patients obtained remifentanil and propofol according to institutional standards. A Narcotrend index <65 was reached to ensure an adequate depth of anesthesia. The baseline neuromuscular block was measured, and the vocal cord area was videorecorded to determine baseline conditions. Then, the patient received 0.1 mg/kg IBW of succinylcholine and an additional dose of 0.9 mg/kg IBW after two minutes. After four minutes of continuous monitoring of the single twitch amplitude and recording of the vocal cord area, the trachea was intubated. Results and Discussion: A non-linear generalized additive multilevel model and a bootstrapped linear analysis demonstrated a clear relationship between decreasing single twitch response amplitude and increasing vocal cord opening (p<0.001). Both models identified the response amplitude as a significant predictor of vocal cord opening. Moreover, 0.1 mg/kg IBW succinylcholine was sufficient for 55.0 ± 29.6% vocal cord opening and thus is equivalent to the effective dose for 50% depression of the single twitch.

Conclusion(s): The electromyographic single twitch monitoring can predict vocal cord opening, which allows to exclude closed vocal cords as a cause of insufficient mask ventilation. In addition. 0.1 mg/kg IBW succinvlcholine was often sufficient for mask ventilation and a monitoring thus helps to prevent the administration of unnecessarily high NBD doses.

42AP10-9

Elective tracheostomy: management of unpredictable difficult airway secondary to lingual tonsillar hypertrophy

M.L.S.G. Botras¹, W. Alaraby², K. Ahmed² ¹Kuwait Institute for Medical Education, Anesthesia, Kuwait City, Kuwait, 2Ibn Sina Hospital, Anesthesia, Kuwait, Kuwait

Background: Lingual tonsils are a part of Waldeyer ring consisting of lymphoid tissue located at the base of the tongue. Lingual tonsillar hypertophy secondary to inflammation or neoplastic process can go unnoticed during periopertiave period creating an unexpected difficult airway scenario.

Case Report: We present a 42 year old gentleman who was referred to our tertiary neurosurgical center for endonasal transsphenoidal pituitary ademona excision. Medical history was remarkable for Obstructive Sleep apnea and obesity. Perioperative airway examination showed large tongue. Mallampati grade 2.sternomental and thyromental distances within normal. General anesthesia induction commenced with 100 mcg fentanyl, lidocaine 90mg, and propofol 120mg, and cisatracurium 12 mg was given. First attempt with VL macintosh blade revealed Cormack Lehane grade 4 with large kissing tonsils. Second attempt using hyperangulated blade was successful despite mild oozing from the hypertrophied tonsils. After surgery, the patient was kept intubated for better assessment of the degree of airway edema in the icu. Dexamethasone was started 8 mg q6. MRI Neck revealed right tonsillar hemorrhagic mass like solid lesion size 7*4 cm involving the Palatine and lingual tonsils with evidence of abnormal signal and enhancement extending towards the base of the tongue on the right side. Further VL examination showed worsening airway edema. Desicion of trachestomy was made on day3 postoperative. After trachestomy, the patient was discharged to the ward the following day and followed up in ENT clinic.

Learning Points: Lingual tonsils in airway management especially with pituitary secreting tumors and timing of tracheostomy in airway edema management.

42AP10-10

Illuminating the difficult airway: a meta-analysis of video versus direct laryngoscopy across expertise levels

G. da Silva Goulart¹, E. Lo Bianco dos Santos¹², C. Nogueira Reis Gurgel¹, E. Atie Xavier de Brito³, V. Telles Martins¹, C.E. Lopes Ramos Xavier¹ ¹Hospital da Força Aérea do Galeão, Anesthesiology, Rio de Janeiro, Brazil, ²Hospital Central da Polícia Militar do Rio de Janeiro, Intensive Care Unit, Rio de Janeiro, Brazil, ³Instituto Dante Pazzanese de Cardiologia, Anesthesiology, São Paulo, Brazil

Background and Goal of Study: Airway management is critical in anesthesia, where achieving first-attempt intubation success minimizes complications such as hypoxemia, aspiration, and cardiac arrest. Video laryngoscopy (VL) has revolutionized airway management by offering enhanced visualization and higher success rates compared to direct laryngoscopy (DL), particularly in difficult airway scenarios. However, its efficacy across operator expertise levels remains uncertain. This meta-analysis evaluates the efficacy of VL versus DL in difficult airways, focusing on first-attempt intubation success, glottic visualization, intubation time, and complications. Subgroup analysis examines the impact of operator expertise (novice vs. expert).

Materials and Methods: Four randomized controlled trials (RCTs) comparing VL and DL in difficult airway patients were analyzed. The primary outcome was first-attempt intubation success. Secondary outcomes included glottic visualization (Cormack-Lehane Grade 1–2), intubation time, and complications such as hypox-

emia. Subgroup analysis assessed novice versus expert operators. Pooled odds ratios (OR) and mean differences (MD) were calculated using random-effects models, with heterogeneity assessed using I² statistics.

Results and Discussion:

- First-Attempt Success: VL significantly improved success rates (Pooled OR: 3.07; 95% CI: 2.63–3.58).
- Glottic Visualization: VL improved Grade 1–2 visualization (Pooled OR: 5.29: 95% CI: 1.59–17.58).
- Intubation Time: VL reduced time to intubation by 6.56 seconds (MD: -6.56; 95% Cl: -7.66 to -5.46).
- Complications: VL showed a trend toward reducing hypoxemia (Pooled OR: 0.38; 95% CI: 0.09–1.65), though not statistically significant
- · Subgroup Analysis:
- Novice Operators: VL improved first-attempt success (Pooled OR: 2.03: 95% CI: 1.64–2.51).
- Expert Operators: VL further enhanced success rates (Pooled OR: 4.86; 95% Cl: 3.89–6.08).
- Heterogeneity: High variability (I² = 91.39%) reflected differences in patient populations and devices.

Conclusion(s): Even with video laryngoscopy, novice operators still need training in orotracheal intubation. Although VL improves first-attempt success, glottic visualization, and intubation time, especially in difficult airways, hands-on experience remains essential. Incorporating VL and structured training into airway management protocols is vital. Future research should refine recommendations for its use.

42AP10-11

Tracheal tumor surgery with a Tritube[®] and flow-controlled ventilation: an anesthetic challenge

A. Hernández Moya¹, <u>J. Duart Benavent</u>¹, A. Lluch Oltra², J.F. Tirados Bueno², S. Astray Gómez³, P. Argente Navarro^{2,4}

¹Hospital Universitàri y Politècnic La Fe, Anesthesiology and Critical Care, Valencia, Spain, ²Hospital Universitàri i Politècnic La Fe, Anesthesiology and Critical Care, Valencia, Spain, ³Hospital Universitàri i Politècnic La Fe, Otorhinolaryngology, Valencia, Spain, ⁴Universitat de València, Surgery Department, Valencia, Spain

Background: Tumor resection and tracheal anastomosis is considered the definitive treatment in most of upper airway neoplasias. In these cases, small-lumen ventilation can be a appropriate airway management.

Case Report: We report the clinical case of a 70-year-old patient with a 17 mm × 16 mm × 19 mm mass arising from the posterior wall of the trachea in the computed tomography scan, which occlude the tracheal lumen by 80%. He was proposed for surgery and general anesthesia was induced. To isolate the airway, we decided to use the endotracheal tube with the Tritube® device, whose external and internal diameters are 4.4mm and 2.5mm respectively. According to the surgeons, the plan was formulated to avoid the excessive manipulation of the area to prevent bleeding due to the friability of the tumor and providing de maximal surgical access to the trachea. First, we inserted 4# Ambú® laryngeal mask (LMA) to ventilate our patient the first part of the surgery. Then the fiberoptic bronchoscopy was inserted through

the LMA and and a 0,035 inch Aerstent® guide wire was placed into the trachea distal to the tumor. We used this guide to lead the Tritube® into the trachea (and thus avoid blind manipulation in the tumor area), and its cuff placement was then confirmed by fiberoptic scope (below the lesion and above the carina). Subsequently, the tube was attached to an Evone® ventilator with optimal oxygenation and ventilation (FIO2=50%, inspiration flow 15L/ min, I:E ratio=1:1, peak pressure= 17mbar, EEP= 6mbar).

Discussion: Tracheal surgery poses significant challenges to the anaesthetist, especially when its lumen is reduced. The goal should be to achieve optimal surgical conditions while maintaining a secure airway. The Tritube is an alternative which provides both improved surgical access and adequate gas exchange.

References:

Molteni G, Dallari V, Segato E, Mattioli F. Post-Covid-19 Airway Stenosis: Tracheal Resection-Anastomosis Using The Tritube® Ventilation. Laryngoscope. 2024 Feb;134(2):897-900. doi: 10.1002/lary.30859. Epub 2023 Jul 19. PMID: 37466298. Saroa R, Gombar S, Palta S, Dalal U, Saini V. Low tracheal tumor and airway management: An anesthetic challenge. Saudi J Anaesth. 2015 Oct-Dec;9(4):480-3. doi: 10.4103/1658-354X.159483. PMID: 26543474; PMCID: PMC4610101.

Learning Points:

Tracheal tumors can provide a unique challenge to the anesthetist

High frequency jet ventilation can be useful in cases of reduced tracheal lumen.

42AP10-12

Comparison of ultrasound guided lung sliding sign and conventional auscultatory method to evaluate endotracheal tube depth in pediatric patients

G. Sfregola¹, G. Montenero¹, A. Ragone¹, M. Ciuffreda², C. Piangatelli2, D. Galante1

¹Hospital G. Tatarella ASL FG, Anesthesia and Intensive Care, Cerignola, Italy, 2Hospital Fabriano AST Ancona, Anesthesia and Intensive Care, Fabriano, Italy

Background and Goal of Study: Accurate placement of the endotracheal tube (ETT) is essential in pediatric patients to ensure effective ventilation and prevent complications. Traditional auscultation methods and recent ultrasound techniques, such as the lung sliding sign (LSS), are used to verify ETT depth. The lung sliding sign is an ultrasound phenomenon that helps assess lung expansion and diaphragm motion during mechanical ventilation, which may serve as a reliable method to confirm ETT position. This study compares the efficacy of ultrasound-guided LSS with conventional auscultatory methods for determining the correct depth of ETT in pediatric patients.

Materials and Methods: This study was conducted through a survey in 6 hospitals where there was experience with this evaluation method and included 70 pediatric patients (aged 4 years to 8 years) who underwent elective surgery requiring general anesthesia and endotracheal intubation. After intubation, two methods were used to verify the correct ETT depth: (1) conventional auscultatory technique, where bilateral breath sounds were assessed, and (2) ultrasound, where the lung sliding sign was visualized using a linear probe placed on the chest wall in the midclavicular line.

Both methods were performed by experienced clinicians immediately after intubation and before starting surgery. Intubation was considered correct when symmetrical and effective bipulmonary ventilation was observed. Data were analyzed to assess the diagnostic accuracy, sensitivity, specificity, and agreement between the two methods.

Results and Discussion: The ultrasound-guided LSS method showed a higher sensitivity and specificity compared to the conventional auscultatory method. The lung sliding sign correctly identified the optimal ETT depth in 95% of cases, with a sensitivity of 93% and a specificity of 97%. In contrast, the auscultatory method showed a sensitivity of 78% and a specificity of 85%. The agreement between the two methods was moderate, with a kappa coefficient of 0.72.

Conclusion(s): Ultrasound-guided lung sliding sign is a highly accurate and reliable method for determining the correct depth of the endotracheal tube in pediatric patients, outperforming the conventional auscultatory method in both sensitivity and specificity. This technique provides a non-invasive, real-time alternative that can improve the safety and accuracy of pediatric intubation.

42AP11-1

Anesthesiological management of a patient with an incidental large lingual cavernous haemangioma

A.G. Fotiadou¹, A. Ntanasis², F. Steliou³, E. Sitos⁴. S. Melissanidis⁵, D. Giannakidis⁶ ¹University Hospital of Heidelberg, General, Visceral and Transplantation Surgery, Heidelberg, Germany, 2General Hospital of Ioannina "G. Hatzikosta", Department of Anesthesiology, Ioannina, Greece, ³General Hospital of Ioannina "G. Hatzikosta", Anesthesiology, Ioannina, Greece, 4General Hospital of Ioannina "G. Hatzikosta". Anesthesiology, Ioannina, Greece, 5 Asklipios Medica Giannitsa, Radiology, Giannitsa, Greece, 6 Aristotle University of Thessaloniki, Medical School, Thessaloniki, Greece

Background: The induction of general anesthesia in patients with airway compromise is challenging, particularly when oral vascular tumours with high propensity for bleeding are present. Hemangiomas are benign vascular tumors characterized by rapid endothelial cell growth, with 50%-60% occurring in the head and neck region. Common intraoral locations include the lips, buccal mucosa, and tongue. We present a case of an 82-year-old woman with an incidental asymptomatic cavernous lingual hemangioma and discuss its anesthesiological management for intubation during general anesthesia prior to elective resection.

Case Report: An 82-year-old woman with an endometrial carcinoma underwent thorough clinical and laboratory evaluation prior to an elective total hysterectomy with bilateral salpingo-oophorectomy (THBSO). A large lingual lesion was discovered during examination, which subsequent imaging identified as a cavernous hemangioma. Anesthetic considerations included challenges with mask ventilation and intubation, bleeding risk from the hemangioma, and potential blood aspiration. Anesthesia induction, mask ventilation, and intubation using a flexible KARL STORZ C-MAC® video laryngoscope proceeded smoothly, as did extubation. The patient was discharged on the fourth postoperative day following an uncomplicated recovery.

Discussion: Comprehensive assessment of managing airways in oral cavity hemangioma cases allows for intubation and general anesthesia without advanced airway tools. Strategic difficult airway management is crucial for optimising outcomes in such cases.

References:

- Mankhair S, Jadhav J A, Chakole V, et al. (June 04, 2023) Anesthetic and Airway Management in a Case of Surgical Excision of Recurrent Buccal Hemangioma. Cureus 15(6): e39951.
- 2. Marciniak D, Kraenzler E: Airway Management and Lung Isolation in a Patient With a Massive Cavernous Hemangioma of the Tongue, Journal of Cardiothoracic and Vascular Anesthesia, Vol 27, No 6 (December), 2013: pp 1337-1338

Learning Points: Airway management in patients with intraoral hemangiomas poses significant challenges that include difficult ventilation and intubation, and an increased risk of bleeding and aspiration. Patients with large lingual cavernous hemangiomas often exhibit significant anatomical distortion that complicates airway management.

42AP11-3

A randomized crossover comparison of the Vie Scope and the STORZ CMAC Miller Video laryngoscope in a Pierre Robin Manikin

A. Vlatten¹, V. Cole¹, D. Vlatten², S. Bird³
¹Dalhousie University, Department of Anesthesia, Pain Management and Perioperative Medicine, Halifax, Canada, ²Ludwig-Maximilians-Universität München, Faculty of Medicine, Munich, Germany, ³Dalhousie University, Department of Pediatric Anesthesia, Halifax, Canada

Background: The Bébé Vie Scope is a new pediatric single use airway devise following the principle of an anterior commissure scope used for laryngoscopy in ENT. In adult studies, the Vie Scope showed non-inferiority compared to video laryngoscopy. In a study using a pediatric manikin representing a 6 year old, it showed comparable success rate and time to intubation to video laryngoscopy. No study is published on the use of the Vie Scope in the infant airway. A Pierre Robin Manikin was used to simulate a pediatric difficult airway as previously published.

Methods: 50 anesthesiologists intubated a Pierre Robin Manikin representing an anatomical correct one year old. Following a full IRB approved consent, participants received a standardized description and time to train the Bébé Vie Scope (BVS) as well as the STORZ CMAC Miller 1 video laryngoscope (VL) using a normal airway pediatric manikin. For the study, participants intubated the Pierre Robin manikin in a random order using BVS and VL. Success Rate, Time To Best View (TTBV) and Time To Intubate (TTI) in seconds, Percentage Of Glottic Opening view (POGO) in % and Ease of Use (VAS) using a likert scale with 10 being the easiest, was measured. Unsuccessful intubation was esophageal intubation or TTI > 60 sec. Null hypothesis was TTI being similar for both devices. Data were analyzed using a paired t-test and presented as Median, interquartile range (IQR), Min Max. Statistical significance was P<0.05 (#).

Results: Success rate was 48/50 (96%) for BVS and 49/50 (98%) for VL. TTBV was significantly longer and POGO significantly worse in BVS versus VL. There was no significant difference between BVS and VL for TTI and VAS.

	BVS	VL	
TTBV (sec)	8 (6, 12) [3, 34]	6 (5, 8) [4, 31] #	P < 0.001
TTI (sec)	20 (16, 25) [11, 41]	22 (18, 30) [11, 54]	P = 0.191
POGO (%)	80 (50, 92) [10, 100]	90 (80, 100) [25, 100] #	P = 0.002
VAS	8 (7, 10) [1, 10]	9 (8, 10) [2, 10]	P = 0.066

Table: TTBV, TTI, POGO, VAS for BSV and VL. Median (IQR) [Min Max]. # P<0.05.

Discussion and Conclusion: The clinically important success rate and TTI using the BSV was comparable to VL, despite a significant prolonged TTBV and reduced POGO, similar to other studies. Both BVS and VL were easy to use. The Vie Scope plays a role in the difficult pediatric airway, especially when video laryngoscopy is not feasible due to weight (resuscitation bags), rare occasion (off-site MRI) or cost. Case reports and studies in children are needed.

42AP11-4

Evaluating the impact of videolaryngoscope adoption on the characteristics of difficult airway consultations in a tertiary care setting: a retrospective cohort study

W.-L. Wang¹, A.-Y. Chao¹
¹National Taiwan University Hospital, Anesthesiology, Taipei City, Taiwan

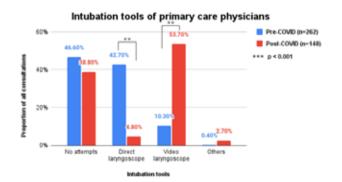

Background and Goal of Study: Emergent tracheal intubation is challenging, associated with significant morbidity. While all hospital physicians receive airway management training, anesthesiologists provide backup consultations for failed intubations. Increased videolaryngoscope use during the COVID-19 pandemic prompted this study to investigate changes in consultation patterns for difficult airways.

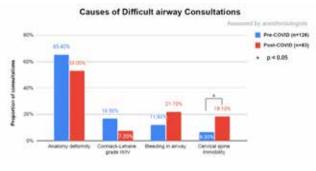

Materials and Methods: We retrospectively analyzed data from our department's emergent intubation registry (August 2017-September 2019, pre-COVID; October 2022-December 2023, post-COVID), including patients aged ≥20 years. We compared intubation indications, tools, and medications used by primary care physicians and anesthesiologists, and the anesthesiologist's assessment of airway difficulty.

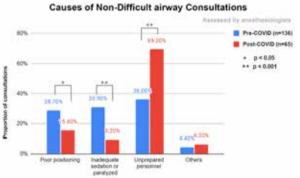

Results and Discussion: 262 and 148 patients were included in each period respectively. There were no statistical differences in age, gender or places where emergent tracheal intubation were performed in both groups. Videolaryngoscope was significantly more applied by the primary care physicians in the post COVID-consultations (10.3% vs. 53.7%).

While overall difficult airway rates in consultations did not significantly differ (48.1% vs. 56.1%), post-COVID consultations found significantly more cervical spine immobility (6.3% vs. 18.1%). Conversely, unprepared personnel (including poor skills, lack of confidence or inadequate equipment use) were significantly more frequent in non-difficult airway consultations post-COVID (36.0% vs. 69.2%).

Conclusion(s): Increased videolaryngoscope use likely contributed to the proportional change in difficult airway types. Emergent anesthesiologist consultations persisted due to inadequate provider skill or confidence, highlighting the need for enhanced videolaryngoscopy training in future airway management workshops.

42AP11-5

Videolaryngoscopy vs. direct laryngoscopy in paediatric tracheal intubation: systematic review & meta-analysis

G. Köpp-Medina¹, A.C. Lusardi², T. Riva¹, A. Afshari³, M. Huber¹, A. Fuchs¹

¹University Hospital of Bern, Inselspital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, 2IRCCS Istituto Giannina Gaslini. Unit for Research in Anaesthesia, Genoa, Italy, ³Juliane Marie Centre, Rigshospitalet, University of Copenhagen, Department of Paediatric and Obstetric Anesthesia, Copenhagen, Denmark

Background and Goal of Study: Paediatric tracheal intubation presents unique challenges due to anatomical and physiological differences in children compared to adults. These include a rostral larynx, a narrow, floppy, u-shaped epiglottis and reduced oxygen reserves. Limiting the number of attempts is critical to minimize complications such as hypoxia, airway trauma, and cardiovascular instability. Videolaryngoscopy (VL) has emerged as a potential alternative to direct laryngoscopy (DL). Despite growing evidence supporting its use, the comparative efficacy, safety, and clinical outcomes of VL versus DL in paediatric tracheal intubation remain under investigation. This systematic review and metaanalysis aim to provide a

comprehensive evaluation of VL versus DL.

Materials and Methods: We systematically searched MEDLINE, Embase, Cochrane Central Register of Controlled Trials, CINAHL, Web of Science Core Collection, and Scopus on 5 February 2024. (PROSPERO registration number: CRD42024498524). The review adhered to Cochrane methodology and included randomized controlled trials (RCTs) comparing videolaryngoscopy and direct laryngoscopy for tracheal intubation in paediatric patients (<16 years).

Results and Discussion: We found 20,389 articles. After title and abstract screening 51 RCTs published between 2009 and 2024, including 4,856 pediatric patients, met the inclusion criteria. The overall risk of bias was assessed low in 22 trials, with some concerns in 24 trials, and high in 5 trials. First attempt tracheal intubation success was reported in 39 RCTs (3,776 patients). VL showed similar rates compared to DL (RR: 1.03, 95% CI: 0.99-1.08, p=0.17). Percentage of

glottic opening was reported in 18 RCTs (1,362 patients). VL significantly enhanced glottic visualisation (mean difference: 10%, 95%CI: 3-16).

Conclusion(s): In paediatric patients, videolaryngoscopy had similiar first attempt success rates when compared to direct laryngoscopy. Videolaryngoscopy improves glottic visualisation in pediatric tracheal intubation, which may be particularly advantageous in challenging airway scenarios, supporting its integration into airway management protocols. Future studies should aim to standardise outcomes and terminology and device used, particularly in specific pediatric subgroups, like children with anatomically or physiologically difficult airways.

42AP11-8 Ludiwg's angina: a face off between anesthesiologist and airway!

S. Garg¹, N. Pathak¹, N. Arora¹, N. Banerjee¹ ¹ABVIMS & DR RML Hospital, Anesthesia, New Delhi, India

Background: Ludwig's angina is an uncommon, critical airway challenge for an anesthetist. It is a life-threatening infection of the soft tissue of the floor of the mouth & neck which leads to lethal complications like airway obstruction, trismus, aspiration pneumonia.

Case report: We are reporting a case of Ludwig's angina posted for incision & drainage under general anesthesia. Patient had decreased mouth opening (1cm) & a diffuse swelling on anterior part of the neck extending superiorly from angle of mandible bilaterally to lower border of cricoid cartilage inferiorly. Ultrasound neck-hypoechoic collection in the muscular plane of the anterior neck & involvement of submandibular glands with multiple lymph nodes. Patient was prepared for awake nasal fibreoptic intubation. Identification & marking of cricoid & thyroid cartilage by ultrasonography was done to allow emergency cricothyroidotomy for which an apparatus was made using 16 G iv cannula attached to a 2ml syringe and a connector of 7mm ID ET Tube.Para-oxygenation using Nasal Oxygenation During Efforts of Securing A Tube was done. Fibreoptic view showed significant airway edema thus, patient was extubated on POD, & subsequently discharged.

Discussion: Ludwig's angina starts as a mild infection, fever, dysphagia & rapidly progresses to trismus & tongue elevation. The most serious complication is airway compromise due to expanding edema of the soft tissues of the neck. Awake fibreoptic intubation is the preferred method of airway management. Limited mouth opening, distorted airway anatomy, upper airway edema, risk of rupture of abscess makes direct laryngoscopy, blind nasal intubation, supraglottic airway insertion difficult. Front of neck access would also be difficult as the surface anatomy is distorted.

References:

- 1. Miah MR, Ali AS. Ludwig's angina. Br Dent J. 2020 Sep:229(5):268.
- 2. Saifeldeen K, Evans R. Ludwig's angina. Emergency medicine journal. 2004 Mar 1;21(2):242-3.

Learning points: Airway management in Ludwig's angina has to be individualized depending on the patient, judgement & expertise of the anesthesiologist. Rapid airway management, appropriate antibiotic therapy & surgical intervention are the goals of treatment.

42AP11-9

Upper lip bite test: a valuable predictive test for difficult intubation. A single-center prospective observational study

I. Lukač¹, A. Smajo Zdovc¹, S. Sakan¹, A. Šribar¹, J. Peršec¹ ¹Clinical Hospital Dubrava, Dept of Anesthesiology, Reanimatology and Intensive Care Medicine, Zagreb, Croatia

Background and Goal of Study: Unanticipated difficult airway is the most important cause of anesthesia-related morbidity and mortality. The aim of this study is to compare the diagnostic value of the upper lip bite test (ULBT) with other predictive tests for difficult intubation.

Materials and Methods: In this prospective observational study the following tests for evaluation of difficult endotracheal intubation were used: mouth opening, upper lip bite test, mandibular protrusion, thyromental distance, sternomental distance, interincisor gap, Mallampati test and head and neck movement. Upper lip bite test (ULBT) was scored using an ordinal scale of 1 (lower teeth can bite above the upper lip), 2 (lower teeth can bite the upper lip) and 3(lower teeth cannot reach the upper lip). This study enrolled 50 patients above the age of 18 who underwent elective or emergency surgery. The modified Cormack-Lehane classification system was used to assess the laryngoscopic view during direct laryngoscopy. IDS (intubation difficulty scale) was used for quantitative evaluation of intubation complexity.

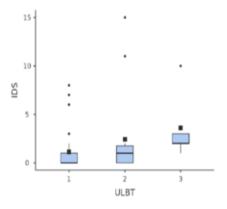

Figure 1. Differences in IDS score between ULBT levels

Results and Discussion: 31 patients (62%) were graded as ULBT 1 score, 14 patients (28%) as ULBT 2 score and 5 patients (10%) as ULBT 3 score. A significant difference in intubation difficulty was found for patients with ULBT level 3 compared to level 1, while statistical significance was lost between levels 1 and 2, and 2 and 3 (Figure 1).

Spearman's rank correlation test showed a statistically significant correlation between IDS and ULBT level which was weak to moderate. A strong correlation was found between IDS and Cormack-Lehane grade. No significant correlation between intubation difficulty and other measured variables was found.

Conclusion(s): Upper lip bite test is a simple bedside test that showed a significant correlation with IDS and should be used in clinical practice. Drawbacks of our study are: a small sample, including toothless patients and a small number of patients with limited head and neck movement. Future studies should include patients with possible/documented difficult airway, obese patients and patients with limited head and neck movement.

42AP11-10

The effect of morphological changes following extensive resection and reconstruction for oral cancer on subsequent tracheal intubation

A. Mawatari¹, K. Kamiutusri¹, T. Suzuki¹, S. Kobayashi¹ ¹Rinku General Medical Center, Anesthesiology, Osaka, Japan

Background and Goal of Study: Extensive resection and reconstruction for malignant tumors of the oral floor, maxilla, and mandible cause morphological changes within the oral cavity. This study aims to investigate the effects of these changes on subsequent tracheal intubation.

Materials and Methods: Patients were included who underwent extensive resection and reconstruction for malignant tumors of the oral floor, maxilla, or mandible at our hospital between September 2011 and September 2024, and subsequently underwent other surgeries under general anesthesia requiring tracheal intubation. Patient backgrounds, reconstruction sites, the presence of obstructions to tracheal intubation, and the use of airway devices were investigated. Fisher's exact test was employed for statistical analysis, with a p-value < 0.05 considered significant.

Results and Discussion: 66 cases of extensive resection and reconstruction were performed during the study period. Among them, 27 cases were selected for the study. Subsequently, 51 cases of surgery under general anesthesia with tracheal intubation were performed. The reconstruction site was the maxilla in 20 cases and the mandible in 31 cases.

After extensive resection and reconstruction, the rate of difficult tracheal intubation increased from 11.1% (3 out of 27 cases) to 39.2% (20 out of 51 cases) (p=0.001). The causes included limited mouth opening in 8 cases, abnormal positioning of the vocal cords in 4 cases, difficulty with laryngoscopy in 3 cases, oral deformities in 2 cases, and other factors in 1 case.

Additionally, the frequency of use of airway devices also increased from 48.1% (13 out of 27 patients) to 84.3% (43 out of 51 patients) (p=0.001).

Conclusion(s): In cases after extensive resection and reconstruction for oral cancer, tracheal intubation was often more difficult than before the surgery due to anatomical and functional changes.

Nevertheless, tracheal intubation was successfully performed in all cases. It is considered that anticipating difficult tracheal intubation in advance and using airway devices proactively contributed to this success.

42AP12-1

Towards safer airway management: an audit of preoperative assessment practices

C. Pereira¹, A. Pinheiro¹, V. Katerenchuk¹, A. Calçada¹, T. Taleco¹, I. Ferreira¹ ¹Unidade Local de Saúde da Arrábida, Anesthesiology, Setúbal, Portugal

Background and Goal of Study: Effective preoperative airway assessment is crucial to guide anesthetic management, minimizing the risk of unanticipated difficult airways (DA) and aspiration. This audit aims to assess the consistency of preoperative airway assessment, the use of standardized documentation of DA, and identify areas for improvement to enhance patient safety.

Materials and Methods: The audit was conducted at a district hospital in Portugal during February 2020 (pre-COVID-19 period), June 2021 (COVID-19 period), and June 2022 (post-COVID-19 period). Patients older than 18 years who attended pre-anesthetic consultations were included.

Results and Discussion: A total of 594 patients were included in the audit, 228 in the pre-COVID, 209 in the COVID, and 157 in the post-COVID periods. Airway assessment was conducted in 291, 146 and 152 patients in the pre-COVID, COVID and post-COVID periods, respectively. Overall, 517 patients (87%) underwent airway assessment. Of these, 40% used the El-Ganzouri score. When not used, the most commonly assessed parameters were the Mallampati score, mouth opening, and neck mobility. 96% of patients with an El-Ganzouri score ≥ 4 were flagged for potential DA. Seven cases of DA were identified. Of these, 4 cases were unpredictably difficult airways. In the pre-COVID and post-COVID periods, 75% and 50% of these cases were notified, respectively, but no DA alert cards were issued. During the COVID period, notification rates reached 100%, with all cases receiving DA alert cards. This finding aligns with other studies demonstrating low compliance with DA notification practices. One in four patients had ≥2 aspiration risk factors, but only 3% were documented. Although no aspiration cases were observed, underreporting may limit the opportunity to implement preventive strategies.

Conclusion: This audit reveals that while preoperative airway assessment practices were generally robust, significant variability in protocol adherence and documentation was observed across the three periods. The COVID-19 pandemic disrupted practices but also prompted adoption of structured documentation, as evidenced by improved notification rates. Standardizing airway assessment protocols, ensuring consistent use of predictive tools like the El-Ganzouri score, and emphasizing documentation through DA alert cards may be critical for improving patient safety. The low flagging rate for aspiration risk highlights another area for improvement.

Artificial Intelligence assisted tracheal intubation: preliminary data on correct tube placement - a pilot study

A. Raeber¹, L. Weber¹, M. Kaempfer¹, R. Greif², A. Fuchs¹, T. Riva1

¹Inselspital, Bern University Hospital, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland, ²University of Bern, Medical Faculty, Bern, Switzerland

Background: Tracheal intubation is a core competence in anaesthesia. Failed intubation or non-detected oesophageal intubation can jeopardise patients. LarynGuide™, a newly developed assistive software implemented at a C-MAC video laryngoscope (Karl Storz, Tuttlingen, Germany), guides laryngoscopy and advises on the position of the tracheal tube. This first-in-human study assesses if larvnGuide™ advice is correct and reliable compared to the judgement of the human airway operator.

Materials and Methods: This ongoing prospective, single-centre, sponsor-initiated, investigator-designed study recruited 54 of 110 planned patients scheduled for elective surgery requiring tracheal intubation, after Ethics Committee approval (BASEC 2024-D0041) and patients' written informed consent. After standardised induction of anesthesia, laryngoscopy with a C-MAC video laryngoscope (Macintosh blade No. 3 or 4) and tracheal intubation were performed by the board-certified anesthesiologist. During that tracheal intubation, larynGuide™ rans parallel on a second screen, covered to the airway operator but visible to the study team. After successful intubation, the airway operator visually assessed the correctness of the tracheal tube position and checked for proper end-tidal CO₂ readings. The primary endpoint was the accuracy of larynGuide™ on the tracheal tube position. We hypothesised that the sensitivity was 95% or above.

Results: So far, 47 patients out of 54 were analysed. Seven patients were excluded because a D-Blade was used or a Rapid Sequence Intubation was performed. Tracheal tube placement was correctly identified by larynGuide™ in 44 out of 47 patients, resulting in a sensitivity of 0.936 (95%-Cl: 0.82-0.99). In three patients, larynGuide™ assessed the tube position not correctly: In one case, larynGuide™ displayed the words "bad intubation" after the tracheal tube was correctly positioned in the trachea. In the other two patients, larynGuide™ displayed neither a green light nor the words "bad intubation". In all three cases, the lens was foggy and vision was impaired. There were no oesophageal intubations up to this point; therefore, no statement regarding the specificity can be made.

Conclusion: This preliminary data suggests a success rate of the larynGuide™ software of 93.6%. Impaired laryngoscopy vision due to fogging was one of the limiting factors for the software's accuracy.

42AP12-3

Can't intubate, can't oxygenate crisis management: case report on the use of tulip airway

E.B. Turan Akar¹, A.B. Aslan¹, H. Türkan¹ ¹Gulhane Training and Research Hospital, Department of Anesthesiology and Reanimation, Ankara, Turkey

Background: "Can't intubate, can't oxygenate" (CICO) scenarios represent rare but catastrophic emergencies in anesthetic practice. These situations require rapid and effective decision-making to prevent severe consequences (1). This report details the use of the Tulip Airway in managing a critical CICO crisis where conventional techniques failed. The case demonstrates the potential of this device in challenging airway management.

Case report: A 44-year-old male scheduled for radical nephrectomy (ASA II) had a BMI of 34.7, hypertension and a 20-pack-year smoking history. Airway assessment suggested manageable intubation (neck circumference: 42 cm; mouth opening: 3 cm; thyromental distance: 8 cm), though restricted neck extension was noted. During induction, face mask ventilation and supraglottic device (i-gel size 5) placement failed, leading to oxygen desaturation (SpO2: 77%). Attempts at direct and videolaryngoscopy revealed a Cormack-Lehane Grade 4 view, preventing intubation. The Tulip Airway (size 3) was introduced, achieving effective ventilation (EtCO2: 44 mmHg). This allowed stabilization of patient and subsequent blind intubation trial using a Frova bougie and a size 8 endotracheal tube. The surgery proceeded uneventfully over four hours. For extubation, the Tulip Airway was reinserted, ensuring continued ventilation. The patient recovered well, with no complications, following 24-hour ICU monitoring.

Discussion: Managing CICO scenarios requires an approach to secure effective ventilation. In this case, the Tulip Airway provided a life-saving solution when traditional methods failed, allowing for controlled intubation planning (2). This case demonstrates Tulip's efficacy and reliability in critical situations. Further research is warranted to evaluate its broader utility in airway management protocols.

References:

- 1. Apfelbaum, Jeffrey L., et al. "2022 American Society of Anesthesiologists practice guidelines for management of the difficult airway." Anesthesiology 136.1 (2022): 31-81.
- 2. Robinson, P. N., et al. "A pilot study to examine the effect of the Tulip® oropharyngeal airway on ventilation immediately after mask ventilation following the induction of anaesthesia." Anaesthesia 69.7 (2014): 707-711.

Learning points: The Tulip Airway is an effective alternative in CICO situations where traditional methods fail. Its simplicity and ease of use make it a valuable addition to airway management strategies, particularly for emergency settings.

The management conundrum of a Myasthenia Gravis patient with high aspiration risk for ultra-short surgery

S. Ng1, L.L. Lean1

¹Ng Teng Fong General Hospital, Anaesthesia, Singapore, Singapore

Background: Myasthenia Gravis (MG) presents a unique challenge for the anaesthetist, particularly during rapid sequence induction. Standard practice with neuromuscular blocking agents (NMBAs) can lead to prolonged paralysis and increased risk of respiratory complications. This case details the successful use of total intravenous anaesthesia (TIVA) with propofol and remifentanil for RSI in a patient with MG undergoing a short procedure to remove a foreign body from the esophagus.

Case Report: The patient, a 60-year-old Chinese female (BMI 30) with well-controlled ocular MG and a small thymoma, was pacemaker-dependent following a previous aortic valve replacement. She presented with a swallowed fish bone lodged at the C7/T1 level. She was noted to have a potentially difficult airway (Mallampati 3, short neck). The surgical plan was a rigid esophagoscopy and removal of foreign body. Given the high aspiration risk and expected short duration of the procedure, RSI was performed with total intravenous anaesthesia (TIVA), avoiding the use of NMBAs. Intubation was achieved using video laryngoscopy, with effect site target-controlled infusions (TCI) of propofol (Schneider Cet 6mcg/ml) and remifentanil (Minto Cet: 7ng/ml), facilitated by topical 10% lignocaine sprays to the glottis. Transient hypotension (BP 77/52, HR 60) was noted post-intubation, and managed by reducing TCI doses and administering phenylephrine. The patient was maintained on mechanical ventilation to reduce respiratory effort. A 2cm fishbone was successfully removed, the patient was extubated uneventfully and discharged the following day.

Discussion: This case demonstrates the effectiveness of RSI without NMBAs in MG patients undergoing ultra-short duration surgery. Remifentanil offers several advantages - avoiding prolonged paralysis from succinylcholine and the unpredictable dosing or reversal requirements with a rocuronium and sugammadex combination. Although the use of remifentanil may lead to hemodynamic instability, its predictable pharmacokinetics and ultrashort duration of action make it an ideal agent - allowing for both optimal conditions for intubation and rapid adjustment of doses to manage hemodynamic changes after intubation. Further studies are recommended to optimise remifentanil dosing and compare clinical outcomes between MG patients receiving remifentanil and NMBAs for RSI.

Learning Points: RSI with remifentanil can be used in short surgeries with high aspiration risk.

42AP12-5

Apneic oxygenation with high-flow nasal oxygen: a safer approach to microlaryngeal surgery

I. de Castro¹, <u>F. Costa</u>², C. Mexedo²

¹Unidade Local de Saúde da Região de Aveiro,
Anesthesiology, Aveiro, Portugal, ²Unidade Local de Saúde
de Santo António, Anesthesiology, Porto, Portugal

Background: Microscopic laryngeal surgery requires sharing the airway between surgeons and anesthesiologists, and demands coordination and teamwork to optimize the procedure. The use of HFNO for surgery under apneic oxygenation allows for a clear surgical field and avoids potential complications secondary to Endotracheal Intubation and Jet Ventilation, such as: vocal cord injuries, edema, and ischemia of the tracheal mucosa, or barotrauma. Case Report: A 53-year-old female patient, ASA I, was scheduled for MLS with laryngoplasty expansion for treatment of dysphonia. for an estimated duration of 20 minutes. This patient had undergone several MLS procedures due to recurrent dysphonia, and had no other relevant history and no predictors of difficult airway. In addition to standard monitoring, cerebral oxygenation, depth of anesthesia with Bispectral Index, and neuromuscular blockade with TOF Scan were monitored. General intravenous anesthesia under apneic oxygenation with HFNO was decided. After preoxygenation with a face mask to an EtO2 >90%, anesthesia was induced with TCI of remifentanil 1 ng/ml, TCI of propofol 3-4 mcg/ ml, and rocuronium 1.3 mg/kg. After induction, arterial blood gas (ABG) analysis was performed, revealing no alterations. The procedure was carried out under apneic oxygenation with HFNO (O2 at 70L/min), with an endotracheal tube at the surgical table for the need of ETI in case of desaturation (SpO2 < 90%). The procedure lasted 20 minutes, without desaturation. At the end of the surgery, neuromuscular blockade was reversed with 4 mg/kg of sugammadex, intravenous infusions were stopped, and ABG was performed, revealing respiratory acidosis (PaCO2 66.2 mmHg. PaO2 233 mmHG, and pH 7.25). The patient was sent to the postanesthesia care unit, where she remained and developed a mild, bilateral headache. After 30 minutes, ABG was repeated, showing correction of respiratory acidosis (PaCO2 41.3 mmHg, pH 7.38) and complete reversal of the headache.

Discussion: The administration of oxygen under HFNO during microlaryngeal surgery under apneic oxygenation is a safe way to ensure oxygenation, optimizing the surgical field and avoiding complications arising from multiple ETIs or JV.

Reference:

Gustafsson et al. Br J Anaesth. 2017;119(4):610-7; Novakovic et al. Microlaryngeal Laser Surgery. The Laryngoscope, 133:634-639, 2023

Learning Points: HFNO as a Safe Alternative for Microlaryngeal Surgery, Careful Patient Selection and Monitoring.

Delayed onset of airway compromise in traumatic neck hematoma: a case of successful awake fiberoptic intubation

E. Balciute¹, R. Aliulyte¹, V. Traskaite Juskeviciene² ¹Lithuanian University of Health Sciences, Department of Intensive Care, Medical Academy, Kaunas, Lithuania, ²Lithuanian University of Health Sciences, Department of Anesthesiology, Medical Academy, Kaunas, Lithuania

Background: Managing cervical hematomas after trauma is challenging, especially with airway compromise. Neck hematomas, caused by blunt force, lead to airway obstruction, vascular injury, respiratory failure. Our case highlights complexities of ensuring airway safety in massive neck hematoma.

Case Report: A 65-year-old asymptomatic male presented to the emergency department 5 hours post motor vehicle collision. Later he developed neck swelling, alterations in voice, difficulty swallowing. Vital signs remained stable. Neck ultrasound revealed a large 10x5 cm hematoma-like mass, confirmed by CT scan. Active extravasation from ascending thyroid artery's branch and thyroid rupture were suspected, displacing structures and narrowing tracheal, laryngeal, and oropharyngeal lumens.

Further evaluation via fibro endoscopy identified hematoma on the right posterior pharyngeal wall, extending into the right laryngeal side and displacing the epiglottis to the left. The epiglottis got swollen, leading to difficulty in visualization of narrowed glottic opening. Awake intubation using flexible fiberoptic bronchoscope with an armored endotracheal tube was chosen as safest method for intubation. Angiography and embolization of the superior and inferior thyroid arteries using glue was done. During continuing treatment in ICU, neck hematoma was surgically revised multiple times. However, patient died in 8 days due to hyperkalemia.

Discussion: Traumatic neck hematomas, caused by blunt force are life-threatening, involving thyroid gland, thyroid and carotid arteries. Hematomas in this area cause significant swelling and airway obstruction. When associated with arterial injury, complications like persistent bleeding and pressure on the trachea and larynx increase (1). Fiberoptic intubation is commonly used for difficult airways. However, its application in massive hematomas is rare (2). Awake fiberoptic intubation was chosen to prevent further airway trauma and ensure safe intubation despite significant displacement of airway structures.

References:

- 2. Kani K, et al. Awake Fiberoptic Tracheal Intubation in a Patient With Traumatic Retropharyngeal Hematoma. 2023.

Learning Points: Traumatic neck hematomas are rare and can lead to severe airway or vascular complications, requiring prompt and precise management. Awake fiberoptic intubation is crucial for securing the airway.

42AP12-7

Critical airway management - could videolaryngoscope be the first option in awake intubation?

G. Devadze¹, A. Dimakopoulou², K. Mendrinou², E. Dimitropoulou², M. Makripodi²

¹Tbilisi State Medical University,, Medicine, Tbilisi, Georgia, ²National and Kapodistrian University of Athens, Medical, Athens, Greece

Background and Goal of Study: The fundamental responsibility of the anesthesiologist is to ensure airway and adequate gas exchange. Airway anatomy with or without pathological abnormalities can progress rapidly to a life-threatening airway obstruction and catastrophic anoxic brain injury. We performed awake tracheal intubation (ATI) with the videolaryngoscope D-blade (C-MAC™) as the gold standard in patients with distorted airway.

Materials and Methods: A retrospective cohort study centered on patients who underwent for emergency airway management between 10/10.2023 and 10.10.2024. C-MAC was the first-choice technique for awake tracheal intubation for Urgent and Emergency difficult ventilation and difficult intubation.

Inclusion criteria were adult patients with acute dyspnea due to infection or pathological masses of the upper airway leading to change of the physiological anatomy of the area.

Exclusion criteria were children, patients patients unable to execute commands.

Our decision to perform a critical awake intubation by VL, has 3 bases: applying high-flow nasal O2, topicalization with lidocaine and sedation with or without dexmedetomidine/remifentanyl.

Primary outcome was the success rate of VL as plan A during Awake intubation. Secondary outcomes were duration of tracheal intubation, level of SPO₃, incidence of intraoperative complica-

Results and Discussion: The study included 56 patients, the mean patient age was 52,1 years (range 27-68 years), the mean BMI 36,4 kg/m² ± 5.75. 11 patients with Ludwig's angina and 24 with progressive cervical edema from infections of the maxillofacial area, underwent for urgent surgical drainage. 88% of them had limited mouth opening <1,5cm. We used wooden spatulas to increase mouth opening >1,5 cm, so that D-blade could be placed in patients' mouth. 21 patients with history of supraglottic/glottic tumors or epglottitis, with stridor and respiratory distress, presented in operating room for emergency management of difficult airway with anticipated difficult tracheostomy. We successfully performed AT in 54 patients. Endotracheal

intubation was unsuccessful in 2 patients due to the tumor covering part of the glottic area. Extubation was successful in all patients but one, who presented severe bronchospasm and Acute Lung Injury (ALI).

Conclusion(s): We believe that VL is very successful in critical airway management in patients with distorted upper airway anatomy due to tumor or infection with ultimately improved intubation conditions.

Unforeseen anaphylactic reaction in a young healthy patient undergoing arthroscopic meniscectomy: a case report

L. Vieira Gonçalves¹, R.M. Agostinho Madeira¹, T. Castanho Santos¹, A.R. Alves¹, D. Gonçalves¹ ¹Local Health Unit of the Leiria Region, Anesthesiology, Leiria, Portugal

Background: This case details an unusual incident of anaphylactic shock in a healthy 25-year-old woman undergoing arthroscopic meniscectomy. Remarkably, the patient had no prior history of diseases or allergies. The preoperative sciatic and saphenous nerve blocks with 80 mg of 0.2% Ropivacaine, accompanied by light sedation using midazolam (2 mg) and fentanyl (50 mcg), initiated a cascade of unexpected events during the subsequent general anesthesia induction.

Case report: Post-peripheral nerve blocks, general anesthesia induction with 50 mcg of fentanyl and 150 mg of propofol resulted in rapid and profound desaturation, indicating severe bronchospasm. She was intubated and was administered 100 mg of ketamine, 2g of magnesium sulfate, 200 mg of hydrocortisone and 30 mg of rocuronium intravenously, 300 mcg of adrenaline intramuscular, 400 mcg of salbutamol and sevoflurane inhaled, with recovery of the vital signs. Despite the presence of ST depression observed on EKG monitoring during the event, both the 12-lead EKG and laboratory assessments revealed no evidence of myocardial ischemia in the patient. Postoperatively, successful extubation in the operating room and subsequent transfer to the post-anesthetic care unit revealed no neurological deficits and a positive recovery. Hypersensitivity to midazolam, propofol, and fentanyl was identified as the cause of the anaphylactic reaction in imunoalergology consult.

Discussion: This case is singular because it not only underscores the rarity and severity of a severe allergic reaction to a combination of commonly used anesthetics as it will demand meticulous preoperative planning, necessitating a specialized anesthetic approach for future elective surgeries and potential emergent scenarios that this patient may require in the future. Several cases of anaphylaxis to propofol or fentanyl have been described.^{1,2} Anesthesiologists must acknowledge the unpredictable nature of such events and respond promptly with tailored interventions. This case serves as a compelling reminder of the imperative for ongoing education and preparedness among anesthesiologists and a permanent high degree of suspicion for the occurrence of these cases.

Learning points: Life threatening bronchospasm to propofol and fentanyl, effective crisis management

42AP12-9

Anaesthetic management of maxillary tumour resection in a patient with Hereditary Angioedema: a case report

R. J. Babu¹, H. R. Singhavi², V. Shetty¹ ¹Fortis Hospital, Mulund, Department of Anaesthesia, Mumbai, India, ²Fortis Hospital, Mulund, Department of Head & Neck Surgery, Mumbai, India

Background: Hereditary Angioedema (HAE) is a rare disorder characterized by potentially life-threatening swelling episodes, often linked to C1 inhibitor deficiency or dysfunction. Surgical procedures, particularly in the oral cavity, pose significant risks due to potential airway complications.

Case report: A 18-year-old female, diagnosed with HAE presented with persistent right maxillary swelling of size 3.1x3.0x2.0cm .The results of the pre-operative laboratory investigation were within normal limits, except for C1-INH level of 0.04(0.21-0.39) & C-4 was 7.8 (10-40mh/dL) with low function. The immunologist advised her Tablet Danzol 100mg and recommended the administration of 1500 units of C1-INH before the surgical procedure and advised to administer an additional 1000 units of C1-INH postoperatively if any symptoms of angioedema were to manifest. One hour before arrival in the operating room, she received intravenous administration of two vials (500mg each) of plasma-derived C1-INH concentrate. The OT was prepared to ensure the availability of emergency airway equipments, including a tracheostomy set. The patient was induced with Propofol 120mg, Fentanyl 50mcg,cis-atracurium 10mg and hydrocortisone was given prior to intubation. The patient was intubated gently using videolaryngoscope, 6 size ET tube was placed nasally after adequate lubrication and pilot balloon of the tube was inflated with the lowest pressure that prevents leakage. Anaesthesia was maintained using oxygen, air and sevoflurane. Compression trauma was tried to be minimized by using proper padding and throat pack was placed. The tumour was excised without any perioperative complications. The patient was extubated without straining after recurarization. The patient was transferred to the intensive care unit for postoperative follow-up.

Discussion: Preoperative treatment is recommended particularly before dental interventions, endotracheal intubation, and endoscopy due to the risk of angioedema development and lifethreatening larynx oedema. We paid attention to face mask not to cause a high compression, to apply endotracheal intubation gently, to use an appropriate sized tube, and not to inflate the pilot balloon of the tube more than necessary.

Learning points: Adequate preoperative assessment and planning ,especially C1-INH concentrate administration, danazol therapy, and meticulous OT preparation to mitigate angioedema risks is vital for the successful completion of this surgery.

Management of airway using videolaryngoscope in a child with Axenfeld-Rieger syndrome: a case report

G. Güngör¹, S. Abdullayev¹, S. Genç¹, C. Yüksel Elgin², L. Yüceyar¹, F. Altındaş¹ ¹İstanbul University- Cerrahpasa Cerrahpasa Medical Faculty, Department of Anesthesiology and Reanimation, Istanbul, Turkey, 2 Istanbul University-Cerrahpasa Cerrahpasa Medical Faculty, Department of Ophthalmology, İstanbul, Turkey

Background: Axenfeld Rieger Syndrome (ARS) is an autosomal dominant disease with variable morphology characterized by malformations of the eye with dental, cardiac and craniofacial defects(1). Glaucoma occurs in 50% of ARS cases. These patients will require surgical interventions to prevent permanent blindness. This syndrome is associated with difficult intubation due to facial anomalies and maxillary hypoplasia.

Case Report: We report the case of a 7 year-old female child who required general anesthesia for glaucoma surgery of the left eye. Written informed consent was obtained from her parents for publication. An extraoral examination revealed hypertelorism, a broad nasal bridge and mandibular retrognathia. Mallampati classification, mouth opening and thyromental distance were preoperatively evaluated. A mallampati score of 3 and a short thyromental distance of < 6.0 cm were considered to represent difficult intubation. Anesthesia was induced with sevoflurane in oxygen via a face mask. Neuromuscular relaxation was achieved with rocuronium bromide (0.6 mg/kg). The patient was intubated on the first attempt with a 5 mm ID endotracheal tube using a videolaryngoscope -Hugemed VL4R 4" VideoLaryngoscope (Shenzhen HugeMed Medical Technical Development Co., Ltd- China) (Figure 1). The surgery, involving the placement of an Ahmed glaucoma valve implant, lasted approximately 45 minutes and was uneventful.

Discussion: Preoperative identification of a difficult airway is crucial in patients with ARS. The Difficult Airway Society recommends videolaryngoscopy as an alternative to direct laryngoscopy in patients with difficult airways. Videolaryngoscope can provide better laryngeal exposure than conventional direct laryngoscope and reduces the incidence of failed attempts and complications such as hypoxemia and airway trauma.

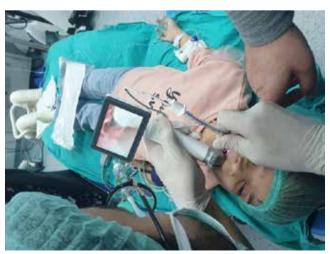

Figure 1. Intubation with videolaryngoscope.

Reference:

1. Baduni N. Anaesthetic challenges in a patient with Axenfeld Rieger Syndrome, Anesth Essays Res. 2012 Jan-Jun: 6(1): 108-109. Learning points: Videolaryngoscopes reduce the risk of failed intubation attempts and major complications in children compared to direct laryngoscopes.

42AP12-11

Management of critical neonatal airway obstruction

A.F. Freitas Silva¹, J. Jesus¹, J. Matos Carvalho², L. Garanito², C. Garcia³, P. Mantas³ ¹Hospital Professor Doutor Fernando Fonseca. Anesthesiology, Amadora, Portugal, 2Hospital Professor Doutor Fernando Fonseca, Otorhinolaryngology, Amadora, Portugal, ³Hospital Professor Doutor Fernando Fonseca, Neonatology, Amadora, Portugal

Background: Congenital airway abnormalities occur at various anatomic levels and their presentation is influenced by the severity and level of obstruction. The prevalence ranges between 0.2 and 1 in 10,000 live births.1

Case report: A 32 year-old, primigravid, at 37 weeks + 2 days had an uneventful eutocic delivery performed by the obstetric nurses. The antenatal ultrasound revealed a lombar scoliosis otherwise the pregnancy was uncomplicated. At delivery, the female newborn was gasping. Positive pressure ventilation (PPV) was administered immediately by the obstetric nurses and the neonatal team was called. PPV failed to adequately produce chest movement and direct laryngoscopy resulted in a Cormack-Lehane grade 1 but the endotracheal tube was unable to progress beyond the vocal cords. A second attempt was performed with videolaryngoscope but the problem persevere. Ventilation via a supraglottic airway device also failed. The anesthesiology and ENT teams were called as the several attempts of tracheal intubation were unsuccessful and oxygenation and ventilation was impossible. The heart rate dropped bellow 60/min and chest compressions were started. ENT team tried to perform percutaneous needle and surgical cricothyroidotomy that again, failed. Finally, a emergent surgical tracheostomy was successfully performed. Adrenaline was administered via ETT, followed by insertion of umbilical venous catheter. After adequate ventilation and oxygenation the heart rate arise above 100. Following resuscitation and stabilization, the newborn was transferred to a central pediatric hospital. Further investigation revealed multiple congenital malformations, including laryngeal web causing complete obstruction of the upper airway.

Discussion: When intubation fails and oxygenation and ventilation are severely impaired or impossible, surgical tracheostomy represents the preferred emergency access to the trachea in neonates and infants.2

Adjunctive fresh frozen plasma versus adjunctive cryoprecipitate in cardiac surgery patients receiving platelets for perioperative bleeding

C.M Fletcher¹, J.V. Hinton², L.A. Perrv^{2,3}, N. Greifer⁴. T.G. Coulson^{1,5,6}, R. Bellomo^{3,7,8,9,10}

¹The Alfred Hospital, Department of Anaesthesiology and Perioperative Medicine, Melbourne, Australia, 2Royal Melbourne Hospital, Department of Anaesthesia and Pain Management, Melbourne, Australia, 3University of Melbourne, Department of Critical Care, Parkville, Australia, 4Harvard University, Institute for Quantitative Social Science, Cambridge, United States, 5University of Melbourne, Department of Critical Care, University of Melbourne, Parkville, Australia, Parkville, Australia, ⁶Monash University, Department of Anaesthesiology and Perioperative Medicine, Melbourne, Australia, 7Austin Hospital, Department of Intensive Care, Melbourne, Australia, 8Monash University, Australian and New Zealand Intensive Care Research Centre, Melbourne, Australia, ⁹Royal Melbourne Hospital, Department of Intensive Care, Melbourne, Australia, ¹⁰Austin Hospital, Data Analytics Research and Evaluation Centre, Melbourne, Australia

Background and Goal of Study: In cardiac surgery patients receiving platelets for perioperative bleeding, we aimed to assess the relative association of adjunctive fresh frozen plasma (FFP) or adjunctive cryoprecipitate with morbidity and mortality.

Materials and Methods: This was a retrospective cohort study using data from the Australian and New Zealand Society of Cardiac and Thoracic Surgeons National Cardiac Surgery Database. We included platelet-transfused cardiac surgery patients treated with either FFP or cryoprecipitate from January 1, 2005, to December 31, 2021, across 58 Australian and New Zealand centers. We completed inverse probability of treatment weighting with entropy balancing to compare the relative risks of operative mortality (defined as mortality within 30 days of surgery or during initial hospital admission), 1-year mortality, and other clinical outcomes. We also assessed year-by-year transfusion trends.

Results and Discussion: We studied 12,889 platelet-transfused patients. Of these, 8,764 received adjunctive FFP and 4,125 received adjunctive cryoprecipitate, with cryoprecipitate increasing over time relative to FFP. After entropy balancing, compared with adjunctive cryoprecipitate, adjunctive FFP transfusion was associated with increased operative mortality (relative risk (RR): 1.49; 95% CI: 1.24, 1.79; p<0.001); 1-year mortality (RR: 1.37; 95% CI: 1.13, 1.66; p=0.001); increased risk of acute kidney injury (RR: 1.16; 95% Cl: 1.02, 1.33; p=0.024); all-cause infection (RR: 1.14; 95% Cl: 1.02, 1.29: p=0.026), and intensive care length of stay in days (adjusted mean difference: 8.02; 95% CI: 1.72, 14.33; p=0.013).

Conclusion(s): In cardiac surgery patients receiving platelets for perioperative bleeding, compared with adjunctive cryoprecipitate, adjunctive FFP was independently associated with greater morbidity and mortality. These hypothesis-generating findings warrant further prospective investigation.

Acknowledgements: We would like to thank Prof Julian A Smith, Prof Christopher M. Reid and Dr Jenni Williams-Spence for their support via the Australian & New Zealand Society of Cardiac & Thoracic Surgeons Cardiac Surgery Database Program.

A meta-analysis for the efficacy and safety of intravenous ferric carboxymaltose vs. iron sucrose for iron deficiency anemia in obstetric and gynecologic patients

H.-W. Shin¹, Y.J. Choi², H.S. You¹ ¹Korea University/Anam Hospital, Department of Anesthesiology and Pain Medicine, Seoul, Korea, Republic of, 2Korea University/Ansan Hospital, Department of Anesthesiology and Pain Medicine, Ansan, Korea, Republic of

Background and Goal of Study: Iron deficiency anemia (IDA) is very common among obstetric and gynecologic patients. This systematic review aimed to assess randomized controlled trials (RCTs) regarding the comparative efficacy and safety of most commonly used intravenous (IV) iron preparations such as ferric carboxymaltose (FCM) and iron sucrose (IS) in the treatment of IDA among obstetric and gynecologic patients.

Materials and Methods: We systematically searched PubMed, Embase, Cochrane, and Google Scholar for eligible RCTs comparing IV iron replacement using FCM or IS. Primary outcomes were the efficacy of FCM and IS as assessed by comparing serum hemoglobin (Hb) and ferritin levels before and after iron replacement. Secondary outcomes were the safety of FCM and IS assessed by comparing the incidences of adverse events during iron replacement. Meta-analysis was performed with RevMan 5.3. We also performed a subgroup analysis of post-treatment Hb and ferritin values according to the classification of study patients (obstetric, gynecologic, and obstetric and gynecologic).

Results and Discussion: We identified 9 RCTs with 910 patients (FCM group, n=456; IS group, n=454). Before IV FCM or IS replacement, the FCM and IS groups had similar baseline Hb and ferritin levels (Hb: MD, 0.04 g/dl; I2=0%; P=0.48 vs ferritin: MD, -0.42 ng/ml; I2=45%; P=0.49). After IV FCM or IS replacement, Hb (MD, 0.67; 95% CI, 0.25 to 1.08; I2=92%; P=0.002) and ferritin (MD, 24.41; 95% CI, 12.06 to 36.76; I2=75%; P=0.0001) levels were higher in the FCM group than the IS group. In all subgroup, post-replacement Hb and ferritin were also higher in the FCM group than the IS group. The FCM group had a lower incidence of adverse events than did the IS group (RR, 0.53; 95% CI, 0.35 to 0.80; I^2 =0%; P=0.003)(Fig. 2). No serious adverse events were reported in any groups.

Conclusion(s): FCM therapy showed better efficacy in increasing Hb and ferritin levels, as well as a more favorable safety profile with fewer adverse events than IS therapy in IDA among obstetric and gynecologic patients. There are no published human data on developmental adverse outcomes associated with the use of IV FCM or IS. There is a need for caution regarding the use of IV iron replacement for the treatment of IDA in the first trimester of pregnancy; however, IV iron replacement may be recommended in the second and third trimesters.

miR-155 regulates antibody-mediated TRALI via mast cell activation

X. Lai¹, R. Liao¹, Q. Fang¹

¹West China Hospital of Sichuan University, Department of Anesthesiology, West China Hospital, Sichuan University, Chengdou, China

Background and Goal of Study: Transfusion-related acute lung injury (TRALI) is one of the leading causes of transfusion-related deaths. miR-155 and mast cells are involved in acute lung injury. This study will verify through animal experiments that: downregulating miR-155 can suppress TRALI via repressing mast cell activation.

Materials and Methods: 9-week-old male BALB/c mice were used as experimental animals. Low-dose lipopolysaccharide (LPS) (0.1 mg/kg) was administered to mice intraperitoneally 24 hours before the experiment. On the day of the experiment, 34-1-2s (1.5 mg/kg) were injected into the tail vein. After 2 hours, isolate the left lung and collect bronchoalveolar lavage fluid (BALF). Finally, collect the lower lobe, middle lobe, and upper lobe of the right lung. Enzyme-linked immunosorbent assay (ELISA) and quantitative real-time PCR (qPCR) were used to evaluate interleukin-6 (IL-6), IL-17A, tumor necrosis factor [] (TNF-[]), and IL-1[] expression. The myeloperoxidase (MPO) activity was measured by ELISA. The BCA method was used to evaluate the total protein in BALF. Lung tissues were subjected to hematoxylin and eosin stain (H&E), and lung injury score was determined based on the evaluation system of the American Thoracic Association.

Results and Discussion: Here, anti-major histocompatibility complex class I antibodies (34-1-2s) were used to establish "two-hit" TRALI mouse models. In TRALI models, we found that miR-155 was down-regulated in plasma and lung tissues. Besides, mast cells were activated and some inflammation factors (e.g. tumor necrosis factor (TNF)-[], interleukin (IL)-1[], IL-17A, and IL-6) were increased. Subsequently, our results suggested that reducing miR-155 repressed MPO activity, decreased lung injury scores, wet-to-dry ratios, and BALF protein contents, and declined TNFand IL-6 expression in TRALI. Besides, miR-155 inhibition diminished the expression of mast cell activation biomarkers prostaglandin-2 and tryptase-1, indicating that mast cell activation was repressed in TRALI. Furthermore, targeting activated mast cells decreased MPO activity, lung injury scores, wet-to-dry ratios, and BALF protein contents, and reduced TNF-□ and IL-6 expression in antibody-mediated TRALI mouse models.

Conclusion(s): These findings suggested that suppressing miR-155 restrains lung injury and inflammation via inhibiting mast cell activation in antibody-mediated TRALI.

43AP01-4

Thromboelastometry-guided hemostatic therapy for hemorrhagic shock in a case of massive hemorrhage in an oncosurgical patient: a case report

P. Raghavan Ravi¹, M. Al Saifi², A. Al Rawahi³ ¹University Medical City/SQCCCRC, Anaesthesia, Muscat, Oman, ²Medical City of Military and Security Services, Surgery, Muscat, Oman, 3University Medical City/ SQCCCRC, Gastrosurgery, Muscat, Oman

Background: Hemorrhagic shock is a medical emergency that often complicates Onco- surgery and can lead to death. Thromboelastometry has been considered an effective tool for bleeding management in critically ill patients. Thromboelastometry can guide transfusion therapy guickly.

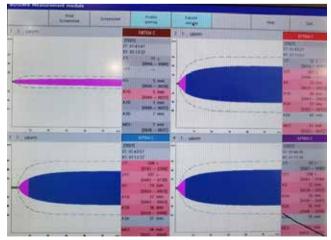

Case Report: 58-year-old a known case of gastric malignancy reported with giddiness and syncope. He was hypotensive (NIBP 70/40) with HR of 125/min.

Ultrasound revealed blood in the abdomen. He was intubated, and a massive transfusion protocol was activated. His laboratory tests revealed severe anemia (hemoglobin 4.4 mg/dL), metabolic acidosis (bicarbonate 10 mEq/L, pH 7.11), hypofibrinogenemia (70 mg/dL), international nationalized ratio 1.95, and lactic acidosis. He was transfused 10 units of PRBC,8 units of FFP, 8 units of Cryoprecipitate and 12 liters of crystalloids in the intensive care unit. His hemodynamics were supported by Noradrenaline and Vasopressin (IABP 85/45).

It was decided to take him up to the hybrid OT for angiography (which failed to stop the bleeding) exploration. On arrival, a ROTEM was done in the OT which showed hyperfibrinolysis with Hypocoagulability.

We gave 1000 mg Tranexamic along with 6 PRBC, 5 Cryoprecipitate, 6 FFP, Platelets, and 4 liters of crystalloids. The total intraoperative blood loss was 5.5 liters. The tumor mass has eroded the gastroduodenal artery.

"Preoperative ROTEM"

A repeat ROTEM done 2 hours (After the majority of transfusion products were given)showed normal thromboelastography.

"Post Resuscitation ROTEM"

Discussion: Thromboelastometry may be considered a useful, feasible, and safe tool to monitor and manage coagulopathy in patients with hemorrhagic shock. ROTEM it has the potential benefit of allowing rapid diagnosis, goal-directed therapy with hemostatic drugs, and coagulation factor concentrates.

43AP01-5

Association of transfusion-free management using intraoperative autologous blood donation (IABD) with postoperative acute kidney injury (AKI) risk in OPCAB surgery

H. Ito1

¹Chigasaki Tokushukai Hospital, Anesthesiology, Chigasaki, Japan

Background: In cardiac surgery, recent studies have reported an association between blood transfusions and an increased risk of AKI. In this retrospective study, we compared the incidence of postoperative AKI between transfusion-free management using IABD and intraoperative allogeneic blood transfusion (ABT) in OPCAB cardiac surgery

Methods: In the previous hospital, among OPCAB surgeries performed from August 2017 to November 2022 (n=223), patients were excluded from the study if they presented with preoperative cardiogenic shock, were on IABP support, were receiving dialysis, had a preoperative serum creatinine level ≥1.25, or received intraoperative infusion of only albumin solution or low-molecularweight dextran (HES). After anesthesia induction, ABD was performed in patients with a hemoglobin level of ≥13 before heparin administration, stored at room temperature with gentle agitation, and retransfused intraoperatively after protamine administration. Group A (GA) included patients who underwent 'IABD without ABT,' while Group B (GB) included those who received 'ABT'. In all cases, intraoperative blood salvage with a cell saver was used, and neither tranexamic acid nor diuretics were administered intraoperatively. Postoperative outcomes, including postoperative AKI classified according to the KDIGO criteria and ICU stay duration, were evaluated and compared. Fisher's exact test and the Mann-Whitney U test were used for intergroup comparisons, with statistical significance set at P<0.05.

Results: A total of 135 cases were included (Group A/B: 68/67 cases), with AKI observed in 21 patients (15.6%). Although there was no significant difference in preoperative serum creatinine levels between the two groups, postoperative AKI incidence based on the KDIGO classification was significantly higher in GB compared to GA (p = 0.0466). In particular, in KDIGO stage 2-3, GA had no cases, while multiple cases were observed in GB (n=4). There was no statistically significant difference in postoperative ICU stay duration (p = 0.0658).

Conclusions: In this study, the risk of developing postoperative AKI in OPCAB surgery was observed even in patients with normal preoperative serum creatinine levels.

Additionally, transfusion-free management with IABD was suggested to significantly reduce the risk of postoperative AKI compared to ABT.

43AP01-6

Optimal administration of tranexamic acid for non-emergency cardiac surgery: a systematic review and network meta-analysis

X. Pan¹, P. Liang¹, Y. Fu¹, Z. Xv¹, H. Yu¹, J. Huang² Sichuan University, Department of Anesthesiology. West China Hospital, Sichuan University, Chengdu. China, ²University of Louisville, Department of Anesthesiology & Perioperative Medicine, Kentucky, **United States**

Background and Goal of Study: There is ongoing discussion on the best way to provide tranexamic acid (TA) and the appropriate dosing regimens for cardiac surgery. We conduct this network meta-analysis to evaluate the efficacy and safety of various TA delivery methods in cardiac surgery.

Materials and Methods: We searched PubMed, Embase, Cochrane Central Register of Controlled Trials, Scopus and Web of Science from inception to July 11, 2024. We included randomized controlled trials evaluated the hemostatic effects of TA in cardiac surgery. Two authors independently selected studies and extracted data. The quality of trials was assessed using the Cochrane risk of bias tool. Our primary outcomes were blood transfusion needs and postoperative seizures. We estimated summary odds ratios and mean differences using pairwise and network meta-analysis.

Results and Discussion: A total of 17909 participants from 54 studies included in this study. Except combination administration, all strategies discussed in this article significantly reduced the transfusion risk. The risk of transfusion was further decreased by high dose TA compared to low dose. When compared to intravenous administration, local administration may raise the risk of blood transfusion in cardiac surgery. High dose TA can dramatically raise the risk of postoperative seizure.

Intervention	Definition
High-dose TA	total dose regimens greater than 80mg/kg or 30mg/kg+10mg/kg/h
Medium-dose TA	total dose regimens greater than 50mg/kg but less than 80mg/kg
Low-dose TA	total dose regimens less than 50mg/kg or 10mg/kg+2mg/kg/h
Topical TA	tranexamic acid diluted in normal saline and poured into mediastinal cavity before closing the chest
Combined TA	additional intrapericardial application of tranexamic acid to the intravenous application

Table. Definitions of interventions included in this study.

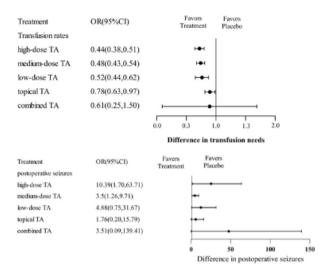

Figure. Forest plot of network meta-analysis results for primary outcomes

Conclusion(s): In cardiac surgery, medium-dose intravenous infusion was the most preferable delivery method which was as effective as high-dose regimen in reducing transfusion rate without increasing the risk of seizure. Topical compared with intravenous infusion was associated with a higher rate of blood transfusions. Larger clinical trials are required to validate these results.

43AP01-7

Plethysmography Variability Index (PVI) versus Pulse Pressure Variation (PPV) as a measure of fluid responsiveness as measured by end-expiratory occlusion test in patients undergoing major surgery

<u>D. Mathew</u>¹, K. Venkatesan¹
¹Khoo Teck Puat Hospital, Anaesthesia, Singapore, Singapore

Background and Goal of Study: Fluid therapy is an integral part of resuscitation as well as the cornerstone in the enhanced recovery after surgery (ERAS) protocol. Plethysmography variability index (PVI) provides a continuous non-invasive measure of the relative variability of the photo-plethysmograph during respiratory cycles. It may be used as a dynamic indicator of fluid responsiveness in mechanically ventilated patients. The end expiratory occlusion test (EEOT) is another method of assessing fluid responsiveness. The pulse pressure variation (PPV) is another index used commonly to assess fluid responsiveness. However, it requires the presence of an intra-arterial line.

The hypothesis of the study was that PVI provides comparable indices of fluid responsiveness as compared to the PPV in patients undergoing major elective surgical procedures in our institution. Fluid responsiveness was assessed using the EEOT at the 5 & 10 minute intervals.

Materials and Methods: This was a pilot prospective study involving 20 patients scheduled for major elective surgery in Khoo Teck Puat Hospital, Singapore.

The study was approved by the Institutional Review Board (IRB) (2022/00890) and written consent was obtained from all subjects. Patients under General Anaesthesia were mechanically

ventilated with a PBW of 8mls/kg. A baseline reading (R1) of PPV & PVI was undertaken. This was followed by PPV & PVI readings at 5 minutes (R2) and 10 minutes (R3) after an EEOT was performed.

Results and Discussion: The results can be divided into R1, R2 and R3 differences. 18 readings were taken for R1 and R2 differences, and 17 for R3 difference. There was variability amongst the differences in readings amongst R1, R2 and R3, with the greatest variability coming with R1 differences ranging from 0 to 41. If a difference of >10 was taken as an outlier, the number of outliers were 5,4 and 3 respectively for R1, R2 and R3 differences. The majority of readings had differences under 10 points. From an analysis of the readings, it seems that PVI readings had the greatest variability and this tended to occur with the R1 difference during the initial baseline measurements. PVI readings seem to be affected by extrinsic causes resulting in multiple outliers.

Conclusion: There may be some utility in using the PVI values as a surrogate for PPV values and fluid status. Further studies with use of a cardiac output monitor would be required to verify this association.

43AP01-8

The role of endogenous heparinization as a perioperative predictor for postoperative admission to the intensive care unit: a pilot study

D. Zafeiriadis¹, D. Papageorgiou¹, S. Lefkaditis¹, G. Koumarampis¹, E. Tsakyridou¹, D. lordanidou¹ 'Hippocrates' General Hospital of Thessaloniki, Anesthesiology, Thessaloniki, Greece

Background and Goal of Study: The phenomenon of endogenous heparinization has been associated with the degradation of the endothelial glycocalyx, a complex layer of proteoglycans and glycoproteins lining the intraluminal surface of blood vessels, with a crucial physiological role. Its degradation products exhibit anticoagulant properties that can be detected through thromboelastography/thromboelastometry methods. We hypothesized that the presence EG degradation and also the degree of it, could function as a perioperative marker of the patients' physiological status, specifically the need for postoperative ICU admission

Materials and Methods: 30 patients were enrolled (mean age: 65.43 years, sd: 10.43, ASA II: 53%, BMI: mean: 27.55, sd: 5.29, male sex: 53%), scheduled for elective or emergency surgery, the need for preoperative ICU bed reservation was assessed. The decision was based on the patients' physiological status (ASA) and the nature of the surgical procedure (SRS) during the pre-anesthetic evaluation. Two ROTEM tests (Intem/Heptem) were performed: one at the beginning of the surgery during the placement of the A-line, and at the end of the surgery during the closure of the surgical wound. Statistical analysis was conducted to investigate potential correlations between the Intem/Heptem ratios and ICU admission, using Mann-Witney Test and Multivariate Logistic Regression Analysis including multiple pre and intraoperative parameters.

Results and Discussion: The Mann-Witney Test indicated that the postoperative Intem/Heptem ratio showed a strong positive correlation with the patient's ICU admission (U = 25.000, Z = -2.880, p = 0.004). The percentage difference of the ratios also approached significance (p = 0.057), indicating a potential association.From the Logistic Regression analysis the post ratio

emerged as a key predictor of the outcome, maintaining significance through multiple regression steps (p = 0.015 in the final model) The model demonstrated good predictive power with an overall classification accuracy of 88.9%. The preoperative ratio itself did not show a significant correlation. The findings suggest that the detection of endogenous heparinization at the end of surgery, as indicated by higher Intem/Heptem ratio values, is associated with the need for ICU admission room.

Conclusion(s): The results underscore the importance of evaluating the phenomenon of endogenous heparinization as a prognostic marker for postoperative admission to the ICU

43AP01-9

Serum exosomes induce transfusion-related acute lung injury via JNK signaling pathway

X. Lai1, R. Liao1, Q. Fang1

¹West China Hospital of Sichuan University, Department of Anesthesiology, West China Hospital, Chengdou, China

Background and Goal of Study: Transfusion-related acute lung injury (TRALI) is one of the leading causes of transfusion-related deaths. c-Jun N-terminal kinase (JNK) is involved in acute lung injury. This study will verify that: serum exosomes induce TRALI via JNK signaling pathway.

Materials and Methods: Exosomes were isolated from normal mouse serum. Serum exosomes were identified by nanoparticle tracking analysis (NTA), transmission electron microscopy (TEM), and western blot (WB). 72 hours before the experiment, JNK inhibitors were injected into the tail vein. Low-dose lipopolysaccharide (0.1 mg/kg) was administered to mice intraperitoneally 24 hours before the experiment. On the day of the experiment, serum exosomes were injected into the tail vein. After 2 hours, isolate the left lung and collect bronchoalveolar lavage fluid (BALF). Finally, collect the lower lobe, middle lobe, and upper lobe of the right lung. Enzyme-linked immunosorbent assay (ELISA) were used to evaluate interleukin-6 (IL-6), IL-17A, tumor necrosis factor α (TNF- α), and IL-1 β expression. The myeloperoxidase (MPO) activity was measured by ELISA. The BCA method was used to evaluate the total protein in BALF. Lung tissues were subjected to hematoxylin and eosin stain (H&E), and lung injury score was determined based on the evaluation system of the American Thoracic Association. CD9, CD63, total and phosphorylated JNK were measured by WB analysis.

Results and Discussion: The results of TEM, NTA, and WB all indicated that the extractions after ultracentrifugation were mainly exosomes. Serum exosomes increased MPO activity, total protein of BALF, lung wet/dry ratios, and lung injury score in mouse lung tissue, indicating that serum exosomes successfully induced TRALI in mice. Serum exosomes raised expression of TNF-α, IL-6, IL-1\u00e3, and IL-17A. Besides, serum exosomes significantly augmented the phosphorylation levels of JNK, and JNK inhibitors significantly inhibited the JNK signaling pathway. JNK inhibitors significantly reduced MPO activity, total BALF protein concentration, lung wet/dry ratio, and lung injury score. These suggested that JNK inhibitors suppressed TRALI. JNK inhibitors also reduce expression of TNF-α, IL-6, IL-1β, and IL-17A.

Conclusion(s): Serum exosomes induced TRALI via the JNK signaling pathway, promoting the release of inflammatory factors. Suppressing the JNK signaling pathway reduces inflammatory response levels, thereby alleviating TRALI.

¹Singapore General Hospital, Endocrinology, Singapore, Singapore, ²Singapore General Hospital, Data Science and Artificial Intelligence Laboratory, Singapore, Singapore, 3National University of Singapore, Department of Pharmacy, Singapore, Singapore, 4Singapore General Hospital, Anaesthesiology, Singapore, Singapore

Background and Goal of Study: Preoperative hyponatremia is associated with poorer outcomes, including increased mortality, ICU admissions, prolonged hospital stays, and readmissions. It is unclear if preoperative hyponatremia is a causal factor for poorer outcomes or simply reflects underlying pathology. Similarly, the effect of intervening to correct preoperative hyponatremia has not been studied before.

This study evaluates the impact of an institutional protocol for managing preoperative hyponatremia with an intervention serum sodium threshold of ≥130 mmol/L on perioperative outcomes using a regression discontinuity design (RDD).

Materials and Methods: We analyzed data from the SingHealth Perioperative and Anesthesia Subject Area Registry (PASAR), including adult surgical patients from 2013 to 2022.

Outcomes evaluated included 30-day mortality, 1-year mortality, ICU admissions, length of stay (LOS), and rapid postoperative sodium correction (defined as greater than 8mmol/L in 24h). RDD models (sharp, kink, triangular kernel) were applied to identify treatment effects at the sodium threshold.

Subgroup analyses included patients with cardiac disease, chronic kidney disease, high operative risk, and emergent procedures **Results and Discussion:** Among 174,792 patients, no significant discontinuity was observed at the sodium threshold for 30-day mortality, ICU admissions, or LOS. However, a significant discontinuity was found for 1-year mortality (Treatment effect = 0.081, p=0.010), with the same discontinuity also observed in subgroups with cardiac disease, chronic kidney disease, or emergent procedures.

Unsurprisingly, lower preoperative sodium (<130 mmol/L) was strongly associated with rapid postoperative sodium correction (Odds ratio = 1.190 per mmol/L decrease, p<0.001). These findings suggest that protocolized sodium correction does not significantly improve short-term outcomes but may influence longerterm mortality.

We also posit that protocolized management of sodium could have unintended consequences such as operative delays, although this was not evaluated in this study.

Conclusion(s): Standardized sodium correction protocols may not significantly improve immediate outcomes but could affect longer-term mortality in specific subgroups. Further studies are needed to assess the role of hyponatremia etiology and patient volume status to refine perioperative management strategies.

Unexpected severe coagulation disorder in a patient undergoing elective cardiac surgery managed with rotational thromboelastometry - a case report

S. Vander Zwaag¹, I. Kukel¹, U. Kappert², J. Fassl¹ ¹Heart Centre Dresden, Institute of Cardiac Anaesthesiology, Dresden, Germany, 2Heart Centre Dresden, Department of Cardiac Surgery, Dresden, Germany

Background: Consumption coagulopathy is common in on-pump cardiac surgery. Rotational thromboelastometry (ROTEM) is often utilized to assess the extent of the disorder. In most cases, its results correlate with the preoperative coagulation panel.

We present a case of a patient with a coagulation disorder despite normal preoperative international normalised ratio (INR) and activated thromboplastin time (PTT).

Case Report: A 57-year-old male patient was scheduled for an aortic valve replacement. Preoperatively, the patient exhibited a normal INR of 0.98 and an PTT of 24 s. His medical history included an intensive care unit stay, complicated with secondary sclerosing cholangitis. On admission, transaminases were within normal ranges. GGT was elevated at 501 IU/I (normal range: < 60 IU/I).

Intraoperatively, following the on-pump time of 75 minutes and heparin reversal, a diffuse microvascular bleeding was diagnosed. ROTEM was performed, the results are presented in Table 1. 2500 IU of 4-factor prothrombin complex concentrate and 4 units of fresh frozen plasma were administered. The follow-up ROTEM showed sufficient coagulation, and the microvascular bleeding ceased.

	FIBTE	M-CT	FIBTE	M-A5	EXTE	м-ст	EXTEN	1-A5	HEPTE	м-ст	HEPTE	M-A5
	NR		NR		NR		NR		NR		NR	
T1	<84 s	233	>5 mm	14	<80 s	227	>32 mm	29	<211 s	365	>34 mm	NA
T2	<84 s	83	>5 mm	17	<80 s	94	>32 mm	57	<211 s	206	>34 mm	51

Table 1. Results of the first (T1) and the second (T2) ROTEM. NR: normal range.

Discussion: In this case, we observed a clinical situation contrary to the ones seen in most patients with chronic liver disease, who tend to have prolonged INR and PTT, but normal ROTEM. It is thought that viscoelastic tests better reflect the in vivo situation than traditional laboratory tests, which do not consider the rebalancing of the coagulation system.

The appropriate coagulation in patients with liver disease depends on the equilibrium between procoagulant and anticoagulant factors, such as protein C[1].

Hemodilution during on-pump surgery further reduces the factor levels. However, the activity of protein C has been shown to increase following aortic declamping[2].

Our hypothesis is that the imbalance of these reactions resulted in a shift towards anticoagulant activity.

Learning Points: The use of rotational thromboelastometry enables the individualisation of therapy by atypical disease manifes-

43AP02-1

Management of patient with Sotos syndrome and factor VIII deficiency undergoing scoliosis surgery

K. Arslan¹, M. Oral¹, M. Yazıcı², R. Ramazanov² ¹Memorial Ankara Hospital, Anesthesiology and Reanimation, Ankara, Turkey, 2Memorial Ankara Hospital, Orthopedics and Traumatology, Ankara, Turkey

Background: Sotos syndrome is rare genetic disorder characterised by a distinctive facial appearance, cognitive impairment, overgrowth. Hemophilia A, factor VIII deficiency, is an X-linked recessive disorder presenting with increased risks of perioperative bleeding.

Case Report: A 11 years old boy weighing 41 kg, diagnosed Sotos syndrome (characteristic facial appearance, mild cognitive impairment, mitral valve prolapsus, aortic insufficiency), factor VIII deficiency was scheduled for posterior instrumentation surgery. Baseline laboratory results showed hemoglobin (Hb) 12.9 g/dl, a prothrombin time (PT) of 13,9s, an activated partial thromboplastin time of 45,3 s, and a platelet count of 192,000/mm³. His preoperative factor VIII activity was <20% of normal. The patient received factor VIII therapy at 40 U/kg before surgery. In operation we used 20 mg/kg tranexamic acid bolus and a 10 mg/kg infusion. We used TİVA (propofol, remifentanil) for anesthesia and one dose rocuronium before intubation. There was 1000ml bleeding during operation, we used 2 packed red cells,1 fresh frozen plasma. The patient was administered 1000 u factor VIII intraoperatively (Hb 11,6). Postoperative 0. Day bleeding was 200ml (hemovac drain), 1. Day bleeding was 290ml and we applied 1000IU factor VIII and 1paced red cells. Postoperative 3. Day the patient was discharged.

Discussion: Hemophilia A is a rare disorder caused by autoantibodies directed against clotting and tend to present with hemorrhage. The incidence of Hemophilia A has been estimated at 0.2-1.0 case per 1 million persons, but this may be underestimated because of difficulty in making the diagnosis ([1]).

Anti-fibrinolytic drugs are widely used in hemophilic patients to reduce blood loss in a variety of bleeding conditions, including severe trauma and surgery [2].

Most used treatment and prophylaxis before major bleeding operations is still factor replacement.

Learning Points: In this case we show our tranexamic acid, blood product use, factor replacement dose in scoliosis surgery of patient with Sotos syndrome and factor VIII deficiency.

43AP02-2 ROTEM-guided transfusion in aortic arch dissection re-operation: a clinical case

C. Amarante Dias¹, <u>J. Borba</u>², D. Paupério³ ¹Unidade Local de Saúde da Região de Aveiro, Anestesiologia, Aveiro, Portugal, ²Hospital do Divino Espírito Santo, Anestesiologia, Ponta Delgada, Portugal, ³Unidade Local de Saúde de Gaia e Espinho, Anestesiologia, Vila Nova de Gaia, Portugal

Background: Aortic arch dissection re-operations are high-risk procedures often complicated by significant blood loss and coagulopathy. Traditional coagulation tests may fail to offer real-time insight into dynamic coagulation status. ROTEM (Rotation Thrombelastometry) provides a more personalized approach for hemostatic management, improving outcomes and reducing unnecessary transfusions.

Case Report: A 60-year-old male with a history of type A aortic dissection previously underwent ascending aorta replacement. Follow-up imaging showed descending aorta aneurysm and intramural thrombus growth, supplied by the left subclavian artery (LSA). The patient underwent left carotid artery and LSA transposition and was proposed for ascending aorta and aortic arch replacement. Peripheral circulatory arrest (PCA) and hypothermia were required, and substantial blood loss anticipated.

Pre-operative haemoglobin was 16.1 g/dL, with no anticoagulant or antiaggregant use. Hemostatic management was guided by ROTEM. A Tranexamic Acid bolus was given after induction, followed by continuous infusion. Initial ROTEM showed normal clotting times (CT), clot formation time (CFT), and maximum clot firmness (MCF). PCA lasted 33 minutes.

After rewarming, ROTEM showed an A5 in Fibtem of 6mm, with prolonged CT in Fibtem, Extem, and Intem, but normal results in Heptem, indicating heparinization effect and lack of fibrinogen. Fibrinogen was administered. Extracorporeal circulation lasted 169 minutes. ROTEM analysis after fibrinogen replacement showed normalization of coagulation. The patient was extubated the following day and discharged 14 days post-procedure.

Discussion: Aortic arch re-operations carry high morbidity and mortality, mainly due to bleeding and coagulation issues. Conventional tests offer limited information on dynamic clot formation. ROTEM assesses multiple coagulation parameters in real-time, incl

References:

- 1. Karrar, et al., JCVA 2022
- 2. Girdauskas, et al., JTCVS 2010
- 3. Monaco, et al., JCA 2020

Learning Points:

ROTEM provides a real-time, dynamic evaluation of coagulation, helping to guide hemostatic management.

ROTEM optimizes blood product use.

ROTEM-based coagulation management algorithms should be mandatory.uding clotting time, clot strength, and fibrinolysis, providing better guidance for hemostatic management.

This case demonstrates ROTEM's role in optimizing hemostatic control and minimizing bleeding and clotting risks during complex surgeries.

43AP02-3

The illusion of warm infusions - an experimental study

<u>P.A. Gerster</u>¹, T. Girard¹, L. Steiner¹, S. Dell-Kuster¹ *'University Hospital Basel, Anaesthesiology, Basel, Switzerland*

Background and Goal of Study: Intraoperative hypothermia is a common complication [1]. We aimed to investigate whether prewarmed infusions are superior to cold infusions, with and without the use of a warming device.

Materials and Methods: This experiment was conducted in an operating room with a room temperature of 19°C. Each NaCl 0.9% infusion bag was connected to an infusion tube. Infusion-pumps (Volumat* Agilia, Fresenius Kabi) maintained flow rates at 100 ml/h for 360 minutes. Temperature was measured in all bags and at distal ends of the infusion lines every 15 minutes using thermistor sensors (a-line™ YSI 400, Anandic Medical Systems AG) and monitors (IntelliVue* X2, Philips). The experiment involved four infusion setups. A cold infusion at room temperature, a pre-warmed infusion at 37.0°C and a cold and pre-warmed infusion with additional use of warming device (Bair Hugger™, 3M™ or Hotline®, Smith Medical). The devices were activated at 60 minutes and deactivated at 300 minutes. All experiments were repeated twice and averages of both are reported.

Results and Discussion: Temperature in warm infusion bags approached room temperature after about 180 minutes. Without using a warming device, there was no temperature difference at the distal end of the infusion line, regardless of using a pre-warmed or cold infusion. Wrapping the infusion line in a forced-air warming device was able to increase the infusion temperature by a maximum of four degrees. Only a fluid-warming device was able to increase temperature at the distal end to about 33°C.

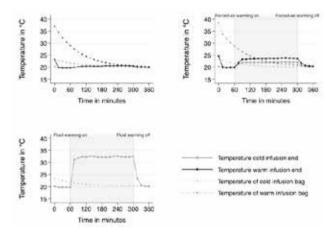

Figure: Scatterplots of temperature measurements over time in the infusion bag and infusion end without and with warming devices for cold and pre-warmed infusions.

Conclusions: Prewarmed infusions offer no thermal advantage at standard flow rates. Only an infusion warming device reliably heats the administered infusion fluids, however, still below the desired body temperature.

43AP02-4

Unexpected bloodshed: diagnosing G6PD deficiency amidst intraoperative hematuria

S.M. Ipe¹, R. Sathi¹, S. Ipe¹, R. Mathew¹, S. Philip¹, A. Joseph²

¹M.O.S.C Medical College, Anesthesiology, Kolenchery, India, ²M.O.S.C Medical College, Anesthesia, Ernakulam, India

Background: Glucose-6-phosphate dehydrogenase (G6PD) deficiency is an X-linked genetic disorder that predisposes individuals to hemolytic anemia under oxidative stress. It is crucial to recognize this condition, especially in surgical settings where blood transfusions are common. This case report discusses a patient who experienced significant postop complications due to undiagnosed G6PD deficiency.

Report: A 47year female with history of diabetes and stroke underwent laparoscopic hysterectomy under general anesthesia with propofol, sevoflurane. Intraoperatively she received 2 blood transfusions and developed bloody urine. Urologists confirmed the absense of bladdder or ureteric injury with methylene blue. The patient developed rashes all over the body and reddish urine in the recovery room not associated with hypotension, itching or breathing difficulty. Differential diagnosis included mistmatched transfusion, acute hemolytic reaction, anaphylaxis. She was managed successfully with crystalloid infusion, steroids and diuretics. Post op blood investigations-CBC indicated mild anemia, elevated reticulocyte count, increased Indirect bilirubin and LDH. Peripheral blood smear showed bite cells and Heinz bodies, suggestive of oxidative damage. DirectCoomb'sTest, IndirectCoomb'sTest, and cold agglutinin test were negative suggestive of intravascular hemolysis. Flow cytometry, osmotic fragility, G6PD levels and APLA screening confirmed G6PD deficiency.

Discussion: Intraoperative hematuria in patients with G6PD deficiency can indicate acute hemolytic anemia due to oxidative stress from surgical procedures or medications. Anesthesia poses additional concerns, as certain agents can trigger hemolysis. Careful selection of anesthetic drugs is essential, avoiding those known to induce oxidative stress, while vigilant monitoring for signs of hemolysis is crucial to prevent severe complications perioperatively.Ref:Valiaveedan S, Anaesthetic management in patients with glucose-6-phosphate dehydrogenase deficiency undergoing neurosurgical procedures. Indian J Anaesth. 2011 Jan;55(1):68-70.

Learning points: This case underscores the necessity of considering G6PD deficiency in patients presenting with hematuria and rashes following surgical interventions and blood transfusions. Early recognition and management can significantly improve patient outcomes. Future recommendations include preoperative screening for G6PD deficiency in at-risk populations to mitigate potential complications.

43AP02-5

Anesthetic management in a patient with a giant neurofibroma

S. Kanbir¹, I. Gunusen¹, A. Sargin¹, A. Yildirim¹, S. Ozcan¹, A. Bicer²

¹Ege University Hospital, Anesthesiology and Reanimation, Izmir, Turkey, ²Ege University Hospital, Plastic Reconstructive and Aesthetic Surgery, Izmir, Turkey

Background: Neurofibromas are benign nerve sheath tumors that may occur as part of neurofibromatosis type 1 (1,3). Managing patients with giant neurofibromas poses challenges such as hemodynamic instability, prolonged surgery, and significant blood loss (2).

Case report: A 41-year-old male (height: 160 cm, weight: 40 kg) with a giant neurofibroma (110 × 50 cm, 60 kg) on his right thigh and presented for surgical excision. He had hypothyroidism, third-degree mitral regurgitation, and severe anemia (hemoglobin: 5.7 g/dL). Preoperative corrections included electrolyte repletion (serum sodium: 128 mmol/L), blood transfusions(recombinant factor VIIa, erythrocyte suspension) and intraoperative embolization of feeding arteries with an aortic balloon. Preoperative sodium and hemoglobin levels improved to 132 mmol/L and 8 g/dL, respectively.

The patient was positioned on two surgical tables. Peripheral venous, arterial, and central venous accesses were established. Anesthesia was induced with propofol, fentanyl, and rocuronium, and maintained during a 12-hour surgery and 13-hour anesthesia duration. Fluid management included crystalloids, colloids, erythrocyte suspension, platelets (apheresis) and fresh frozen plasma. Noradrenaline infusion was used to maintain hemodynamics. A VAC device was applied to close a 35 × 30 cm defect.

Discussion: Managing giant neurofibromas requires meticulous planning (2). Preoperative embolization and intraoperative aortic balloon placement minimized blood loss. Recombinant factor VIIa and VAC devices were critical in addressing coagulopathy and wound healing.

Learning points: This case highlights the importance of multidisciplinary collaboration and tailored anesthetic strategies to achieve favorable outcomes in patients with giant neurofibromas.

43AP02-6

Patient Blood Management implementation program in laparoscopic surgery in colorectal cancer: update

S. López García¹, M. Mallol Oliva¹, G. Puig Sanz¹, G. Batet Álvarez¹, I. Aparicio Rubio¹, M.J. Colomina^{1,2,3} ¹Bellvitge University Hospital, Anaesthesiology and Intensive Care, Hospitalet de Llobregat, Spain, ²Barcelona University, Schoole of Medicine, Barcelona, Spain, 3Institut d'Investigació Biomèdica de Bellvitge, Health Group, Neuroscience Program, Perioperative Physiopathology and Pain, Hospitalet de Llobregat, Spain

Background and Goal of Study: The inappropriate transfusion of blood components is a frequent risky practice with real consequences for the patient and the healthcare system. Strategies such as Patient Blood Management (PBM) have proven useful in optimizing blood products and improving the clinical outcome of patients undergoing colorectal cancer surgery. PBM programs focus on improving blood volume, minimizing bleeding and optimizing anaemia tolerance by applying strict transfusion criteria. The aim of this study was to track and update the progressive adherence to a PBM protocol in patients undergoing laparoscopic colorectal cancer surgery at our centre over a period of six years. Materials and Methods: We used data collected at our institution between 2017 and 2022 as part of a multi-centre, observational, and non-interventional study created in order to better optimize the use of blood products (MAPBM project1). A descriptive statistical analysis was used.

Results and Discussion:

		2017	2018	2019	2020	2021	2022
	N	45	74	78	73	101	103
1st	Anaemia treated pre-intervention (%)	5.4	23.5	40.5	50	51.1	52.6
Pillar	Intervention with anaemia (%)	8.6	4.2	3.2	6.5	2.2	2.9
	Transfusion rate (%)	13.3	8.1	10.3	11	6.9	10.7
3rd	Haemoglobin trigger to transfusion (g/dL)	9.1	9.2	8.1	8	7.8	7.6
Pillar	Transfusion with haemoglobin > 8 g/dL (%)	60	80	50	60	50	33.3
	Complications (%)	22.2	17.8	14.1	20.3	10.1	12.6
Outco-	Mortality (%)	2.2	1.3	1.3	0	0	0
mes	Length of stay (days)	9.8	9.5	10.6	7.7	7.3	9.1
	Readmission (%)	13.6	4.2	3.9	8.1	3	8.8

Over the period of the study, the number of anaemic patients receiving preoperative treatment has been increasing in parallel with a decrease in the number of patients undergoing procedures with anaemia. The transfusion trigger has decreased from 9,1 g/dL to 7,6 g/dL, with a decrease in the number of transfusions with haemoglobin over 8 g/dL and a trend towards a reduction in the transfusion rate. A tendency for morbimortality to decline was seen.

Conclusion(s): Despite the improvement in some points, more efforts should be made to improve adherence among all professionals to enhance clinical outcomes. In order to treat preoperative anaemia, intravenous iron was used nearly exclusively. However, the recent addition of erythropoietin stimulants to our PBM protocol may improve results.

Rationalizing blood reserves in elective neurosurgery: learning from observed practice

A. Perdiguero Cosano¹, J. Martínez Cabañero¹, A. Fernández Colorado¹, S. López Galera¹, A. Izquierdo Guerrero¹, M. Serrano Martín¹ ¹Hospital Parc Taulí, Anaesthesia, Resuscitation and Pain Management, Sabadell, Spain

Background and Goal of Study: In neurosurgical patients, preventing and managing anaemia is essential to improve neurological outcomes. Although reserving blood for elective surgeries is a common practice, it can lead to inefficient resource utilisation and increased workload for blood banks. In our centre, we have an established protocol following the fundamentals of Patient Blood Management in order to optimize preoperative anaemia and determine the necessity of blood reservations.

This study examines the correlation between preoperative blood reservations and actual transfusions in elective craniotomies, aiming to identify opportunities for reducing unnecessary blood reservations and optimise resource use.

Materials and Methods: A retrospective observational study was conducted on 136 patients undergoing elective craniotomies for tumour pathology (109 cases) or vascular surgery (28 cases) between October 2021 and July 2024. We excluded non-craniotomy neurosurgeries, craniotomies for other indications and emergency procedures. Data collected included preoperative haemoglobin (Hb) levels, blood reservation requests, intraoperative and early postoperative (24 hours) transfusions, and postoperative Hb levels. The transfusion index (TI) was calculated as the number of units transfused divided by the number of patients with cross-matched blood.

Results and Discussion: Preoperative blood reservations were made for 87 patients (63.97%), with an average Hb of 13.83 g/ dL. Only five patients (3.7%) required transfusions, all intraoperatively, receiving an average of 1.2 units each. These transfusions occurred exclusively during tumour surgeries, with 80% involving benign tumours; all had preoperative blood reservations.

The TI was 0.069. According to available literature, an ideal TI is situated at values ≥0.5 to ensure good use of resources.

These results highlight an overestimation of haemorrhagic risk in elective neurosurgery, leading to an excess of blood reservations. This excess has notable economic implications and affirms the need to improve transfusion practices.

Conclusion: A low TI suggests excessive blood reservations relative to current usage, indicating inefficiencies in current practices. Implementing stricter criteria for preoperative blood reservations could enhance resource efficiency and eliminate unnecessary practices in transfusion medicine. These findings will aid in reviewing our blood reservation protocol for elective neurosurgeries.

43AP02-10

Heparin-Induced Thrombocytopenia in patients with circulatory support: literature review and case series

C. Castro Calderón¹, L. Goñi Galindo¹, <u>I. Folch Navarro¹</u>, S. Dreispiel¹, P. Alfaro Navarro¹, F. Hidalgo Martínez¹ ¹Clinica Universidad de Navarra, Anesthesia and Intensive Care, Pamplona, Spain

Background and Goal of Study: Circulatory assist devices expose blood to external surfaces, triggering platelet activation and the coagulation cascade, which increases coagulability. To prevent device failure due to thrombosis, anticoagulation – typically with unfractionated heparin (UFH) – is used. UFH's short half-life allows for monitoring and dose adjustment, but it can lead to heparin-induced thrombocytopenia (HIT), a rare immune reaction caused by anti-platelet factor 4 antibodies. These complexes cause ischemic events and hemorrhagic complications. Patients with temporary circulatory devices may face increased risk due to prolonged UFH use. This study evaluates the incidence of HIT, risk factors, and clinical outcomes in a cohort treated from 2000 to 2022

Materials and Methods: A single-center study analyzed 68 patients with temporary circulatory support receiving UFH for ≥5 days. HIT diagnosis was based on the 4T score and confirmed using serological tests (anti-PF4-H antibodies) and functional assays (serotonin release) in selected cases. Clinical variables, including demographics, complications, and mortality, were recorded.

Results and Discussion: HIT incidence was 17.65%, higher than the general population's 0.1-5%. Women had a higher incidence (31.25%) than men (13.46%), reflecting immunological gender differences. Average UFH therapy lasted 18.7 days. Complications occurred in 85% of patients: infections (66.2%), bleeding (63.2%), and thrombosis (29.4%).

Overall mortality was 53%, but lower in HIT patients (33%) versus non-HIT patients (57.1%), likely due to alternative anticoagulants like argatroban and bivalirudin. These managed thrombotic complications without increasing bleeding. HIT correlated with thrombosis but not infections or bleeding, emphasizing timely diagnosis and treatment.

The 4T score was effective for screening, with serological tests confirming HIT. Prolonged UFH use increased HIT risk, highlighting the need for alternative anticoagulants in high-risk patients.

Conclusion(s): HIT is a significant complication in patients with temporary circulatory support, especially women. Early diagnosis and alternative anticoagulants are essential to minimize complications and improve outcomes. This study underscores the importance of tailored protocols to balance thrombotic and hemorrhagic risks in this critical population.

43AP02-11

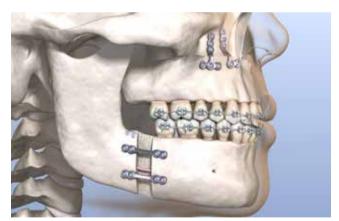

Acute normovolemic hemodilution (ANH) and intraoperative autotransfusion during the orthognathic two-jaw surgery (bimaxillary osteotomy)

N. Serhieieva¹, I. Kuchyn¹, K. Bielka¹
¹Bogomolets National Medical University, Department of Surgery, Anesthesiology and Intensive Care of the Institute of Postgraduate Education, Kyiv, Ukraine

Background: Orthognathic surgery, or two-jaw osteotomy, is a treatment choice for jaw deformities and malocclusion in adults and often differs in complexity and large blood loss. The expected blood loss during orthognathic surgery is 1 to 2 liters, which reasonably increases the risk of hypotension, acute cardiovascular events, acidosis, coagulopathy, and finally, the demand for massive allogenic blood transfusions followed by reactions and infections. Acute normovolemic hemodilution is recognized as an evidence-based method that improves outcomes in liver transplantation and cardiac surgery. The idea to implement ANH in our Center for Orthognathic Surgery was based on a hypothesis that it can also be helpful in the blood-saving strategy.

Case Report: A 20-year-old male, diagnosed with congenital anomaly of both jaws, planned surgery – orthognathic two-jaw surgery. To reduce the risk of blood loss, ANH was used. Hemoglobin, erythrocyte, and hematocrit values are shown in Table. Before the operation, 800.0 whole blood (2 units) was collected from the patient, which was calculated according to the formula and replaced with crystalloid solutions.

Total blood loss during the operation was 1500 ml was recorded. After the main stage of the operation and surgical hemostasis, autohemotransfusion was performed. The volume of blood loss was also replaced with a crystalloid solution. ABP was maintained due to the infusion of norepinephrine with a dose of 0,1 mcg/kg/min.

	Hb	Htc	RBC
Before operation	147	43,8	3,84
Next day	116	34,4	3,78

Discussion: Orthognathic surgery is characterized by acute blood loss, leading to the need for massive allogenic blood transfusion and increased associated risks. ANH allows for reduced whole blood loss during surgery and eliminates the need for blood transfusion. The patient spent 4 days in the surgical department; total blood loss was 1500,0. No transfusion was required, so the patient was discharged without complications.

Learning points: ANH may be considered a blood-saving strategy for patients requiring orthognathic surgery.

43AP02-12

Pulmonary embolism under general anesthesia: A rare complication requiring vigilant monitoring

R. Leite Aguiar¹, C. Bastos Magalhães², F. Santos², A. Agrelo², I. Fonseca² ¹São João University Hospital Center, Anesthesiology, Porto, Portugal, 2IPO Porto, Anesthesiology, Porto, Portugal

Background: Acute pulmonary embolism (PE) is a rare but potentially fatal perioperative complication, with a mortality rate of approximately 25% in massive PE and even higher with cardiac arrest. Severity is linked to the degree of pulmonary artery obstruction, potentially leading to rapid hemodynamic instability.1 Intraoperative detection is especially difficult under general anesthesia, as classic symptoms like dyspnea and pleuritic chest pain are absent.² Early recognition and treatment are crucial for improving outcomes.

Case Report: A 35-year-old female with prior history of protein S deficiency and previous unilateral PE and deep vein thrombosis, for which she was under anticoagulant therapy, underwent left adrenalectomy, ipsilateral radical nephrectomy and inferior vena cava (IVC) thrombectomy, under general anesthesia. During tumor resection, a sudden decrease in end-tidal CO₂ (ETCO₂) combined with oscillation of the plateau phase of capnography and an increase in PaCO_a raised suspicion about PE. No other change in hemodynamics or ventilation was noted. Surgery was completed under stable hemodynamics. The patient underwent emergent chest computer tomography angiography, which showed filling defects in an inferior branch of the left pulmonary artery. The patient was then transferred to the ICU and weaned from the ventilator on the same day. Since there was no evidence of respiratory insufficiency or hemodynamic instability, the initiation of anticoagulation therapy with low-molecular-weight (LMWH) heparin was deferred for 24 hours to mitigate the risk of bleeding.

Discussion: Intraoperative PE, though rare, demands rapid recognition and management to improve survival. Under anesthesia, classic symptoms are absent, making indirect signs key diagnostic tools. Management involves anticoagulation therapy, to mitigate the risk of clot propagation and recurrent thromboembolic events. However, postoperative patients often present a dual challenge of balancing thromboembolic risk with bleeding risk. requiring an engaging multidisciplinary team to optimize timing of anticoagulation therapy.

References:

1. Ann Thorac Cardiovasc Surg 2020;26:65-71;110:1072-1080. 2. J Cardiothorac Vasc Anesth 2020;34:1972-1984

Learning Points: Sudden ETCO2 decrease and an elevation in PaCO2 on blood gas analysis are diagnostic clues to detect potential PE. Successful treatment involves collaborative management.

Tissue perfusion response to fluid challenges using a novel urothelium perfusion monitor targeted perfusion based fluid management in critically ill patients using urethral perfusion (the **TARGET-UP study)**

A. Wong¹, N.L. Roslan², R. McDonald³, K. Bramham⁴, S. Hutchings^{1,5}

¹King's College Hospital, Dept of Critical Care, London, United Kingdom, ²Hospital Kuala Lumpur, Department of Emergency Medicine, Kuala Lumpur, Malaysia, 3King's College London, School of Immunology and Molecular Biology, London, United Kingdom, 4King's College Hospital, Department of Renal Medicine, London, United Kingdom, ⁵Royal Centre of Defence Medicine, Defence Professor Military Anaesthesia and Critical Care, London, United Kingdom

Background and Goal of Study: Traditionally, resuscitation efforts have focused on macrocirculatory targets, such as blood pressure and cardiac output. However, achieving these targets does not always correlate with improved microcirculatory perfusion. The urethral perfusion index (UPi) is a marker of tissue perfusion, offering a novel approach to monitoring. Utilizing photoplethysmographic technology, the UPi is measured through a specialized device integrated into a Foley catheter.

The aim of this study is to explore the relationship between the macrocirculatory response and tissue blood flow to a fluid challenge (FC).

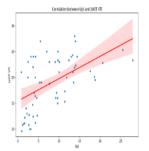

Materials and Methods: This single-center, prospective study was conducted at a tertiary-level hospital. All patients were adult, mechanically ventilated, in which the treatting team had equipoise about fluid responsiveness. LVOT VTi and UPi were measured before and after FC. Patients were considered responders if either LVOT VTi or UPi increased by 10% after FC.

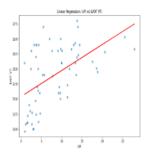

Results and Discussion: Patient demographics are shown in table 1. There was no difference in baseline characteristics between responders and non-responders. The most common phenotype were VTi AND UPi unresponder, followed by VTi unresponder BUT UPi responder (Table 1).

	Total	Unresponsive (n=12)	Responsive (n=15)	P-value
Male	16	5	10	0.094
Ago	57.1 (12.4)	54 (12.7)	55.5 (11)	.352
Baseline MAP	74 (10)	74 (11)	77 (12)	.463
Baseline HR	89 (25)	87 (29)	88 (23)	.303
Baseline UPi	8.2 (7.0)	10.0 (8.3)	7.3 (12.7)	.730
Baseline LVOT VTi	17.9 (4.9)	17.3 (5.1)	18.56 (4.5)	.584

	UPi responder	UPi unresponder
VTi responder	5	6
VTi unresponder	11	14

The relationship between LVOT VTi and UPi are shown in fig 1 with a coefficient index of 0.552 (p<0.001) and a R2 value of 0.272.

There was a trend towards lower UPi in patients who were dead at 28- and 90-days.

Conclusion(s): There is weak correlation between LVOT VTi and UPi but a heterogeneous response was seen in UPi and LVOT VTi response to fluid. This may be reflective of incoherence between circulatory beds or an issue with the way the UPi signal is calculated. Further research is required to further investigate this monitoring modality.

Distinctive features of rotational thromboelastometry in infective endocarditis: a retrospective propensity score-matched observational study

S. Vander Zwaag¹, I. Kukel¹, K. Towarek-Nocon², J. Fassl¹¹Heart Centre Dresden, Institute of Cardiac Anaesthesiology, Dresden, Germany, ²Hospital Radebeul, Department of Anaesthesiology and Intensive Care, Radebeul, Germany

Background: The hemostatic system is involved in the formation of valvular vegetations and in the systemic activation of coagulation, which can lead to both thrombosis and consumption coagulopathy. Consequently, patients with infective endocarditis undergoing valvular surgery present a set of specific challenges to cardiac anaesthesiologists. Rotational thromboelastometry (ROTEM) is a point-of-care viscoelastic clotting test that may assist in understanding the patient's coagulation status and in the tailoring of therapy.

In the present retrospective propensity score-matched study, we examine the distinctive features of ROTEM in patients with endocarditis in comparison to the general population undergoing cardiac surgery.

Materials and Methods: A retrospective analysis was conducted on the database of patients who underwent valvular procedures between 31st May 2022 and 31st August 2024. We aimed to identify patients in whom ROTEM was conducted once during the extracorporeal circulation and once after heparin reversal. The study group comprised patients with endocarditis, while the control group was created by propensity-score matching of patients without endocarditis.

The primary outcome of this study is the result of the on-pump ROTEM examination.

Secondary outcomes include the differences between the utilisation of prothrombin complex concentrate (PCC), fibrinogen concentrate (FC), fresh frozen plasma (FFP) and platelets.

Results and Discussion: 23 patients were analysed in each group. Our findings indicate that patients with endocarditis exhibit prolonged clotting times in EXTEM (156 vs 117 s, p=0.001) and augmented clot firmness in FIBTEM (19 vs 15 mm, p=0.012) and in EXTEM (48 vs 43 mm, p=0.045) when compared to similar patients without endocarditis. To restore optimal coagulation in this cohort, more PCC (3391 vs 2652 units, p=0.014) and FFP (7 vs 5 units, p=0.038) need to be administered. The number of transfused units of platelets (p=0.089) and amount of FC (p=0.109) did not differ significantly.

Conclusions: Patients with infective endocarditis exhibit distinctive viscoelastic profiles, characterised by prolonged clotting time and elevated maximum clot firmness. They require more FFP transfusions and PCC supplementation.

Further research is necessary to establish the optimal target values in ROTEM tests, with the aim of minimising bleeding risk while avoiding an increase in thrombotic risk.

Dose-response relationship of clotting time in the EXTEM rotational thromboelastometry assay after administration of prothrombin complex concentrate - a retrospective observational study

S. Vander Zwaag¹, K. Towarek-Nocon², I. Kukel¹, J. Fassl¹ ¹Heart Centre Dresden, Institute of Cardiac Anaesthesiology, Dresden, Germany, ²Hospital Radebeul, Department of Anaesthesiology and Intensive Care, Radebeul, Germany

Background: Coagulopathy after cardiac surgery results in increased morbidity and mortality. Four-factor prothrombin complex concentrate (PCC) allows rapid replacement of coagulation factors with a safety profile comparable to that of standard care. Although rotational thromboelastometry (ROTEM) is often used to guide PCC dosing, the dose-response relationship of clotting time (CT) in ROTEM and the dose of PCC has not been investigated.

This may lead to under- or over-dosing of PCC and failure to achieve the desired CT target in the EXTEM assay. In this study, we aimed to investigate this relationship in patients undergoing cardiac surgery.

Materials and Methods: We retrospectively analysed the patients who underwent cardiac surgery between May 2022 and August 2024. We included patients who underwent ROTEM during cardiopulmonary bypass (CPB), who received PCC after heparin reversal, and who subsequently underwent repeat ROTEM. Patients who received fresh frozen plasma between the two tests were excluded from the analysis. Logistic regression analyses were used to determine the relationship between change in clotting time, dose of PCC and initial CT.

Furthermore, we compared doses per total, ideal (IBW), and lean body weight to investigate which allows for the best predictions of the change in clotting time (Δ CT).

Results and Discussion: Data from 178 patients were analysed. The initial CT in EXTEM (EXT1-CT) was 104 (IQR 92-135) s, the median PCC dose was 3000 (IQR 2500-4000) units and the CT in the second EXTEM was 77 (IQR 70-88) s. The EXT1-CT

(p<0.001) but not the PCC dose per kg (p=0.648) was a significant predictor of Δ CT. The overall regression model was significant: R2=0.595, f(0.177)=128, p<0.001. The equation of the line of best fit was: $\Delta CT = 52 + 0.244 \cdot EXT1-CT [s]$.

Our data questions the existence of a strong dose-response relationship between the weight-based dose of PCC and Δ CT. The magnitude of the response primarily depends on the initial CT, with greater change per unit per kilogram in patients with severely prolonged EXT1-CT and weak responses with an EXT1-CT close to normal. Only a weak correlation exists between PCC dose per kg IBW and Δ CT (Pearson's r=0.365, p<0.001).

Conclusions: The initial clotting time in EXTEM is the strongest predictor of Δ CT. PCC dose per kg body weight does not significantly predict the response. Further research is needed to determine the efficacy and safety of different CT targets in cardiac patients.

Comparing liberal and restrictive blood transfusion strategies in moderate to severe acute brain injury: a systematic review and metaanalysis

C.Y. Liao1, Y.-H. Tai1,2, J.-T. Chen1,2 ¹Shuang Ho Hospital, Taipei Medical University, Department of Anesthesiology, New Taipei City, Taiwan, ²School of Medicine, College of Medicine, Taipei Medical University, Department of Anesthesiology, Taipei City, Taiwan

Background and Goal of Study: Maintaining adequate hemoglobin levels is crucial for delivering oxygen to the brain and may influence the neurological prognosis of patients with acute brain injuries. However, the precise hemoglobin threshold for initiating blood transfusions in these patients has not been definitively established.

Materials and Methods: We conducted a systematic review and meta-analysis to evaluate the clinical impact of liberal (transfusion threshold by hemoglobin <9 g/dL or <10 g/dL) versus restrictive (transfusion threshold by hemoglobin <7 g/dL) red blood cell transfusion strategies in adult patients with moderate to severe acute brain injury. Our search included PubMed, the Cochrane Central Register of Controlled Trials (CENTRAL), and Embase to identify relevant randomized controlled trials from inception to October 15, 2024.

The primary outcome was the occurrence of unfavorable neurological outcomes at six months. Secondary outcome was allcause mortality.

Results and Discussion: A total of four studies met the inclusion criteria for the meta-analysis. The liberal blood transfusion strategy was associated with a lower likelihood of unfavorable neurologic outcomes at 6 months than liberal blood transfusion strategy (odds ratio: 0.77, 95% CI: 0.63 to 0.94, p=0.009). However, there was no statistically significant difference in the six-month mortality rate between the two groups (odds ratio: 0.94, 95% CI: 0.76 to 1.18, p=0.61).

Conclusion(s): A liberal blood transfusion strategy may improve neurological outcomes in patients with acute brain injury. However, the moderate heterogeneity observed in previous studies indicates that further research is needed to clarify the optimal transfusion strategies for this population.

Periarticular vasoconstrictor infiltration (PVI) technique for lumbar arthrodesis

I. Carreras Auger¹, M. Martínez García¹,

A. Fuentes Gutiérrez¹, A. Sáenz Cerna¹, F. Espin Rearte¹, C. Manzano Martin¹

¹Consorci Sanitari de Terrassa, Anaesthesia, Terrassa, Spain

Background and Goal of Study: Significant blood loss is a welldocumented complication in major orthopedic procedures, like lumbar arthrodesis. Tranexamic, although effective as a prophylactic agent, has contraindications that limit its use. Building upon WALANT technique, periarticular vasoconstrictor infiltration (PVI) offers an alternative. This pilot study aims to evaluate PVI as a potential strategy for reducing perioperative bleeding in these procedures.

Materials and Methods: Ten patients undergoing lumbar arthrodesis received this treatment. Three patients were excluded from receiving tranexamic acid due to contraindications. Under general anesthesia, patients were positioned prone and underwent ultrasound-guided periarticular adrenaline infiltration. The adrenaline solution was diluted to a concentration of 1:400,000 for non-cardiopathic patients and 1:1,000,000 for those with cardiac conditions. A total of 30 ml was injected at each level, infiltrating the thoracolumbar fascia, the retrolaminar space, and the supraspinous ligament. Intraoperative bleeding was assessed by recording the volume of aspirated blood and the subjective evaluation of the trauma surgeons.

Results and Discussion: The procedure was carried without complications in all cases, without any hemodynamic disturbances attributable to the infiltration of adrenaline. Trauma surgeons' subjective assessments were positive, observing reduced intraoperative bleeding compared to patients who received either tranexamic acid or no prophylactic treatment.

Conclusion(s): The data obtained, although limited, suggest that PVI could be a valuable tool to decrease intraoperative bleeding in arthrodesis procedures, without producing adverse effects. However, larger studies are warranted to confirm these findings.

Perioperative ROTEM-guided management of haemorrhage and anticoagulation in pancreatic cancer with portal vein thrombosis: a case report

N.L. Pacheco Comino¹, M. Barquero López¹, N. Gómez López¹, E. Moret Ruiz¹, A. Martí Acebedo¹, I.D. Jahnke López¹

¹University Hospital Germans Trias i Pujol, Anaesthesiology, Perioperative ICU, and Pain Management Department, Badalona, Spain

Background: Portal vein thrombosis, particularly when accompanied by portal hypertension due to thrombotic occlusion of the portal vein(PVT), presents therapeutic challenges for the anaesthesiologist. Oncologic patients are at heightened risk for both thromboembolic events and bleeding, complicating perioperative anticoagulation management. ROTEM offers dynamic assessment of coagulation, guiding bleeding treatment as well as personalized anticoagulation(1)(2).

Case report: A 37-year-old woman with pancreatic adenocarcinoma and portal hypertension secondary to PVT underwent mechanical thrombectomy and transjugular intrahepatic portosystemic shunt(TIPS) placement.

Post-procedural complications included severe hemoperitoneum due to splenic artery injury, leading to hypovolemic shock. The patient developed coagulopathy due to transient hepatic injury. ROTEM was employed to guide haemorrhagic shock's treatment and anticoagulation reintroduction, balancing bleeding and thrombosis risk. The patient's condition was successfully stabilized, illustrating ROTEM's value in this case.

Discussion: Although ROTEM is not validated for guiding anticoagulation therapy, this case underscores its potential utility in similar clinical scenarios (1)(2)(3). ROTEM provides a comprehensive, real-time assessment of coagulation, offering advantages over traditional tests. Cancer patients often face both thrombotic and haemorrhagic complications, and ROTEM's ability to tailor anticoagulation therapy helps optimize treatment and improve outcomes (1)(3).

The use of interventional radiology and ROTEM-guided treatment demonstrates the importance of a personalized, multidisciplinary approach in managing complex coagulopathy and vascular conditions (1)(2).

Learning points:

- TIPS effectively decompresses portal hypertension but requires close monitoring for bleeding, ischemic complications and coagu-
- ROTEM-guided anticoagulation ensures precise control over haemostasis improving patient outcomes.
- Perioperative ROTEM management of every anaesthesiologist should be mandatory.

43AP03-7

Acute pulmonary edema in hysteroscopy intravascular absorption syndrome

F. Ramos¹, J. Lin¹, N. Pinto¹, P. Paredes¹ ¹Unidade Local de Saúde Lisboa Ocidental, Anestesiologia, Lisbon, Portugal

Background: Intravascular absorption syndrome in hysteroscopy is a rare condition caused by intravascular absorption of uterine distending fluid¹. This fluid overload may lead to life-threatening complications, in which acute pulmonary edema is an example^{1,2}. We present the case of a woman who developed pulmonary edema during hysteroscopic surgery.

Case Report: A 61-year-old woman with a history of uterine polyps was proposed to ambulatory hysteroscopic surgery. She had hypertension, depressive disorder and Crohn's disease and was medically controlled. Pre-operative assessment, including routine investigations were normal. The procedure was performed under total intravenous anesthesia with propofol. Normal saline (0.9%) fluid was used during the hysteroscopy. During the procedure, an increase in blood pressure to 213/142 mmHg was observed and oxygen saturation decreased to 85%.

After checking possible causes, a deficit of approximately 2000 mL of irrigation fluids was found and bilateral inspiratory crackles with decreased breath sounds were noted during auscultation. Acute pulmonary edema was suspected. Surgery was stopped and a set of measures were taken: oxygen was increased to 100%, secretions were suctioned and isosorbide dinitrate plus furosemide were administered. Workup showed pulmonary edema on chest radiograph and mild metabolic acidosis (without hvponatremia) in blood gas analysis.

The patient responded well to these measures and was hospitalised for 2 days for further ventilatory and hemodynamic improve-

Discussion: This case reports an acute pulmonary edema in hysteroscopic surgery caused by excessive absorption of fluid. We aim to increase awareness to this condition and highlight the importance of rigorous monitoring of the fluid balance. Normal saline fluids decreases the development of hyponatremia and neurological symptoms.

- 2. Elegante MF. et al. Operative Hysteroscopy intravascular absorption syndrome causing hyponatremia with associated cerebral and pulmonary edema. Clin Pract Cases Emerg Med. 2019 Jun 4;3(3):252-255.

Learning Points: Close monitoring of the fluid balance together with early recognition of clinical changes during hysteroscopy surgery are essential to prevent complications.

43AP03-8

Transfusion and mortality within 24 hours after major trauma in patients with direct-acting oral anticoagulants

J.H. Wersäll¹, E. Ekdahl^{2,1}, H. Hedelin³, P. Larsson¹, A. Vidlund¹, D. Högberg⁴

¹Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Anesthesiology and Intensive Care Medicine, Gothenburg, Sweden, 2Södra Älvsborg's Hospital, Department of Anesthesiology, Borås, Sweden, ³Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Orthopedics, Gothenburg, Sweden, ⁴Institute of Clinical Sciences, Sahlgrenska Academy, University of Gothenburg, Emergency and Trauma Surgery, Gothenburg, Sweden

Background and Goal of Study: Major trauma in patients treated with direct oral anticoagulants (DOACs) is an increasing event. DOACs have gradually replaced warfarin due to favorable efficacy and safety profiles. However, treatment with anticoagulants may be a complicating factor in trauma due to the increased risk of bleeding. Drug-specific reversing agents are available for DOACs, but evidence is lacking regarding their benefits on mortality and morbidity in trauma.

Only one such agent (idarucizumab for dabigatran) is used in Sweden, while administration of andexanet alfa (for reversal of apixaban, edoxaban and rivaroxaban) is not endorsed by national recommendations since proof of benefit has not been presented compared to administration of prothrombin complex concentrate.

The aims were to analyze if patients treated with DOACs presenting with major trauma were more likely to receive blood transfusions, and if they had a higher mortality rate within the first 24 hours after hospital admission, compared to patients with no anticoagulant medication.

Materials and Methods: This was a single-center, retrospective study. Inclusion criteria were age ≥ 18 years and a New Injury Severity Score of > 15. The Swedish trauma register (Swetrau) and medical records were used to identify patients and to retrieve data on treatment with DOAC.

Cases were matched to controls for sex, age, injury mechanism, and for pre-injury physical status according to the classification system of the American Society for Anesthesiology (ASA).

Controls were selected using an exact matching procedure with replacement. Conditional logistic regression was used to analyze dichotomous outcomes.

Results and Discussion: A total of 653 patients admitted to the Sahlgrenska University Hospital in Gothenburg, Sweden between the years 2020-2023 were surveyed. Of these, 47 patients had DOAC.

Mortality within 24 hours was observed in 6/47 (13%) patients in the DOAC group compared to 17/222 (8%) in the matched non-DOAC group, OR 1.69 (95% CI 0.62 to 4.58). Erythrocytes transfusion was required in 18 (38%) patients among the cases compared to 49/222 (22%) in the matched control group, OR 2.11 (95% CI 1.07 to 4.17).

Conclusion(s): Patients with major trauma during treatment with DOACs were more likely to receive erythrocyte transfusions during the first 24 hours after hospital admission compared to patients without anticoagulant treatment, while 24-hour mortality was not higher among patients with DOACs.

43AP03-10

Evaluation of anticoagulation in patients undergoing ECMO-assisted bilateral lung transplantation and its impact on perioperative bleeding and thrombotic complications: a single-center, retrospective study

C. Valenza¹, M. Vander Kuylen², Y. Sokolow², T. Tuna¹, C. Boudart1

¹Erasme Hospital, Anesthesiology, Brussels, Belgium, ²Erasme Hospital, Thoracic Surgery, Brussels, Belgium

Background and Goal of Study: Lung transplantation often requires intraoperative support with extracorporeal membrane oxygenation (ECMO), which exposes patients to risks of bleeding and thrombotic complications.

However, no consensus currently exists regarding the optimal anticoagulation strategy during ECMO. This retrospective study describes anticoagulation strategies during ECMO initiation in bilateral lung transplantation and evaluates their impact on associated perioperative bleeding and thrombotic events.

Materials and Methods: We focused on bilateral lung transplantations performed at Erasme Hospital between 2014 and 2023. Patients were classified into two groups according to whether ECMO was used or not, and whether anticoagulation was administered or not.

Primary and secondary outcomes of interest included the incidence of bleeding and thrombosis (of the ECMO circuit and occurring in patients) respectively, during intraoperative period and postoperative period.

The Chi-square test was used for the categorical variables and the independent t-test was used for the continuous variables. A p-value < 0.05 was considered statistically significant. Analyses were performed with IBM SPSS Statistics.

Results and Discussion: Among 134 lung transplant patients over a 10-year period, 18% required perioperative ECMO. Of those who received ECMO, 40% were anticoagulated with unfractionated heparin (UFH).

The rate of intraoperative thrombosis was not associated with the presence of ECMO (p > 0.05) and was not prevented by the administration of UFH (p > 0.05).

The rates of transfusions of red blood cell (RBC) and fresh frozen plasma (FFP) during the intraoperative period were higher when ECMO was implemented (p < 0.05) and were not influenced by the administration of UFH (p > 0.05).

Postoperative thrombotic and hemorrhagic complications were influenced by the presence of ECMO (p < 0.05) but were not influenced by perioperative anticoagulation (p > 0.05).

Conclusion(s): In this observational study, ECMO was associated with more hemorrhagic and thrombotic complications. Contact between blood and the foreign surfaces of the ECMO activates the coagulation cascade, leading to important hemostatic changes. The administration of UFH during the procedure did not prevent perioperative thrombotic complications from happening, nor did it increase perioperative transfusion requirements or the number of postoperative hemorrhages. This study could encourage a meta-analysis to confirm first the safety of withholding anticoagulation in ECMO patients.

43AP03-11 IRON-FIT: Investigating Recovery Outcomes in Neck of Femur fracture surgery following IV Iron Therapy (IVIT)

L. Rutter¹, T. Schulz¹, P. White², K. Walsh³, E. Cairns¹, Patient Blood Management Group ¹North Bristol NHS Trust, Anaesthetics, Bristol, United Kingdom, ²UWE Bristol, Professor of Applied Statistics, Bristol, United Kingdom, ³North Bristol NHS Trust, Orthogeriatrics, Bristol, United Kingdom

Background: Post-operative anaemia affects 87% of patients after hip fracture, increasing transfusion rates, perioperative morbidity and mortality1. Effective patient blood management (PBM) to minimise blood transfusion and improve outcome are required. One strategy is the use of intravenous iron, although its effectiveness in emergency surgery, especially in hip fracture patients remains unclear¹. We wished to evaluate the impact of implementing an IVIT protocol on patient outcomes after hip fracture surgery. Methods: Primary outcomes were haemoglobin (Hb) change and transfusion rates and secondary outcomes; the impact on recovery - length of stay (LOS), change in mobility and residential status. Data was retrospectively collected from the National Hip Fracture and PBM audit databases. Patients receiving inpatient IVIT formed the case group, with a control group matched for demographics (age, gender, ASA, admission residential status and AMT). Outcomes were compared and statistically analysed between the two groups using independent samples t-test.

Results: The groups (64 patients in each) had statistically similar demographics. The IVIT group had lower starting Hb (111 vs 123, p=0.001) compared to controls (Fig 1).

However, by discharge there was no significant Hb difference between the two groups (101 vs 103), with a smaller Hb drop in the IVIT group. The IVIT group received more transfusion (0.85 units/person vs 0.5). After excluding transfusion recipients (35 in case

group, 18 in control), the IVIT group still had a smaller Hb drop. There were no significant difference in LOS or post-operatively mobility, but 12% more IVIT patients returned to their own home on discharge.

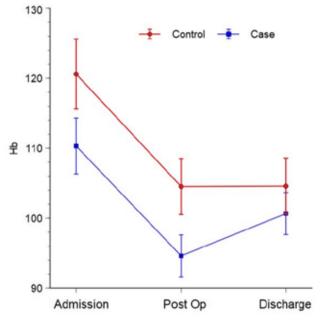

Figure 1: Change in Hb

Conclusion: Results suggest IVIT may benefit recovery and anaemia after hip fracture. Hb drop was lower, including in those not transfused, and despite more initial anaemia the IVIT group showed similar recovery, and more patients returned home. Larger RCTs are needed in this patient cohort.

43AP04-1 Metabolic effects of intravenous iron therapy following blood loss

R. Szabo¹², M. Baican¹, B.-M. Farcas¹
¹″Iuliu Hatieganu" University of Medicine and Pharmacy
Cluj Napoca, Department of Anaesthesia and Intensive
Care, Cluj-Napoca, Romania, ²Emergency Clinical County
Hospital Cluj, Department of Anaesthesia and Intensive
Care, Cluj-Napoca, Romania

Background and Goal of Study: Anemia following major surgery is a complex, multifactorial condition that often presents as iron-deficiency anemia and inflammation-induced anemia, caused by the surgical insult. Variable results from studies on intravenous iron administration after surgery highlight the need for a deeper understanding of the underlying processes.

Perioperative anemia arises from pre-existing chronic anemia, intraoperative blood loss and postoperative inflammation. Intravenous iron administration is a key strategy in minimizing the need for perioperative blood transfusions.

The objective of this study is to assess, on an experimental model, the impact of iron administration after blood loss. **Materials and Methods:** This experimental study involved 35 Wister rats divided into four groups: iron deficiency anemia (n=10), inflammatory anemia induced by administration of intraperitoneal lipopolysaccharide (n=10), combined iron deficiency and inflammatory anemia (n=10) and control group (n=5).

Each group (except control) was split into untreated (n=5) and treated (n=5) subgroups, with the treated subgroup receiving 10mg/kg of ferric carboxymaltose.

Liver tissue was used to determine markers of inflammation and oxidative stress such as malondialdehyde, catalase, IL-6, hepcidin and ferritin.

Results and Discussion: This experimental model was designed to mimic blood loss as well as inflammation following surgery such as cardio-vascular or major abdominal surgery. The combined anemia group showed the highest oxidative stress, though all groups experienced elevated stress. Ferritin levels increased with iron treatment, while IL-6 and hepcidin were highest in iron-deficient and combined anemia groups, suggesting blood loss itself induces inflammation.

Previous studies on postoperative iron therapy have generated conflicting results. This model highlights that hemorrhage can trigger inflammation and secondary anemia, despite general belief that blood loss primarily leads to iron-deficiency anemia.

Our results indicate that further research with better patient stratification is needed to understand the physiopathology of anemia in different surgical contexts. Until then, preoperative assessment and treatment of iron deficiency is the recommended practice.

Conclusion(s): This study explores the intricate responses related to blood loss and inflammation as well as to iron therapy in the context of iron-deficiency, inflammation-induced and combined anemia.

43AP04-2

The causal effect of plasma solution administration on intraoperative hypotension: an illustration of causal inference methods for analyzing time-dependent perioperative treatments

M. Huber¹, P. Wüthrich¹

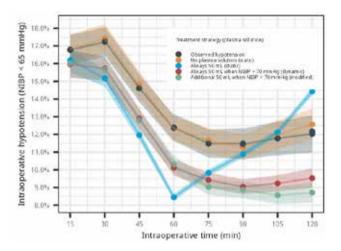

Inselspital, Bern University Hospital, University of Bern, Department of Anaesthesiology and Pain Medicine, Bern, Switzerland

Background and Study Goals: Intraoperative fluid administration remains a crucial component of anaesthetic care. Despite decades of clinical practice and evidence from clinical trials, optimal fluid treatment strategies are still unknown and warrant further investigation. Using modern causal inference methods, we examine the causal effect of plasma solution administration on intraoperative hypotension for the first time in observational data.

Material and Methods: We used perioperative data (N=10'000) of the publicly available INSPIRE dataset (South Korea, period 2011-2020, doi.org/10.1038/s41597-024-03517-4). Primary outcome was intraoperative hypotension (non-invasive blood pressure (NIBP) < 65 mmHg).

We examined the following treatment strategies (15-min intervals): no plasma solution administration, always 50 mL plasma solution, 50 mL plasma solution only when NIBP dropped < 70 mmHg and an additional (compared to the observed administra-

tion) 50 mL plasma solution when NIBP dropped < 70 mmHg. These strategies model the outcome and treatment assignment and adjust for time-dependent confounders and treatment-confounder feedback.

Results and Discussion: Figure 1 highlights the causal effect of plasma solution administration in reducing hypotension. The beneficial effect increases over time: For example, administrating always 50 mL of plasma solution when NIBP drops < 70 mmHg reduced intraoperative hypotension after 1 hour by -1.5% (95-Cl: -1.8% to -1.2%) and after 2 hours by -2.6% (95-Cl: -3.6% to -1.6%). In a counterfactual setting where clinicians had administered additional 50 mL plasma solution when NIBP dropped < 70 mmHg, our analysis suggests that hypotension after 2 hours could have been reduced by -3.5% (95-Cl: -4.2% to -2.7%).

Conclusions: Recent advances in causal inference methods allow to investigate perioperative treatment strategies relevant in daily clinical practice, for example a NIBP threshold of when to initiate fluid administration. Assuming no unmeasured confounding, we demonstrated the causal effect of so-called static, dynamic and modified treatment strategies on intraoperative hypotension in a large cohort undergoing general anaesthesia.

What is the compliance and use of blood products in terms of the maximum surgical blood ordering schedule (MSBOS)?

L. Walsh¹, J. Lynch², M. Fay², S. Barry Fuglsta², D. Buggy¹

¹Mater Misericordiae University Hospital, Anaesthesia, Dublin 7, Ireland, ²Mater Misericordiae University Hospital, Haematology, Dublin 7, Ireland

Background and Goal of Study: Blood products are a scarce, expensive but life-saving resource. It is vital that an adequate number of blood products are available for major surgeries. A maximum surgical blood ordering schedule (MSBOS) aims to avoid wasteful crossmatching of blood products while ensuring a safe amount of blood products remain available. The Misericordiae University Hospital have developed a MSBOS specific to their patient cohort.

Aims of study included:

- · To determine the adherence rate to MSBOS
- To determine the consumption rate of the blood cross matched
- · To determine if MSBOS requires updating

Materials and Methods: Retrospective analysis was carried out from four major surgical specialties across a four-week period. The specialties chosen were cardiothoracic surgery, general surgery, spinal surgery and vascular surgery. All cases that occurred were screened. The data collected included the surgical procedure, the number of red cells cross matched, and the number of red cells used. Basic demographic data and the preoperative haemoglobin were also collected. The number of units cross matched were then compared to the current MSBOS to determine compliance. Compliance was defined as cross matching red cells equal to or less than the maximum allowed for each surgery by the MSBOS.

Results and Discussion: 100% of patients (n=237) were screened. 52% (n=124) had red cells cross matched so were assessed. The compliance rate was 66%. The consumption rate of the red cells ordered was 14%. Of the 124 patients assessed; 41% of these were cardiothoracic patients, 26% were spinal patients, 18% were general patients, 15% were vascular patients.

Speciality	Adherence	Consumption
Cardiothoracic	(n=38) 74%	13% (n= 23)
General	(n= 17) 77%	18% (n= 16)
Spinal	(n= 25) 78%	12% (n= 15)
Vascular	(n=2) 11%	19% (n= 10)

Table.

Conclusion(s): The spinal surgery department has the highest rate of compliance with the MSBOS at 79% (n=25). Both the cardiothoracic (n=38) 74%, and general surgery (n=17) 77% departments compliance rates were also above 70%. The vascular department's compliance rate with the MSBOS was the lowest at 11% (n=2). Indicating that the MSBOS needs updating for the vascular department but is appropriate for the other departments assessed.

Rapid monitoring of new oral anticoagulants: qualitative vs. quantitative methods - are they reliable enough?

I. Mladic Batinica¹, J. Morović¹, N. Kovač¹, S. Margetić², I. Ćelap3, T. Radočaj1

¹UHC Sestre milosrdnice, Department of Anesthesiology, Intensive Care Medicine and Pain Management, Zagreb, Croatia, ²UHC Sestre milosrdnice, Department of Laboratory Hematology and Coagulation, Zagreb, Croatia, 3UHC Sestre milosrdnice, Department of Clinical Chemistry, Zagreb, Croatia

Background: Monitoring the efficacy of Non-Vitamin K Antagonist Oral Anticoagulants (NOAC) remains a significant challenge. particularly when rapid decision is essential. In the era of NOAC it has become necessary to develop diagnostic tool that provides rapid results of significant NOAC blood concentration (20-50 ng/ mL) in the preoperative period.

Materials and Methods: We evaluated effect of NOAC therapy during preoperative period in 14 patients. As quantitative method, laboratory assays for precise levels of drug concentration were used and as qualitative one, two point of care tests (DOASENSE Dipstick and ClotPro) for rapid assess of effects. The DOASENSE Dipstick test detects NOAC concentrations exceeding 20 ng/ mL in blood via urine analysis, whereas ClotPro test determines NOAC concentrations exceeding 50 ng/mL. A statistical analysis was conducted using pairwise Cohen's kappa, all variables were binary. The results were visualized using an agreement Heatmap and an ROC curve.

Results and Discussion: Two qualitative tests DOASENSE Dipstick and ClotPro can be utilized as quick indicators in the assessment of coagulation status, providing results in less than one hour. Our intention was to assess sensitivity of those two tests in intention to implement them in daily clinical practice. The Cohen's kappa value of 0,81 for the DOASENSE indicates a strong level of agreement, suggesting that DOASENSE is good predictor of NOAC blood concentration. On other side, the kappa value of 0,55 for ClotPro indicates a moderate level of agreement, which suggests that while ClotPro may still provide useful information it might not be so reliable as the DOASENSE. Using two logistic regression models, an ROC curve was generated with DOASENSE as the outcome variable and ClotPro and blood concentration as the predictors. The AUROC for blood concentration was determined to be 0.88, while ClotPro yielded an AUROC of 0.71. The results indicate that DOASENSE exhibits a strong correlation with NOAC blood concentration, whereas ClotPro shows a weak or negligible correlation.

Conclusion(s): The assessment of bleeding risk is a crucial aspect of an anesthesiologist's daily practice. In the era of new anticoagulants, although clinical experience remains essential, rapid bedside qualitative tests provide invaluable support. The DOA-SENSE Dipstick is a highly reliable tool for the swift detection of novel anticoagulants, enhancing patient safety and facilitating timely decision-making.

Superiority of four-factor prothrombin complex concentrate vs. frozen plasma for bleeding management in adult cardiac surgery patients with coagulopathy: results from a phase 3, randomised, active-control study

K. Karkouti^{1,2}, J. Callum^{3,4}, C. Solomon⁵, S. Knaub⁵, K. Tanaka⁶, J.H. Levy⁷, FARES-II Study Group ¹University of Toronto, Department of Anesthesia and Pain Management, Toronto, Canada, ²University Health Network, Department of Anesthesia and Pain Management, Kingston. Canada, 3Queen's University, Department of Pathology and Molecular Medicine, Kingston, Canada, 4Kingston Health Sciences Centre, Department of Transfusion Medicine and Hematology, Kingston, Canada, 5Octapharma AG, Department of Clinical Research and Development, Lachen. Switzerland, 6University of Oklahoma Health Sciences Center, Department of Anesthesiology, Oklahoma City, United States, ⁷Duke University School of Medicine, Department of Anesthesiology, Critical Care and Surgery, Durham, United States

Background and Goal of Study: Cardiac surgery involving cardiopulmonary bypass (CPB) is often complicated by coagulopathic bleeding, leading to morbidity and mortality. Guidelines recommend treatment with frozen plasma (FP) or four-factor prothrombin complex concentrate (PCC) in this setting, but large randomised comparisons were lacking. This trial compared the efficacy and safety of PCC (Octaplex/BALFAXAR, Octapharma) with FP in cardiac surgery.

Materials and Methods: LEX-211 (FARES-II; NCT05523297) was conducted at 12 sites in Canada and the U.S. Patients (pts) aged ≥18 years undergoing cardiac surgery with CPB with coagulopathic bleeding, international normalised ratio (INR) ≥1.5, and requiring coagulation factor replacement, were randomised 1:1 to receive PCC (1500 IU if ≤60 kg; 2000 IU if >60 kg) or FP (3 U if ≤60 kg; 4 U if >60 kg). The clinical team was blinded to group allocation until treatment initiation.

The primary endpoint was haemostatic response (effective if no additional haemostatic interventions were administered from 60 min to 24 h after treatment initiation). Key secondary endpoints included the amount of chest tube drainage, change in INR, incidence of severe to massive bleeding using a modification of the universal definition of perioperative bleeding, and safety. The study was funded by the Canadian Institutes of Health Research and Octapharma.

Results and Discussion: LEX-211 included 420 randomized, treated and consented pts (PCC=213; FP=207). Baseline characteristics were comparable between groups; the median (range) age was 66 (20-88) years and 74% of pts were male. Effective haemostasis was achieved in 77.9% of PCC pts vs. 60.4% of FP pts (estimated difference, 17.6%; 95% CI 8.7, 26.4; p<0.0001 for superiority). The mean±SD change in INR from 30 min before to 1 h after treatment initiation was greater for PCC pts vs. FP pts (-0.9±0.8 vs. -0.7±0.9; p=0.0081). Mean±SD cumulative blood loss at 24 h after the start of surgery was lower in PCC pts vs. FP pts (690.9±465.6 mL vs. 922.9±631.9 mL; p<0.0001). Severe to massive bleeding within 24 h after the start of surgery was lower in PCC pts vs. FP pts (17.4% vs. 37.7%; p<0.0001). Thirtyday treatment-emergent thromboembolic events and mortality occurred in 8.5% and 3.3% of PCC pts and 7.2% and 3.9% of FP pts, respectively.

Conclusion(s): Results from the phase 3, randomised, activecontrol LEX-211 study support the use of PCC over FP for bleeding management in cardiac surgery.

43AP04-6

Maximum Surgical Blood Ordering Schedule (MSBOS) in a tertiary public hospital of Greece

A. Theodorou-Kanakari¹, A. Ntavanos¹,

G. Dimitrakopoulos¹, G. Frangedakis¹, A. Katsioulas¹, C. Zolindaki1

¹General Hospital of Nikaia - Piraeus "St. Panteleimon", Anaesthesiology, Athens, Greece

Background and Goal of Study: MSBOS targets at the optimization of blood ordering management. It depends on the type of operation, patient history (age, comorbidities, bleeding profile, medication) and preoperative Hb level. Ordering of blood products is recorded by transfusion indices: C/T (Crossmatched units/ Transfused units), T% (Tranfusion probability= Patients transfused/Patients cross-matched x100%), TI (Tranfusion Index= Units Tranfused/ Patients cross-matched). Appropriate transfusion management is defined as C/T ≤ 2.5, T% >30%, TI≥ 0.5. Aim of this study was to record blood ordering practice in a tertiary Greek public hospital.

Materials and Methods: Audit of blood bank records from January and Seprember 2023 reported 802 surgical cases. Elective (60.8%) and emergency (39.2%) procedures involved general surgery (38.1%), orthopaedics (22.2%), gynaecology (13.2%), urology (9.6%), neurosurgery (9.2%), ENT, thoracic and vascular surgery. Three different values were recorded: Blood units requested by the surgeons, units cross-matched by the blood bank and units transfused intraoperatively. Statistical analysis was performed using SPSS.

Results and Discussion: A total of 629 blood units were requested, 492 were cross-matched and 92 units were administered intraoperatively. Utilizing transfusion indices, the overall ratios' results were: 'C/T REQUESTED' = 6.84 (units surgeons requested to be cross-matched), 'C/T' = 5.35 (units actually cross-matched by blood bank). T% = 15.3% (64 patients transfused /419 patients cross- matched), TI = 0.22 (92 units transfused/ 419 patients cross-matched). In other words, the units requested were 6.84 times higher and the units prepared 5.35 times higher than those actually transfused intraoperatively. Moreover, in almost half of the cases 2 units were requested, only 1 was cross-matched (84/177 cases, 47.5%). No case was postponed because the cross matched blood units were less than requested. Hence, C/T deviation from the desired 2.5 could be interpreted as an increased order of blood units by surgeons, as well as, a high number of cross-matched units-although lesser- by the blood bank.

Conclusion: C/T requested= 6.84, C/T= 5.35 indices are higher than the expected C/T ratio ≤2.5. This is due to lack of MSBOS and a transfusion committee that would ensure compliance to MSBOS in clinical practice. Application of the above could reduce unnecessary hospital expenses and the workload of blood bank personnel.

Delayed epidural catheter removal due to acquired coagulation abnormalities after cytoreductive surgery and hyperthermic intraperitoneal chemotherapy: a case report

C. Queiroz dos Santos¹, M.B.C. Fernandes¹, F.M. Akamine¹, J.C.R. Nascimento¹, F.d.L. Cabral Junior¹, D.S. Marinho¹

¹Fortaleza General Hospital, Anesthesiology, Fortaleza, Brazil

Background: Cytoreductive surgery and hyperthermic intraperitoneal chemotherapy (CRS-HIPEC) are associated with massive fluid shifts, bleeding and surgery-induced activation of hemostasis¹. Pain control and coagulation abnormalities are frequent challenges in the early postoperative period (PO).

Case Report: A 48 years-old, 50 kg, female underwent CRS-HIPEC for mucinous appendiceal neoplasm. A combined epidural-general anesthesia was used, and an epidural catheter was placed at T12-L1 for postoperative patient-controlled analgesia. A minimally invasive cardiac output monitor was installed to guide goal-directed hemodynamic therapy (GDHT). Surgery consisted of peritonectomy of abdominal wall and diaphragm, hepatic lobe capsule resection and ileocolectomy. A pneumothorax aggravated the hemodynamic instability during CRS-HIPEC. GDHT demanded 9 L of Plasma-Lyte®, 3.6 L of 5% human albumin, 1 unit of PRBC's and norepinephrine infusion. Blood loss estimated: 1.7 L. Severe pain during the first two PO days required an infusion of 244 mL of epidural solution (Ropivacaine 0.1% and Fentanyl 4 μg/mL) and 5 on-demand boluses. Epidural catheter was planned to be removed after 48h, but coagulation lab abnormalities (INR: 2.25; aPTT ratio: 2.0; Platelet: 298k/µL) delayed it. Coagulation status spontaneously normalized after 61h and catheter was uneventfully removed.

Discussion: Postoperative thoracic epidural analgesia is strongly recommended in ERAS pathways for CRS-HIPEC procedures². Coagulation abnormalities are a frequent finding after these surgeries and may last up to 10 days¹, posing an issue for catheter removal. Such risk–benefit assessment should integrate usual preoperative planning and must be decided on a case-by-case basis. **References:**

2. Hübner M, Kusamura S, Villeneuve L, et al. Guidelines for Perioperative Care in Cytoreductive Surgery with or without hyperthermic Intraperitoneal chemotherapy: ERAS® Society Recommendations - Part II: Postoperative management and special considerations. Eur J Surg Oncol. 2020;46(12):2311-2323.

Learning points: Risk-benefit assessment of epidural catheters should integrate preoperative planning of surgeries in which early postoperative coagulation abnormalities are expected to occur.

43AP04-8

Prevalence of protein S deficiency in Japanese patients with newly developed deep vein thrombosis after surgery

K. Yamaura¹, T. Nakagawa², M. Higashi¹, K. Shirozu², J. Maki³

¹Kyushu University, Department of Anesthesiology and Critical Care Medicine, Fukuoka, Japan, ²Kyushu University Hospital, Operating Rooms, Fukuoka, Japan, ³Kyushu University Hospital, Intensive Care Unit, Fukuoka, Japan

Background and Goal of Study: Venous thromboembolism (VTE) remains a serious complication that can arise even with the use of standard prophylaxis. The exact cause of this phenomenon remains unclear; however, it may be associated with protein S deficiency in Asia, including Japan (1). In this study, we examined the association between a decrease in the total and specific protein S activity, which is a risk factor for venous thrombosis, and newly developed VTE after surgery.

Materials and Methods: This prospective multicentre observational study was approved by the Ethics Committee (IRB No.22127-02), and registered in the UMIN-CTR Clinical Trial Database (ID: UMIN000051555). From January 2023 to September 2024, we targeted patients who underwent non-cardiac surgery at our hospital and affiliated research facilities and subsequently developed new VTE postoperatively. After obtaining written consent from the patients, the total protein S activity and its specific activity (protein S ratio activity: total activity/Protein S amount) were measured in patients with new VTE.

Results and Discussion: Of approximately 45,000 patients, 15 (0.03%) developed new VTE after surgery. Among these, two patients exhibited reduced total protein S activity and two showed reduced protein S ratio activity, totaling four cases (27%). Thirty-two percent of Japanese patients with VTE have at least one genetic defect. Additionally, mutations in the protein S gene are 5–10 times more frequent in Japanese patients compared with Caucasians. Protein S activity is reported to decline by 2–3% in the general population (1, 2). These findings suggest a significant relationship between decreased protein S activity and the development of VTE in Japanese patients undergoing surgery, despite standard precautions.

Conclusion(s): In Japanese patients with new postoperative VTE, total or specific protein S activity was reduced, suggesting that protein S deficiency may contribute to the development of VTE in this population.

A case of hysteroscopic intravascular absorption (OHIA) syndrome caused by saline in the irrigation fluid during high-risk hysteroscopic myomectomy requiring intensive care management

Y. Hatayama¹, T. Nagai¹, Y. Saito², Y. Kurokawa³, S. Noguchi3, T. Suzuki1 ¹Saitama Medical Center, Saitama Medical University, Obstetric and Anesthesiology, Kawagoe, Japan, 2Kvorin university. School of Medicine. Anesthesiology. Mitaka. Japan, ³Saitama Medical Center, Saitama Medical University, Anesthesiology, Kawagoe, Japan

Background: hysteroscopic myomectomy is a key option for improving fertility and preserving the uterus, with increasing demand. While bipolar devices mitigate risks of hypotonic solutions. the use of isotonic fluids at high perfusion pressures still poses a risk of fluid absorption, potentially leading to severe complications such as isotonic water intoxication. Proper intraoperative monitoring and fluid management are critical.

Case report: A 48-year-old woman underwent hysteroscopic myomectomy under general anesthesia for infertility treatment. During the procedure, she developed hypothermia, reduced SpO2, neck edema, and abdominal distention. Suspecting anaphylaxis or uterine perforation, ultrasound was performed, ruling out rupture. The underlying issue was excessive perfusion fluid absorption due to prolonged use and inadequate recovery. This resulted in systemic edema, pulmonary congestion, hypochromic anemia, and hyperchloric acidosis.

Postoperative treatment involved diuretics, leading to the removal of 6000 mL of fluid. Electrolyte balance was restored, and the patient regained consciousness on the same evening. She was extubated the following day and discharged without complications on postoperative day 4.

Discussion: Operative Hysteroscopic Intravascular Absorption (OHIA) syndrome occurs when perfusion fluid is absorbed into the systemic circulation during hysteroscopy, causing electrolyte imbalances, pulmonary edema, and circulatory disturbances. Bipolar devices using isotonic solutions reduce risks compared to monopolar devices and hypotonic fluids, but complications remain possible.

Anesthesiologists play an important role in the detection and management of OHIA syndrome. Supraglottic devices are commonly used for short procedures such as hysteroscopy, but early intubation should be considered if laryngeal edema or other airway complications are observed. To detect and treat abnormalities early, comprehensive monitoring of the patient's body fluids as well as their general condition during surgery is essential.

- 2. Propst AM, et al. Obstet Gynecol. 2000;96:517-520.
- 3. Gonçalves TN, et al. Eur J Case Rep Intern Med. 2023;10(11):004132.

Learning points: This case shows that comprehensive monitoring and early detection are important for preventing and dealing with complications caused by isotonic fluid during hysteroscopic surgery.

43AP04-10

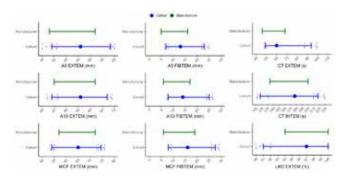

Preoperative reference ranges for ROTEM Sigma in cardiac surgery patients - a single-centre prospective observational study

M. van Haeren^{1,2}, M. Brouwers¹, J. Schenk^{1,3,2}, A.P.J. Vlaar². M.C.A. Müller², H. Hermanns¹, VHALID Study Group ¹Amsterdam University Medical Centres, Department of Anaesthesiology, Amsterdam, Netherlands, ²Amsterdam University Medical Centres, Department of Intensive Care. Amsterdam, Netherlands, 3Amsterdam University Medical Centres, Department of Epidemiology and Data Science, Amsterdam, Netherlands

Background and Goal of Study: Rotational thromboelastometry (ROTEM) is widely used in cardiac surgery. ROTEM reference ranges are now derived from healthy volunteers but may not be interchangeable with those from cardiac surgery patients. Furthermore, sex and age seem to influence ROTEM profiles. This study establishes preoperative ROTEM Sigma reference ranges for adult cardiac surgery patients and examines sex- and agespecific variations.

Materials and Methods: The reference ranges (lower limit = 2.5th percentile, upper limit = 97.5th percentile) in this cohort were compared to the manufacturer's (based on 120 samples from healthy volunteers) by calculating 95% confidence intervals (CIs). If the Cls did not overlap with the manufacturer's limits, the reference ranges were considered statistically different.

Results and Discussion: The study included 381 patients and found notable differences in ROTEM reference ranges compared to the manufacturer's (Figure 1). The upper limits for amplitude parameters in EXTEM and FIBTEM were higher, and clotting time ranges in EXTEM and INTEM were wider. The lower limit of LI60 EXTEM was lower than the manufacturer's value. When comparing medians of ROTEM variables of males (n=260) with females (n=121), females had shorter CT EXTEM (3 s. 95% CI 1 to 5), higher A5 (3 mm, 95% CI 2 to 5), A10 (3 mm, 95% CI 2 to 4) and MCF (3 mm, 95% CI 2 to 4) EXTEM, higher A5 (2 mm, 95% CI 1 to 2), A10 (2 mm, 95% CI 1 to 3) and MCF (2 mm, 95% CI 1 to 3) FIBTEM. However, the bounds of the reference ranges of females were not statistically different to those of males. When comparing four age categories, divided by the quartiles (<58, 58-66, 67-73, >73), no differences in medians or in the reference bounds were found. Conclusion(s): Reference ranges for the total cohort differed from the manufacturer's reference ranges based on results from healthy volunteers. Preoperatively, females exhibited a slightly more hypercoagulable ROTEM profile than males when comparing medians, though the reference ranges were similar to males. No differences were found across age categories. Cardiovascular-specific, but not sex- or age-specific, ROTEM reference ranges might be needed.

A new human fibrinogen concentrate for the management of severe bleeding in patients undergoing major spinal or abdominal surgery: the AdFIrst prospective, randomized study

A. Roy¹, H. Boehm², S. Aigner², S. Abraha², J. Schuettrumpf^{2,3}, N. Rahe-Meyer⁴, AdFIrst Study Group ¹Hampshire Hospitals NHS Foundation Trust, Peritoneal Malignancy Institute Basingstoke, Basingstoke, United Kingdom, ²Biotest AG, Clinical Strategy & Development. Dreieich, Germany, 3Grifols, Scientific Innovation Office, Barcelona, Spain, 4Franziskus Hospital, Clinic for Anesthesiology and Intensive Care Medicine, Bielefeld, Germany

Background and Goal of Study: Fibrinogen levels decrease during excessive bleeding in complex surgeries, requiring a quick replacement to manage bleeding effectively. To achieve it, supplementation with human fibrinogen concentrate (HFC), cryoprecipitate (cryo) or fresh frozen plasma (FFP) is recommended. To determine whether HFC is non-inferior to standard of care (FFP/ cryo) for managing intraoperative bleeding during surgeries.

Materials and Methods: The AdFIrst was a phase 3, prospective, randomized, active-controlled, multicenter, partially blinded, non-inferiority trial conducted at 15 European sites. Patients with severe bleeding undergoing major spinal or abdominal surgery with clinically relevant blood loss were randomized (1:1) for intravenous administration of either HFC (BT524, Biotest) versus FFP or cryoprecipitate. Primary endpoint was intra-operative blood loss from the decision to treat to the end of the surgery, with a non-inferiority margin of 150 mL in reducing blood loss. Secondary endpoints were the percentage of patients that successfully corrected fibrinogen levels and the time to achieve the correction, measured by FIBTEM A10.

Results and Discussion: Baseline fibringen levels were similar between groups. Patients received either HFC (n=107) or FFP/ cryo (n=104). In a sensitivity analysis of the modified full analysis set, least square mean (95% CI) intraoperative blood loss was -1432.58 (1237.20-1627.95) mL, HFC group, and 1607.63 (1409.61-1805.66) mL, FFP/cryo group (p<0.001), indicating noninferiority of HFC vs FFP/cryo and confirming the primary analysis. The mean duration of first infusion and the time to start of first infusion after decision to treat was shorter in the HFC (7.1 and 40.3 min, respectively) vs FFP/cryo group (33.1 and 69.0 min, respectively). After 15 min of infusion, the HFC group had higher fibrinogen levels than FFP/cryo and 59 (55.1%) patients achieved successful correction of fibrinogen levels vs 19 (18.3%) patients in the FFP/cryo group. Overall, a higher proportion of patients successfully corrected fibrinogen levels in the HFC (81.3%) vs FFP/ cryo (44.2%) groups (p<0.001).

Conclusion(s): HFC was efficacious as an early treatment maintaining hemostasis during intra-operative bleeding in patients undergoing major surgeries. In the HFC group, this was achieved through an effective increase and maintenance of fibrinogen levels and a shorter time to fibrinogen level correction compared to standard of care.

Rethinking blood transfusion in critical care: insights from a retrospective observational study

G. Puig Sanz¹, M. Koo^{1,2}, C. Peña², S. López¹, E. Méndez^{1,3}, M.J. Colomina^{1,3,2}

¹Bellvitge University Hospital, Anaesthesiology and Intensive Care, L'Hospitalet de Llobregat, Spain, ²Barcelona University, Schoole of Medicine, Barcelona, Spain, ³Institut d'Investigació Biomèdica de Bellvitge, Health Group, Neuroscience Program, Perioperative Physiopathology and Pain, L'Hospitalet de Llobregat, Spain

Background and Gool of study: Blood transfusion is a widespread practice in critical care units (CCU), but it is associated with higher morbidity, and longer hospital stay. The correct transfusion trigger has been widely discussed in the literature, with experts recommending a hemoglobin (Hb) threshold of 8 g/dL, although other patient factors can introduce variability in transfusion indications. The objective of this study was to determine the transfusion rate, transfusion index, and transfusion trigger in patients admitted to our CCU.

Materials and Methods: Data from patients admitted from January 1 and December 31, 2023 were collected. For the adequation and variability we analysed the haemoglobin just before the first transfusion during the admission. Data analysis was descriptive. The hospital's ethic committee approved the study.

Results and Discussion: 469 patients were admitted to the CCU. The transfusion rate was 31,6% (148 patients). Difference between groups is resumed in Table 1.

	Transfused (n=148)	No transfused (n=321)
Age (yrs)	67(19-88)	53.2 (19-90)
Male	72.3 %	69,16 %
Weight (kg)	75 (45-129)	75(52-170)
Hight (cm)	170 (92-185)	170 (135-185)
BMI	26,84 (17-53)	26.3(19-40)
SAPS3	59.5 (40-79)	40(11-94)
Surgery before admission	47.3 %	40.81 %
Hb<13 g/dL when admission	85.14%	59.19 %
Hb trigger (g/dL)	7.9 (4-11.4)	-
Transfusion index (units)	2 (1-20)	-
Iron treatment	14.86 %	1.87 %
Ingress mortality	11.49 %	2.8 %
Length of stay (days)	23 (1-254)	9 (0-174)

Table 1. Data are presented as median (IQR), or percentage.

Conclusion: Our findings confirm that transfused critical care patients have higher SAPS3 scores, longer hospital stays and the transfusion rate of 31.6%, slightly higher than other larger cohorts (1). The median haemoglobin trigger of 7.9 g/dL adheres to recommended thresholds. However the low rate of iron treatment underscores the need for better anaemia management strategies to further minimize transfusion-related risks and improve patient outcomes. However, the study has limitations due to its retrospective design and the lack of proper electronic medical record documentation.

Evaluation of coagulation factors in patients undergoing pancreatic cancer surgery with curative intent; preliminary results from a prospective observational study

M.P. Ntalouka¹, D. Aretha², A. Bouzia¹, K. Grigoriou¹, P. Kotsi³, E. Arnaoutoglou¹ ¹Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa University Hospital, Anaesthesiology, Larissa, Greece, ²University Hospital of Patras, Department of Anaesthesiology & Intensive Care. Rion, Patras, Greece, 3Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa University Hospital, Transfusion Medicine, Larissa, Greece

Background and Goal of Study: Pancreatic cancer is probably the most thrombotic malignancy, with an incidence of venous thromboembolism (VTE) of up to 18%. Our aim was to assess the perioperative coagulation status of patients undergoing pancreatectomy due to pancreatic cancer.

Materials and Methods: This prospective observational study (NCT05964621) included patients with primary pancreatic cancer (resectable or borderline resectable, NCCN 2.2023) who underwent pancreatectomy under general anaesthesia. Three blood samples were taken (preoperatively, immediately after surgery, and before discharge) and the values of the following parameters were determined: von Willebrand factor (vWF), factors VIII and XI, Adamts-13 and anti-Xa. Perioperative care was provided by the same medical team and low-molecular-weight-heparin was routinely administered in accordance with institutional guidelines. Repeated measurements of coagulation factors were analysed using the Anova Repeated Measures Test (Tukey's multiple comparisons tests). Normally distributed values are expressed as mean (SD), non-normally distributed values as median and interquartile range (IQR).

Results and Discussion: At this preliminary analysis, fifteen consecutive patients with a mean (SD) age of 72 (±5) years were included. The majority of patients (8/15) underwent Whipple procedure, 5 patients total pancreatectomy and only 2 subtotal pancreatectomy, respectively. Eight patients were classified as ASA-PS III and the rest of them as II. The mean (SD) operation time was 247 (±60) minutes. For Adamts-13, there were significant differences between the preoperative, early (p=0.005) and late postoperative values (p=0.0005). Furthermore, for factor VIII, there was a significant difference between the preoperative and early postoperative values (p=0.02). However, perioperatively there were no significant differences for vWF (p=0.10) and factor XI (p=0.34). Due to the small number of patients, no multivariable regression analysis was performed.

Conclusion(s): According to our preliminary results, in patients who underwent pancreatectomy there were significant differences between the preoperative and postoperative values for Adamts-13 and factor VIII, respectively.

The relationship between capillary leak index and coagulation parameters as indicators of endothelial dysfunction in critically ill patients

W. Szpunar¹, M. Cicio¹, T. Składzień¹, J. Szpor¹, T. Drygalski¹, M. Terlecki¹ ¹Jagiellonian University Medical College in Kraków. Interdisciplinary Intensive Care Unit, Kraków, Poland

Background and Goal of Study: An acute inflammatory injury and profound hypoperfusion initiate a cascade of proinflammatory mediators leading to endothelial damage, which is often present in critically ill patients with sepsis, trauma, and after cardiac arrest. Endothelial injury results primarily in capillary leak and may also lead to coagulopathy. The capillary leak index (CLI), calculated as serum C-reactive protein level divided by serum albumin level, has been shown to be an effective predictor of endothelial dysfunction in critically ill patients including those with sepsis, trauma or cardiac arrest. Viscoelastic hemostatic assays (VHA), have proven to be comprehensive tools for detecting coagulopathies and, in some cases, appear to be superior to classic coagulation tests (CCTs). However, the relationship between CLI, CCTs and VHA parameters has not been studied extensively.

The aim of this study was to evaluate the relationship between CLI, CCTs and VHA parameters (measured by ROTEM®) in critically ill patients with sepsis, trauma or after cardiac arrest.

Materials and Methods: We conducted a retrospective, singlecenter observational study including consecutive, adult patients admitted to the ICU in the University Hospital in Krakow. Poland from January 2020 to December 2023 with diagnosis of sepsis. trauma, or cardiac arrest who had measured CLI, CCTs and VHA within the first 72 hours since ICU admission. The associations between the CLI, CCTs and VHA results were analyzed using Spearman's rank-order correlation.

Results and Discussion: This study included 114 patients (76 males [66.67%]) median age, 50.0 years [IQR: 34.00-64.25], median APACHE II score 27.0 [IQR: 22.0-32.0]). Among analyzed CCTs parameters a significant correlation was found between CLI and prothrombin time and fibrinogen (r=-0.441, p<0.001 and r=0.767, p<0.001, respectively). Among VHA parameters, the significant correlations were observed between CLI and MCF FIBTEM, CFT FIBTEM, MCF EXTEM, CFT EXTEM, MCF IN-TEM, CFT INTEM, (r=0.645, p<0.001; r=0.632, p<0.001; r=0.505, p<0.001; r=-0.522, p<0.001; r=0.510, p<0.001, r=-0.487, p<0.001, respectively).

Conclusion(s): There is a pathophysiologic rationale indicating that endothelial dysfunction in critically ill patients is related to coagulopathy and the significant correlations between CLI and both CCTs and VHA confirm it. Thus, the coagulation tests may serve as indirect markers of endothelial dysfunction.

Intraoperative anticoagulation in patients with Heparin-induced Thrombocytopenia type II undergoing vascular surgery

A. Arjona¹, M. Campos¹, N. Guadalupe¹, A. Hostalot-Sanchez¹, E. Ardant¹, S. Sabaté¹ ¹Hospital de la Santa Creu i Sant Pau, Anesthesiology, Barcelona, Spain

Background: HIT is an adverse effect diagnosed in patients exposed to heparin, characterized by thrombocytopenia and thrombosis, it leads to significant morbidity and mortality. Its estimated incidence is around 0.5-1% and poses a challenge in the management of intraoperative anticoagulation.

Case Report: A 59-year-old post-CABG patient presented with acute right lower limb ischemia, rhabdomyolysis, and cardiogenic shock, requiring VA-ECMO implantation and axillofemoral bypass surgery.

On the 5th day of ECMO support, the patient developed progressive thrombocytopenia down to 20,000/µL and tested positive for anti-PF4 antibodies, confirming a diagnosis of HIT type II. After 20 days, with recovered platelet levels and the patient hemodynamically stable off ECMO, surgery was scheduled for the removal of the infected axillofemoral bypass and limb revascularization.

Under general anesthesia, intraoperative anticoagulation was managed with argatroban, starting at 1 mcg/kg/min. After 40 minutes, an activated clotting time (ACT) of 176 ms (aPTT 1.8) was achieved; at 80 minutes, ACT was 180 ms (aPTT 2.24). Anticoagulation was maintained within therapeutic ranges for the 4-hour procedure without need for dose adjustment.

The surgery involved bilateral femoral thromboendarterectomy and endovascular treatment of the iliac arteries. Postoperative anticoagulation with fondaparinux was continued, and no HIT recurrence occurred.

Discussion: In patients with HIT requiring intraoperative anticoagulation, platelet count, anti-PF4 antibodies, and functional platelet testing are recommended. Patients with normal platelet counts and a negative serotonin release assay, regardless of anti-PF4 status, may receive intraoperative heparin.

In all other cases, surgery should be delayed or alternative anticoagulants such as argatroban or bivalirudin should be used, plasmapheresis or heparin + antiplatelet agents might be considered. Based on institutional experience, argatroban was chosen for its short half-life, aPTT-guided monitoring, and hepatic metabolism, achieving stable intraoperative anticoagulation with favorable outcomes.

Reference:

Heparin-Induced Thrombocytopenia and Cardiovascular Surgery. Hematology Am Soc Hematol Educ Program 2021;2021:536-44. Learning Points: Anesthesiologists should be familiar with intraoperative anticoagulation alternatives to heparin, and protocols should be established for managing patients with HIT undergoing vascular and cardiac procedures.

43AP05-4

Use of human fibrinogen replacement therapy for the management of postpartum hemorrhage in a patient with congenital hypofibrinogenemia and prothrombin gene deficiency

I. Jiménez¹, A. Sánchez Cano¹, M. Illán Illán¹, M.D. Lorente¹, J. García Cayuela¹, P. Amate¹ ¹Hospital Universitario Santa Lucía, Anaesthesiology, Cartagena, Spain

Background: Congenital hypofibrinogenemia is a rare coagulation disorder characterized by Clauss fibrinogen levels <150 mg/ dL, which significantly increases the risk of bleeding, especially during childbirth (1). Human fibrinogen replacement therapy is the best option for achieving hemostasis and ensuring successful pregnancy outcomes. (1)

Case Report: A 36-year-old woman with congenital hypofibrinogenemia, prothrombin gene deficiency, and a history of four recurrent miscarriages carried a twin pregnancy to 37+2 weeks. Starting at 14 weeks, fibrinogen replacement therapy was initiated due to low plasma Clauss fibrinogen levels, increasing to 8 g weekly in the third trimester. She underwent an elective cesarean section under spinal anesthesia, which proceeded uneventfully. Two hours post-cesarean, the patient experienced severe postpartum hemorrhage (3,000 mL). Guided by thromboelastogram (TEG) results, management included 5 g of fibrinogen and 2 g of tranexamic acid. In the ICU, fibrinogen was administered every 8 hours for 24 hours to maintain Clauss fibrinogen levels above 150 mg/dL. The patient was safely extubated 36 hours later.

Discussion: Congenital hypofibrinogenemia is a rare yet critical disorder that poses significant anesthetic challenges, particularly in obstetric scenarios such as postpartum hemorrhage. TEGguided fibrinogen replacement therapy enables real-time coagulation monitoring and tailored treatment, imperative for reaching stability in such crucial scenarios. The anesthesia team's vigilant monitoring and management throughout pregnancy were pivotal in ensuring a successful pregnancy outcome.

Reference:

1. Brunclikova M, Simurda T, Zolkova J, Sterankova M, Skornova I, Dobrotova M, et al. Heterogeneity of genotype-phenotype in congenital hypofibrinogenemia-A review of case reports associated with bleeding and thrombosis. J Clin Med [Internet]. 2022;11(4):1083. Disponible en: http://dx.doi.org/10.3390/ jcm11041083

Learning Points: Congenital hypofibrinogenemia is a rare coagulation disorder that requires specialized management and careful monitoring, particularly in the obstetric setting. Clauss fibrinogen replacement therapy, guided by TEG, is essential for managing congenital hypofibrinogenemia and postpartum hemorrhage. Anesthesia plays a crucial role in the successful management of rare coagulation disorders with tailored interventions ensuring hemodynamic stability and optimal outcomes for both the mother and the neonate.

Meningioma excision and defect reconstruction in a Jehovah's Witness - case report

J. Guimaro¹, M. Almeida Santos², I. Rodrigues², L. Ormonde² ¹ULS Arrábida, Anesthesiology Department, Setúbal, Portugal, ²ULS Santa Maria, Anesthesiology Department,

Background: Jehovah's Witness patients pose unique challenges in blood management during surgeries with high hemorrhage risk. due to the refusal of blood products. 1. This case report highlights the successful multidisciplinary management of a meningioma resection and reconstruction, balancing religious beliefs and medical requirements.

Case Report: 37-year-old male Jehovah's Witness, with no significant medical history, presented with meningioma of the right great wing of the sphenoid and ocular extrusion. Due to the potentially high hemorragic risk a multidisciplinary team including anesthesiologists, surgeons and immunohematologists discussed the available options with the patient and his family. Cell saver technology was accepted. The 14-hour procedure involved CENS with meningioma excision, right orbit exenteration and recontruction with Duragen underlay, fascia lata, and frontal and bilateral nasoseptal flap, performed under total intravenous anesthesia. Permissive hipotension was prefered and intraoperative blood loss was approximately 1100 mL, 350 mL of salvaged blood were reinfused. The patient remained hemodynamically stable throughout, with no significant complications. Postoperative recovery was uneventful.

Discussion: This case underscores the importance of tailored surgical and blood management strategies in Jehovah's Witness patients. The cell saver effectively mitigated the risk of severe anemia without violating the patient's religious beliefs. The literature supports the utility of cell saver systems in neurosurgical procedures, which carry high hemorrhagic risks. 2. The case highlights the necessity of multidisciplinary planning and individualized care for complex surgical cases.

References:

- 1. Rashid M, Kromah F, Cooper C. Blood transfusion and alternatives in Jehovah's Witness patients. Curr Opin Anaesthesiol. 2021 Apr 1;34(2):125-130.
- 2. Cataldi S, Bruder N, Dufour H, Lefevre P, Grisoli F, François G. Intraoperative autologous blood transfusion in intracranial surgery. Neurosurgery. 1997 Apr;40(4):765-71; discussion 771-2. doi: 10.1097/00006123-199704000-00021. PMID: 9092850.

Learning points: Comprehensive preoperative planning is crucial for managing potential hemorrhagic complications in neurosurgical procedures. Multidisciplinary planning is essential for managing high-risk surgeries in Jehovah's Witness patients. Cell saver technology allows for effective intraoperative blood conservation while respecting religious beliefs.

43AP05-6 Comparative study of Quantra® with ROTEM **DELTA®** in cardiac surgery

C. Palau Martí¹. M.A. Paiares Moncho¹. J. Fernández Ruiz¹, I. Moreno Puiadollers¹, P. Solís Albamonte², M.P. Argente Navarro¹ ¹Hospital Universitari I Politècnic La Fe, Anaesthesiology, Valencia, Spain, ²Consorcio Hospital General Universitario de Valencia, Anaesthesiology, Valencia, Spain

Background and Goal of Study: Cardiac surgery with extracorporeal circulation (ECC) poses a challenge for hemostatic mechanisms. It is the type of surgery with the highest incidence of postoperative bleeding. In this context, viscoelastic tests (ROTEM DELTA® and QUANTRA®) have proven to be a dynamic, rapid, and precise method for assessing hemostasis. According to the literature, QUANTRA® may provide advantages over ROTEM DELTA®. The main objective of this study is to evaluate the correlation and agreement between the QUANTRA® analyzer and the ROTEM DELTA® system in patients undergoing cardiac surgery with ECC.

Materials and Methods: This is a prospective, multicenter observational study. Sequential recruitment was conducted. A sample size of 25 was estimated for a minimum correlation of 0.7. Patients who did not adequately discontinue anticoagulation and/or antiplatelet therapy were excluded.

Results and Discussion: 30 patients were recruited. Tables 1 and 2 show the results obtained for correlation and coincidence.

Correlations	R	p-valor
СТ НЕРТЕМ / СТН	0,464	0,010
A10 FITBEM / FCS	0,756	< 0,001
A10 EXTEM / CS	0,619	< 0,001

Table 1. Correlations results.

Fibrinógeno < 200	CS < 13	26 (86,7 %)	0,000	0,897	0,000	0,963	0,86
Sangrado	RS (QUANTRA)	14 (45,7 %)	0,867	0,067	0,481	0,333	0,46

Table 2. Coincidence results.

Conclusion(s):

- 1. The measurements from both systems show a significant correlation, at least of a moderate degree.
- 2. The A10 of the EXTEM from the ROTEM DELTA®, followed by the CS of the QUANTRA®, are the best indicators in our sample for predicting low platelet count in the postoperative period.
- 3. The prediction of postoperative bleeding showed low accuracy, with the QUANTRA® device being more sensitive compared to the ROTEM DELTA®.
- 4. New studies are needed to predict clinically significant hemostatic alterations related to postoperative bleeding.

Red cell ordering practices for trauma and orthopaedic patients not requiring transfusions at the Royal Alexandra Hospital, NHS Scotland

K. Ravi¹, R. Fairlie*¹, D. Alcorn¹, T. Watson²
¹Royal Alexandra Hospital, Department of Anaesthesia, Paisley, United Kingdom, ²NHS National Services
Scotland, Better Blood Transfusion, Paisley, United Kingdom

Background and Goal of Study: The Scottish National Blood Transfusion Service have issued 5 notices of unprecedentedly low levels of blood stocks in the last year. The Maximum Surgical Blood Ordering Schedule (MSBOS) is a guideline for ordering blood pre-operatively. The only Trauma and Orthopaedic (T&O) procedure for which MSBOS recommends ordering red blood cells (RBCs) is a revision total hip replacement.

To facilitate targeted awareness-raising of MSBOS recommendations, we assessed the characteristics of patients undergoing T&O procedures at Royal Alexandra Hospital (RAH) who had RBCs crossmatched but no transfusions between August and December 2023.

Materials and Methods: A list of all patients who had RBCs crossmatched in 2023 at RAH was obtained from the RAH Blood Transfusion Laboratory, and filtered to select patients who were under the care of T&O surgeons between August and December 2023. Details of patients' surgeries and crossmatch requests, and the presence of red cell antibodies were noted for each patient on a secure online spreadsheet within the NHS IT system. Analysis of patient and procedure characteristics were conducted using Excel.

Results and Discussion: Between August and December 2023, there were 146 crossmatch events for 82 patients under the care of T&O surgeons at RAH which did not require transfusion of any requested components. Of these events, 18 (12%) involved 1 crossmatched unit, 119 (82%) involved 2 units, 2 (1%) involved 3 units, and 7 (5%) involved 4 units, amounting to a total of 290 RBC units. 22 crossmatch events (15%) did not involve patients with RBC antibodies, which are associated with increased time required for the issue of RBCs. Only 6 crossmatch events (4%) were for temporary patient identification numbers, which dis-

proportionately represent acutely unwell patients who are not normally resident in the area or whose identity cannot be established. 82 (56%) events involved preoperative crossmatches for emergency surgery, and 3 (2%) events for elective surgery. Only 17 events (20% of all preoperative crossmatch events), amounting to 36 RBC units (20% of all RBC units issued preoperatively), were for revision total hip replacements.

Conclusion(s): Adherence to MSBOS may have prevented the preoperative crossmatch of up to 141 RBC units for T&O patients. Raising awareness of MSBOS among clinicians caring for T&O patients has significant potential to conserve blood transfusion resources.

43AP05-8

Cangrelor in the perioperative management of cardiac surgery: A strategy to minimize risks and optimize outcomes

H.R. Hernández Durán¹, A. Moral Bonet¹, C. Palau Martí¹, R. Ferrandis Comes¹, M.A. Pajares Moncho¹, M.P. Argente Navarro¹ ¹Hospital Universitari i Politècnic La Fe, Anaesthesiology and Reanimation, Valencia, Spain

Background: Cangrelor is a reversible P2Y12 receptor inhibitor administered intravenously. It achieves platelet inhibition within two minutes, with effects dissipating one hour after discontinuation. A bolus of 30 mcg/kg is followed by a continuous infusion of 4 mcg/kg/min unless prior anti-P2Y12 therapy has been administered, in which case a dose of 0.75 mcg/kg/min is used after the washout period.

We present a case of acute coronary syndrome requiring percutaneous revascularization followed by coronary surgery. Cardiogenic shock required an intra-aortic balloon pump (IABP), which led to a left femoral artery pseudoaneurysm. Cangrelor was used as bridging therapy until pseudoaneurysm embolization.

Case report: A 67-year-old hypertensive male presented with chest pain and electrocardiographic signs of acute ischemia. Coronary angiography revealed multivessel disease and a stent was placed in the right coronary artery. In the ICU, the patient required vasoactive drugs and an IABP. Tirofiban and oral aspirin were initiated. Seven days later, coronary revascularization surgery was performed. Postoperatively, cangrelor and aspirin were started and after 24 hours a pseudoaneurysm caused by the IABP was treated. Antiplatelet effects of cangrelor were monitored with the VerifyNow system. Figure 1 outlines the timeline of antiplatelet agents.

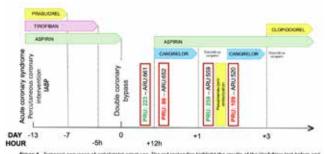

Figure 1. Temporal sequence of arreparent agent use. The red rectanges highlight the results of the verifyhole test before and after the initiation of cangellor, confirming effective platelet inhibition through the P2Y12 Reaction Units (PRU) values.

Discussion: Cangrelor offers immediate and reversible platelet inhibition, providing a safer alternative to oral agents. Its use enabled pseudoaneurysm treatment without compromising antiplatelet management after stenting. VerifyNow confirmed cangrelor's pharmacokinetics and clinical effectiveness.

Learning points:

- · Cangrelor's pharmacokinetics make its use ideal for patients at high risk of bleeding and thrombosis.
- VerifyNow allowed precise monitoring of antiplatelet effects.
- · Oral agents may be less safe than cangrelor in post-stenting cardiac surgery patients.

References:

Connery A, et al. (2024). Antithrombotic stewardship: Evaluation of platelet reactivity-guided cangrelor dosing using the VerifyNow assay. J Cardiovasc Pharmacol, 83(5), 482-489. https://doi.org/10.1097/fjc.000000000001543

43AP05-9

Efficacy and safety of hypertonic sodium lactate in the critical care setting: A systematic review and meta-analysis

V. Duldulao¹, M.G. Sosa², P. Smith³ ¹De La Salle Medical and Health Sciences Institute, Anesthesiology, Dasmarinas, Cavite, Philippines, 2De La Salle Medical and Health Sciences Institute, Department of Clinical Epidemiology, Dasmarinas, Cavite, Philippines, ³The University of Edinburgh, Edinburgh Medical School: Deanery of Clinical Sciences, Edinburgh, United Kingdom

The use of hypertonic solution to improve fluid balance and hemodynamics has been investigated both in animal models and clinical practice and revealed some promising results.

The present research investigated the available evidence to determine the efficacy and safety of hypertonic sodium lactate (HSL) in critically ill patients. After a thorough search conducted on Medline, Pubmed, Embase, and Cochrane Library, from inception until September 30, 2023, five randomized controlled trials (RCTs) were selected, with a total of 405 patients, which compared HSL with other crystalloids in fluid management in this setting. Risk of Bias 2 (RoB2) tool was utilized to assess the risk of bias of each RCT included, while GRADEpro tool was used to evaluate the certainty of the evidence for the outcomes assessed. Mean difference (MD) was used for continuous outcomes, while risk ratio (RR) was used for dichotomous outcomes, both with 95% confidence interval (CI). Random-effects model was used for all analyses.

The findings indicate that HSL likely results in a significant increase in blood pH (MD 0.08, 0.04 - 0.13, 95% CI) and bicarbonate (HCO3-) (MD 9.06, 5.71-12.41 mmol/L, 95% CI). Moreover, HSL causes an increase in serum sodium (Na) (MD 2.99, 0.55-6.53 mmol/L, 95% CI) and a slight decrease in serum chloride (CI) (MD 4.69, 13.53-4.15 mmol/L, 95% CI). In addition, HSL may improve the hemodynamic status while reducing the fluid balance (moderate grade of evidence). These findings imply that HSL can be an alternative fluid therapy for critically ill patients. However, a larger cohort is required to confirm these results.

43AP05-10

Successful perioperative management of a patient with immune-mediated thrombotic thrombocytopenic purpura undergoing complex endovascular aneurysm repair of thoraco-abdominal aneurysm

N. Ntalarizou¹, M.P. Ntalouka¹, A. Michou¹, P. Kotsi², M. Matsagkas³, E. Arnaoutoglou¹ ¹Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa University Hospital. Anaesthesiology, Larissa, Greece, ²Faculty of Medicine. School of Health Sciences, University of Thessaly, Larissa University Hospital, Transfusion Medicine, Mezourlo, Greece, ³Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa University Hospital, Vascular Surgery, Larissa, Greece

Background: Immune-mediated thrombotic thrombocytopenic purpura (iTTP) is a life-threatening syndrome, characterized by thrombotic microangiopathy with peripheral thrombocytopenia, microangiopathic haemolytic anaemia and organ failure of varying severity and reduced activity of Adamts-13. We present the successful perioperative management of a patient with iTTP who underwent complex endovascular aneurysm repair (EVAR) of a 5.2 cm thoraco-abdominal aneurysm (TAAA).

Case Report: A 68-year-old female, with newly diagnosed iTTP, presented for elective complex EVAR of a 5.2 cm TAAA. Preoperatively, according to haematological consultation, the disease went into remission [Adamts-13=65.4%. Haematocrit (Hct)=33%. Platelets (PLTs)= 361 x 109/L] and she was scheduled for complex EVAR with custom made fenestrated graft under general anaesthesia. Apart from basic monitoring, monitoring of invasive arterial blood pressure, of central venous pressure and of the depth of anaesthesia were applied. The surgery lasted for 230 minutes and the patient received 2000 ml of balanced crystalloid and two units of packed red blood cells. The intraoperative course was uneventful and she was extubated in the operating theater. On postoperative day 1 Hct was 32,8% and PLTs were 209.000 x 10°/L, respectively. On postoperative day 3 laboratory data showed a decrease on PLTs (162 x 109/L) and Adamts-13 (44,1%). The patient was discharged on the postoperative day 5, treated with acetylsalicylic acid 100mg o.d. and rivaroxaban 2.5mg b.d.

Discussion: Reduced Adamts-13 activity leads to pathological platelet adhesion and aggregation, diffuse small vessel occlusion, thrombotic episodes, and ischemia. The EVAR per se due to the usage of the guidewires may lead to injury to vessel walls and endothelial damage. Thus, we measured Adamts-13 activity perioperatively to assess the degree of impairment of endothelial function and the possibility of fatal iTTP recurrence. We performed the surgery after haematological consultation and when the disease went into remission (Adamts-13 levels within normal range). Postoperatively we re-evaluated the Adamts-13 levels and the patient was under close surveillance.

Learning points: The perioperative management of patients with iTTP who undergo complex endovascular aneurysm repair proves to be challenging. An appropriate preoperative management, a multidisciplinary approach, Adamts-13 evaluation and close postoperative surveillance are extremely important.

A tale of twos: AMI treated surgically and endovascularly in a patient with double heterozygosity for Factor V Leiden and Factor II mutations - Case report

M. Sirovica¹, M. Kasalo¹, T. Tomić Mahečić¹, D. Karmelić¹, L. Bračun¹, I. Tucić¹

¹UHC Zagreb, Department for Anesthesiology and Intensive care Medicine, Zagreb, Croatia

Background: Acute mesenteric ischemia (AMI) is a life-threatening condition caused by reduced intestinal blood flow. While rare, it has a high surgical mortality rate. Etiologies include mesenteric arterial embolism, arterial thrombosis (caused by atherosclerosis, vasculitis, or hypercoagulable states), and venous thrombosis (1). Case Report: We present the case of a 48-year-old Caucasian male with acute-onset abdominal pain. His medical history included bladder cancer, for which he underwent surgery a year prior. MSCT angiography confirmed AMI, prompting an emergency embolectomy of the superior mesenteric artery. Postoperatively, he was admitted to the ICU. The following day, follow-up MSCT angiography revealed re-thrombosis of the superior mesenteric artery and thrombosis of the celiac trunk. Emergency surgical revascularization was performed. The abdominal wall was left open. Continuous heparin infusion was initiated and adjusted via APTT. On postoperative day two, elevated transaminases prompted successful endovascular intervention with recanalizing the celiac trunk and stent placement. Dual antiplatelet therapy (IV acetylsalicylic acid and eptifibatide) was introduced. Hematologic evaluation identified double heterozygosity for Factor V Leiden (FVL) and prothrombin (FII) mutations. After multiple second-look surgeries, the abdominal wall was closed. The patient transitioned to the general ward and was discharged in good health after 30 days, with acetylsalicylic acid and rivaroxaban prescribed for long-term management.

Discussion: This case underscores two key considerations. First, while exceptionally rare, simultaneous heterozygosity for FVL and FII poses a thrombotic risk comparable to FVL homozygosity. Second, the need for dual antiplatelet therapy following stent placement in the context of an open abdominal wall highlights the challenges of balancing anticoagulation and surgical risks.

References:

1. Bala M, Catena F, Kashuk J, De Simone B, Gomes CA, Weber D, et al. Acute mesenteric ischemia: updated guidelines of the World Society of Emergency Surgery. World J Emerg Surg. 2022 Oct 19:17(1):54.

Learning points: Given the impaired drug absorption associated with AMI, we opted for IV GPIIb/IIIa inhibitors, whose short action duration allows faster platelet recovery for potential future surgeries. As endovascular therapies become more common, cases like this will increase, emphasizing the urgent need for standardized, evidence-based guidelines.

43AP05-12

Effect of body mass index and sex differences on perioperative outcomes in hip surgery

F. Žigman¹, M. Sirovica¹, I. Šitum¹, T. Tomić Mahečić¹, D. Ivanković¹, D. Karmelić¹ ¹UHC Zagreb, Department for Anesthesiology and Intensive care Medicine, Zagreb, Croatia

Background and Goal of Study: Hip fractures impact approximately 4.5 million adults globally, with higher incidence in women and those with lower BMI. This study aimed to evaluate the influence of sex and BMI on perioperative outcomes in hip fracture

Materials and Methods: A retrospective analysis of 626 patients undergoing unilateral hip fracture surgery (January 2020-September 2023) was performed. Patients were grouped by sex and BMI (underweight <18.5 kg/m²; normal 18.5-25.0 kg/m²; overweight 25.1-30.0 kg/m²; obese >30 kg/m²). Data collected included age, ASA scores, comorbidities, anticoagulant use, hemoglobin levels, transfusion requirements, symptoms of anemia, surgery duration, complications, LOS, and mortality. Statistical analysis included Mann-Whitney and χ^2 tests to compare medians and categorical variables.

Results and Discussion: The median patient age was 82 years (IQR 73-87). Women were older, had higher ASA scores (3-4), had a higher incidence of preoperative anemia, and required more transfusions. Men, despite fewer comorbidities, had longer LOS and comparable complication and mortality rates. Underweight patients had lower preoperative hemoglobin and, more often, symptoms of anemia. Obese patients underwent longer surgeries and LOS but no significant differences in complications or mortality. Anticoagulant use was linked to higher complication rates but did not affect mortality.

Conclusion(s): Women were generally sicker with higher anemia and transfusion needs, while men had similar perioperative outcomes despite appearing less ill. Obesity did not increase complications or mortality, aligning with the "obesity paradox," previously noted in various medical conditions.

Hemorrhagic shock and disseminated intravascular coagulation following initial presentation of peritonsillar abscess: a case report

Đ. Čučević¹, M. Kasalo¹, L. Bračun¹, M. Tripković¹, T. Tomić Mahečić¹, I. Balenović¹ ¹UHC Zagreb, Department for Anesthesiology and Intensive care Medicine, Zagreb, Croatia

Background: This case highlights the complexity and rapid progression of DIC and MOF in a previously healthy individual triggered by a seemingly localized infection.

Case Report: A previously healthy 38-year-old male was transferred to our emergency department from another hospital, presenting with hemorrhagic shock.

Initially, he had been admitted for a peritonsillar abscess. On the third day of hospitalization, despite goal-directed therapy, he developed progressive thrombocytopenia and elevated D-dimer levels. By the fifth day, his condition had worsened, with the onset of watery diarrhea, abdominal pain, abdominal wall distension, and rectorrhagia. Despite bleeding, on VEM, he was hypercoagulable. A CT pulmonary angiography revealed a segmental pulmonary embolism, while abdominal CT indicated mesenteric thrombosis with no signs of active contrast extravasation. Disseminated intravascular coagulation (DIC) was suspected. The combination of DIC, clinical signs of abdominal compartment syndrome, and progressive hemodynamic collapse necessitated urgent abdominal surgery. An ileal resection was performed during surgery, and a double-barrel ileostomy was created. Due to the inability to close the abdominal wall, a Bogota bag was placed. On the 1st postoperative day, CVVHD is started due to oliguria and protracted metabolic acidosis. A positive HIT test result on the fifth postoperative day prompted a switch to fondaparinux. However, due to the progression of disseminated intravascular coagulation (DIC) and multiorgan failure (MOF), coupled with worsening visceral perfusion, a subtotal colectomy, jejunal resection, and formation of a unipolar jejunostomy were performed on the seventh postoperative day.

Despite these intensive care interventions, the patient developed refractory hemodynamic instability and was unresponsive to maximal vasoactive support. The patient's condition further deteriorated, marked by absolute vasoplegia, fulminant liver failure, and ARDS, culminating in the patient's death on the eighth postoperative day.

Discussion: Despite aggressive management, including advanced critical care strategies such as plasmapheresis and CV-VHD, the patient's condition deteriorated rapidly, culminating in fulminant MOF and death.

Learning points: This report emphasizes the need for heightened vigilance in managing coagulopathies in critically ill patients and the potential for severe outcomes even with timely interventions.

43AP06-2 A case of treatment of hereditary coagulopathy

D. Shamov^{1,2}, A. Gritsan¹, S. Rostovtsev^{1,2}, A. Popov¹ ¹V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Anaesthesiology and Intensive Care, Krasnoyarsk, Russian Federation, 2N.S.Karpovich Krasnoyarsk Interdistrict Clinical Hospital of Emergency Medical Care, Anaesthesiology and Intensive Care #5, Krasnovarsk, Russian Federation

Background: To describe a clinical case of a patient with a carrier of thrombophilia genes for MTFHR, MTRR, PAI-I d in homozygous form for FGB, ITGA2, ITGB3 in heterozygous form with moderate homocysteinemia.

Case Report: Patient T. 52 years in January 2024, she was admitted with a diagnosis of acute ascending varicothrombophlebitis (ARV) 18 mm from the left mouth, was hospitalized in the vascular department for crossectomy of ARV, the next day due to uterine bleeding on the background of large uterine fibroids of 3-4 types (according to FIGO) adenomyosis, endometrial pathology urgently solving the issue of endovascular hemostasis.

On the background of spinal anesthesia before the start of surgery, cardiac arrest by asystole type, CPR for 7 min with the restoration of an organized rhythm, surgical treatment is postponed until the condition stabilizes.

Parameter	1 day	3 day	6 day
INR	1.4	1.39	1.08
PTI, %	59.6	60.2	88.3
Fibrinogen, g/l	1.52	0.85	3.36
APTT, s	30.1	36.1	30.2
AT III,%	89	71	84
HGB, g/l	76	123	118
RBC	3.11	4.65	3.87
PLT	40	95	136
AST	2827	399	49
ALT	1433	600	201
GCS	3	3	6
SAPS II	53	54	21
SOFA	11	9	2
NRS 2002	3	6	2

Despite the positive dynamics, the patient had moderate serous discharge from the genital tract, while there was an increase in ischemia in the lower extremities in the area of the right foot at the level of the cuboid bone and the toes of the left foot, which, when the demarcation line appeared, required amputation of the right lower extremity at the level of the upper third of the leg and amputation of the toes of the left foot on the 14th day.

Learning points: After discharge (on the 35th day), it was revealed that she was a carrier of thrombophilia genes for MTFHR, MTRR, PAI-I d in homozygous form for FGB, ITGA2, ITGB3 in heterozygous form with moderate homocysteineemia in her and her brother.

The patient was re-hospitalized for endovascular embolization of the uterine arteries. The course of surgical treatment and anesthesia was without complications.

Perioperative coagulopathy management in adults underwent liver transplantation

<u>V. Mutagirov</u>¹, T. Kuandykov¹

¹National Scientific Center of Surgery, Anesthesiology and Intensive Care, Almaty, Kazakhstan

Background and Goal of Study: End-stage liver disease is always associated with severe coagulation disorders. Optimal coagulation management is the greatest challenge in liver transplantation anesthesia. Some pts after liver transplantation still need transfusions for many reasons.

The study aims to specify conditions when fresh frozen plasma (FFP) or cryoprecipitate (cryo) transfusions are used in pts underwent liver transplantation.

Materials and Methods: We studied 226 adult pts who underwent liver transplantation. APPT, PT, INR, FbgA, PLT, thromboelastography (K; R; α angle; MA; LY30), vol of FFP and cryo used perioperatively were studied.

Results and Discussion: 154 (68.1%) of pts had severe coagulopathy and active bleeding during surgery, these pts were transfused FFP, cryo, PLT, and concentrates of coagulation factors. Triggers were significant coagulopathy and bleeding. The mean vol of bleeding was 1312±1345.7 ml (1500-3500).

The trigger for FFP transfusion was blood loss over 1500 ml and coagulopathy with APPT 87.8±35.8 sec; PI 28.5±13.0%; INR 3.17±0.91; R 8.7±3.6 min; K 5.1±2.6 min.

The trigger for cryo transfusion was active bleeding over 1320 ml with a level of FbgA 0.56±0.74 g/l and α angle 44.0±14.2 deg. The trigger for PLT transfusion was active bleeding over 1850 ml with PLT 24.3±12.2×109/mcl and MA 24.6±10.8 mm.

The trigger for concentrates of coagulation factors were bleeding over 4720 ml and coagulopathy with APPT 98.7 \pm 45.2 sec; PI 18.4 \pm 19.8 %; INR 5.69 \pm 3.75; FGA 1.1 \pm 2.7 g/l; R 14.4 \pm 7.9 min; K 12.4 \pm 8.3 min; α angle 25.0 \pm 26.9 deg.

After surgery 12 (5.3%) of pts had severe coagulopathy and 8 (66.6%) of them had active bleeding, all these pts were transfused FFP and/or cryo. The coagulation tests showed APPT 102.5 \pm 57.2 sec, PT 19.6 \pm 10.8%, INR 5.7 \pm 4.2, FGA 0.7 \pm 1.0 g/l, R 9.2 \pm 1.8 min, K 12.1 \pm 4.6 min, α angle 31.5 \pm 13.0 degree, MA 30.9 \pm 8.0 mm, LY30 0.1 \pm 0.3%. The mean vol of FFP postoperatively was 3222.5 \pm 3274.8 (690-8650) ml. Cryo vol was 80 \pm 193.7 (0-600) ml. FFP and cryo transfused the first 72 h after surgery.

Conclusion(s): 68% of pts who underwent liver transplantation require coagulation factors replacement to control bleeding during surgery. 5.3% of pts after liver transplantation had severe coagulopathy and 66.6% of them had active bleeding.

In case of active bleeding and severe coagulopathy (APPT 102 sec, PT 19.6%, INR 5.7, R 9.2 min, K 12.1 min, α angle 31.5 deg.) FFP and/or cryo might be transfused.

43AP06-5

Development of data-driven clinical decision support tool for clinical assessment of ROTEM in cardiac surgery

S. Noteboom^{1,2}, E. Kho¹, D.P. Veelo¹, B.J.P. van der Ster¹, A.P. Vlaar^{2,3}, J. Schenk^{1,4}, VHALID Study Group ¹Amsterdam UMC, University of Amsterdam, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, University of Amsterdam, Intensive Care, Amsterdam, Netherlands, ³Amsterdam UMC, University of Amsterdam, Laboratory of Experimental Intensive Care and Anesthesiology, Amsterdam, Netherlands, ⁴Amsterdam UMC, University of Amsterdam, Department of Epidemiology and Data Science, Amsterdam, Netherlands

Background and Goal of Study: Bleeding complications during cardiac surgery are associated with morbidity and mortality. Point-of-care viscoelastic hemostatic assays, such as rotational thromboelastometry (ROTEM), provide critical insights into patient coagulation status. However, ROTEM interpretation is complex and requires training and experience. This study aimed to develop a prediction model that integrates ROTEM data with patient- and procedure-specific parameters to detect abnormalities and determine the necessity for intervention to ultimately support personalized clinical decision-making.

Materials and Methods: We prospectively collected ROTEM data of 190 patients during three pre-specified moments during elective cardiac surgery. Expert annotations served as the ground truth for training and validating predictive models. A comprehensive machine learning pipeline was developed to diagnose abnormalities and subsequently to determine the necessity of intervention. The final model was evaluated using nested cross-validation with metrics as F1-score and AUC.

Results and Discussion: The final model was able to diagnose abnormalities in ROTEM data with an F1-score of 0.81 (95% CI: 0.80 – 0.83) and AUC of 0.83 (95% CI: 0.83 – 0.85). Subsequent recommendation for intervention resulted in an F1-score of 0.63 (95% CI: 0.59 – 0.68) and AUC of 0.65 (95% CI: 0.61 – 0.71). CT INTEM and CT EXTEM were the most important parameters to detect abnormalities, while MAXV HEPTEM and ML HEPTEM were the most dependent parameters for recommending intervention. Besides model performance, explainability is a crucial aspect of clinical decision support. In clinical practice, such decision support should efficiently rule out abnormality, and thus intervention, to optimize coagulation strategy during cardiac surgery.

Conclusion(s): Clinical decision support using automated ROTEM interpretation effectively diagnoses abnormalities. However, further optimization is needed to enhance the accuracy of intervention recommendation.

Acknowledgements: We would like to thank the VHALID study group for annotating the data.

Intraoperative myocardial infarction with refractory cardiogenic shock and cardiac arrest during radical cystectomy: a case report of a critical event

D. Carvalho¹, D. Campante¹, C. Rodrigues¹, A. Eufrásio¹, A. Bernardino¹

¹Unidade Local de Saúde de Coimbra, E.P.E, Anesthesiology Department, Coimbra, Portugal

Background: Intraoperative myocardial infarction (MI) complicated by refractory cardiogenic shock and cardiac arrest is a critical event with serious repercussions on morbimortality.

Case report: 65-year-old male with multiple cardiovascular (CV) risk factors and non-ST elevation MI with 3 drug eluding stents 3 months earlier was scheduled for radical cystectomy due to bladder cancer. Cardiology was consulted and approved proceeding with surgery. Patient was asymptomatic, MET score>4, preoperative hemoglobin of 13g/dL, normal electrocardiogram (ECG) and echocardiographic ventricular function. Due to dual antiplatelet therapy, aspirin was maintained up to the surgery day and clopidogrel withheld 5 days prior. Intraoperative monitoring: ASA standard, invasive blood pressure and ProAQT/PulsioFlex® monitor. Despite 600 mL blood loss, anesthesia/surgery went without complications and with hemodynamic stability.

Near the end, ECG monitor showed ST-segment elevation, followed by refractory cardiogenic shock and cardiac arrest minutes after. Advanced cardiac life support was initiated, followed by extracorporeal membrane oxygenation (ECMO) support. Emergent coronariography showed stent thrombosis, and revascularization was done. Left ventricular dysfunction was irreversible, leading to the patient's death two days later.

Discussion: Despite fulfillment of the minimum timings recommended by European guidelines¹, perioperative management should consider factors such as surgical stage at the time of MI. bleeding risk, hemodynamic status and MI severity². This case highlights how challenging the management of intraoperative myocardial infarction with refractory cardiogenic shock and cardiac arrest can be. Appropriate intra-operative CV monitoring leads to early diagnosis and treatment.

This case triggers the discussion of whether these patients need to be done in an ECMO prepared center. Available literature remains limited, with only 2 similar cases found2,3.

References:

- 1. Eur Heart J, 2022 Oct 14;43(39):3826-24. doi:10.1093/ eurheartj/ehac270.
- 2. JA Clin Rep 2022 Mar 9;8:19. doi:10.1186/s40981-022-00510-x 3. Egyptian Journal of Anaesthesia, 39(1): 518-20. doi:10.1080/111 01849.2023.2230405

Learning points:

- Appropriate individual risk identification, preoperative CV evaluation and antiplatelet management is crucial.
- Anesthesiologists need to be trained and ready to act accordingly to critical events.

43AP06-7

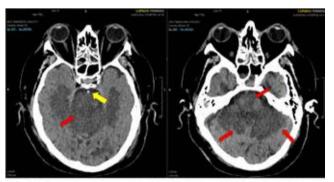

Basilar thrombosis after mitral valve surgery: challenges in anticoagulation initiation

A. Moral Bonet¹, H.R. Hernández Durán¹, C. Palau Martí¹. R. Ferrandis Comes¹. M.A. Pajares Moncho¹, M.P. Argente Navarro¹ ¹Hospital Universitari i Politècnic La Fe, Anaesthesiology and Reanimation, Valencia, Spain

Background: Mitral valve replacement is a common procedure. but managing postoperative bleeding and thrombotic risks is challenging, especially in complicated cases. Delayed anticoagulation heightens the risk of thrombotic events, such as basilar artery thrombosis, presenting unique management dilemmas.

Case Report: A 56-year-old male with hypertension, dyslipidemia, obesity, smoking history, and mild COPD was treated for severe rheumatic mitral stenosis. After ruling out percutaneous valvuloplasty, he underwent mitral valve replacement with a mechanical prosthesis. Surgery was complicated by a prior Amplatzer device (2010), requiring complex valve exposure. Intraoperative challenges included instability and coagulopathy, preventing sternal closure. A temporary Bogota bag and sternal packing controlled bleeding.

Postoperatively, the patient developed mixed shock (vasoplegic and cardiogenic), needing mechanical ventilation, vasopressors, and inhaled nitric oxide. Anticoagulation was postponed due to bleeding risks. On postoperative day three, right-sided anisocoria occurred, and CT revealed basilar artery thrombosis with infarction affecting the pons, midbrain, and cerebral peduncles.

Discussion: This case underscores the delicate balance between preventing thrombotic events and managing bleeding risks postoperatively. Early anticoagulation is crucial but must align with the patient's clinical situation. In this case, delayed anticoagulation led to a devastating neurological outcome.

Despite stabilization and sternal closure, severe neurological damage was confirmed via somatosensory evoked potentials and EEG. Family discussions centered on the poor prognosis, leading to adjusted therapeutic efforts.

Learning Points:

- · Balancing anticoagulation after mitral valve replacement is critical amid bleeding risks.
- · Early anticoagulation helps prevent events like basilar artery thrombosis but requires individualization.
- Neurological monitoring and imaging are essential for detecting complications early.
- · Clear family communication aids decision-making in cases with poor outcomes.

Anesthetic and hemostatic management in total hip arthroplasty in a patient with hemophilia B: A case report

J. Llopis-Lorente¹, J. Fernández Ruiz¹, M. Blesa Ripollés¹, V. Vilar Bianchi¹, R. Izquierdo Aguirre¹, P. Argente Navarro¹ ¹Hospital Universitari i Politecnic la Fe, Valencia, Valencia, Spain

Background: Hemophilia B is a rare coagulation disorder caused by factor IX deficiency, occurring in 1 in 20,000 males. Surgical procedures in these patients pose high bleeding risks. Advances in factor IX concentrates have reduced perioperative mortality from 25-50% to ~1%, yet management in severe cases remains under-documented.

Case Report: A 28-year-old male (173 cm, 65 kg) with severe Hemophilia B presented for left THA due to hemophilic arthropathy. His history included mild bleeding episodes treated with factor IX and no prior surgeries. Preoperative biweekly infusions of 2,000 IU factor IX achieved Hb of 12.9 g/dL and prolonged aPTT (46.6s). Thirty minutes before anesthesia, 6,000 IU factor IX and 750 mg tranexamic acid were administered.

General anesthesia was chosen to avoid spinal hematoma. Induction included lidocaine (1 mg/kg), propofol (2.5 mg/kg), fentanyl (1.5 µg/kg), and rocuronium (0.6 mg/kg), with propofol (5 mg/ kg/h) and remifentanil for maintenance. The 5-hour surgery was stable until significant bleeding during femoral canal reaming caused hemodynamic decompensation (MAP 80/40 mmHg, HR 120 bpm) and Hb drop to 9.4 g/dL. Intervention included 2,000 IU factor IX, arterial catheterization, and 3 red blood cell units.

Postoperatively, Hb fell to 7.0 g/dL, requiring 2 transfusions, ferric carboxymaltose, tranexamic acid, and 7,000 IU factor IX. By postoperative day 1, factor IX levels stabilized at 69.1 IU/dL, allowing transfer to the ward. Hemostatic management included 3,000 IU factor IX every 12 hours and tranexamic acid (750 mg/8 h). Discharge occurred on day 8 with stable Hb and daily factor IX (3.000 IU).

Discussion: General anesthesia minimized spinal hematoma risk, aligning with WFH guidelines. Factor IX concentrates, preferred over prothrombin complex concentrates (PCCs) due to thromboembolic risks, ensured effective hemostasis. Tranexamic acid reduced bleeding without increasing thrombotic risk, consistent with Dunn et al. (2015). Intensive monitoring and prompt intervention were critical for managing complications.

Learning Points:

- · Multidisciplinary planning is vital for Hemophilia B surgery.
- Factor IX concentrates and antifibrinolytics ensure effective hemostasis.
- · Early recognition and management of bleeding improve outcomes.

43AP06-9

Perioperative anticoagulation management for a patient undergoing cardiac surgery with a history of Heparin Induced Thrombocytopenia (HIT): a case report

M. Carballo Delgado¹, C. Keaveney Jiménez¹, J. Escobar¹, S. Rubín Alduán¹, P. Segura de Cea¹, J. Villahoz Martínez¹ ¹Hospital Universitario Ramón y Cajal, Anestesiología y Reanimación, Madrid, Spain

Background: Heparin Induced Thrombocytopenia (HIT) is an immune-mediated disorder in which heparin causes production of antibodies against the complexes formed between heparin and platelet factor-4 (PF4). Platelet count falls and paradoxically thrombosis is promoted. This results in a challenge for the management of patients undergoing cardiac surgery with extracorporeal circulation.

Case Report: A 65 year old female with a history of systemic lupus erythematosis, anti-phospholipid syndrome and HIT diagnosed in 1994 was scheduled for aortic valve replacement. Following multidisciplinary discussion and in line with American Society of Haematology 2018 guidelines, unfractionated heparin was administered for the surgery as the patient met the criteria of normal platelet count, >3 months since HIT diagnosis and undetected anti-PF4 antibodies.

In the immediate postoperative, veno-arterial extracorporeal membrane oxygenation (ECMO) was initiated for severe right ventricular failure (RVF). The patient also suffered a massive haemorrhage requiring polytransfusion and developed an acute kidney injury.

Following control of haemorrhage, anticoagulation was initiated with argatroban. On postoperative day (POD) 5, due to unsuccessful weaning of ECMO, right-sided VA-ECMO was initiated for ongoing severe RVF. On POD 9, in the absence of improvement, care was redirected to palliation.

Discussion: Heparin is the cornerstone of anticoagulation in cardiac surgery and ECMO. In patients with HIT, direct thrombin inhibitors argatroban and bivalirudin are first line alternatives. However, in the context of ECMO for patients with a history of HIT, there is a lack of guidance. Argatroban is recommended in patients with renal insufficiency due to its hepatic elimination, a half-life of 40 to 50 minutes and predictable dosing. Unlike bivalirudin whose elimination depends on creatinine clearance, having unstable dosing.

Reference:

Koster A, Nagler M, Erdoes G, Levy JH. Heparin-induced Thrombocytopenia: Perioperative Diagnosis and Management. Anesthesiology. 2022 Feb 1;136(2):336-344. doi: 10.1097/ ALN.0000000000004090. PMID: 34910815.

Learning points:

- The importance of multidisciplinary preoperative evaluation of complex patients.
- The choice of anticoagulation for a patient requiring ECMO with a history of HIT is multifactorial (pharmacokinetics, availability of local protocols).

Acquired factor XIII deficiency and postoperative bleeding events

B. Abejaro¹, A. Pajares¹, M.A. Ferrer¹, P. Argente¹, R. Ferrandis¹

¹Hospital Universitari i Politècnic La Fe, Anaesthesiology and Critical Care, Valencia, Spain

Background and Goal of Study: Persistent postoperative bleeding, with normal screening coagulation studies and no evidence of platelet deficiency and dysfunction in critical ill patients may be produced by acquired factor XIII deficiency (DAFXIII) . Low levels of factor XIII (FXIII) produce unstable clots with bleeding events. not detected by coagulation and viscoelastic tests. Acquired FXIII deficiency is related to clinical situations of hyper consumption like surgery or trauma. Our hypothesis is that acquired coagulation FX-III deficiency is underrepresented in the perioperative setting. Our aim is to assess transfusion requirements with FXIII levels.

Materials and Methods: We present a single-centre, retrospective observational study, of patients admitted to the postanaesthesia critical care unit with clinical situation of factor XIII consumption after trauma, major surgery (abdominal and major trauma), extracorporeal membrane therapy and major burn from January 2023 to January 2024, where FXIII levels were monitor. FXIII deficiency was described as levels <70% and moderate deficiency <30%. Blood product transfusion requirements and need of urgent reintervention for bleeding control was recorded. Results are represented as percentage for categorical data and as median and inter quartile range for non-normally distributed data. Chi-square statistical test was realized. A P value < 0.05 was considered statistically significant.

Results and Discussion: 17 postsurgical patients were included. 16 patients presented acquired factor FXIII deficiency (94%), 8 (47%) presented moderate deficiency. The median of FXIII levels in patients with acquired deficiency were 37.7%. Patients on ECMO therapy and patients with necrotizing fasciitis had lower FXIII levels <30%. The median of daily transfusion (number of packed red blood cells / days of admission in post anesthesia critical care) was 2±3.8 tduring hospitalization in patients with DAFXIII. The median transfusion in DAFXIII <30% was 34 CH, and DAFXIII >30% was 12 CH without reaching a significant difference (p= 0.19). 60% required surgical reintervention to control the bleeding, with no significant differences found between DAFXIII <30% (71.4%) and DAFXIII > 30% (44%). 5 patients (31%) with moderate DAFXIII <30% received FXIII replacement therapy. Mortality was 31%. Acquired factor deficiency is frequent during the postoperative setting. FXIII levels may decrease during postoperative days due to high consumption and low synthesis. FXIII has a long half life, involving late bleeding disorders unresponsive to coagulopathy treatment, or disturbed wound healing. Increasing blood product trasfusion, adverse events and morbi-mortality Conclusion(s): Acquired FXIII deficiency is an underdiagnosed entity during the perioperative process, being a cause of preventable postsurgical bleeding. High clinical suspicion is important in patients with delayed bleeding with normal coagulation tests. It is still not clear the cutoff of FXIII level to ensure a correct hemostasis, neither when to monitor or an optimal factor replacement.

Anesthetic management of a complex AAA with impending rupture in an anticoagulated patient for DVT and PE

A.V. Espinosa¹, R. Alharbi¹, S.E. Hassan¹, V.E. Poletti², I.J. Isa1, M. Jain3

¹King Salman Specialist Hospital, Hail Health Cluster, Department of Anesthesia, Hail, Saudi Arabia, ²Sanatorio Plaza Huincul, Department of Image Study Sciences, Plaza Huincul, Argentina, 3Royal Brompton Hospital, Department of Critical Care, London, United Kingdom

Background: Managing patients with impending rupture of abdominal aortic aneurysm (AAA) on anticoagulation for DVT and pulmonary embolism (PE) is challenging, with a precarious balance between life-threatening bleeding from the aneurysm and thromboembolic risks if AC is reversed. Anesthetic strategies must combine rapid BP stabilization, judicious blood product management, and correct timing of surgical intervention.

Case Report: A 70-year-old man w.h.o. severe smoking and hypertension was diagnosed with DVT after a long flight. Got admission for dyspnea & lower leg pain. CT revealed bilat. pulmonary emboli, pleural effusion, and ground-glass infiltrates. CKD-induced hyperkalemia was managed. Discharged on apixaban and antibiotics for respiratory infection.

Returned 10 days later with severe epigastralgia & constipation. Physical exam revealed a pulsatile mass. CT confirmed an infrarenal 8 x 7 cm AAA involving proximal right illiac artery. Hypertension was urgently treated, anticoagulation stopped, Kidney function optimized and EVAR was planned. Under general anesthesia, hemodynamic stability was maintained with hypnosis monitoring and GDHT to avoid hypoperfusion or overhydration. A perforated iliac artery required overlapping stents to control bleeding. Ventilatory challenges from COPD + infection were managed with PCV. permissive hypercapnia, corticoids. The patient was extubated in ICU, with good healing of inguinal hematoma, good distal perfusion and mobility without spinal ischemia. He was discharged on anticoagulation.

Discussion: Impending rupture of AAA carries high mortality, with survival <25% post-rupture. Multiorgan dysfunction, incl. kidney and respiratory issues is common. Thrombotic events and anticoagulation complicate perioperative course. POC coagulation tests are crucial for optimizing hemostasis.

- 2. Chaikof, Elliot L. et al. The Society for Vascular Surgery practice guidelines on the care of patients with an abdominal aortic aneurysm. Journal of Vascular Surgery, Vol 67, Issue 1, 2 - 77.e2

Learning points:

- Optimize kidney function perioperatively to prevent electrolyte imbalances & arrhythmia
- · Control BP to avoid AAA rupture.
- Use point-of-care coagulation tests to safely time the proce-
- Anesthesiologists play a key role managing these factors to prevent complications and improve survival.

Preoperative haemolysis in Evans syndrome

T. Rocha¹, R. Felgueiras¹, C. Pereira¹, R. Oliveira¹, J. Pinto¹, A. Guedes¹

¹ULS Viseu Dão-Lafões, Department of Anaesthesiology, Viseu. Portugal

Background: Evans Syndrome is an autoimmune disease combining Haemolytic Anaemia and Immune Thrombocytopenia. Perioperative management of these patients is challenging due to rapid onset cytopenia and need for corticosteroid therapy. We detail the management of a patient with Evans Syndrome with preoperative haemolysis.

Case Report: A 72-year-old female was diagnosed with a Rectum Neoplasia and scheduled for an Anterior Rectum Resection. On a pre-anaesthetic appointment, her history was relevant for Evans Syndrome, diagnosed 6 years prior with Thrombocytopenia and Haemolytic Anaemia. Bloodwork was unremarkable (Hg 13.2g/dL, Plat 114000/uL) under 5mg/d Prednisolone, being decided that the regimen should be maintained throughout the admission.

After admission for scheduled surgery, bloodwork 12 hours before the procedure detected anaemia (Hg 9.0g/dL) with increased levels of Bilirubin, LDH, and decreased Haptoglobin. Discussion with Haematology showed that the patient was incompatible with any Red Blood Cell Concentrate (RBC) due to acute haemolysis.

The surgery team was contacted and the procedure rescheduled. Prednisolone 40mg/d was prescribed, later reduced to 20mg/d. After six weeks, new preoperative bloodwork showed mild anaemia (Hg 11.4g/dL). Prednisolone 20mg/d was maintained. 2 matched RBC Units and 2 units of Pooled Platelets were reserved. General anaesthesia was induced with Propofol 2mg/kg, Fentanyl 1.3µg/kg and Rocuronium 0.8mg/kg.

The maintenance agent was Sevoflurane, with Remifentanil and Dexmedetomidine perfusions. Analgesia included Ketamine 0.26mg/kg, Paracetamol 18mg/kg and Tramadol 1.75mg/kg. Dexamethasone 8mg and Ondansetron 4mg were used as anti-emesis. Surgery ended in 3h55min without incidents and estimated blood loss was 150cc. Post-operative Hg was 9.7g/dL, without increased bilirubin nor LDH. The PACU stay was uneventful and the patient was discharged after 4 days.

Discussion: Acute haemolysis and thrombocytopenia substantially increase perioperative risk. Preoperative measures can reduce this risk, though adverse events may be further complicated by unavailability of matched blood products. Intraoperative stability is paramount to best minimize events and consequences.

Learning points: Evans Syndrome management requires effective multidisciplinary communication between the anaesthesiologist, the surgical team, haematology and internal medicine to provide adequate perioperative care and planning for acute events.

43AP07-1

The relation between hemorrhage and hemodynamic instability on the incidence of postoperative delirium in elderly patients undergoing urological procedures

H. Gani¹, M. Naco¹, K. Lilaj¹, A. Cani¹, J. Gani², A. Janko³
¹UHC "Mother Teresa", Anesthesia, Tirana, Albania,
²University of Toronto, Department of Statistical Sciences,
Toronto, Canada, ³UHC "Mother Teresa", Surgery, Tirana,
Albania

Background and Goal of Study: Postoperative delirium (POD) is a common complication in the elderly in urology: **The purpose of this study** is to find out if there is a relationship between hemorrhage, hypotension and bradycardia in the incidence of postoperative delirium in the elderly in urology.

Materials and Methods: A total of 648 patients were included in the study, aged over 65, men. All underwent prostate surgery, TURP or open prostatectomy.

The patients were evaluated for intraoperative hemorrhage, as well as bradycardia hypotension and their respective treatment with blood, ephedrine, atropine. The patients who developed POD were compared with those who did not: The comparison consisted in presence of hemorrhage, hypotension, bradycardia, and the need for hemotransfusion.

While the preoperative factors were the same based on ASSA . Statistically significan.P-value (python) (p<0.05)

Results and Discussion: Out of 648 patients, 99 patients experienced POD, which means 15% of the patients in total. There were 36 patients with hemorrhage that required hemotransfusion, 18 of them (50%) experienced postoperative delirium (they were over 71 years old). Hypotension and bradycardia accounted for 216 of which 36 had hemorrhage, and of these 180 who had hypotension without hemorrhage, postoperative delirium accounted for 54 (25%) of the patients. These 54 patients were the patients whose hypotension lasted longer and required to consume higher doses of ephedrine and atropine. While among the patients without hemorrhage and hemodynamically stable (432 patients) delirium was encountered in 27 (6.25%) patients.

Conclusion(s): We noticed that hemorrhage was significantly associated with postoperative delirium, and especially if it was combined with advanced age. The p-value is significantly less than 0.0001, indicating a highly statistically significant relationship between hemorrhage and postoperative delirium. (Delirium in these patients occurred in 50%).

Also, we noticed that lasting hemodynamic instability with long use of ephedrine and atropine was an important component for postoperative delirium. P-value ≈3.1×10−13This extremely small p-value (much less than 0.0001) indicates a highly statistically significant relationship between hypotension, bradycardia that received ephedrine atropine and postoperative delirium. (Delirium in these patients was found in 25%). Meanwhile, in patients without hemorrhage and with hemodynamic stability, it occured in 6.25%

Clinical evaluation of cell salvage in paediatric surgery: Outcome data from our clinic

S. Pycz1, J. Kečkéšová1

¹University Hospital Brno, Faculty of Medicine, Masaryk University, Department of Paediatric Anaesthesiology and Intensive Care Medicine, Brno, Czech Republic

Background and Goal of Study: Cell salvage is an essential component of Patient Blood Management in paediatric surgery, where limited blood volume and transfusion risks pose significant challenges. This study evaluates the use of the CATSmart® CellSaver system, focusing on its impact on blood loss and transfusion reduction.

Materials and Methods: This prospective, observational study was conducted with local Ethics Committee approval and a waiver for informed consent. We analysed data from patients undergoing surgeries (scoliosis, major abdominal, and lower limb orthopaedic) with expected high blood loss, where the CATSmart® system was used. Collected data included patient demographics (age, weight, height, and gender), surgical classification (acute or elective), haematocrit, blood loss, salvaged blood volume, reinfused packed red cells, and the type of wash protocol (Low or Smart Volume Wash). The data were analysed descriptively using mean and median values for absolute and relative blood loss, calculated according to patient weight.

Results and Discussion: During the study period, data from 11 paediatric surgical procedures utilising the CATSmart® CellSaver system were analysed. The mean absolute blood loss was 550.27 ml (range: 100-1570 ml), with a median of 352 ml. For patients ≤ 20 kg, the mean was 142.5 ml (median: 135 ml), and for patients > 20 kg, 697.57 ml (median: 500 ml). The mean relative blood loss was 13.3% (range: 4.93%–26.47%), with a median of 14.29%. For patients ≤ 20 kg, the mean relative blood loss was 13.59% (median: 11.84%), and for those > 20 kg, 13.14% (median: 14.3%). These findings suggest that the CATSmart® system effectively manages blood loss in paediatric patients, particularly in those with higher body weight (> 20 kg) or significant blood loss (> 500 ml). In smaller patients (≤ 20 kg), the system's impact was less pronounced due to lower blood loss volumes and limited reinfusion requirements.

Conclusion(s): Cell salvage systems are an important part of paediatric patient blood management, especially in surgeries with higher estimated blood loss and in children above 20 kg of weight. Further studies with larger cohorts are needed to confirm these

Intraoperative stroke during retroperitoneal surgery: case report

Z. Ouzounova¹, A. Babo Pedroso¹, M. Azenha¹, A. Raimundo¹ ¹ULS Coimbra - Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: The incidence of perioperative stroke following noncardiac, nonneurologic surgery is 0,1-0,8%. Perioperative strokes are more common in certain populations and specific surgical procedures, posing a significant risk for postoperative morbidity and mortality. Prompt identification and treatment of perioperative stroke can improve neurological outcomes. We present a case of a patient who suffered an intraoperative stroke.

Case Report: A 73-year-old male, ASA III, with a history of atrial fibrillation, hypertension, and overweight status, previously underwent surgery for perivesical hemangiopericytoma. Anticoagulation was discontinued due to recurrent bleeding episodes. He was scheduled for resection of a large retroperitoneal pelvic mass and underwent combined anesthesia. Massive intraoperative bleeding led to hemodynamic instability and activation of the massive hemorrhage protocol. Postoperatively, the patient presented with confusion, expressive aphasia, central right facial palsy and right hemiparesis. A stroke protocol was immediately activated, and a computed tomography (CT) confirmed an acute ischemic stroke with a thrombus in the middle segment of the left M1. The patient underwent thrombectomy and was anticoagulated with enoxaparin. He remained hospitalized for 14 days and was discharged hemodynamically stable, with mild motor deficits in the right upper limb and anticoagulation with edoxaban.

Discussion: Several cardiovascular risk stratification tools are valuable in predicting perioperative complications. According to the CHA₂DS₂-VASc score, this patient had an estimated stroke risk of 2.9%. However, this risk was underestimated, as the patient was not on anticoagulation therapy and experienced an intraoperative period of hypotension due to massive bleeding. Identifying stroke symptoms in the perioperative period is challenging because factors like prolonged intubation and residual effects of anesthesia can mask clinical signs. Rapid response protocols should be activated promptly when stroke is suspected, enabling immediate neurological assessment, imaging, and therapeutic intervention.

Reference:

Circulation, Volume 143, Issue 19, May 11, 2021; Pages e923-e946 Learning points: An early activation of the stroke protocol contributed to a favorable outcome. Continuous education of healthcare providers on recognizing stroke signs and the importance of immediate action is crucial to improving patient outcomes.

Acquired FXIII deficiency in patients witg ECMO: case reports

<u>B. Abejaro</u>¹, R. Ferrandis¹, A. Pajares¹

'Hospital Universitari i Politècnic La Fe, Anaesthesiology and Critical Care, Valencia, Spain

Background: Coagulopathy induced by ECMO, exacerbated by patient-specific characteristics, may lead to persistent bleeding despite normal coagulation tests. Acquired factor XIII (FXIII) deficiency, though rare, is an important cause.

We present four cases of acquired FXIII deficiency in patients receiving ECMO, all of whom experienced severe haemorrhagic complications and coagulation tests.

Case Report:

- 1: A 55-year-old male with severe thoracic trauma and acute respiratory distress syndrome (ARDS) required venovenous ECMO. Despite discontinuation of heparin, he experienced persistent haemorrhaging, requiring a total of 12 units of red blood cells. FXIII deficiency was confirmed with a level of 15%. ECMO was discontinued, and 1000 UI FXIII were administered, achieving bleeding control without further transfusions. Follow-up showed a FXIII level of 46%.
- 2: A 21-year-old male with severe trauma, developed ARDS requiring venovenous ECMO. After ECMO removal, thrombosis was noted in the inferior vena cava, and anticoagulation with enoxaparin was initiated. He developed bleeding from the oropharyngeal mucosa and tracheostomy site. Acquired FXIII deficiency was confirmed with a level of 28%. 2 doses of 750 IU FXIII were administered, resulting in bleeding control and a follow-up level of 41%.
- **3**: A 57-year-old male, after cardiac transplantation, required venous-arterial ECMO due to primary graft dysfunction. Following ECMO removal, he developed progressive anaemia with daily transfusion requirements (21 units). FXIII was 18%. After 1500 IU FXIII replacement, bleeding persisted. Follow-up level after one week was 28%.
- **4**: A 52-year-old female with fulminant myocarditis required peripheral venous-arterial ECMO as a bridge to heart transplantation. Postoperatively, she developed significant anaemia, with abundant drainage from chest tubes. FXIII level was 46%. Following reintervention and ECMO removal, no further transfusions were required.

Discussion: Persistent bleeding in ECMO patients may be attributed to acquired factor XIII deficiency, a condition that goes undiagnosed by standard coagulation tests. Early recognition and replacement of factor XIII can effectively control bleeding and reduce transfusion requirements.

Reference:

J Clin MEd 2023;12:4115

Learning points: Factor XIII deficiency should be considered in the differential diagnosis of coagulopathy in ECMO patients, and its measurement included in routine coagulation assessments.

43AP07-6

Impact of red blood cell storage duration on hemoglobin response in elderly patients undergoing non-cardiac surgery

<u>G. Massoth</u>¹, H. Ehrentraut¹, A. Delis¹, P. Meybohm², M. Velten³, M. Wittmann¹

¹University Hospital Bonn, Department of Anesthesiology and Intensive Care Medicine, Bonn, Germany, ²University Hospital Würzburg, Department of Anaesthesiology, Intensive Care, Emergency and Pain Medicine, Würzburg, Germany, ³University of Texas Southwestern Medical Center, Department of Anesthesiology and Pain Management, Dallas, United States

Background and Goal of Study: Severe anemia resulting from blood loss remains a predominant reason for perioperative red blood cell (RBC) transfusions. Concerns about the clinical impact of RBC storage-induced changes, termed "storage lesions", and their potential harm in elderly patients warrant further investigation (1,2).

This study aimed to assess the effect of RBC storage duration on hemoglobin (Hb) increments in patients aged ≥70 undergoing non-cardiac surgery.

Materials and Methods: 1,626 RBC transfusion events in 505 patients (2018-2022) across two study sites of a still ongoing prospective randomized controlled trial to determine the transfusion threshold of non-cardiac surgery patients above 70 years (LIBERAL). A linear mixed effects model assessed the influence of RBC storage duration and confounders, such as pre-transfusion Hb levels, measurement intervals, and manufacturing variations, on Hb increments. RBC characteristics, such as hemoglobin content and production methods, were incorporated into the analysis. Analysis neither unblinded nor corrupted any data of the larger LIBERAL trial.

Results and Discussion: Analyses revealed no statistically significant effect of RBC storage duration on Hb increments. Significant predictors of Hb response include pre-transfusion Hb levels, measurement intervals, and manufacturer-specific Hb content. Differences in production methods and additive solutions contributed to variations in transfusion outcomes between centers, with no clinical disadvantage noted for longer-stored RBCs.

These findings align with existing studies, such as the ABLE and RECESS trials, indicating no adverse impact of storage duration on transfusion efficacy within standard limits.

Conclusion(s): RBC storage duration does not significantly affect Hb response in elderly perioperative patients. Transfusions with standard-stored RBCs remain effective, supporting their continued use up to standard storage limits. These findings, corroborated by existing studies, (3) emphasize the need for future studies to refine transfusion practices through tailored strategies particularly for elderly patients.

Assisted fluid management (AFM) as a guide to intraoperative fluid therapy

- L. Martínez Pérez¹, A.M. Pérez Carbonell²,
- J. Monserrat Nondedeu², J.J. García Romero²,
- J. López Amorós²

¹Hospital General Universitario de Elche, Anesthesiology, Elche, Spain, ²Hospital General Universitario Elche, Anesthesiology, Elche, Spain

Background: Anesthesiology is one of the disciplines that most successfully integrated Al-based technologies. Intraoperative fluid therapy is a critical area, where Al has proven its usefulness. The objective of fluid therapy is to provide fluids to increase the patient's SV and, CO. However, its administration must be careful, since a positive fluid balance due to excessive administration, is associated with increased morbidity and mortality. In the same way, hypovolemia or preload-dependency has risk of hypoperfusion. Therefore, predicting how our patient will respond to volume administration is crucial.

The AFM software includes an AI and machine learning algorithm that integrates patient hemodynamic variables and individually assesses preload-dependency. This algorithm learns from the patient and predicts the response to fluids based on the previous response and the current hemodynamic situation.

Case report: 55-year-old, male, diagnosed with sigmoid cancer, who underwent laparoscopic robotic sigmoidectomy. Advanced hemodynamic monitoring with minimally invasive CO monitoring was used, supported by the HPI and AFM systems. After pneumoperitoneum, the patient presented an increase in Blood pressure (BP) with an increase in SVR requiring analgesia adjustment with remifentanil infusion and occasional urapidil boluses.

Although the patient maintains BP, AFM recommends a fluid bolus. The bolus is accepted and it turns out positive, with an increase in SV > 15% and CI after the administration of 3 fluid boluses.

During the rest of the surgery, we achieved hemodynamic optimization: normal BP (MAP > 70mmHg), SVR and CI (> 3,5 I/min/m2), a SVV < 12%. Surgery lasted 2:50h. 1200ml of crystalloids were administered.

After analyzing the case data using the Acumen Analytics system, we observed that the patient had a total of 0 minutes of hypotension, and the administration of fluids following the AFM algorithm also allowed to optimize CI values after fluid administration.

Discussion: The development of intraoperative hypotension is detrimental to the patient as it is associated with adverse outcomes, such as, acute kidney injury, myocardial injury, and even increased mortality. The chances of an adverse outcome increase with the duration and magnitude of hypotension and even short periods of hypotension appear to be associated with adverse outcomes. These outcomes occur due to hypoperfusion.

Therefore, if our patient has normal BP, does that mean that we are managing the patient's hemodynamics the best as possible and can ensure that hypoperfusion is not occurring?

Although a large number of cohort studies have suggested an association between perioperative hypotension and poor outcomes, RCTs have failed to demonstrate improved outcomes with higher BP maintenance. In the BP formula (CO \times SVR), we observe that combinations of different CO and SVR changes represent different physiological states underlying a BP value.

Thus, with a normal BP value, this may be due to an increase in arterial load, to compensate for a drop in CO; this decrease in flow, together with the increase in SVR, may compromise tissue perfu-

sion and therefore cause organic damage. Avoiding intraoperative hypotension is crucial to reduce its possible adverse effects. Although hypotension does not always cause tissue hypoperfusion, we must also understand that a normotensive patient may not have adequate CO and perfusion, as occurs in certain states of shock.

Therefore, BP is not always a faithful reflection of CO and therefore, optimizing CO and flow are also priorities when it comes to optimizing the patient's hemodynamics, despite normal BP values. Preload-dependence identifies a patient who can improve their CO (flow) with volume administration if they have an adequate vascular tone (arterial elastance).

In these cases, and if the CO target is not met (CI < 2.5), the benefit of fluid therapy is proven. Thus, the increase in CO will lead the arterial system to regulate itself, normalizing SVR values and thus optimizing organic perfusion.

Studies show that the hemodynamic management of patients can be improved with the help of Al. Joosten's study (1) is a prospective randomized controlled study that compares Al-assisted or manual hemodynamic management, and it is shown that individualized Al-assisted management reduces intraoperative hypotension, compared to a manually directed approach, as well as, maintaining the patient in the preload-independence zone. Maheshwari et. al (2), showed the greater effectiveness of AFM software in fluid administration, 66% of the fluid administered by boluses recommended by the software, resulted in the desired increases in VS, compared to the reference rate of 30%, when AFM is not used. (2).

A high percentage of time in the preload-independence zone was not achieved. This was due to a lack of adherence by physicians to AFM indications because the patient presented normal BP values. If a patient is preload-dependent, he will benefit from fluid administration as long as it is beneficial for the patient to increase CO. This is supported by other studies where it has been observed that maintaining blood volume optimized, that is, patients who remain in the preload-independence zone for longer, maintain a cardiac index > 2.5 for a significantly longer time. (3). AFM software combines the identification of the preload-dependence state with the patient's hemodynamic response to fluid administration, discriminating hemodynamic situations in which the patient responds or not.

Learning points: AFM software is a useful tool that allows for personalized fluid administration, allowing the patient to be kept in the preload-independence zone with less fluid administration.

Analysis of requests for red blood cell reservation in surgical patients at a tertiary care hospital from 2021 to 2023: a cross-sectional observational study

B.B. Silva Jr¹, V.A.B. Silva², L.d.S. Garrido², G.B. Campos², C.S. Goveia³, <u>L. Azi²</u>

¹Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil, ²Faculty of Medicine - Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil, ³University of Brasília, Department of Anesthesiology, Brasília, Brazil

Background and Goal of Study: Evaluating transfusion patterns across different surgical specialties is essential for establishing rational blood use strategies in healthcare institutions.

This study aims to assess the profile of concentrated red blood cell requests and utilization at a tertiary university hospital in Brazil.

Materials and Methods: This is a retrospective cross-sectional study conducted at the Professor Edgard Santos University Hospital, a tertiary healthcare facility. Data were obtained from surgical and hemotherapy department records for patients undergoing surgical procedures between 2021 and 2023. Three indices were used: crossmatch-to-transfusion ratio (C/T), transfusion probability (TP%), and transfusion index (TI). The following are the ideal values for each index: C/T should be ≤ 2.5, TP% should be ≥ 30%, and TI should be ≥ 0.5.

Results and Discussion: A total of 12,466 surgeries were performed, including 941 urgent procedures. Concentrated red blood cells were reserved for 1,814 patients, with 3,885 units crossmatched. However, only 54 patients received transfusions, utilizing 102 units. When analyzing only surgeries with more than 10 red blood cell requests, major procedures such as oncological neurosurgeries, open cardiac surgeries, and large abdominal surgeries were included. No surgery had a C/T ratio below 2.5, with the closest being cystectomy (C/T = 3.4). Cystectomy was also the only surgery with TP ≥30%. Regarding TI, cystectomy (TI = 0.6) was the only procedure with TI ≥0.5, followed by abdominal-perineal amputations (TI = 0.36) and surgeries for myocardial revascularization and valve replacement (TI = 0.35). Some procedures, such as penile plastic surgery, and vaginal hysterectomy, had C/T ratios close to infinity and no transfusions. The transfusion indices serve to evaluate the red blood cell usage profile, verifying the efficiency of transfusion systems (Stanworth et al, 2002).

Conclusion(s): The study demonstrates that there is an excess of concentrated red blood cell requests that are not utilized in most surgical procedures. Implementing a personalized blood reservation protocol based on these data would lead to more efficient blood usage and reduced unnecessary transfusions.

Perioperative fluid management in CRS-HIPEC: associations, and impact on ICU stay and postoperative outcomes

<u>J. van Zwol</u>^{1,2}, A.G. Aalbers³, D.P. Veelo^{2,4}, M.W. Hollmann², S.N. Hemmes^{1,2}

¹The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Anesthesiology, Amsterdam, Netherlands, ²Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ³The Netherlands Cancer Institute – Antoni van Leeuwenhoek Hospital, Surgical Oncology, Amsterdam, Netherlands, ⁴Amsterdam UMC, Intensive Care Medicine, Amsterdam, Netherlands

Background and Goal of Study: Cytoreductive surgery (CRS) with hyperthermic intraperitoneal chemotherapy (HIPEC) improves outcomes for peritoneal metastasis but may cause intra-operative hemodynamic instability. A hyperdynamic state lowers vascular resistance, requiring catecholamines and fluids. Fluid management is challenging due to extensive surgery, HIPEC, blood loss, and ascites. Excess fluids may cause tissue edema and morbidity. This study evaluates fluid use during CRS-HIPEC, its link to complications, and patient characteristics tied to high fluid needs.

Materials and Methods: This single-center retrospective cohort study included all 583 patients who underwent CRS-HIPEC at Antoni van Leeuwenhoek (2007–2023). Fluid administration at T1 (end CRS-HIPEC), T2 (ICU stay - 08:00 day 1), T3 (08:00 day 1 - 08:00 day 2), and T4 (08:00 day 2 - 08:00 day 3) was collected. We explored the correlation between intraoperative fluid volumes and post-operative fluid administration; association between fluid administration and outcome (kidney function, ICU length of stay), when dividing intra-operative fluids in 4 quartiles; and examined independent association of patient characteristics.

Results and Discussion: Median age was 61 years (20–82). Median fluid administration: T1 5239 mL [566–18297], T2 1914 mL [670–4541], T3 3763 mL [1320–9025], and T4 2598 mL [1151–8339]. No correlation was found between intraoperative and ICU fluid volumes (p=0.3704). Patients in quartile Q4 (receiving >6866 mL) had longer ICU-LOS compared to those in Q3 (receiving 5239–6866 mL) (p=0.025).

No association was found between intraoperative fluid and postoperative creatinine changes (p=0.4684, p=0.7017). Fluid administration was not associated with age, NYHA class, BMI, MET score, smoking, ASA score, or mean intraoperative ABP, when adjusted for propofol dose, anesthesia duration, and blood loss (e.g., age p=0.1372, NYHA p=0.1996).

Conclusion(s): High intraoperative fluid volumes are common during CRS-HIPEC and seem linked to longer ICU stay. No correlation exists between intraoperative and postoperative fluid volumes, and no patient characteristics were associated with abovemedian fluid use.

43AP07-10

Coagulation management of a patient with von Willebrand disease undergoing cardiac surgery: Case report

D. Tkachenko^{1,2}, O. Loskutov^{1,2}, Y. Markov¹, A. Shkandala³, B. Todurov⁴

¹Shupyk National Healthcare University of Ukraine, Anesthesiology and Intensive Care, Kyiv, Ukraine, 2Heart Institute of Ministry of Health of Ukraine, Anesthesiology, Kyiv, Ukraine, 3Heart Institute of Ministry of Health of Ukraine, Iscemic Heart Disease Treatment, Kviv, Ukraine, ⁴Heart Institute of Ministry of Health of Ukraine, Cardiac Surgery, Kyiv, Ukraine

Background: Von Willebrand disease (VWD) is inherited blood clotting disorder characterized by a deficiency or dysfunction of von Willebrand factor (vWF). This condition increases the risk of severe bleeding, especially during cardiac surgery which often accompanied using cardiopulmonary bypass (CPB) and poses significant risks for such patients.

This report outlines the challenges and solutions implemented to ensure a successful surgical outcome during cardiac surgery with

Case Report: 36-year-old men with history of VWD type 1, ASA 3, was admitted to the hospital for aortic valve replacement due to severe aortic valve insufficiency and ventricular septal defect. Clinical blood test: hemoglobin 13.6 g/dL, platelet count 197g/L, prothrombin time 13.0s, partial thromboplastin time 33.0s, international normalized ratio 1.4. Before CPB 25 mg/kg of tranexamic acid was arranged. Activated clot time (ACT) before heparin was 234s. ACT after heparin (27000 IU) was 856s. Intraoperative mild hypothermia (34.4°C) was maintained during CPB. After the patient was weaned from CPB deliberate hypotension was employed to minimize blood loss. Mean arterial pressure was kept 70 mmHg, heart rate - 80. Coagulopathy treatment was guided by thromboelastography (TEG) that indicated impaired platelet function, a deficiency in clotting factors and unstable clot formation during CPB. Blood component transfusion included: 1 IU of platelets, 4 IU of fresh frozen plasma, 2 IU of cryoprecipitate, 1 IU of red blood cells. A bolus of 1000 IU of inactivated concentrate of clotting factors II, VII, IX, X and 3000 IU of concentrate vWF 1500 IU and factor VIII 3000 IU IV was administered. ACT after protamine (270 mg) was 112s. Subsequent TEG demonstrated effective clot formation and clot stability. The patient was transferred to the ICU with a hemoglobin at 10.2 g/dL. In the first two hours, the fluid output in the Pleur-Evac drain system was 140 mL. The patient no longer required blood components. He continued receiving 3000 IU vWF and factor VIII daily, until the removal of the last catheter. Discussion: Transfusion of vWF and factor VIII is the only proven treatment for VWD. This strategy shows favorable outcomes and is commonly used in practice.

Learning points: We determined that TEG could be helpful in developing a therapeutic plan for patients with coagulation disorders as it provides a qualitative assessment of the coagulation status and improving blood transfusion management.

Intraoperative cardiopulmonary resuscitation in prone position during massive bleeding: a case report

T. Nastasovic^{1,2}, S. Bojic^{3,2}, M. Minic¹, A. Gavrilovska Brzanov⁴, T. Ivosevic^{5,2}, M. Milenovic^{6,2} ¹University Clinical Center of Serbia, Department of Anesthesiology and Resuscitation on Neurosurgery Clinic. Belgrade, Serbia, 2School of Medicine, Department of Surgery with Anesthesiology, Belgrade, Serbia, 3Clinical Hospital Center Dr Dragisa Misovic, Department of Anesthesiology and Intensive Care, Belgrade, Serbia, ⁴University Clinical Center Mother Teresa, Department of Anesthesiology and Intensive Care, Skopje, North Macedonia, The Republic of, 5University Clinical Center of Serbia, Department of Anesthesiology and Resuscitation on Clinic for ENT and Maxillofacial Surgery, Belgrade, Serbia, 6University Clinical Center of Serbia, Emergency Department, Belgrade, Serbia

Background: Cardiac arrest (CA) in prone position demands measures for cardiopulmonary resuscitation (CPR) which are similar to those performed in supine position. The causes of can be different.

We will present a case report a female patient which is resuscitated in prone position in operating theater.

Case Report: A 45-year-old female patient was admitted to our hospital for neurosurgical removal of intracranial arterio-venous malformation (AVM). She was awake, communicative, without neurological deficit. After induction into general endotracheal anesthesia, the patient was placed into prone position with arms along with the body. She was hemodynamically stable with appropriate oxygenation. 3 peripheral intravenous cannulas were placed as well as arterial line.

From the moment resection of AVM was initiated, the profuse bleeding occurred. Aggressive volume resuscitation was done (crystaloids, packed blood cells, fresh frozen plasma).

Despite our resuscitation measures, the arterial blood pressure has fallen and Noradrenalin infusion was initiated. After a few minutes, the patient was in CA, without arterial pressure, capnography and pulse.

Chest compression with frequency 100-120/min was done along with Epinephrine 20 mg intravenously and the blood products resuscitation. At the moment when the surgeon got the control of the bleeding, and about 30 minutes after compressions, the pulse occurs.

After surgery, the patient was transferred to intensive care unit, unconscious, hemodinamically unstable, with dilated and slowly reacted pupils.

Discussion: CPR is performed in patients who are at the moment of CA in prone position. The outcome depends on cause of the cardiac arrest. In our case, the cause was uncontrolled bleeding from intracranial arteriovenous malformation. CPR was necessary for patient's outcome, till the moment of appropriate blood substitution was done.

Preliminary study of the comparison of **Contrafluran and Anesthetic Gas Scavenging** System (AGSS) in capturing waste anaesthetic gases in the real-world operating theatre environment

B.P.Y. Tan¹, X. Yang¹, F. Jing², P.S. Au Yong², K.Y. Fong¹, H.R. Abdullah¹

¹Singapore General Hospital, Anaesthesiology, Singapore, Singapore, ²Singapore General Hospital, Operating Theatres, Singapore, Singapore

Background and Goal of Study: Chronic exposure to waste anesthetic gases (WAG) is a significant occupational health risk for operating theatre (OT) staff. However, limited evidence links WAG exposure levels to specific surgical procedures. This study evaluates ambient WAG levels during robotic and open abdominal surgeries, assessing compliance with National Institute for Occupational Safety and Health (NIOSH) limits and exploring procedural differences. A parallel non-crossover design was used, with an Active Anesthetic Gas Scavenging System (AGSS) applied for 30 days, followed by a passive mode with the Contrafluran volatile capture device in the same OT. This abstract focuses on AGSS phase findings.

Materials and Methods: Ambient desflurane and sevoflurane concentrations were measured during 27 surgeries (21 robotic, 6 open) at Singapore General Hospital using the GT5000 gas analyzer (Gasmet Technologies, Terra, Finland). Sampling sites included distal to the Contrafluran canister/anesthesia machine, 5 cm from the patient's nose/mouth, and 1 meter from the anesthesia workstation. Gas samples were collected every 10 minutes, with key time points including baseline, after connection to the breathing circuit, extubation, and patient departure. Differences in WAG levels between robotic and open surgeries were analyzed using the Mann-Whitney U test.

Results and Discussion: Robotic surgeries exhibited higher time-weighted average exposures to desflurane (0.05 ppm vs 0.04 ppm, P< 0.001) and sevoflurane (0.15 ppm vs 0.06 ppm, P < 0.001). Both values were well below the NIOSH limit of 2 ppm. Higher WAG exposure during robotic surgeries may result from factors such as endotracheal tube leaks under high intra-abdominal pressure and head-down positioning. Despite statistically significant differences, the clinical significance is negligible given compliance with NIOSH limits. The small sample size limits the study's generalizability.

Conclusion(s): Although robotic surgeries showed higher WAG exposure levels, these differences are not clinically significant. The long-term risks of exposure remain unclear. These findings support the potential for increased adoption of TIVA in robotic procedures and emphasize customizing exposure management strategies based on surgical factors.

50AP01-3

Evaluation of accuracy of capnography sampling lines: a bench study of procedural bite blocks and EtCO₂ masks

J. Mulier¹, D. Glozman², H.J.A. Oglesby³, T.L. Jones⁴ ¹UGhent, Anesthesiology, Ghent, Belgium, ²Medtronic, Research & Development, Jerusalem, Israel, 3St Joseph's/ Candler Health, Pulmonary Medecine, Savannah, GA, United States, 4Virginia Commonwealth University, School of Nursing, Richmond VA, United States

Background and Goal of Study: Accurate end-tidal CO₂ (EtCO₂) monitoring relies on dependable sampling lines for consistent and reliable measurements. In this study, a series of bench tests were conducted to evaluate EtCO2 accuracy of commercially available sampling lines (Microstream™ and third-party) claiming compatibility with Microstream™ enabled capnography monitoring systems across diverse respiratory scenarios.

Materials and Methods: A series of bench tests were performed on a selection of commercially available sampling lines (procedural bite blocks and EtCO2 masks) to assess EtCO2 accuracy when used in tandem with a Microstream™ enabled capnography monitoring system (Medtronic, Minneapolis, MN). A 3D printed oral-nasal model connected to a lung simulator was set to two different breathing modes to simulate "normal" and "shallow" breathing. Under both breathing modes, oral-only and nasal-only breathing conditions with supplemental oxygen levels of 0, 5, and 10 lpm were tested for the procedural bite block. For EtCO₂ masks, accuracy was assessed for both breathing modes (normal and shallow) during oral-only and nasal-only breathing conditions with supplemental oxygen levels of 0, 4, and 15 lpm. For each testing procedure, three separate sampling lines from the same manufacturer were assessed for five repetitions.

Results: See table showing the accuracy of end-tidal carbon dioxide by sampling line and breathing condition.

Discussion: Both procedural bite blocks and EtCO2 masks from the Microstream family demonstrated lower EtCO2 error estimates across all tested conditions compared with similar sampling lines from other manufacturers.

Conclusion: These findings highlight potential risks when using sampling lines from outside the Microstream[™] family in tandem with a Microstream™ enabled capnography monitoring system, which may compromise EtCO₂ accuracy in clinical applications.

In-Ear-EEG in anesthesiology - a comparison with the standard frontal montage

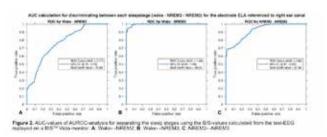

D. Fröhnel¹, S. Schwerin¹, G. Schneider¹, M. Kreuzer¹ ¹TUM University Hospital, Klinikum rechts der Isar, TU Munich, Deptartment of Anesthesiology and Intensive Care, Munich, Germany

Background and Goal of Study: EEG-based patient monitoring is a common practice during anesthesia. For numerous surgical interventions, the standard forehead placement is unsuitable. Tested alternative placements remain "off-label" but in-ear-EEG monitoring could be a promising alternative. Due to parametric similarities, polysomnography EEG records may help validate parameters for neuroanesthesia monitoring.

Materials and Methods: We used data from OpenNeuro (dataset ds004348), including sleep-scored polysomnography EEGs from nine healthy patients. We re-referenced the in-ear channels to the opposite ear canal. A 12-minute test-EEG (containing Wake, NREM2 and NREM3) was created for each patient and replayed to a BIS(TM) Vista monitor. BIS and spectral edge frequency (SEF) values were extracted for the frontal and in-ear channels. Additionally, the "openibis" index was calculated. Area under the receiver operating characteristic (AUROC) values were calculated for separating W, N2 and N3.

Results and Discussion: A Bland-Altman analysis comparing the frontal electrodes with re-referenced in-ear-electrodes showed a Pearson's r² ranging from 0.80 to 0.96 for openibis values (Fig. 1) and from 0.64 to 0.89 for the BIS replay. BIS scores of the test-EEG showed a near-perfect discriminatory ability between W and N3 (AUC = 1.00 [95% CI: 0.99, 1.00]) (Fig. 2B). Discrimination between N2 and W or N3 also yielded acceptable results throughout (AUC ≥ 0.75) (Fig. 2A/C).

Conclusion(s): The calculated openibis values, also the re-referenced ones, correlated well with sleep stages and can be used to discriminate between W and N3, with lesser performance between N2 and W or N3. The replay to a BIS monitor showed strong discriminatory power for the BIS index and even better results for SEF. In-ear EEG may offer a viable alternative to frontal montages for anesthesia neuromonitoring.

50AP01-5

Antibacterial efficacy of nanofiber antibiotics coated central venous catheter: simulation-based pilot study

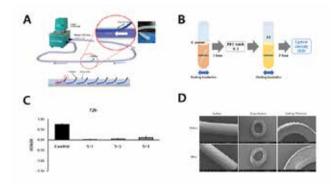

J.E. Cho1, H. Seong1, J.J. Park2, S.Z. Yoon1 ¹Anam Hospital, Korea University College of Medicine, Department of Anesthesiology and Pain Medicine, Seoul, Korea, Republic of, ²CHA Bundang Medical Center, CHA University School of Medicine, Department of Anesthesiology and Pain Medicine, Seongnam, Korea, Republic of

Background and Goal of Study: Central venous catheters (CVCs) are essential in managing critically ill or hemodynamically unstable patients but pose a risk of catheter-related bloodstream infections (CRBIs). To reduce bacterial adherence, the most commonly used CVC is coated with Chlorhexidine and Silver Sulfadiazine (CSS-CVCs) with broad-spectrum antibacterial effects and cost-effectiveness. However, CSS-CVCs may lose antibacterial effects due to shear stress from blood flow, with prior studies showing complete loss of antibacterial activity within 48 hours. Therefore, in this study, we collaborated with the Department of Chemistry at Korea University to develop a new antibiotic nanofiber-coated CVC designed to maintain antibacterial effects for a longer duration. Our goal was to evaluate whether the newly developed CVC could sustain its antibacterial effect longer than conventional CVCs.

Materials and Methods: Eight standard CVCs (ARROW, Arrow International, Inc., USA) served as controls, alongside three types of antibiotic nanofiber-coated CVCs (8 of each type coated with different ampicillin dose, S-1, 6wt%; S-2, 3wt%; S-3, 1wt%). These were exposed to a blood flow rate of 4 L/min for 0, 24, and 72 hours (Figure A). Antibacterial efficacy was assessed by measuring optical density (OD) 600 after Staphylococcus aureus culture (Figure B). Coating wear was analyzed via Scanning electron microscope (SEM).

Results and Discussion: After 72 hours of exposure, the OD 600 measurements demonstrated superior antibacterial efficacy for all three nanofiber-coated CVC types compared to controls (Figure C). SEM analysis showed approximately 50% retention of the coating thickness (Figure D).

Conclusion(s): Antibiotic nanofiber-coated CVCs maintained antibacterial activity for 72 hours, whereas CSS-CVCs lost efficacy after 48 hours. These findings suggest that nanofiber-coated CVCs may be a more effective option for reducing CRBIs when central venous catheters are required for over 48 hours.

Racial and gender disparities in Al-generated image representation of hospital leadership in the United States

M. Gisselbaek¹, J. Berger-Estilita², L. Minsart³, E. Köselerli Akyüz⁴, M. Suppan¹, S. Saxena⁵ ¹Geneva University Hospitals and Faculty of Medicine. Division of Anesthesiology, Department of Anesthesiology, Clinical Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland, 2University of Bern. Institute for Medical Education, Bern, Switzerland. ³Cork University Hospital, Department of Anesthesia, Cork, Ireland, 4University of Ankara School of Medicine. Department of Anesthesiology and ICU, Ankara, Turkey, ⁵Helora, Department of Anesthesiology, Mons, Belgium

Background and Goal of Study: Artificial intelligence (AI) is designed to enhance human actions and supporting decision-making, has become an integral part of modern healthcare systems. However, its inherent algorithmic biases related to gender, race, and age raise concerns about systemic inequities. Despite the near-equal number of male and female students in medical education, the over-representation of white males in Al-generated outputs underscores the urgent need for ethical practices that promote diversity, equity, and inclusion in Al development and healthcare leadership. This study aims to evaluate demographic representation in images of hospital leaders generated by Al models

Materials and Methods: This cross-sectional study analyzed Algenerated images from Midjourney 6.0, ChatGPT 4.0, and Gemini 3 between October and November 2024 to evaluate demographic diversity in U.S. hospitals across four key leadership categories within the C-suite: Chief Executive Officer, Chief Medical Officer, Chief Nursing Officer, and Chief Financial Officer. The focus was on gender, age, and race/ethnicity to reflect the scope and complexity of these roles. Two independent reviewers classified the images using a simplified version of the Chicago Face Dataset, ensuring consistency and minimizing bias. Statistical analyses were conducted using Stata 17.0 (StataCorp LLC, College Sta-

Results and Discussion: A total of 1,200 images were analyzed, revealing distinct patterns in the representation of four key leadership categories within the C-Suite across various Al models. In ChatGPT, 94.5% of individuals were portrayed as 'white' and 86.5% as 'male.' In Midjourney, these proportions were 75% and 69.5%, respectively, while in Gemini, they were 51.5% and 50.3%. Age representation also showed significant variation, with younger individuals notably underrepresented. Discrepancies in ethnicity classification were observed in 176 cases (14.7%; kappa 0.670), with the highest proportion occurring in Midjourney-generated images (91/400, 22.8%; P<0.001).

Conclusion(s): This study highlights the underrepresentation of women and diverse groups in healthcare leadership, mirrored in Al-generated content, emphasizing the need for systemic reforms in hiring, leadership evaluations, and Al datasets to promote equity, dismantle biases, and reflect workforce diversity and expertise.

50AP01-7 **HOLOSIM:** the way forward in complex crisis training

S. Gupta¹, F. Alam¹, J. Tarshis¹, S. Choi¹, L. Kaustov¹, J. Wiegelmann¹ ¹Sunnybrook Health Sciences Centre, Anesthesia, Toronto, Canada

Background and Goal of Study: The current state-of-the-art in medical simulation is mannequin-based and utilizes highly specialized and costly personnel, equipment, and centers. We have created a new mixed reality (MR) platform, HoloSIM, which consists of laptop-based instructor software and Microsoft Hololens headset-based student software. The Microsoft Hololens allows spatially stable, interactable, and animated holograms to be inserted into a user's workspace (MR). Though infrequent, anaphylaxis is a high-risk crisis that requires rapid decisive action. which presents a challenge for trainees. HoloSIM simulation will be non-inferior in knowledge acquisition and application of decision-making concepts in anaphylaxis management compared to high-fidelity mannequin-based simulation.

Materials and Methods: This study is a REB-approved prospective randomized control trial where 40 junior medical students were randomized to either a Hololens-based or a mannequin-based simulation regarding anaphylaxis management (NCT04591041). Both groups completed a pre-test and practiced anaphylaxis management using their assigned modality. We invited the participants to return one week later to complete a posttest and knowledge application test on a new mannequin-based crisis assessment scenario.

Results and Discussion: For the knowledge application test, the HoloSIM group had an average score of 25.7+/-5.5, and the mannequin group had an average score of 26.7+/-6.1 (P=0.59). We were unable to demonstrate non-inferiority. Conversely, there were no statistically significant differences either. The system usability score (SUS) for the HoloSIM platform was 59.9, which is considered below average (SUS Average = 68) and in the 'marginally acceptable' category. Despite the usability scores, when asked if 'this type of simulation was beneficial to my learning' and if they 'would participate in this type of simulation session in the future', 89% and 95% of participants in the HoloSIM group agreed or strongly agreed with the statements.

Conclusion(s): MR is still a new innovation in medical education. This study is among the first to create MR critical care simulations using comprehensive learning theories. Given the HoloSIM platform is still a prototype platform, the low SUS could have interfered with the desired learning outcomes. However, given the medical students' enthusiasm, we believe these issues can be improved with further development and studies.

pyAKI - an open source solution to automated acute kidney injury classification in large datasets

C. Porschen¹, J. Ernsting^{2,3,4}, P. Brauckmann⁵, H. Booke¹, T. von Groote¹, T. Hahn³ ¹Universitätsklinikum Münster, Klinik für Anästhesiologie, Operative Intensivmedizin und Schmerztherapie, Münster, Germany, ²University of Münster, Institute for Geoinformatics, Münster, Germany, 3Institute for Translational Psychiatry, University of Münster, Münster, Germany, ⁴University of Münster, Faculty of Mathematics and Computer Science, Münster, Germany, 5University of Applied Sciences, Münster School of Business, Münster, Germany

Background and Goal of Study: Acute Kidney Injury (AKI) is a frequent and often severe complication in critically ill patients, affecting up to 50% of ICU admissions. Standardized AKI classification using the Kidney Disease Improving Global Outcomes (KDIGO) criteria is essential, but challenging in large datasets due to the lack of accessible and consistent tools. This project introduces pyAKI, an open-source tool designed to automate AKI classification by implementing the KDIGO 2012 definitionin time series data, addressing this gap to improve reproducibility and quality in AKI research.

Materials and Methods: PyAKI was developed and validated using the Medical Information Mart for Intensive Care (MIMIC-IV) database. The pipeline applies KDIGO 2012 guidelines for AKI classification based on serum creatinine (SCr) and urine output (UO). A standardized data model was constructed, and interpolation techniques were used to process sparse data. Validation involved comparing pyAKI's output with expert annotations by a panel of junior and senior physicians.

Results and Discussion: Validation results demonstrate that pyAKI achieved an accuracy of 1.0 in all KDIGO stages, surpassing the performance of human annotations, which had a sensitivity of 0.96 and specificity of 0.99. The pipeline was highly efficient, labeling the dataset in 0.27 seconds compared to 970 minutes required by physicians. PyAKI's consistent high accuracy and efficiency make it a valuable tool for AKI classification in large-scale datasets, reducing the variability inherent in human annotation and enabling more reproducible research.

Conclusion(s): PyAKI offers a reliable, open-source solution for AKI classification using KDIGO 2012 AKI criteria. PyAKI exceeds human-level accuracy. Its availability enhances the consistency and scalability of AKI research, providing a powerful tool for clinical research and decision support in critical care that can spare time for AKI classification for research projects.

50AP01-9 When robotics leave the operating room

N. Alcada¹, M.M. Gomes², V. Costa³ ¹Unidade Local de Saúde Entre Douro e Vouga, Anesthesiology, Santa Maria da Feira, Portugal, ²Unidade Local de Saúde de Gaia e Espinho, Anesthesiology, Vila Nova de Gaia, Portugal, 3Unidade Local de Saúde de Gaia e Espinho, Anesthesiology, Santa Maria da Feira, Portugal

Background: Robotic systems for interventional radiology (IR) are in early stages of implementation. They promise advantages, such as precise navigation and guidance, reducing radiation exposure and providing better access to challenging areas.1

However, the anesthetic management is rarely mentioned. In this report we detail the anesthetic management of a patient undergoing robot-assisted hepatic thermoablation (RAHTA) and its challenges.

Case Report: An 89 yo, American Society of Anesthesia (ASA) III patient, was proposed for RAHTA guided by computed axial tomography (CT). The patient was positioned in supine, arms adducted, inside the CT machine. ASA standard, depth of anesthesia and neuromuscular blockade monitoring was used. Total intravenous anesthesia was performed.

Fentanyl was administered prior to intubation and thermoablation. The patient was intubated. Short periods of apnea were used during CT-scan and robotic navigation.

To prevent desaturation, the patient was ventilated with 80% FiO_a immediately prior and after apnea. Multimodal analgesia was used for adequate analgesia. Ondansetron was administered to avoid nausea and vomit. Neuromuscular blockade was reversed and the patient was extubated. The patient was admitted to the recovery ward. There were no adverse events and patient was stable throughout.

Discussion: Scientific and technological developments impose an anesthetic challenge outside the operating room. Patient positioning changes according to lesion location and the patient should be positioned comfortably and the optical camera unimpeded. Apnea or high frequency jet ventilation ensure minimal impact on imaging and robot navigation.2

Any movement after imaging can alter the robot's planned path, with severe consequences. To ensure immobility, neuromuscular blockade should be applied. If periods of apnea are performed, the patient should be adequately oxygenated. Pain can be severe and prolonged, often requiring opioids to treat visceral pain.2 Nausea and vomiting due to opioid use and visceral inflammation should be treated. Throughout medical advancements, the quality and safety of patients' procedures must always be guaranteed.

References:

- 1. Br J Radiol. 2023 Dec;96(1152):20230620.
- 2. Local Reg Anesth. 2019 Dec 4;12:127-137.

Learning points:

- · Minimizing movement is mandatory for optimal targeting and safety during RAHTA.
- General anethesia with neuromuscular blockade appears to be the optimal anesthetic plan.

Non-invasive vs biological blood hemoglobinemia determination for perioperative management: systematic review and meta-analysis

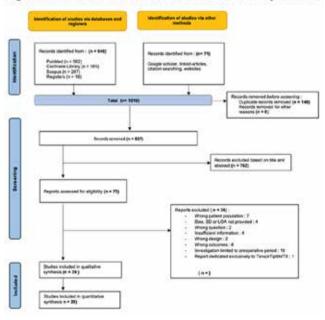

L. Moreira¹, E. Engelman¹, I. Estruch-Pons¹, M. Parvais¹, A. Lecucq¹, P. Pandin¹

¹Université Libre de Bruxelles, Anesthesiology & Critical Care, Brussels, Belgium

Background and Goal of Study: Hemoglobin is an essential parameter for quantifying anemia and used for guiding transfusion. Conventional methods require intermittent invasive sampling (time to obtain). Hemoglobinemia by pulsed co-oximetry is noninvasive, immediate and offers the advantage of continuous monitoring. The aim of this systematic review is to assess the diagnostic accuracy of pulsed co-oximetry compared with biological determinations in perioperative management.

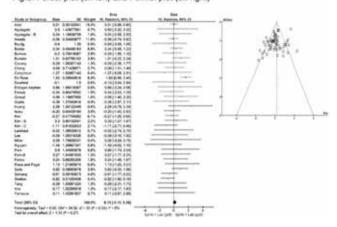

Materials and Methods: The review was performed according to the PRISMA statement (Fig.1). Searches in Pubmed, Cochrane Library and Scopus databases were performed from January 2000 to February 2024 for studies comparing non-invasive haemoglobin measurement with invasive methods. The QUADAS-2 scale was used to assess the risk of bias. For data analysis, Review Manager 5.4.1 software was employed, using the inverse variance method and a random-effects model to calculate the mean difference (MD) and 95% confidence intervals. Sensitivity of analysis were performed to determine the influence of several variables on the results

Fig.1. Prisma flowchart of the literature search and study selection

Results and Discussion: The meta-analysis included 36 studies involving 1888 patients (Fig.2). Meta-analysis revealed a mean difference between the non-invasive and invasive methods of 0.13 g.dL-1 (95% confidence interval [CI]: 0.10- 0.36) (P-value > 0.05). Sensitivity analyses showed no statistically significant difference between the two methods. There was a very good homogeneity among the studies (I2=0%). Trending analysis was considered acceptable in a majority of the studies (Fig.2)

Fig.2. Forest plot (on left) and Fennel plot (on right)

Conclusion(s): The results obtained support the reliability of pulsed co-oximetry. Considering the potential benefits of this parameter, it seems rational to integrate this technology perioperatively to guide standard clinical practices for optimizing the management of surgical patients.

50AP01-11

Analgesia Nociception Index (ANI) for guiding intraoperative opioid administration during living donor liver resection and its impact on postoperative nausea and vomiting

N. Mysynchuk¹, A. Wojtanowski², M. Pomeranskyi¹, O. Kotenko3, Y. Kuchyn1

¹Bogomolets National Medical University, Department of Surgery, Anesthesiology and Intensive Care of Postgraduate Education, Kyiv, Ukraine, ²Lille University Hospital, Cic-It Lille, Lille, France, 3Universal Hospital "Oberih", Center for Liver, Pancreas and Transplant Surgery, Kyiv, Ukraine

Background and Goal of Study: Anaesthesiologists often rely on changes in the autonomic nervous system, such as heart rate, blood pressure, and sweating, to help determine the need for pain relief medication. The analgesia nociception index (ANI) is a noninvasive tool used for monitoring the intraoperative state of the autonomic nervous system, particularly the parasympathetic nervous system. During long-lasting high nociceptive surgery, fentanyl was infused at our institution. Opioids can lead to postoperative nausea, vomiting, and other complications when an overdose occurs. The fentanyl dosage changes significantly after hours of infusion due to context-sensitive halftimes.

This study aimed to assess whether intraoperative analgesia nociception monitoring (ANI) could affect the average intraoperative dose of fentanyl and, subsequently, the occurrence of postoperative nausea and vomiting.

Materials and Methods: Patients who were included in this study underwent living liver donor resections with fentanyl infusion and thoracic epidural analgesia. Two groups of patients were analyzed: the ANI group (n = 24), in which the fentanyl dose was adjusted with ANI monitoring, and the retrospective control group (n = 25), with standard practice.

Results and Discussion: A t test, Wilcoxon test, a chi-square test were conducted to assess the difference between the ANI and control groups. Statistical significance: p<0.05. We found a 36.63% decrease in the average dose of fentanyl in the ANI group (1.28 (±0.48) µg·kg⁻¹·hour⁻¹) compared with that in the control group (2.02 (± 0.46) ug·kg⁻¹·hour⁻¹) (p < 0.001).

Additionally, there was a 24.25% reduction of PONV in ANI group but without the statistic significance (p = 0.636). The negative results may be due to the greater number of females in the control group and the use of sevoflurane.

	ANI (n=24)	Control (n=25)	p value	
ANI mean value	62.59 (±8.69)			
Time of anaesthesia (min)	565 (540–600 [320-730])	510 (450–600 [360-930])	0.1546	
Fentanyl (µg·kg ⁻¹ ·hour ⁻¹)	1.28 (±0.48)	2.02 (±0.46)	1.613e-06 (<0.001)	
PONV	8 (33.33%)	11 (44%)	0.636	

Conclusion(s): We suggest that ANI monitoring can be used for guiding fentanyl infusion, reducing opioid consumption in comparison with standard practice.

Further randomized trials with other modalities, such as ASA III-IV patients, total intravenous anaesthesia with opioids with stable context-sensitive halftime and surgery with low nociceptive stimuli, are needed.

50AP02-1

Comparative study of the concordance between BIS® and CONOX® registers for monitoring cerebral hypnosis in general anesthesia

V. Fernández¹, R. Navarro Suay¹, N. Díez Navarro² ¹Hospital Central de la Defensa Gómez Ulla, Anesthesiology, Madrid, Spain, ²Universidad Politécnica, Biomedical Engineering, Madrid, Spain

Background and Goal of Study: We have multiple devices for monitoring cerebral hypnosis during general anesthesia. The analysis of the electroencephalographic trace allows us to adjust the doses of anesthetic drugs, reducing their side effects, shortening the duration of anesthetic emergence, and minimizing the incidence of intraoperative awakening.

The aim of the study was to correlate the values obtained using the BIS® monitor and the gCON index of the CONOX® monitor to determine their agreement and interchangeability in the monitoring of cerebral hypnosis during general anesthesia.

Materials and Methods: 31 patients scheduled for otorhinolaryngological surgery under general anesthesia and orotracheal intubation were recruited, following a pre-established anesthetic protocol. Based on the BIS® index and the CONOX® qCON index data, as well as their respective signal quality index (SQI) and electromyogram (EMG) values, collected randomly every 5 minutes by the principal investigator, two types of recordings were established: those independent of SQI and EMG, and those considered "optimal" with SQI ≥90 and EMG ≤30.

Results and Discussion: A total of 941 pairs of measurements were obtained over 4705 minutes, of which 75.24% were considered "optimal." The recordings showed a high overall agreement (ICC 77.3%, 95% CI; p<0.001). For the "optimal" measurements, high agreement was also found (ICC 78.4%, 95% CI; p<0.001). 95.4% of the values were within the acceptable range of ± 2 SD, while 97.3% were within the range of ± 10 U. Considering only the "optimal" measurements, these values were 95.7% and 97.7%, respectively. The difference between the two sensors was 0.6 units for both total and "optimal" measurements, in favor of the BIS®

Conclusion: The variability obtained between BIS® and CONOX® recordings for monitoring cerebral hypnosis during general anesthesia is acceptable for routine clinical practice, with no expected changes in anesthetic management based on differences in the recordings. Therefore, both are interchangeable without compromising patient safety.

50AP02-2

Bilateral bispectral index and asymmetries in patients with high risk of postoperative delirium: second preliminary report of an observational, prospective, exploratory study

M.P. Lauretta¹, A. Di Tizio¹, E. Marra¹, S. Busignani¹, L. Querci²

¹IRCCS Azienda Ospedaliero Universitaria S.Orsola di Bologna, Anestesiologia e Terapia del Dolore, Bologna, Italy, ²ASTT Grande Ospedale Metropolitano Niguarda di Milano. Terapia Intensiva ad indirizzo neurologiconeurochirurgico, Milano, Italy

Background and Goal of Study: Postoperative delirium (PD) and postoperative cognitive dysfunction (POCD) are significant complications after general anesthesia (GA). Bispectral Index (BIS) is a non-invasive monitor to access electroencephalographic information during GA and their asymmetry in right and left cerebral hemispheres (ASYM). BIS values correlates with depth of GA. This study has the aim to evaluate ASYM in a cohort of surgical patients with high risk of PD.

Materials and Methods: Thirty-four patients undergoing head & neck surgery, having 3 of the following criteria ("a priori" high risk), were enrolled: Age>70, male sex, ASA III, status of smoker, arterial hypertension. In theatre, a bilateral BIS probe was applied on their forehead. BIS Vista® monitor recorded left and right total power (0-30 Hz) and ASYM at these timepoints: (t1) BIS probe application (t2) 60" before GA administration (t3) 60" after myoresolution (t4) intubation (t5) surgical incision (t6) end of ipnosis (t7) 10 minutes after extubation. Daily follow-up was performed with CAM scale over 5 post-op days for PD diagnosis and a telephone follow-up with CIT-6 scale at 30 and 90 days for POCD.

Results and Discussion: ASYM of 50% indicates the same inter-hemispheric power; while ASYM<50% indicates a lower power in the left cerebral hemisphere. In our study, patients developing PD had higher power in the right hemisphere at t1, t2, t3 (ASYM<50%), while presented higher power in the left hemisphere at t6, t7 (ASYM>50%). Similarly, patients who developed POCD at 30 days presented prevalence in the right hemisphere at t1, t2 and prevalence in the left hemisphere at t6.

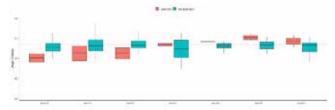

Fig.1 ASYM at different timepoints in patient developing PD at 5 post-op days.

Fig.2 ASYM at different timepoints in patients developing POCD at 30 post-op days.

asym_6	31	50.40 (50.18, 50.62)	49.78 (49.23, 50.29)	0.034
asym_7	31	49.88 (49.20, 50.02)	50.00 (49.00, 50.72)	0.4

¹Median (IQR)

Table 1. Asym values in patient developing PD and POCD.

Conclusion(s): Despite our result are preliminary, they highlight the association between intraoperative inter-hemispheric EEG differences and onset of PD and POCD. BIS monitor appear a promising tool to predict neurological complications after GA.

50AP02-3

Monitoring anesthetic depth and nociceptive response using the CONOX monitor in thoracic surgery: an observational study

- J. Llopis-Lorente¹, J. Duart-Benavent¹, M. Blesa Ripollés¹,
- J. Fernández Ruiz¹, N. Garcia Gregorio¹,
- P. Argente Navarro¹

¹Hospital Universitari i Politecnic la Fe, Valencia, Valencia, Spain

Background and Goal of Study: Thoracic surgery poses significant challenges due to intense nociceptive stimuli, requiring precise intraoperative pain management. Effective control enhances patient comfort, reduces surgical stress, and improves recovery. Regional analgesia, such as paravertebral block (PVB) and thoracic epidural analgesia (TEA), provides effective, localized pain relief with fewer systemic side effects. Variability in patient response highlights the need for advanced monitoring tools. The qNOX index, generated by the Conox monitor, assesses nociception objectively and facilitates intraoperative adjustments. This study aimed to evaluate the correlation between qNOX values and intraoperative pain events in thoracic surgery.

Materials and Methods: A prospective observational study included 9 patients (mean age 68.3±7.6 years; 55% female; ASA II–III) undergoing scheduled thoracic surgery. Six received PVB, and three underwent TEA with general anesthesia. Exclusion criteria included emergency surgery, contraindications to regional techniques, and conditions impairing pain communication. Anesthetic protocols included TIVA with propofol and rocuronium, with remifentanil (0.1 μg/kg/min) for PVB cases.

Monitoring included qNOX, qCON, patient state index (PSI), and standard parameters (heart rate, MAP, SpO2). Measurements were taken at baseline, after laryngoscopy, pre-surgical incision, during surgery, and every 30 minutes. Pain events were defined as qNOX >60, heart rate or MAP increases >20% from baseline, or patient movement.

Results and Discussion: qNOX remained <60 for 88.2±17.0% of the intraoperative period, reflecting effective nociceptive control. Three patients had critical pain events (qNOX >60):

- A PVB case showed qNOX elevation 25 minutes into surgery, preceded by tachycardia and hypertension.
- Another PVB case had sustained qNOX >60 after VATS (videoassisted thoracoscopic surgery)-to-thoracotomy conversion.
- 3. A TEA case had qNOX >60 after laryngoscopy and early surgery, suggesting suboptimal catheter function.

qNOX correlated directly with PSI, with qNOX >60 coinciding with PSI >50, indicating nociceptive perception and inadequate anesthetic depth.

Conclusion: The qNOX index is a valuable tool for real-time nociceptive monitoring in thoracic surgery, enabling personalized analgesic adjustments. Its integration with PSI enhances anesthetic management by identifying critical moments requiring optimized analgesia and hypnosis. Ongoing patient recruitment aims to validate these findings and further explore correlations between regional techniques and monitoring parameters.

50AP02-4

Integrated pulmonary index for monitoring respiratory status in deeply sedated children during botulinum toxin injections: a prospective clinical cohort trial

T. Fataliyev¹, <u>Z.I. Arslan</u>¹, C. Kiy Kiliç¹, N. Kandemir¹ ¹Kocaeli University Medical Faculty, Anesthesiology and Reanimation, Kocaeli, Turkey

Background and Aim: Evaluating respiratory status solely based on oxygen saturation (SpO₂) or capnography (ETCO₂) may lead to delayed detection and interventions. The integrated pulmonary index (IPI) combines SpO₂, ETCO₂, respiratory rate, and heart rate into a single value between 1 and 10. This trial aims to evaluate the effectiveness of IPI in providing early warnings of respiratory compromise in deeply sedated children undergoing botulinum toxin injections.

Methods: This trial commenced after receiving approval from the ethics committee and written informed consent was obtained from families following the Helsinki Declaration. 70 children between 1-17 years of age were enrolled in this trial. All patients were premedicated with midazolam, sedation was achieved using 3 mg/kg propofol plus 1 mcg/kg fentanyl intravenously. A continuous propofol infusion at 125 mcg/kg/minute (min) was maintained to keep the bispectral index (BIS) level between 40-60. If the IPI decreased to ≤ 6, the propofol infusion rate was reduced by 25

²Wilcoxon rank sum exact test

mcg/kg/min, and the jaw thrust maneuver was applied. If the IPI decreased to ≤ 3, sedation was discontinued, and mask ventilation was initiated.

Results: The family of one child didn't give consent: thus, 69 children were analyzed. The gender distribution of pediatric patients was similar. The majority of the children were ASA-2, and 49 of them had only cerebral palsy. Others had additional epilepsy and hydrocephalus. Recorded values at 5-minute intervals for heart rate, blood pressure, respiratory rate, BIS, IPI, SPO,, and ETCO, were consistent among the groups after sedation. IPI ≤ 6 was observed in 51 (%74) out of 69 patients (p<0.001). ETCO2 had decreased more than %20 in 34 out of 69 children (%49) (p=0.042). 8 out of 69 patients' SPO₂ observed ≤ 92 (%12). 25 apnea occurred in these 69 children. IPI ≤ 6 was 24 of 25 apnea-detected children (%96). ETCO2 decreased more than %20 in 16 patients of these 25 (%64). $SpO_2 \le 92$ in 8 children of these 25 (%32). Decreasing sedation plus jaw thrust maneuver was applied in all apnea cases. Stopping sedation and administering mask ventilation were required in 4 patients who experienced apnea.

Conclusion: The Integrated pulmonary index, which combines four monitoring parameters, could be an early predictor of respiratory compromise in deeply sedated children.

Anaesthetic Considerations for the hinotori™ Surgical Robot System: a singapore-based experience

B. Yip¹, V.K. Ho¹, A.K.Y. Lee¹, J. Wong¹, J.M.H. Cheng¹ ¹Singapore General Hospital, Division of Anaesthesiology and Perioperative Medicine, Singapore, Singapore

Background: The hinotori™ Surgical Robot System, the first robotic platform developed in Japan, offers an alternative to the da Vinci system for laparoscopic surgeries. Early studies show comparable outcomes in urological procedures, positioning hinotori™ for broader adoption.[1] The system's unique design of undocked robotic arms and advanced optics introduces specific anaesthetic challenges. This report highlights the first Singaporean experience with hinotori™, focusing on key anaesthetic considerations for safety and outcomes.

Case Report: Teams underwent rigorous training in Japanese centres and rehearsed at Singapore's simulation lab. The first human case was a radical intra-peritoneal prostatectomy for a patient with prostate neoplasm. Anaesthetic protocols included IV Propofol, TCI Remifentanil, IV Rocuronium, and sevoflurane with end-tidal control. Port placement required 8 minutes, and robot docking took 12 minutes. The total surgical time was 127 minutes with a blood loss of 30 ml. The patient was positioned in lithotomy and steep Trendelenburg using non-slip silicone mats and secure strapping to maintain stability. Post-surgery, anaesthesia was reversed fully and the patient recovered uneventfully.

Discussion: Key anaesthetic challenges included non-docked robotic arms requiring precise positioning to prevent pressure on the patient's face, mitigated by a guardrail. The undocked ports pose a movement risk, managed through non-slip mats and straps. Advanced optics necessitated adjustments in ventilatory parameters to reduce respiratory artefacts. The hinotori™ system, despite its challenges, can be managed effectively to ensure perioperative safety and optimal outcomes. Ongoing experience and refinements will be crucial as the system is applied across various surgical disciplines.

References:

1. Miyake, H. & Fujisawa, M. (2024) 'Early experience and future prospects regarding use of newly developed surgical robot system, hinotori, in the field of urologic cancer surgery', International Journal of Clinical Oncology, 29(6), pp. 640-646. doi: 10.1007/s10147-024-02503-5.

Learning Points:

- 1. Careful patient positioning and equipment setup is necessary to mitigate risks associated with undocked ports and robotic arm movement.
- 2. Adjustments to ventilatory settings, including low tidal volume and paralysis, are critical to minimizing respiratory artefacts.
- 3. Ongoing experience is key to expanding the hinotori™ system's use across surgical disciplines.

50AP02-6

Virtual reality headset and peripheral nerve blocks for amoutation surgery: addressing the emotional and physical burden through innovative strategies

F. Remédios Duque¹, M. Pereira¹, J. Pereira¹, J. Valente¹, A.d.S. Rocha^{1,2}, A. Resende¹

¹North Lisbon University Hospital Centre (CHULN). Anestesiologia, Lisboa, Portugal, ²University of Lisbon, University Clinic for Anaesthesiology and Reanimation, Faculty of Medicine, Lisboa, Portugal

Background: Amputation surgery poses significant emotional and physical challenges, especially in elderly patients with cardiovascular comorbidities. Alongside physiological demands, the psychological burden - including anxiety, fear, and emotional distress-often necessitates sedatives during regional anesthesia. Virtual reality (VR) is an emerging tool to manage perioperative anxiety, but its role in vascular surgery and amputations is underexplored.

Case Report: We report two cases of limb amputation in patients with heavy cardiovascular comorbidities, using peripheral nerve blocks and a VR headset, without sedative drugs or anxiolytics. An 82-year-old man underwent below-knee amputation with sciatic and femoral nerve blocks; a 66-year-old man had a forefoot amputation with saphenous and sciatic nerve blocks. The VR headset provided an immersive, calming experience, distracting patients from the surgical environment. There was no need to administer sedatives, oxygen or supplementary analgesia during the procedure. Both patients went to the ward after surgery, without the need for post-anesthesia care unit (PACU) surveillance.

Discussion: The VR experience, combining noise-cancellation headphones and verbal relaxation commands, was crucial in maintaining patient comfort and mitigating the emotional distress of limb loss. Postoperative assessments using the Quality of Recovery-15 (QoR-15)[1] and Evaluation du Vécu de l'Anesthésie Générale-Légère et Régionale (EVAN-LR)[2] scores revealed excellent recovery and high satisfaction, with no reported pain or discomfort. Both patients expressed willingness to undergo similar anaesthesia regimens in the future. VR offers a novel strategy to address the emotional challenges of amputation surgery by fostering relaxation and reducing perioperative stress. This innovative approach warrants further investigation to establish its potential to replace sedatives and analgesics, minimizing complications in high-risk patients. It also enhances perioperative care by reducing recovery times, avoiding PACU stays, and advancing patient-centered care.

References:

- 1. Axel et al. Development and Validation of Perioperative Satisfaction Questionnaire in Regional Anesthesia.
- 2. Kiani & Simbar. Development and Psychometric Evaluation of a Perioperative Quality Assessment Tool.

Learning Points: The potential of VR as a complementary tool in regional anesthesia with peripheral nerve blocks, advancing patient-centered care in amputation surgery.

50AP02-8

Electromyography vs. kinemyography in neonates, infants, toddlers and children - A monocentric randomised prospective agreement study – ETCETERA

M. Marb1, F. Scheffenbichler1, B. Ulm1, B. Jungwirth1, M. Blobner¹, S. Schmid¹ ¹Hospital Ulm, Department of Anaesthesia and Intensive Care Medicine, Ulm, Germany

Background and Goal of Study: Neonates and infants are particularly susceptible to residual paralysis, which is aggravated by the lack of licensed quantitative neuromuscular monitoring (NMM) [1, 2]. We tested the precision of kinemyography (KMG) and electromyography (EMG) in children.

Materials and Methods: Four age groups of children (n=16 each) undergoing elective surgeries under sevoflurane anaesthesia were included: neonates including preterm born (≤44 weeks post-menstruation (p.m.)), infants (>44 weeks to ≤3 months p.m.), toddlers (>3 months to ≤2 years) and children (>2 years to <5 years). Calibrated NMM was performed using train-of-four (TOF) stimulation: KMG (Paediatric Mechanosensor, GE Healthcare) on one arm and EMG (children-sized, single-use electrode, Senzime) on the contralateral arm. Rocuronium was given aiming for a TOF count ≤2 and Sugammadex (2 mg kg-1) if the TOF ratio was <0.95 at the end of surgery. Primary endpoint was the precision of TOF ratios, expressed as repeatability coefficient (RC) with 95% confidence interval (CI).

Results and Discussion: A total of 64 children were enrolled, of which 32 were ASA I. 18 ASA II. and 14 ASA III. At baseline, the RC of KMG was 0.131 (0.130 to 0.132) and that of EMG was 0.093 (0.093 to 0.094) for all children. During neuromuscular recovery, the RC of KMG was 0.186 (0.186 to 0.187) and that of EMG was 0.171 (0.170 to 0.171). RCs of age groups are shown in Table 1. After sugammadex, 50 of 64 children reached a KMG TOF ratio >0.8, while 60 reached an EMG TOF ratio >0.8. More than one attempt was required to calibrate the KMG in 5 and the EMG in 2 neonates as well as the KMG in 4 and the EMG in 1 infant.

Conclusion: EMG was more precise than KMG, in particular in neonates (for whom no device is approved). Reasons for incomplete TOF recovery, even after sugammadex, must be investigated. As the RC indicates the range, in which the next value will be measured with 95% probability, improved precision is required to reliably protect especially neonates from unmonitored residual paralysis.

Table 1				KMG			EM		
	Age	Patients (n)	Measure- ments	RC	95% CI	Patients (n)	Measure- ments	RC	95% CI
200	Neonates	16	186	0.164	0.159 to 0.168	16	689	0.087	0.086 to
9	Infants	16	143	0.118	0.114 to 0.122	16	352	0.101	0.099 to 0.102
Baseline (before rocuronium)	Toddlers	16	159	0.101	0.098 to 0.104	16	332	0.108	0.106 to 0.109

Rapid determination of rocuronium bromide concentrations in beagles using portable mass spectrometer

L. Xiaoxiao1, P. Chang2, W. Zhang2 ¹West China Hospital, Sichuan University, Department of anesthesiology, Chengdu, China, 2West China Hospital, Department of anesthesiology, Chengdu, China

Background: This study investigates the application of a portable mass spectrometer (MS) for the rapid detection of Rocur concentrations in whole blood from beagles, with the aim of facilitating the development of individualized PK-PD models.

Materials and Methods: Four beagles aged 1 to 1.5 years and weighing 8 to 12 kg were included in this study. A single intravenous dose equivalent to 3 ED₅₀ (0.748 mg/kg) of Rocur was administered. Neuromuscular monitoring was conducted using the TOF ratio (TOFR). Blood samples (0.1 mL) were collected at predetermined intervals and recovery stages following Rocur administration, with the TOFR recorded at corresponding time points. Rocur concentrations in whole blood ($C_{\text{b-Rocur}}$) were determined using the Cell portable MS and the HPLC-MS for consistency comparison. Furthermore, a PK-PD model based on C_{h-Rocur} measurements obtained from the Cell portable MS was developed.

Results and Discussion: A strong linear relationship was observed for Rocur concentrations measured by the Cell portable MS within the range of 10-10,000 ng/mL (y = 1108.32 * x+ 14873.99, R^2 = 0.993). Both methods demonstrated that after injection, $\rm C_{b\text{-}Rocur}$ increased rapidly before declining. The $\rm T_{max}$ of $\rm C_{b\text{-}}$ $_{\text{Rocur}}$ was 0.5 minutes, with C $_{\text{max}}$ values of 4.52 \pm 1.16 $\mu\text{g/mL}$ (measured by the Cell portable MS) and 4.89 \pm 0.52 μ g/mL (measured by HPLC-MS), respectively. The mean concentration RSD for both methods was <15%. Results from the two methods showed a strong linear correlation ($y = 1.07 * x + 30.08, P < 0.0001, R^2 =$ 0.8948). As $\rm C_{b\text{-}Rocur}$ decreased, the TOF ratio gradually recovered, with an IC $_{50}$ of C $_{\text{b-Rocur}}$ determined to be 0.25 \pm 0.05 μ g/mL.

Conclusion: This study successfully applied the Cell portable MS for rapid quantitative analysis of Rocur concentrations in whole blood, demonstrating good consistency with the traditional HPLC-MS method.

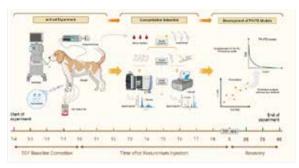

Figure 1. Workflow for the analysis of Rocur using the Cell portable MS.

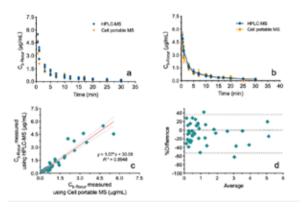

Figure 2 Full-scan mass spectrum of Rocur in blood samples measured using the Cell portable MS.

50AP02-10

Immersive virtual reality as adjunct to spinal anesthesia in two patients undergoing orthopaedic surgery in lateral decubitus position

M. Pereira¹, J. Pereira¹, F. Duque¹, S. Pereira¹, A. Rocha^{1,2}, A. Resende¹

¹North Lisbon University Hospital Centre (CHULN), Department of Anaesthesia, Lisbon, Portugal, ²Faculty of Medicine, University of Lisbon, University Clinic for Anaesthesiology and Reanimation, Lisbon, Portugal

Background: Immersive Virtual Reality (IVR) is emerging as a nonpharmacological adjunct to anesthesia, providing the patient with a distraction from the intraoperative environment and potentially sparing the use of sedative agents and medical costs. Aditionally, lateral decubitus positioning in the operating room can cause neck and shoulder discomfort during surgery, in patients under spinal anesthesia. While this technology has already been applied in operating rooms worldwide, there is a lack of large scale studies analysing its clinical utility in different operative settings.

Case Report: In the present case report, we evaluate two patient's overall experience and satisfaction when using IVR as an adjunct to spinal anesthesia, in procedures requiring lateral decubitus positioning.

Discussion: The first patient underwent surgical reduction and osteosynthesis of a trimalleolar fracture and the second patient underwent total hip replacement. In both cases, the IVR glasses were turned on before the spinal anesthesia technique, with the patient in supine position. Afterwards, the patients were positioned in lateral decubitus and during the spinal anesthesia both remained distracted and calm, facilitating the technique. Throughout the surgical procedures, no sedative agents were used and there was no report of nausea or any other symptom of discomfort. During the postoperative period, the experience of both patients was assessed through the application of the QoR-151 and EVAN-LR2 scores, with both patients providing positive feedback. Even more significantly, the two patients stated in the postoperative interview that they would opt again for spinal anesthesia combined with IVR if they are ever in need of undergoing a surgical procedure in the future.

References:

1. Myles, Paul S et al. "Measurement of quality of recovery after surgery using the 15-item quality of recovery scale: a systematic review and meta-analysis." British journal of anaesthesia vol. 128,6 (2022): 1029-1039. doi:10.1016/j.bja.2022.03.009; ²Maurice-Szamburski, Axel et al. "Development and validation of a perioperative satisfaction questionnaire in regional anesthesia." Anesthesiologyvol. 118,1 (2013): 78-87. doi:10.1097/ ALN.0b013e31827469f2

Learning Points: Conducting these procedures with IVR as adjunct has the potential of reducing the use of sedative agents and consequently minimizing the risk of respiratory or hemodynamic complications and medical costs.

50AP02-11 Can ChatGPT4 write a narrative review on locoregional anesthesia?

S. Brunetti¹, D. Gaetano¹, F. Coppolino¹, G. Trivelli¹, V. Riccardi¹, P. Sansone¹

¹Università degli Studi della Campania Luigi Vanvitelli, General and Specialized Surgery for Women And Children, Naples, Italy

Background and Goal of the Study: ChatGPT4o, an Al model by OpenAI, can analyze, interpret, and generate text while retrieving information from diverse online sources. Its increasing use has raised questions about its reliability and validity for scientific research. This study evaluated ChatGPT-4o's ability to produce a narrative review based on pre-selected papers and specific instructions. The aim was to assess whether researchers and clinicians with limited AI expertise could use the tool effectively and to identify its strengths and limitations.

Materials and Methods: Between August and October 2024, a PubMed search identified studies on Continuous Paravertebral Blocks (CPVB) in thoracic surgery. The search used "Continuous Paravertebral Block" and "Thoracic Surgery" as terms and targeted RCTs, meta-analyses, and case reports published between 2000 and 2024. Studies on single-shot blocks, pediatric populations, and breast or cardiac surgery were excluded. Of 146 retrieved articles, 69 met inclusion. The selected articles were uploaded to ChatGPT-4 in groups of 10 due to system limitations. Instructions focused on CPVB efficacy, safety, adverse events (e.g., hypotension, urinary retention, pneumothorax), and benefits like improved pain scores and reduced opioid use. A 2,000-word limit was imposed on the review

Results and Discussion: ChatGPT-4o generated pertinent, wellstructured, and readable text that addressed key topics and provided additional insights beyond the instructions given. However, multiple iterations were needed to achieve a deeper analysis. Batch processing caused later uploads to predominate, limiting integration of earlier content. Defining and applying qualitative criteria for study evaluation was challenging. While ChatGPT-4o could outline these criteria, it was unclear if they were consistently applied. Some papers were omitted without explanation. and references required manual correction.

A study by Mostafapour et al. (2024) found ChatGPT-4o matched human reviews in accuracy but underperformed in contextual understanding. In our experience ChatGPT-4o excelled in speed and breadth of knowledge but struggled with methodological rigor.

Conclusion(s): ChatGPT-40 offers rapid synthesis and adaptability, making it a valuable supplemental research tool. However, its limitations in study quality assessment and methodological rigor require significant human oversight to ensure accuracy and reliability.

50AP02-12

Al detectives cracked the abstracts: evaluating correlation between tools in identifying artificial intelligence use in Euroanaesthesia 2024 abstracts!

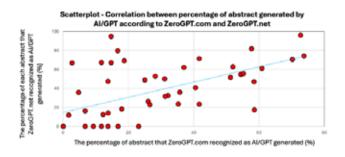

G. Prizmic¹, S. Stojanovic Stipic¹, A.M. Mitar¹, F. Peris¹, S. Pavicic Perkovic¹, A. Bego¹ ¹University Hospital Split, Department of Anesthesiology and Intensive Care, Split, Croatia

Background and Goal of Study: The prevalence of artificial intelligence (AI) has brought forward increased usage in research articles in the medical field. The challenges we've come across include the questionable accuracy of the data it provides, unanswered ethical questions, the bias of said data, and the confidentiality risk that has not been resolved thus far, for the sake of proper and reliable use. Tools like ZeroGPT.com and ZeroGPT.net are commercially available and designed to detect Al-generated texts. Their effectiveness relies on their ability to analyze syntax, linguistic patterns, and repetitions characteristic of Al-generated content. The aim of this study is assessing correlation rate between these two AI detection tools in identifying AI usage in scientific abstracts.

Materials and Methods: Fifty abstracts were selected from the Euroanaesthesia Abstract Book 2024 for analysis. These included case reports and non-case reports. All texts were analyzed using ZeroGPT.net and ZeroGPT.com in order to detect the percentage of Al usage in the abstracts. Pearson's correlation coefficient was used to evaluate the relationship between the two programs' detection rates.

Results and Discussion: Results are shown with a scatterplot. 6 out of 50 abstracts (12%) had high discrepancies rate (>50%). while 21 out of 50 (42%) had almost no difference (<0,4%) in detecting Al usage between ZeroGPT.com and ZeroGPT.net. Pearson's correlation coefficient was 0.5958, which indicates a moderate correlation between these tools in the success ratio of recognizing Al use. Although a moderate positive correlation exists between these two tools in detecting percentage of Al usage in abstracts, caution is advised as significant discrepancies were observed in some cases showing that these two tools are not consistent.

Conclusion(s): ZeroGPT.com and ZeroGPT.net show potential in identifying Al-generated content but their moderate correlation and observed inconsistencies indicate that caution is needed in interpreting the results. There is a need for development of better and more accurate tools for the detection of Al.

50AP03-1

Ultrasound assessment of the gastric content in scheduled surgery (ecoGAS Pro study)

E. Torres Palomares¹, L. Serra Serra¹, F. Torregrosa Torralba¹, D. Jareño Torrente¹, E. Martínez Gonzalez¹, J.V. Llau Pitarch¹ ¹Doctor Peset Hospital, Anesthesiology, Resuscitation and Pain Managment, Valencia, Spain

Background and Goal of Study: Throughout various publications, the recommended fasting hours before surgery have varied, depending on the type of patient, the type of surgery, and kind of intake. However, these recommendations are still based on expert consensus without objective evidence of the actual gastric content resulting from the fasting hours.(1)

In our study, we aim to assess through gastric ultrasound whether adhering to the current fasting recommendations (6 h. for solids and 2 hours for liquids) ensures the absence of residual gastric content at the time of anesthetic induction.

Materials and Methods: We propose a pivotal, observational, prospective, and non-randomized study, in which members of the Anesthesiology Service will measure, via bedside ultrasound in the pre-operative area, the gastric residue of patients scheduled for surgical intervention just before anesthetic induction fasting at least 6h.

The main variable will be the gastric volume measured based on the cross-sectional area of the antrum measured in the right lateral position combined with the patient's age. The result is obtained following this equation:(2)

VOL (ml) = 27 + (14.6 x Right Lateral CSA (cross-sectional area of the antrum)) - 1.28 x Age.

According to the value obtained in milliliters, we will divide the sample into two groups. Solid or liquid content greater than 1.5 ml/kg will be considered a full stomach, and no solid or liquid content inferior to 1.5 ml/kg will be considered an empty stomach.(3) Obesity, diabetes mellitus, hepatic failure, kidney failure were considered as possible risk factors in the delay of the gastric emptying.

Results and Discussion: As a pivotal study, we included 35 patients. 32/35 had empty stomach and 3/35 was categorized as full stomach (all due to a high liquid content, none with solid content.) In the first group 10/32 had at least one risk factor to delay the emptying and in the second one only 1/3 had a risk factor.

Conclusion(s): Our preliminary study showed that most patients had an empty stomach when following main recommendations, even with risk factors for delaying the emptying. Nevertheless, some patients had a full stomach after at least 6 h fasting, what should make us to be cautious in all scheduled inductions.

50AP03-2

Comparison of simultaneous electromyographic responses from the adductor pollicis and abductor digiti minimi muscles during rocuronium-induced neuromuscular block

G. Nagy¹, B. Fülesdi¹, L. Asztalos¹, O. Farkas¹, R. Nemes¹, S.J. Brull²

¹University of Debrecen, Department of Anesthesiology and Intensive Care, Debrecen, Hungary, 2 Mayo Clinic College of Medicine, Department of Anesthesiology, Jacksonville, United States

Background and Goal of Study: Recent neuromuscular monitoring (NM) guidelines endorse the use of quantitative monitors (Thilen 2023), specifically recommending the adductor pollicis (AP) muscle. However, many clinicians monitor the abductor digiti minimi (ADM) muscle using electromyography (EMG).

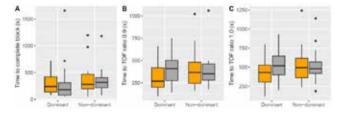

We aimed to evaluate the performance of the two muscles using EMG during onset and recovery from nondepolarizing block.

Materials and Methods: NM used the EMG-based TetraGraph (Senzime, Sweden); one electrode (TetraSens) was placed over the ulnar nerve (stimulating electrodes) and the thumb (recording electrode) to measure the AP muscle response on one hand, and another TetraSens was placed over the ulnar nerve (stimulating electrodes) and the hypothenar eminence to measure the ADM muscle response on the opposite hand.

In half of measurements, the AP was monitored on the dominant hand (DH), while in the other half, the ADM was monitored on the DH. Simultaneous train-of-four (TOF) stimulations every 20 sec were applied to both ulnar nerves while cMAP responses were recorded from the two muscles simultaneously during onset and recovery of neuromuscular block until TOF ratio >0.90.

The primary outcome was onset time (sec), level of block prior to reversal (TOF ratio), and the rate of recovery of the AP and ADM muscles.

Results and Discussion: Wilcoxon signed rank tests showed no significant differences in time to complete block, time to TOF ratio 0.9, or time to TOF ratio 1.0 between ADM and AP measurements (p > 0.08).

Boxplots of time to complete block (A), to TOF ratio 0.9 (B), and to TOF ratio 1.0 (C) in ADM measurements (in orange colour) and AP measurements (in gray colour) at the dominant and non-dominant hands. Boxplots show median (thick horizontal line), interquartile range (box), range (vertical lines) and outliers (dots). (n=46)

Conclusions: The principal finding is the lack of significant differences in key metrics related to neuromuscular block monitoring (onset and recovery) between the AP and ADM muscles. This result indicates that either muscle group can serve as an effective monitoring site for assessing neuromuscular function during surgery.

50AP03-3

Unveiling the code: how effective are Al detection tools in Euroanaesthesia abstracts 2024?

A.M. Mitar¹, S. Stojanovic Stipic¹, G. Prizmic¹, A. Bego¹, F. Peris¹, S. Pavicic Perkovic¹ ¹University Hospital of Split, Anesthesiology, Reanimatology and Intensive Care, Split, Croatia

Background and Goal of Study: ChatGPT was developed by OpenAl and was launched in 2022. Since it was introduced it has found a place in the academic community and in research articles in medical field. ZeroGPT.com and ZeroGPT.net are commercially available detectors created for the detection of the Al.

The aim of this study is to detect the percentage of Al usage in abstracts from Euroanaesthesia Abstract Book 2024.

Materials and Methods: 50 abstracts from the ESAIC Abstract Book 2024 were selected for analysis. Case reports and noncase reports from Japan, Turkey, the USA, the UK, Albania, North Macedonia, Greece, Portugal, and Switzerland were selected. Differences between AI usage percentages were tested either with the t-test or the Mann-Whitney U test.

Results and Discussion: According to ZeroGPT.com. case reports had 27.7%±26.52%* Al usage, while non-case reports had 41.21±30.58%*. There was no statistically significant difference between these two groups(P=0.107). Using ZeroGPT.net,case reports had 23.1(14-32 %)* Al usage, while non-case reports had 16.8 (7-52 %)*. There was no statistically significant difference between these two groups (P=0.857).

According to ZeroGPT.com,Portugal had the lowest percentage of Al usage(11.54±13.32%*), while according to ZeroGPT.net, Turkey had the lowest (20.82±17.66 %*).

Both tools identified Switzerland as having the highest percentage of Al usage:46.93±39.51%* with ZeroGPT.com and 39.53±31.21%* with ZeroGPT.net. According to ZeroGPT.net, English-speaking countries had an AI usage of 29.26±27.42%*,while non-English-speaking countries also showed 29.26±27.42%*. There was no statistically significant difference between these two groups(P=0.557).

Even though it was expected that case reports have lower AI usage than non-case reports, but no statistically significant difference was found. This may be due to the fact that a major part of a case report can be written using an Al.

Another interesting result is that there was no statistical difference between English and non-English-speaking countries. This can be explained by the widespread and growing accessibility of Al technology.

*Results are shown as average ± standard deviation or median (interquartile range).

Conclusion(s): There are geographical differences in the percentage of AI usage. Even though ZeroGPT.com and ZeroGPT.net have the potential to identify Al-generated content, their results may show inconsistencies; therefore, caution is needed when interpreting them.

50AP03-4

Divergent interpretations between the CONOX monitor and Surgical Plethysmographic Index (SPI) on the nociceptive response during open hemihepatectomy

B. García-Conde Hillman¹, J. Blázquez Martin¹, L. Rodríguez Martin¹, Y. Saleh Rabbu¹, R. Casans-Francés¹, A. Mayor Cacho¹ ¹Hospital Universitario Infanta Elena, Anesthesia and Pain Medicine, Valdemoro, Spain

Background: In anesthesiology, the correct perception and management of nociception is essential. The comparison between CONOX and SPI provides insight into the interpretation of pain in the surgical context.

Case Report: A 53-year-old patient undergoing open hemihepatectomy. A thoracic epidural catheter was placed at T9 with 0.125% Levobupivacaine infusion. No opioids were administered. Desflurane at 5% was used for anesthetic maintenance. During the procedure, both the cava and portal veins were partially clamped, preventing venous return. Although the trends of qNOX and gCON showed a parallel behavior, with gCON about 10 to 15 points above gNOX, the SPI indicated nociception.

Discussion: Functional thoracic epidural anesthesia is the gold standard for ensuring a pain-free patient during abdominal surgery⁽¹⁾, providing effective analgesia and minimizing the side effects of opioids. In this scenario, the parallel and constant behavior of gNOX and gCON on the CONOX monitor suggests that the patient is adequately anesthetized and not experiencing pain, consistent with the effective use of thoracic epidural anesthesia. However the SPI, which relies on pulse wave and heart rate variability to infer nociception, interpreted the hemodynamic change due to clamping as a sign of pain(2).

It is crucial to understand how both devices infer nociception. CONOX analyzes EEG trends to determine both anesthetic depth (gCON) and nociceptive reflex (gNOX)(3). In contrast, SPI interprets hemodynamic changes to determine nociception⁽²⁾, which can lead to misinterpretations in situations like vascular clamping. In this particular case, the SPI misinterpretation could have led to overadministration of analgesics, potentially compromising patient safety.

The presented clinical situation highlights the need for careful interpretation of data provided by these tools and the importance of contextualizing information within the clinical and surgical scenario.

Learning points: : While CONOX and SPI are valuable tools for monitoring nociception, it is essential to understand their mechanisms and potential limitations. Proper and contextualized interpretation is vital to ensure patient welfare and safety in the operating room.

50AP03-5

Integrating automated feedback in resident education: EpiFaith CV for Central Venous Catheterization training

T.-C. Yang¹, W.-L. Wang¹, M.-L. Wang¹ ¹National Taiwan University Hospital, Department of Anesthesiology, Taipei, Taiwan

Background and Goal of Study: Central venous catheterization (CVC) is a critical skill for anesthesiology residents, demanding precise execution to prevent complications such as arterial dilatation. Pressure monitoring typically involves connecting external monitoring systems, which can increase procedural complexity. The EpiFaith CV syringe, equipped with automated feedback, provides real-time high-pressure detection (>30 mmHg), offering the potential to enhance procedural safety and training efficiency.

This study evaluates the impact of EpiFaith CV on adherence to procedural standards and its effectiveness in resident education.

Materials and Methods: Five first-year residents, each with fewer than 20 prior CVC procedures, underwent institutional training, including conventional syringe techniques, EpiFaith CV instructional videos, and silicone phantom practice. Three residents started with the conventional syringe, transitioning to EpiFaith CV, while two followed the reverse sequence.

Each resident performed 15 procedures with both techniques (n=150). All procedures were supervised, with faculty intervention provided as needed. Residents completed post-procedure selfassessments covering independent completion, procedural duration, the occurrence of arterial puncture, and subjective ratings (confidence, ease, satisfaction).

Results and Discussion: EpiFaith CV showed a higher independent success rate (94.7% vs. 88.0%) compared to the conventional syringe, though not statistically significant. Procedural times were similar (59.1s vs. 59.0s). The incidence of arterial puncture was low and comparable between both methods.

No arterial dilatation happened. User ratings for ease and satisfaction were slightly lower with EpiFaith CV, likely due to a learning curve and additional procedural steps. Confidence ratings were similar across methods.

The findings highlight EpiFaith CV's potential to maintain procedural safety while introducing automated feedback into training. Conclusion(s): EpiFaith CV is a viable tool for enhancing resident education in CVC, providing comparable safety and efficiency to conventional methods. Further optimization of training processes is needed to address the learning curve and maximize the benefits of automated feedback. Expanding the study size is recommended to confirm the findings.

Automated machine learning for ASA-PS prediction: Leveraging demographic, medication, and questionnaire data from routine preoperative

S.F. van den Heuvel¹, P. Jonker¹, S.E. Hoeks¹, R.J. Stolker¹, J.-W.H. Korstanje¹ ¹Erasmus MC, Anaesthesiology, Rotterdam, Netherlands

Background and Goal of Study: The American Society of Anesthesiologists Physical Status (ASA-PS) classification is essential for perioperative risk stratification, payment systems, and determining suitability for day surgery centers. Its subjectivity limits reliability.

This study used machine learning (ML) models, developed with H2O's AutoML1, to predict ASA-PS classes I-IV (multiclass) and binary classifications (I&II vs. III&IV) based on routine preoperative data (demographics, BMI, and Anatomical Therapeutic Chemicalcoded (ATC) medication and health questionnaires).

Materials and Methods: This retrospective study at Erasmus MC, Netherlands, used data (2018-2023) meeting criteria (age ≥18, ASA-PS classifications I-IV, validated medication, and completed questionnaires). Three datasets included 50,431 cases (demographics, BMI, medication), 32,600 cases (demographics, BMI, questionnaire), and 28,582 cases (combined). H2O's AutoML trained models using algorithms such as Generalized Linear Models, Random Forest, Gradient Boosting Machines, Deep Neural Networks, and ensembles (combinations) for improved performance. Metrics included F1 score, accuracy, precision, recall, and area under the receiver operating characteristic curve (AUC-ROC). Calibration curves assessed reliability; explainability analyses identified key predictors.

Results and Discussion: Binary classification models using demographics, BMI, and medication achieved an F1 score of 0.78, accuracy of 0.77 and AUC-ROC of 0.85. Using questionnaire data instead of medication improved performance slightly (F1: 0.79, accuracy: 0.78, AUC-ROC: 0.86). Combined data performed best (F1: 0.83, accuracy: 0.82, AUC-ROC: 0.90). The best multiclass model (all data) achieved an F1 score of 0.64, accuracy of 0.64 and AUC-ROC of 0.88. Medication-only models perform comparably to combined data, offering efficiency where questionnaires are unavailable. Reliability was confirmed, and key predictors were highlighted. Validation in other settings is needed to ensure generalizability.

Conclusion(s): Demographics, BMI, and medication enable effective ASA-PS prediction. Enhanced models with questionnaires may perform better in specialized settings. This study highlights the potential of routine healthcare data and machine learning tools to improve perioperative workflows.

From paper to Al: Transformation of the surgical area management model based on technology and process management

M. Bausili¹, M. Morales¹, N. Nieto², S. Delgado³, Y. Cuesta⁴ ¹Hospital Mútua Terrassa, Anaesthesiology, Terrassa, Spain, ²Hospital Mútua Terrassa, Nursery, Terrassa, Spain, 3 Hospital Mútua Terrassa, Institucional Medical Management, Terrassa, Spain, ⁴Hospital Mútua Terrassa, Institucional Executive Management, Terrassa, Spain

Background and Goal of Study: The Surgical Area is a key component of hospitals around which concentrate many of the care processes and resources. We decided to implement a structured management model supported by digital tools, which provides quality data at each level of decision-making and contributes to the implementation of a new work model based on planning and empowerment.

The impact areas where it is tempted to influence:

- 1. Facilitate day-to-day management.
- 2. Effective and efficient model of planning and scheduling.
- 3. Improving patient experience.
- 4. Facilitate natural team coordination.
- 5. KPI acquisition.

Materials and Methods:

- 1. ANALYSIS AND PROCESS DESIGN. Prior analysis and redesign of the processes that guarantee that the implementation of the technological tool is adapted to the specific needs. We set up working groups (WG) as essential step to get qualitative and relevant data, and performance, and to develop the Value Stream Map.
- 2. IMPLEMENTATION, TECH DEPLOYMENT AND SYSTEM MAINTENANCES. Work on the information between systems in the tasks of integration, network points and cabling necessary to supply and network the equipment and identify the necessary
- 3. TRAINING. A fundamental element of change management to help all professionals adapt to he new work situation and favoring the work philosophy of continuous improvement.
- 4. SUSTAINABILITY AND MAINTENANCE Accompanying professionals in the correct use of technology and monitoring the efficiency of the surgical area, ensuring that it becomes a regular practice and promoting a culture of continuous improvement of results. Work will be done on the definition of key indicators, their associated objectives, and on monitoring the evolution and the degree of compliance.

Results and Discussion:

- 1. IMPROVING TACTICAL SCHEDULING. Empowerment and effectiveness of the Operating Theatre Committee and Surgical Programming Center. Better efficiency in scheduling.
- 2. IMPROVING PATIENT EXPERIENCE AND PROFESSIONAL PERFORMANCE. (Real Time Location System). Patient's Families and providers receive information about the perioperative flow.
- 3. STRATEGIC PLANNING MODULE. New AI supported tool is the best result, providing new dashboards and scenario simulation of surgical planning.

Conclusion(s): We achieved a more agile management, more efficient use of resources and improving the satisfaction of care providers and patient experience. New AI tool to simulate OR planning scenarios.

Prediction of volume responsiveness by using end-expiratory occlusion test in a patient with severe diastolic dysfunction undergoing hepatectomy: a case report

G. Pinho Cardoso1, M.B.C. Fernandes1,

F.d.L. Cabral Junior¹, G.P. Medeiros¹, C.Q.d.S. Cavalcante¹, J.C.R. Nascimento1

¹Fortaleza General Hospital, Anesthesiology, Fortaleza, Brazil

Background: Hemodynamic management in major surgeries in patients with diastolic dysfunction can be challenging. Assessment of fluid responsiveness using end-respiratory occlusion test is an underutilized technique, which allows adequate volume titration and use of vasoactive drugs in critically ill patients.

Case Report: A 49-year-old man, diagnosed with systolic dysfunction (Simpson LVEF 34%) and diastolic dysfunction grade III, idiopathic. Surgery was left hepatectomy. Patient was monitored by the ASA standard in addition to insertion of an invasive arterial pressure in the right radial artery coupled to the cardiac output monitor (FLOTRAC®) and central venous access was placed into right internal jugular vein.

Anesthetic technique of choice was total intravenous general anesthesia associated with an epidural catheter placed at T11-T12. For goal-guided volume replacement, the end-expiratory occlusion pressure test was used. Test was performed in two moments of hemodynamic instability during the intraoperative period, with apnea of 15 seconds. Cardiac output variation of 4.2 to 5.8 L/min (38%) was obtained in the 1st test and 3.9-6.7 L/min (71%) in the 2nd test

After the test, 250 mL of Ringer lactate was used and an increase of 21% and 42% was observed in cardiac output, respectively. Patient received a total of 3500 mL of intraoperative fluids. Transferred to the Postoperative Intensive Care Unit, hemodynamically stable and in spontaneous ventilation, being discharged on the 8th postoperative day.

Discussion: The use of dynamic methods to guide fluid replacement is essential for perioperative hemodynamic management in high-risk cardiovascular patients. These strategies ensure adequate oxygen delivery to the tissues, reducing the side effects of excessive fluid use. Although studies are still conflicting, the volume prediction technique using the end-expiratory occlusion pressure technique is an accessible and reproducible method to optimize intraoperative hemodynamic management.

Reference:

Velmurugan Selvam, Dilip Shende, Anand RK, Kashyap L, Ray BR. End-expiratory Occlusion Test and Mini-fluid Challenge Test for Predicting Fluid Responsiveness in Acute Circulatory Failure. Journal of Emergencies, Trauma, and Shock. 2023; 16 (3):109-15. Learning points: Goal-directed fluid therapy can optimize hemodynamic management in major surgeries and, thus, minimize the side effects of inappropriate use of vasopressors or excessive fluid.

50AP03-9

Automatic detection of circulatory arrests using smartwatch technology: First results

W. van den Beuken¹, B. Nideröst², B.A. Goossen³. T.A. Kooy⁴, L.A. Schwarte^{1,5}, P. Schober^{1,5}, **HEART-SAFE Consortium**

¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, ²Utek B.V, Research and Development, Buurmalsen, Netherlands, 3MiBida B.V., Research and Development, Eindhoven, Netherlands, 4STAN B.V., International Business Development, Nunspeet. Netherlands, ⁵Amsterdam UMC, Helicopter Emergency Medical Service Lifeliner 1, Amsterdam, Netherlands

Background and Goal of Study: Out-of-hospital cardiac arrest (OHCA) is a leading cause of mortality worldwide. Early detection and alarming of emergency medical services (EMS) are key challenges in the chain of survival, as they currently depend entirely on the presence of bystanders.

This study provides a proof of concept for a device-independent application capable of automatically detecting OHCA using smartwatch sensor signals.

Materials and Methods: Participants included volunteers (n = 3) in which we temporarily ceased the blood flow in the arm, 4 times, using a blood pressure cuff inflated to 300 mmHg, and patients undergoing cardiac surgery or cardiological procedures involving temporary artificial cardiac arrest (n = 6).

Photoplethysmography (PPG) sensor data were collected from Samsung Galaxy Watch5 smartwatches and events were annotated. A preliminary cardiac arrest detection algorithm was developed and evaluated using the raw sensor data collected.

Alarms in the absence of annotated circulatory arrests were considered false positive alarms. Moreover, we established connectivity with a virtual dispatch center to test whether the system is capable of alerting Emergency Medical Services in the case of a detected OHCA.

Results and Discussion: In total, 9 participants were included in the study. Our preliminary algorithm positively identified all subjects as having a spontaneous circulation prior to the onset of circulatory arrest (specificity 100%) and also identified circulatory arrest at the wrist in most patients (sensitivity 94%).

Moreover, the connectivity with the virtual dispatch center worked as intended, demonstrating the potential of the system to not only detect OHCA but to also trigger an emergency response.

A key limitation is that the algorithm, for the purpose of demonstrating a proof-of-principle, was developed and tested using the same dataset. This approach likely overestimates the algorithm's diagnostic accuracy. More data and real-world settings are needed to evaluate the true performance.

Conclusion(s): We have demonstrated as a proof of concept that it is feasible to automatically detect circulatory arrest using commercially available smartwatch sensors, achieving excellent sensitivity and specificity with limited data.

This technology holds significant potential to reduce response times and improve survival outcomes. Future research should focus on real-world testing and integration with EMS to fully realize its potential.

50AP03-10 Assessment of nociception with the CoreSafe

P. Lucena¹, H. Litvan², W. Tharp³, M.A. Mañanas Villanueva¹, L.Y. Serna Higuita¹ ¹Polytechnic University of Catalonia, ETSEIB, Barcelona, Spain, ²Hospital Sant Pau, Anesthesiology, Barcelona, Spain, 3University Of Vermont, Anesthesiology, Vermont, **United States**

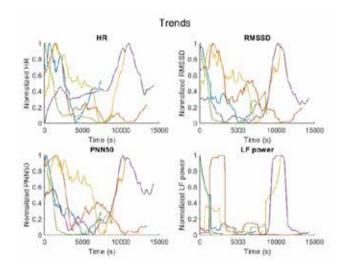

Background and Goal: This study assesses the CoreSafe One (CoreSafe, Barcelona, Spain) for developing a neuro-autonomic states (NAS) index to quantify autonomic nervous system changes related to nociception during sedation and analgesia.

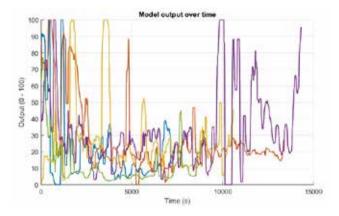

Data from five surgical patients and five healthy subjects were analyzed using HRV metrics (HR, RMSSD, PNN50, LF power) as inputs to an Adaptive Neuro-Fuzzy Inference System (ANFIS) model to classify analgesia versus no-analgesia states.

Materials and Methods: Ten participants – five surgical patients and five healthy subjects - provided ECG data collected via Core-Safe after IRB approval. Surgical patients were monitored for 3-5 hours. HRV metrics were extracted from noise-filtered ECG signals, and physician annotations categorized data into analgesia (0) and no-analgesia (1) states. An ANFIS model trained on normalized HRV metrics was validated using leave-one-out crossvalidation.

Results and Discussion: HRV analysis revealed a significant decline in HR, RMSSD, PNN50, and LF power during analgesia, reflecting reduced autonomic nervous system activity. The ANFIS model classified analgesia and no-analgesia states with 76.92% accuracy, achieving a precision of 86.82% and recall of 80.89% for the no-analgesia state.

The ROC curve demonstrated an AUC of 0.80. Application of the NAS index to surgical data showed the index remaining relatively flat. While the model performed well, challenges such as overlapping signal characteristics and artifacts during state transitions highlight areas for refinement.

Conclusion: The CoreSafe One shows potential for developing a NAS index to monitor nociception during surgery. While promising, further work is needed to improve data size, artifact handling, and state transition definitions, enhancing its reliability as a noninvasive tool for nociception monitoring.

50AP03-11 ATHENA: Virtual anaesthetic consultations – From human to Al-assisted anaesthesia

S.A. Bosholdt¹, F.R. Christensen², K.N. Jespersen². R.T. Hesselfeldt¹, A. Møgelmose², K.B. Buggeskov¹ ¹Rigshospitalet, Head and Orthopedics, Copenhagen, Denmark, ²Aalborg University, Visual Analysis and Perception Lab, Aalborg, Denmark

Background: ATHENA represents a paradigm shift in anaesthesia, transitioning from traditional human-led to Al-assisted processes. Traditional preoperative assessments (PA) are timeconsuming and resource-heavy consultations. ATHENA addresses this by integrating AI technology and 3D imaging to automate consultations. Our prototype ATHENA app marks first steps towards Al-driven PA.

Methods: The study enrolled 25 participants. An avatar guide standalone app for automated PA was developed using image processing. ResNet neural network and for neck tilt posture system/trigonometric method including CSRT trackers using side images for ground truth comparison. Participants performed exercises that allowed the AI system to classify their Mouth Opening, Mallampati scores (1+2 and 3+4) and Neck tilt. The Al's assessments were then compared to an anaesthesiologist's evaluation of 794 still images.

Results: The ATHENA app correctly predicted mouth openings over 4 cm in 72% of cases, however no correlation was found between manually calculating mouth height and system's mouth opening increase. It accurately classified 63.4% of patients' Mallampati scores and on average tended to overshoot 25.2 degrees in both forward and backward tilt calculations. A qualitative study reported high user satisfaction, indicating that users found the avatar guidance sufficient and trustworthy.

Discussion and conclusion: ATHENA project lays the early groundwork to develop avatar guided Al assisted PA which, when finally implemented, could triage patients into three categories: red: physical PA needed, yellow: Al evaluation requires anaesthetic second opinion on video material, and green: patient is ready for surgery. Addressing the future double demographic pressure and worldwide shortage of healthcare personnel. The prototype was by no means flawless but underlines the importance of avatar guiding patients in how to perform airway assessment exercises correctly. A live adaptable avatar to patient's actions is a future necessity. Further development and inclusion of visual data on more diverse patient groups are required to improve the ATHENA app before tested clinically.

50AP03-12

Clinical validation of oscillometric blood pressure using a multiparameter monitor in anaesthetised dogs

S. Campos^{1,2}, T. Coelho¹, D. Pancrácio¹, L. Martins¹, J. Martins¹,

¹Universidade Lusófona, Faculty of Veterinary Medicine, Lisbon, Portugal, ²Universidade Lusófona, Veterinary and Animal Research Center (CECAV), Lisbon, Portugal

Background and Goal of Study: Intra-operative hypotension (mean arterial pressure [MAP] <60 mmHg) is one of the most common complications in anaesthetised dogs due to anaesthetic-induced depression of sympathetic tone. Untreated hypotension is associated with increased morbidity and mortality in dogs during the post-anaesthetic period. This study aims to compare non-invasive blood pressure (NIBP) with invasive blood pressure (IBP) from a Mindray multi-parameter monitor in anaesthetised dogs, as both methods are currently accepted for blood pressure monitoring.

Materials and Methods: 14 Client-owned adult dogs, classified as ASA II animals, were anaesthetised for various surgical procedures using different anaesthetic protocols. Measurements were obtained using the Mindray Bennevion N15 multi-parameter monitor via a pneumatic cuff placed over the medial dorsal artery (NIBP) and a transducer connected to a catheter placed in the contralateral artery (IBP). Data were recorded using Mindray software and paired readings for MAP, systolic and diastolic blood pressure (SAP and DAP, respectively) were matched every 5 minutes during surgery. 266 Paired blood pressure measurements were analysed using the Bland-Altman test, which assessed the agreement between IBP and NIBP and its clinical significance. Data were reported as mean bias (lower, upper limits of agreement (LoA)).

Results and Discussion: Analyses of agreement showed biases of 5.13 mmHg [95% limits of agreement (LoA); -31.7 to 41.3 mmHg] for SAP values, 1.61 mmHg [95% LoA -18.3 to 22.05 mmHg] for DAP and 0.605 mmHg [95% LoA -23.051 to 24.262 mmHg] for MAP. Considering the complete data set, the precision was acceptable as the SD of the differences between paired measurements was less than 15 mmHg for all parameters (DAP=6.8; MAP=7.8; SAP=11.2). The mean bias for SAP, DAP and MAP measurements was positive for all subsets, indicating that NIBP measurements were underestimated compared to IBP measurements (Figure 1).

Conclusion(s): NIBP measurements using the Mindray multiparameter monitor were generally in agreement with IBP measurements obtained during general anaesthesia and appear to be suitable for use in dogs. However, inaccuracies, often underestimations, observed with NIBP measurements should be interpreted with caution, especially with regard to the use of drugs to maintain normotension during anaesthesia.

50AP04-1

Can Artificial Intelligence (AI) algorithms predict the risk of post-induction hypotension in cesarean section operations using only preoperative data?

S. Yavuzel¹, <u>B. Kilicaslan</u>¹, O.B. Ozdemir², E. Öz³, Y. Er Öztaş³, B. Akca¹

¹Hacettepe University, Department of Anesthesiology and Reanimation, Ankara, Turkey, ²Artvin Coruh University, Department of Computer Engineering, Artvin, Turkey, ³Hacettepe University, Department of Biochemistry, Ankara, Turkey

Background and Goal of Study: Al is a core component of new clinical tools being developed for predicting adverse intraoperative events like hypotension during a cesarean section, which can affect not only the mother but also the baby. Therefore, this study aimed to develop deep learning algorithms to predict the risk of post-induction hypotension in cesarean section operations under spinal anesthesia.

Materials and Methods: After this study was approved by the Hacettepe University Clinical Research Ethics Committee, we prospectively analyzed preoperative data from 370 patients undergoing cesarean sections with spinal anesthesia, comprising 122 unique features. Using univariate feature selection, we refined this set to 50 key predictors, optimizing model performance and interpretability. Eight deep learning models were evaluated, including four variations of Fully Connected Neural Networks (FCNN), two 1D Convolutional Neural Networks (1D-CNN), and two Long Short-Term Memory (LSTM) models. Each model was assessed with 10-fold cross-validation for robust evaluation.

Results and Discussion: Averaging the 10-fold cross-validation results, the FCNN-2 model emerged as the top performer, achieving an AUROC score of 0.6883. Statistical analyses revealed risk factors, such as age over 30, history of hypotension in previous cesareans, reduced intravenous fluid volume at hospital admission, elevated CRP levels, and the presence of diabetes mellitus. Conversely, regular iron and multivitamin use emerged as protective factors against hypotension. Preoperative Syndecan-1 levels were found not to have a significant association. In terms of model feature importance, in addition to these features, the following are also important for the occurrence of hypotension: Elevated MCV, ferritin, and D-dimer levels, presence of polycystic ovary syndrome, hypertension, extended fasting duration before surgery. The only significant feature related to spinal anesthesia was the dose of bupivacaine.

Conclusion(s): This study successfully developed a predictive model (FCNN-2) for hypotension risk in cesarean patients under spinal anesthesia, achieving an AUROC of 0.6883. This model has potential clinical utility as a preoperative screening tool, identifying patients at higher risk for hypotension. With preoperative identification, clinicians can implement tailored interventions to mitigate hypotension risk and enhance maternal-fetal outcomes.

50AP04-2

Brain injury monitored by bispectral index and near-infrared spectroscopy in cardiac surgery

M.T. Rivilla Lizano¹, I. Zaragoza García², M.L. Maestre Hittinger¹, M. de la Torre Weinreiter¹, A. Parera Ruiz¹, A. Bueno Izquierdo¹ ¹Hospital Sant Pau i Santa Creu, Anestesiologia i Reanimació, Barcelona, Spain, 2Hospital del Mar, Anestesiologia i Reanimació, Barcelona, Spain

Background: Severe intraoperative cerebral hypoperfusion is a critical issue in cardiac surgery, particularly in patients with complex cardiovascular disease. Non-invasive monitoring techniques (BIS (Bispectral Index), DSA (Density Spectral Array) and NIRS (Near-Infrared Spectroscopy)1) can help us to manage it

Case Report: A 77-year-old woman presented for aortic valve replacement due to severe aortic regurgitation, severe left ventricular dysfunction and moderate pulmonary hypertension. Anaesthesia induction was with invasive arterial monitoring, BIS, bilateral NIRS, DSA, transesophageal echocardiography and cardiopulmonary bypass (CPB). Intra-operatively there was massive bleeding due to accidental cannula removal. Coma was induced with pentothal, together with 100% FiO2 ventilation and hypothermic manoeuvres for neuroprotection. During cardiac arrest, cerebral monitoring parameters deteriorated. The source of bleeding was identified and corrected, allowing the operation to be continued. Immediately after aortic clamping, severe alterations in cerebral monitoring persisted, including delta wave activity on DSA, a suppression rate of 100% and BIS value of 0. Surgical field inspection revealed no compromise of the brachiocephalic trunk and surgery was continued. Nevertheless, after aortic unclamping, brain monitoring parameters improved. Post-operatively, the patient was transferred to the ICU intubated and sedated. There was delayed wakefulness and left-sided brachial-crural hemiparesis. MRI revealed a stable ischaemic lesion in the right fronto-subcortical region, that could explain the clinical presentation and intraoperative findings

Discussion: This case underscores the crucial role of cerebral monitoring in cardiac surgery under general anesthesia to prevent long-term deficits. Despite the absence of surgical evidence indicating impaired cerebral perfusion, the non-invasive monitoring tools provided early detection of significant cerebral hypoperfusion

References:

1. Sinha et al. "Changes in BiSpecteral Index Values During Cardiopulmonary Bypass" doi:10.1016/S0377-1237(11)80009-2 Learning Points: Advanced monitoring techniques can provide crucial insights into intraoperative, enabling timely interventions. Cerebral hypoperfusion can occur in cardiac surgery without direct surgical field compromise. However, early identification of the problem allows the medical team to act much more effectively and improve patient's outcomes.

50AP04-5

Integrating anesthetic variables into machine learning for enhanced surgical time forecasting

J.-H. Wu¹. P.F. Chen¹. T.Y. Lin^{1,2} ¹Far Eastern Memorial Hospital, Department of Anesthesiology, New Taipei City, Taiwan, 2Yuan Ze University, Department of Mechanical Engineering, Taoyuan, Taiwan

Background and Goal of Study: Accurately predicting operation duration is critical for efficient operating room scheduling and resource allocation. The introduction of machine learning models to predict operation duration offers a data-driven approach that enhances the efficiency of scheduling. Previous studies have demonstrated that machine learning models can effectively predict operation duration, but most predictions overlook critical anesthesia factors.

In this study, we address the limitation by integrating anesthesia factors into machine learning models, aiming more accurate predictions.

Materials and Methods: Data from all cases utilized the operating room of our institute, performed between February 2014 and July 2021, were collected. Emergent procedures, patients classified as ASA V, or cases missing key data were excluded. Features selected for prediction includes patient, procedure, and anesthesia factors. Several algorithms are chosen and compared, and the performances of the models are evaluated based on mean absolute error (MAE).

Results and Discussion: 106.306 cases are included after data exclusion and preprocessing. The dataset is randomly split into 80% for training and 20% for validating. The following table summarizes the performances of the algorithms across two different feature sets. Feature set 1 includes all features, while feature set 2 excludes anesthesia factors, to compare the impact of anesthesia factors.

Algorithms	Feature set 1, MAE (minutes)	Feature set 2, MAE (minutes)	
Linear Regression	33.09	34.29	
Gradient boosting regression	36.05	41.12	
Random forest	31.15	33.48	
Bagged trees	31.09	33.07	
Multi-layer perception regression	30.42	33.80	
Supported vector regression	28.53	29.02	

Table. Prediction Outcomes for all Algorithms.

In general practice, prolonged surgeries are typically performed under general anesthesia rather than regional anesthesia for patient comfort; and advanced techniques, such as arterial line or central venous catheter, are often prepared for complex procedure or high-risk patients. These make anesthesia factors strong predictors for prediction of the operation duration.

Conclusion(s): Our study demonstrates that incorporating anesthesia factors into machine learning models improves the accuracy of operation duration predictions.

50AP04-7

Comparison of cardiac index values between VenArt® device and transthoracic echocardiography during anesthesia for laparoscopic gynecological procedures

C. Paschoud¹, N. Silvestrini¹, J. Daniels¹, J. Koegel¹, S. Mulin¹, G.L. Savoldelli¹

¹Geneva University Hospitals and Faculty of Medicine, Division of Anesthesiology, Department of Anesthesiology, Clinical Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland

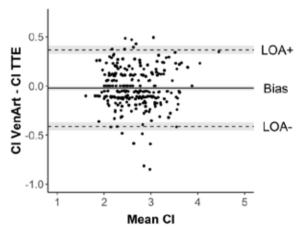

Background and Goal of Study: Non-invasive cardiac output (CO) monitoring during anesthesia for gynecological procedures needs to be simple yet accurate. Transthoracic echocardiography (TTE) is non-invasive but skill-dependent and only provides intermittent measures. The VenArt® device (Mespere life sciences, Waterloo, Ontario, CA) provides a non-invasive beat-by-beat CO based on the Fick principle, measuring the differences in saturation between venous and arterial blood using near-infrared spectroscopy (NIRS). The input of patient's height and weight allows for the derivation of cardiac index (CI).

This study aimed to compare CI values using the VenArt® device with TTE in gynecological laparoscopic surgery.

Materials and Methods: This single-center prospective observational study included adult women (ASA 1-3) undergoing laparoscopic gynecological surgery. CI was measured simultaneously at five perioperative time points expected to involve substantial haemodynamic fluctuations using the VenArt® device and TTE (single operator). Agreement between methods was assessed using Bland-Altman analysis providing bias, precision, mean percentage error (MPE) and limits of agreement (LoA).

Results and Discussion: Fifty-five patients (ASA 1/2/3 n=8/45/2; mean age 44.1 (±10.8) years; BMI: 24.9 (±4.4) kg/m²) were enrolled: 273 distinct pairs of CI measurements were analyzed. The Bland-Altman analysis revealed a bias of -0.02 L/min/m² (95%Cl, -0.05 to 0.00), a precision of 0.20 and a MPE of 14.71% (95%CI, 13.17 to 16.25). LoA were -0.41 (95%CI, -0.45 to -0.37) and 0.37 L/ min/m2 (95%CI, 0.33 to 0.41).

Conclusion(s): The VenArt® device showed good agreement with TTE, with a negligible bias and a MPE well below the 30% threshold generally considered as clinically acceptable. These findings suggest that the VenArt® device is reliable for non-invasive CI monitoring during the perioperative period in gynecological laparoscopic procedures. Further analyses need to confirm the interchangeability between these methods during other surgical procedures.

Optimizing occupational safety in paediatric anaesthesia: assessment of an additional scavenging device during inhalation induction

M. Somri¹, A. Abu Foul², N. Hawash², H. Khalaili², F. Somri³ ¹Technion - Israel Institute of Technology, Anesthesia, Hifa, Israel, ²Bnai Zion Medical Center, Anesthesia, Haifa, Israel, ³Università degli Studi "G. d'Annunzio" Chieti - Pescara, Medicine, Pescara, Italy

Background and Goal of Study: Inhalational anaesthesia induction, particularly common in pediatric cases, poses occupational health risks due to Waste Anesthetic Gases (WAGs) exposure. Despite built-in scavenging systems and adequate room ventilation, recent measurements in a Pediatric Induction Room showed concerning levels of sevoflurane (up to 33.4 ppm, exceeding the 1-2 ppm safety standard) and N2O (up to 125 ppm, exceeding the 10-25 ppm normal range). This study aims to evaluate the effectiveness of an additional external scavenging device in reducing healthcare workers' exposure to WAGs during paediatric anaesthesia induction by comparing environmental sevoflurane and N_oO levels with and without the system.

Materials and Methods: Ethical approval was accepted from the University Bnai Zion Medical Center, Haifa, Israel.

Inclusion criteria included healthy paediatric patients scheduled for minor surgery undergoing inhalational anaesthetic induction with N₂O and sevoflurane using a face mask.

Those in Group A the technique was realized without the presence of the scavenger system; those in Group B underwent anaesthetic induction using the new scavenger system (suction device CBT280).

Twenty measurements of gas concentrations in each group were collected

Results and Discussion: The averages of Sevofluorane concentration prior using the additional scavenger system (Mean = 10.86 ±8.67) significantly exceeded the mean concentration observed subsequent to the scavenger's application (Mean = 0.18 ± 0.31) concentration. P Value = 0.004 (ppm)

The mean N₂O level was 292±55 ppm. Differed significantly from the mean concentration after the use of the Scavenger 25.75± 0.96 ppm. P Value = 0.001 (ppm).

Conclusion(s): The integration of this new scavenger system into the paediatric induction room could be an affordable and cost-effective choice to promote a safer working environment for medical staff.

Healthcare providers' attitudes on smartwatchbased cardiac arrest detection

W. van den Beuken¹, T.A. Koov², H. van Schuppen^{1,3}, S.A. Loer¹, L.A. Schwarte^{1,3}, P. Schober^{1,3}, **HEART-SAFE Consortium** ¹Amsterdam UMC, Anesthesiology, Amsterdam, Netherlands, 2STAN B.V., International Business Development, Nunspeet, Netherlands, 3Amsterdam UMC, Helicopter Emergency Medical Service Lifeliner 1, Amsterdam, Netherlands

Background and Goal of Study: Out-of-hospital cardiac arrest (OHCA) is a critical and time-sensitive event, significantly contributing to global mortality. Several research groups are currently working on technologies to automatically detect OHCA, aiming to reduce delays in detecting cardiac arrests, in particular in cases of unwitnessed arrests. The implementation of this technology presents new challenges for healthcare professionals.

This study investigates the attitudes of healthcare professionals towards this technology and identifies perceived barriers.

Materials and Methods: An online survey was sent to local Emergency Medical Services (EMS) personnel in the Netherlands and to community first responders of HartslagNu (HSN). HartslagNu is a nationwide Dutch organization which includes more than 250,000 CPR-trained community volunteers.

The surveys were developed and tested in collaboration with The Dutch Association of Medical Managers Ambulance Care (NVMMA) and STAN, the technical provider from HartslagNu. The quantitative data was descriptively analyzed and a content analysis of the open-ended questions was performed.

Results and Discussion: A total of 412 participants from EMS and 1401 from HSN were included in the study. The majority of participants, 70.1% (95% CI: 65.9 - 74.9) from EMS and 94.4% (95% CI: 93.1 - 95.5) from HSN, indicated interest in the technology. Additionally, 53.6% (95% CI: 48.7 - 58.5) of EMS participants and 88.2% (95% CI: 86.3 - 89.8) of HSN participants agreed to

The most cited reason for not agreeing with the use of automated cardiac arrest detection was the fear of too many false alarms. When asked what an acceptable amount of false alarms would be out of 100 calls, the EMS group indicated 5 (IQR: 5-10) and the HSN group 5 (IQR: 5-10).

The qualitative analysis showed the importance of accuracy and reliability of the technology and a fear of too many false alarms. The analysis also showed that participants recognized the value of timely detection and the life-saving potential this technology may have.

Conclusion(s): The majority of participants have a positive attitude towards automated cardiac arrest detection and recognize the life-saving potential of this technology. However, participants emphasize the importance of the reliability of the device to minimize false alarms as much as possible.

50AP05-3

Use of CONOX monitor to guide superficial sedation during auditory evoked potentials in a 3-year-old child

B. García-Conde Hillman¹, J. Blázquez Martin¹, L. Rodríguez Martin¹, Y. Saleh Rabbu¹, R. Casans-Francés¹, A. Mayor Cacho¹ ¹Hospital Universitario Infanta Elena, Anesthesia and Pain Medicine, Valdemoro, Spain

Background: During auditory evoked potential studies it is essential to achieve sedation that does not compromise neurological responses. In this context, the CONOX monitor emerges as a key

Case Report: A 3-year-old child underwent auditory evoked potential testing for the diagnosis of deafness. Sedation was initiated with CAM 1. Subsequently, the sevoflurane dose was maintained around 0.8%, adjusting it according to the qCON index readings from the CONOX monitor, aiming to reach and maintain a qCON near 70, indicative of superficial sedation. During the procedure, the patient was administered 40% oxygen via a facial mask, maintaining spontaneous ventilation without intubation. Thanks to sedation, the patient remained still and the auditory evoked potential signals were clearly recorded.

Discussion: Sedation in auditory evoked potential studies presents a special challenge. These studies require the patient to remain calm and motionless, while at the same time, it is crucial that neurological responses are not compromised by excessive sedation. The CONOX monitor, by providing real-time qCON index readings, allows healthcare professionals to rate sedation accurately and adaptively.

Sevoflurane-adjusted use according to qCON readings ensured optimal sedation, allowing the collection of high-quality auditory evoked potentials without interferences. It is noteworthy that in pediatrics, achieving adequate sedation can be even more challenging due to the variability in patient responses and lower tolerance to invasive procedures. Therefore, real-time sedation control is particularly valuable in this age group.

This experience reinforces the importance of detailed and personalized monitoring in procedures requiring sedation. While induction with CAM 1 marks the initiation of sedation, adjusting the sevoflurane dose based on the qCON index ensures continuous and adaptive sedation that meets the patient's exact needs at each moment.

Learning points: The CONOX monitor provides invaluable guidance for the precise titration of sedation, especially in delicate procedures such as auditory evoked potentials in pediatrics. Adjusting the anesthetic dose in real-time based on sedation depth optimizes the efficacy and safety of the procedure.

Efficacy of point-of-care thromboelastography (TEG) with Platelet Mapping® beyond cardiac surgery: adjustment of antiplatelet therapy in at-risk patient in ICU. A case report

E. Pereda González¹, V. Pérez Marí², L. Mora³, R. Martínez Plumed¹, J. Hernández Laforet¹, J. de Andrés Ibáñez²

¹Hospital General Universitario de Valencia, Anestesiología v reanimación, Valencia, Spain, ²Hospital General Universitario Valencia. Anestesiología v Reanimación. Valencia, Spain, 3Hospital General Universitario Castellon, Anestesiología y Reanimación, Castellon, Spain

Background: Antiplatelet agents are vital for managing coronary atherosclerotic disease, especially during surgery. The choice to continue or stop therapy should be personalized, considering each patient's thrombotic and hemorrhagic risks. Research shows increased thrombotic risk for surgeries within six months after coronary stent placement, often suggesting delays when possible. The risk of severe perioperative bleeding is also important. Techniques like TEG and PlateletMapping offer insights for managing antiplatelet therapy, enabling tailored approaches. We present a case where this device allowed precise adjustments to dual antiplatelet therapy, enhancing patient outcomes.

Case Report: 57-year-old man with a history of smoking, hypertension, and dyslipidemia had angioplasty with a drug-eluting stent and was on aspirin (ASA) and clopidogrel. Three months later, he needed surgery for a 57 mm infrarenal aortic aneurysm. Endovascular treatment was chosen, continuing ASA and stopping clopidogrel the day before. The procedure went well, and TEG results allowed early reintroduction of dual antiplatelet therapy. The patient was monitored and discharged without complications.

Discussion: Patients on antiplatelet therapy in the operating room is increasing. This therapy can greatly impact intra and post-op management. Devices like the TEG6s with PlateletMapping will enable a more personalized approach to managing each patient effectively.

Learning points: Personalizing antiplatelet therapy in the perioperative period is essential, considering the patient's thrombotic/ hemorrhagic risks.PlateletMapping, assesses platelet functionality in clinical settings, even outside the OR.

50AP05-7

Virtual reality: a teaching-learning strategy for cognitive mastery in airway trauma management

S. Gupta1, E. Belfiore1, C. Matava2, J. Tarshis1, L. Kaustov¹, F. Alam¹ ¹Sunnybrook Health Sciences Centre, Anesthesia, Toronto, Canada, ²University of Toronto, Anesthesia, Toronto, Canada

Background and Goal of Study: As anesthesia education evolves, innovative and effective supplemental teaching methods are needed for educating medical trainees on crisis management skills. Virtual Reality (VR) offers immersive, scalable, and self-directed learning environments, but its effectiveness compared to traditional mannequin-based simulations remains underexplored for teaching complex decision-making skills such as airway trauma management.

This randomized controlled trial evaluates the efficacy of VRbased simulation versus traditional mannequin-based training in enhancing both knowledge acquisition and application of decision-making concepts for airway trauma management.

Materials and Methods: Forty medical students were randomized to either the VR (intervention) group or the Mannequin (control) group. Participants practiced airway trauma management using their assigned modality. Both groups completed a pre- and postintervention knowledge acquisition test, and a knowledge application mannequin-based crisis scenario one week later.

Results and Discussion: Both groups demonstrated significant knowledge acquisition (VR: +2.0, P=0.006; mannequin: +3.2, P<0.001). However, no differences were observed between the groups in the knowledge acquisition assessment (P=0.15). While for the knowledge application test, the Mannequin group outperformed the VR group (mean difference: 1.58, P=0.021), with faster recognition of a potential airway injury (P=0.004). Finally, the VR group reported higher engagement and satisfaction, preferring VR as a future learning modality.

Conclusion(s): VR-based training is comparable to traditional mannequin simulation for knowledge acquisition but may be less effective for practical knowledge application in critical clinical scenarios. Given the participants' excitement and satisfaction towards VR, we believe it can be incorporated into the medical curricula. Future research should focus on larger multi-site studies and improvement of the VR technology.

Evaluation of cost savings through continuous vital sign monitoring in post-surgical patients: a two-country health-economic analysis

J. Svan^{1,2}, T. Muench³, C. Fernandez-Barceló³, M. Luchetti⁴, J. Attebery⁵, S. Khan^{1,2} ¹Chelsea and Westminster Hospital NHS Foundation Trust, Cardiology, London, United Kingdom, 2Imperial College London, National Heart and Lung Institute, London, United Kingdom, 3Coreva Scientific GmbH & Co KG, Health Economics, Königswinter, Germany, 4GE HealthCare, Anesthesia and Intensive Care, Milano, Italy, 5GE HealthCare, Patient Monitoring, Chicago, United States

Background and Goal of Study: Adverse events following surgical procedures create a substantial clinical, resource and environmental burden. Intermittent monitoring in low-acuity settings such as general surgical wards can miss early detection of patient deterioration and may impede timely intervention to prevent adverse events. Continuous vital sign monitoring (CVSM) systems were developed to mitigate these complications and to enhance patient safety. While the clinical impact of CVSM is well reported, the economic impact of CVSM implementation is lacking. Here we assess the costs and consequences of CVSM in post-surgical patients from the hospital perspective in the United Kingdom (UK) and Netherlands (NED).

Materials and Methods: A structured review was conducted to extract data from published literature. A health-economic model was developed following ISPOR's guidelines to capture cost, resource use, and environmental consequences comparing CVSM to intermittent monitoring. A decision tree was used to model the care pathway for a cohort of 100 patients. Outcomes considered were total costs, presented in 2023 GBP/EUR, number of hospital days, rapid response team activations, and environmental impact (CO₂₀₀ and waste). Model uncertainty was assessed using probabilistic sensitivity analysis.

Results and Discussion: The results of the literature search showed CVSM's potential to prevent intra-hospital cardiac arrests, decrease ICU transfers, and decrease length of stay in both ICU and general wards.

However, data gaps for CVSM still exist on the individual country level. The model found that CVSM implementation costs of €436 (NED) and £342 (UK) per patient could be offset by savings in avoidable patient adverse events (Table 1). Hospital waste and carbon output was also reduced with use of CVSM.

		Netherland	ls	UK			
Outcomes	Standard of care	Continuous Monitoring	Difference (95% Credible interval)	Standard of care	Continuous Monitoring	Difference (95% Credible interval)	
Rapid response team activations (N)	4	3	1 (1.1-1.4)	37	27	11 (10-12)	
General ward length of stay (days)	410	382	28 (25-31)	772	720	52 (47-57)	
Intensive care unit length of stay (days)	21	12	9 (8-11)	14	8	5 (4-6)	
Costs (Euros, Great Britain Pound)	€321,915	€278,346	€43,569 (€35,989- €51,002)	£302,665	£268,481	£34,184 (£28,763- £39,574)	
CO ₂ equivalents (tons)	54	49	5 (4-6)	98	91	7 (6-9)	
Waste (kilograms)	1,391	1,266	125 (108-143)	2,521	2,335	186 (157-218)	

Table 1. Model results summary for Netherlands and UK on the impact of continuous monitoring for 100 patients

Conclusion(s): CVSM is expected to enhance patient safety and create savings in terms of costs and resources. Further research, particularly with real-world data, to confirm or contest these model findings are encouraged.

50AP05-10

Development and validation of a machine learning algorithm for Prediction of complete **NEuromuscular recovery in adult Surgical** patients (PINES)

A. Szabo^{1,2}, B. Ulm¹, B. Jungwirth¹, M. Blobner^{1,2}, S. Kagerbauer^{1,2}, F. Scheffenbichler^{1,2}, Work Group for postoperative Pulmonary Complications ¹University Hospital Ulm, Department of Anaesthesiology and Intensive Care Medicine, Ulm, Germany, 2TUM School of Medicine and Health, Technical University of Munich, Department of Anaesthesiology and Intensive Care Medicine, Munich, Germany

Background and goal of study: Rocuronium is the most used neuromuscular blocking agent. Despite many advantages, its duration of action varies greatly and is difficult for clinicians to predict[1].

Multiple patient- and anaesthesia-related factors are known to influence the effect of rocuronium [2, 3] and should optimally be considered for adequate dosing of neuromuscular blocking agents. We performed different machine learning model to predict the neuromuscular recovery of rocuronium prior to its administration.

Materials and Methods: Patient records from 2014/07 to 2023/01 with non-cardiac surgery, a single rocuronium dose and spontaneous neuromuscular recovery were analysed (ethical approval 2022-198-S).

A total of 101 variables were used as input for the development of our machine-learning model. The dataset was split into 80%-20% for training and validation cohorts.

Using the AutoML framework and other regression models, 12 different machine-learning algorithms were trained to predict neuromuscular recovery after rocuronium administration to a train of four-ratio >0.9

Results: A total of 25,412 records were analysed. Median age was 54 years, surgeries had a median duration of 58 minutes, and ASA II was the dominant classification (44%). A scatter plot showing observed and predicted recovery times is shown in Figure 1A. The most relevant predictors were rocuronium dose, patient age and height (Figure 1B, importance plot). The difference between observed and predicted recovery time (root mean square error (RMSE)) to a train of four-ratio of >0.9 was 20 minutes and 46 seconds of the best model and did not vary between machinelearning algorithms (Figure 1C).

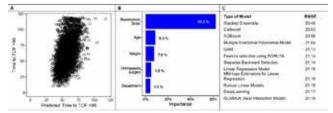

Figure 1.

Discussion: An RMSE of 20 minutes was considered clinically acceptable for predicting neuromuscular recovery. This is supported by pilot data showing that even clinicians had an average deviation of 26 minutes between predicted and observed recovery time.

Our findings confirm that dose and patient characteristics have most influence on the duration of neuromuscular blockade. The uncertainty of the prediction emphasises the importance of neuromuscular monitoring and the use of effective reversal drugs.

50AP05-11

Preliminary development of an Al-driven meta-model combining deep learning and Al-ECG for enhanced clinical deterioration prediction on general wards

<u>J. Syan^{1,2}</u>, K. Patlatzoglou², L. Pastika^{1,2}, M. Joshi², S. Khan^{1,2}, F.S. Ng^{1,2}

¹Chelsea and Westminster NHS Foundation Trust, Cardiology, London, United Kingdom, ²Imperial College London, National Heart & Lung Institute, London, United Kingdom

Background and Goal of Study: Despite advances in healthcare monitoring, up to 80% of unplanned ICU admissions result from undetected clinical deterioration on general wards. Continuous vital signs monitors offer a potential solution but can be prone to false alarms, generating alarm fatigue and reducing clinical effectiveness. Al-driven models address this challenge, though few are integrated into clinical workflows.

We aimed to develop a comprehensive predictive model using deep learning techniques, trained on patient-specific data (demographics, medical history and continuous vital signs), with the ultimate goal of model stacking with our 12-lead AI-ECG risk prediction model. This will provide an advanced, more holistic and accurate assessment of clinical risk deterioration.

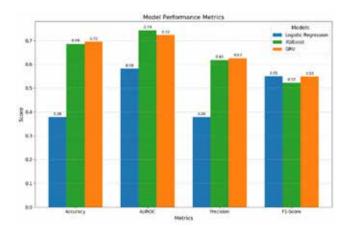

Materials and Methods: A dataset of 500 post-surgical patients from Chelsea and Westminster NHS Foundation Trust was used. Clinical deterioration was labelled as having either one of the following: sepsis, an elevated NEWS score triggering a rapid response team activation or cardiac arrest call, an unplanned ITU admission or mortality during that hospitalisation.

The dataset was stratified and a logistic regression, gradient boosted model (XGBoost) and GRU model were sequentially trained on standardised features. After hyperparameter tuning, models were validated and the highest performing selected.

Results and Discussion: Preliminary results from the trained clinical prediction models show that GRU has better overall accuracy (0.70) and F1-score (0.55) compared to the logistic regression and XGBoostmodels. Logistic regression lags significantly in AUROC (0.58) and overall performance. The GRU model appears to balance accuracy and F1-score effectively.

Conclusion(s): These preliminary results show that deep learning models significantly outperform logistic regression and gradient boosted machines, which are the current standard used in clinical prediction analytics.

Further development of a meta-model integrating the predictions from the GRU and an Al-enhanced electrocardiogram platform is planned, with the potential to enhance accuracy and robustness in clinical prediction tools.

50AP05-12 Neuromuscular monitoring, are we really doing it right?

<u>J. Bailey</u>¹, T. Singh¹

'Lister Hospital, Anaesthetics, Stevenage, United Kingdom

Background and Goal of Study: The Association of Anaesthetists (AoA) recommends quantitative neuromuscular monitoring (NM) during all phases of anaesthesia involving neuromuscular blocking (NMB) drugs. NM is initiated prior to NMB drug administration and continues until adequate recovery (Train-of-four ratio >0.9) is confirmed.

This audit aimed to assess our department's compliance with the AoA's recommendations regarding the frequency of NM, choice of nerve stimulator, and assessment of neuromuscular recovery during anaesthesia involving NMB drugs.

Materials and Methods: An anonymous questionnaire was distributed to all members of the anaesthesia department at Lister Hospital, to assess compliance with NM use during general anaesthesia with NMB drugs. The survey aimed to identify understanding of current guidelines, current practices, and organisational or practical barriers to NM use.

Results and Discussion: Of 31 respondents, 27 (87%) were aware of the AoA's NM recommendations. However, only 7 (23%) routinely used a nerve stimulator during induction, and 26 (84%) during extubation. For intubation without NM, 24 (77%) relied on 'time since administration'. Barriers to NM use for extubation included limited stimulator availability and a reliance on the assumed adequacy of NMB drug pharmacokinetics.

The majority, 25 (81%), used the Train-of-four (ToF) ratio for neuromuscular blockade assessment. Five (16%) assessed neuromuscular blockade using the ulnar nerve, while 22 (71%) used the facial nerve.

Compliance with current NM guidelines remains suboptimal. Despite a high level of awareness regarding the AoA recommendations, our audit revealed limited use of NM, particularly for intubation. While most participants utilised qualitative NM for extubation, quantitative NM was not employed at all.

Key barriers to NM adoption included limited stimulator availability and an overreliance on subjective assessments to determine adequate reversal.

To address these issues, our department has secured funding for new NM monitors and conducted a comprehensive teaching session on the importance and proper use of NM.

678 Devices and Technology

Conclusion: Our audit revealed suboptimal compliance with NM guidelines. Despite awareness, reliance on subjective assessment persists. To address this, we have procured additional NM monitors and conducted training sessions. A future audit will evaluate the impact of these interventions.

Intensive Care Medicine

51AP01-1

Cutting deep: when air pressure steals the spotlight in a percutaneous tracheotomy

S. Stojanovic Stipic¹, F. Peris¹, G. Prižmic¹, A. Maria Mitar¹. T. Stipic², S. Pavicic Perkovic¹

¹University Hospital Split, Department of Anaesthesiology and Intensive Care, Split, Croatia, 2University Hospital Split, Department of Dermatology, Split, Croatia

Background: Percutaneous tracheotomy is a "blind" surgical procedure that can cause damage to the trachea and surrounding tissue and result in fatal complications (pneumomediastinum and tension pneumothorax).

Case Report: The patient was diagnosed with MS 25 years ago. On the day of admission, she has a feeling of new-onset dyspnea. The diagnostic work-up proved the perforation of the hollow organ, and a hemicolectomy with a terminal ileostomy was performed. After 10 days of mechanical ventilation, we decided to perform a percutaneous tracheotomy.

Since we were not sure where the guide tube ended, the inexperienced bronchoscopist confirmed that the guide tube was in the trachea when, in fact, we placed the cannula in the para-mediastinal tissue.

Complications occurred in terms of complex ventilation and ventilation with enormous resistance. An x-ray of the lungs is done. The thoracic surgeon was unsure if there was a pneumothorax, so he requested an MSCT of the thorax, after which a diagnosis of pneumomediastinum with bilateral pneumothorax was made.

The patient was hemodynamically unstable, and vasoactive support with noradrenaline and vasopressin was included. due to complicated ventilation, adrenaline was also included in intrapulmonary.

Discussion: Risk factors for tracheal injury include tracheal anatomy and the rigidity that makes the trachea vulnerable, including female gender, older age, shorter stature, COPD, and corticosteroid therapy. It most often occurs in connection with a direct injury to the trachea but can also occur without a specific tracheal injury. The cause of tension pneumothorax can be classified into two types: direct tracheal injury and false lumen passage without definite tracheal injury.

To compensate for hypoxia, significantly ventilated air creates a large amount of pneumomediastinum through the injury of the trachea, then spreads to the subcutaneous tissue, mediastinum, pleura, neck and thorax, actually through the weakest points of the tissue.

Learning Points: Percutaneous tracheotomy can have fatal complications like bilateral tension pneumothorax, and despite a delayed diagnosis after bilateral thoracocentesis, this patient survived.

51AP01-2

Biomarkers of bacterial translocation and intestinal wall damage in patients with multiple organ dysfunction syndrome

A. Ogizbayeva¹, S. Assamidanova², Y. Turgunov² ¹NJSC Karaganda Medical University, Department of Emergency Medical Care, Anaesthesiology and Resuscitation, Karaganda, Kazakhstan, 2NJSC Karaganda Medical University, Department of Surgical Diseases, Karaganda, Kazakhstan

Background and Goal of Study: The aim of this study was to evaluate the potential biomarkers of bacterial translocation: lipopolysaccharide-binding protein (LBP), soluble CD14 subtype (sCD14-ST), and intestinal wall damage: intestinal fatty acid binding protein (I-FABP), Zonulin, regenerating islet-derived protein- 3α (REG3 α), in the patients with multiple organ dysfunction syndrome (MODS).

Materials and Methods: The study involved 327 patients divided into 2 groups: Group 1 - 227 patients with MODS (main group), Group 2 - 100 patients without MODS with identical pathologies (control group). MODS was diagnosed according to the SOFA scale, and mortality prediction scores APACHE II was also assessed.

To determine biomarkers, venous blood was taken in the control group on the day of admission, and in patients with MODS when detecting signs of MODS, on the 3rd and on the 7th day of its development. Markers were determined by the ELISA method according to the manufacturer's instructions.

Results and Discussion: The control and main groups did not differ in age, sex, main pathology and comorbidities (p=0.133, p=0.672, p=0.582 and p=0.441, respectively). In the control group, the values of all the studied markers were significantly lower than in the main group (p<0.0001). In the main group mortality rate was 44.9% (n=102).

Deceased patients with MODS had significantly higher sCD14-ST level on day 1, I-FABP and REG3 α levels on days 1 and 3 (p=0.043, p=0.004, p=0.018, p=0.010 and p=0.049, respectively). The LBP level on the day 7 was lower in deceased patients (p=0.006). The threshold values of the studied markers, at which the risk of death in patients with MODS increases, were determined.

Conclusion(s): In patients with MODS, increased I-FABP, REG3a, sCD14-ST levels and decreased LBP level may indicate increased intestinal wall permeability and bacterial translocation, which may worsen the course of multiple organ dysfunction and increase the risk of death.

Despite the limitations of this study, the studied potential biomarkers of intestinal wall damage and bacterial translocation are interesting candidates for identifying patients with a high risk of mortality to revise the tactics of therapy in order to reduce the stay of patients in the intensive care unit and lower mortality rate.

51AP01-3

To salt or sweeten? Management dilemma in concomitant diabetic ketoacidosis and central diabetes insipidus

Y.T.M. Chia1, S.Y.F. Tan1 ¹Khoo Teck Puat Hospital, Anaesthesia, Singapore, Singapore

Background: Managing concomitant diabetic ketoacidosis (DKA) and central diabetes insipidus (DI) is extremely challenging. First. DKA with fluid deficit masks underlying central DI. Second, the choice of resuscitation fluids directly influences serum sodium which can result in severe life-threatening complications. Fluid resuscitation with isotonic fluids in DKA can worsen hypernatremia, yet using hypotonic fluids may rapidly lower serum osmolarity causing cerebral oedema.

Case Report: A 33-year-old female was admitted to the Intensive Care Unit with severe DKA. She presented with altered mental status and vomiting with severe metabolic acidosis. She was initially resuscitated with 2.5L intravenous plasmalyte. She was later diagnosed with a large pituitary neuroendocrine macroadenoma for which she underwent an urgent transsphenoidal excision and later developed central DI.

Urgent consultation was made with Endocrinology. Due to hypernatremia, the patient was first started on dextrose 5% intravenous fluid 83mL/hr with free water boluses 600mL/day via an orogastric tube.

However, she developed significant hyperglycemia despite being on IV insulin infusion. She was switched to intravenous 0.45% normal saline infusion at 83mL/hr where her serum sodium was closely monitored with subsequent clinical improvement.

Discussion: When in fluid deficit, severe DKA will mask underlying DI due to low urine output, thus providing a diagnostic dilemma¹. In DKA, the preferred resuscitation fluid is an isotonic fluid. However, this is dangerous in patients with DI as it causes precipitous increases in serum sodium.

The preferred intravenous fluid of dextrose 5% in patients with DI also worsens hyperglycemia in DKA. As it is extremely rare to have concomitant DKA and DI, there are few available case reports. It is pertinent to accurately diagnose and carefully resuscitate these patients to prevent life-threatening complications.

References:

1. Gonzalez E et al. Central Diabetes Insipidus Masked by Uncontrolled Diabetes Mellitus: A Challenging Case Managed With Indapamide. Cureus. 2022 Feb 4;14(2):e21897. doi: 10.7759/ cureus.21897. PMID: 35265423; PMCID: PMC8898342

Learning Points: No guidelines exist for managing concomitant DKA and DI. Polyuria and persistent hypernatremia in a patient with DKA should raise the suspicion for DI. Choice of fluid resuscitation must also be carefully deliberated to balance the risks of worsening hypernatremia with decreasing osmolarity rapidly.

51AP01-4

The Role of Point of Care Ultrasound (POCUS) guided rescue thrombolysis in the management of postpartum pulmonary embolism with cardiac arrest in secondary care setting - the road between scylla and charybdis

M. Elnahas¹, A. Gerneth¹, S. Hochrein¹, P.M. Lang¹ ¹Sozialstiftung Bamberg, Anesthesiology, Intensive Care Medicine, and Pain Therapy, Bamberg, Germany

Background: Pulmonary embolism (PE) is a life-threatening condition that significantly affects postpartum women due to the hypercoagulable state. PE-induced cardiac arrest (CA) has a mortality rate of about 65% (1).

This case report highlights the importance of early thrombolytic therapy, Point of care Ultrasound (POCUS), and management of severe bleeding and hemorrhagic shock after thrombolysis.

Case Report: A 28-year-old woman, G1P1, who had undergone an emergency C-section due to early placenta abruption and rupture of the uterus with smooth recovery, presented on postoperative day one with sudden dyspnea and hemodynamic instability.

This was shortly followed by a witnessed sudden CA, prompting immediate Cardiopulmonary resuscitation (CPR). Urgent POCUS revealed right ventricular dysfunction consistent with acute PE. Due to the lack of availability for emergent catheter-directed local thrombolysis, the decision was made to proceed with systemic thrombolytic therapy despite the high risk of bleeding.

The patient received the recommended thrombolytic therapy using Alteplase, After About 60 minutes of Prolonged CPR, ROSC was achieved, and the patient was transferred to the Intensive Care unit

A detailed transthoracic echocardiogram confirmed the diagnosis of PE, showing an enlarged right ventricle, D-sign, distended inferior vena cava and a TAPSE of about 11 mm. As expected, the patient suffered significant bleeding complications, requiring massive blood products and clotting factors transfusion.

After several hours of controlling the bleeding, the patient's condition stabilized. A CT angiogram confirmed a massive PE. The patient developed multiorgan dysfunction that required critical care management, including renal replacement therapy and liver support, the patient recovered fully without neurological sequelae and was discharged home after 20 days.

Discussion: Thrombolytic therapy during CA due to PE has been increasingly reported, with several studies showing improved outcomes compared to conventional CPR alone (2).

Studies have shown that applying POCUS during CPR aids in rapidly diagnosing the underlying causes, enabling targeted treatment (3).

- 2. https://doi.org/10.2147/oaem.s275767,
- 3.https://doi.org/10.3390/diagnostics14040434

Learning Points: The high suspicion index and POCUS use in the setting of sudden CA can be life-saving in such highly complicated cases. Expect the unexpected.

51AP01-5

Paradoxical embolism: a rare culprit in an unexpected clinical presentation

E. Kılıç Çakmak¹, <u>U.C. Ozagar</u>¹, M. Dayıoglu¹, J. Ergil¹ ¹Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Patent foramen ovale(PFO) is a congenital disease that is often seen in adults. Patients are usually asymptomatic and are noticed during etiological investigation of paradoxical embolism. When etiology of stroke is investigated in patients younger than 60 years of age, atrioventricular septal defect (ASD) and (PFO) should be considered when cause is not found.

In our case, we aimed to discuss a patient who was diagnosed with deep vein thrombosis (DVT) and came to emergency service with respiratory distress and seizure.

Case Report: A 52 years old male has hepatit B,asthma and epilepsy. Patient was diagnosed with DVT in lower extremity, 3 weeks after meniscus operation and was discharged home after treatment adjustment. Patient who had no history of seizure for 5 years had seizure on the way home and was brought to emergency room with loss of consciousness and respiratory distress. No acute changes were detected in the patient's brain computer tomography (CT).

Filling defects were detected in the patient's pulmonary artery CT angiography and embolism could not be excluded. Patient had sinus tachycardia and hypertension in the ICU follow-up, but respiratory parameters were normal. Patient who had no neurological defects, had a severe headache resistant to analgesics and continued nausea.

Control brain CT revealed acute ischemia in both cerebellar hemispheres, left occipital and parietal lobes. In addition "intraparenchymal hematoma area in left temporal lobe" was observed. It was consistent with the diffusion MR and CT taken on same day. Echocardiogram (ECHO) was planned for the patient with suspicion of paradoxical embolism and suspicious atrial transition was observed during ECHO. Transesophageal echocardiography was performed for further evaluation and PFO was detected; PFO closure was performed on the same session.

Discussion: Patients who have embolic stroke without obvious cause, PASCAL (PFO-Associated Stroke Causal Likelihood) classification system, which also includes RoPE score (Paradoxical Embolism Risk) is used. Our patient's RoPE score was 7, according to PASCAL, probability of cerebrovascular disease (CVD) being associated with PFO in our patient was high. Coexistance of DVT and syncope should suggest paradoxical embolism, if neurological examination is normal.

Learning Points: Paradoxical embolism, PFO, Syncope

51AP01-7

Unveiling diaphragmatic rupture: intensive care management in a late diagnosed case

A.G. Yilmaz Selimoglu¹, S. Evren¹, İ. Erkan¹, N. Niftaliyeva¹, C. Nikbay¹, N. Turgut¹

¹Univesity of Health Sciences Prof. Dr. Cemil Taşçıoglu City Hospital, Anesthesiology and Reanimation, İstanbul, Turkey

Background: Diaphragmatic rupture (DR) can result from thoraco-abdominal traumas (TAT)¹. Chest X-Rays may fail in diagnosing, because air-containing abdominal organs in thorax can be misinterpreted and confused with other diagnosis like pneumothorax (PX)¹⁻³.

Most specific radiographic signs are herniated organs or nasogastric tube (NG) in thorax³.

Case Report: 24-year-old male admitted after TAT. During his stay, respiratory distress occured, PX was suspected, and chest tube was placed (Fig.1a).

Respiratory distress persisted. More imagings performed, revealing a defect in diaphragm, and a herniated stomach (Fig.1b-c).

Surgery for reduction and repair was perfomed. Patient was admitted to ICU. Intolerance to enteral feeding developed. Intra-abdominal (IA) pressure, along with infectios parameters, increased. CT showed contamination, promting laparatomy. Necrotic and perforated ileum resected. Ileostomy was performed.

Septic shock due to IA sepsis developed. Cytokine-filtered continue renal replacement therapy and neuromuscular electrostimulation therapy to diaphragm applied. Diaphragm thickness fractions calculated and extubated accordingly, then discharged on 42nd day.

1 a) Chest X-Rays interpreted pneumothorax and thorax tube inserted

1 b) Upright abdominal X-Rays

(c) CT scan revealing herniated stomach

Figure 1: Chest and abdominal X-Rays and CT scan

Discussion: When evaluating DR, misdiagnosis and consequential damage can occur³.

Placing NG is helpful in confirming the diagnosis, and preventing further herniation^{1,4}.

In this case our belief is, ileal perforation, may have been occured during chest tube insertion, or due to possible necrosis while in thorax.

- 4. Goh, B.K., et al., Delayed presentation of a patient with a ruptured diaphragm complicated by gastric incarceration and perforation after apparently minor blunt trauma. Canadian Journal of Emergency Medicine, 2004. 6(4): p.277-280.

Learning Points: After TAT, DR and herniation must be considered. Differential diagnosis must be evaluated, and interventions should be performed accordingly.

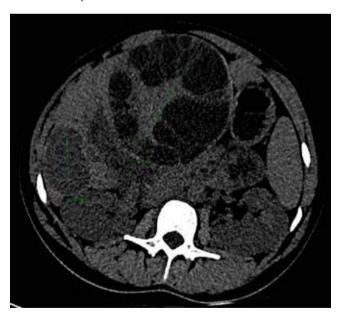

51AP01-8

A severe refractory cardiogenic septic shock as a result of the echinococcus infection

O. Yehorov¹, E. Mangoubi¹, D. Kompaniets¹, K. Negem¹ ¹Carmel Medical Centre, Anesthesiology, Intensive Care and Pain Medicine, Haifa, Israel

Background: Human echinococcosis is a parasitic disease caused by tapeworms of the genus Echinococcus. Human infection with echinococcosis leads to the development of one or more cystic structures in different organs. A cyst damage can lead to a potentially life-threatening infection.

Case Report: A 28-year-old female with a medical background of liver Echinococcosis, Gastritis, and Smoker was admitted to the hospital due to a fever and possible cyst infection after she decided to stop the treatment with Albendazole.

Discussion: The abdominal CT showed echinococcal cysts in the liver with significant pressure on the stomach and duodenum, suggesting a rupture in the larger cyst due to inflammation or infection. The patient was treated with Albendazole, Rocephin, and Metronidazole for possible secondary infection and discharged to continue treatment, with elective surgery scheduled in one month. Eight days later, she was rehospitalized for abdominal pain and underwent exploratory laparotomy with partial hepatectomy and PAIR for cysts in segments 4B, 6, and 7. The surgery was successful, but by day 6, her condition worsened, showing signs of multiple organ failure: hemodynamic instability, acute respiratory and renal failure. She was transferred to the ICU, intubated, and started on inotropic support. ECHO revealed poor ventricular contraction (EF 20%). Lab results showed acute inflammation (WBC 38.1, CRP 29.9, Procalcitonin 34.1). Diagnosed with refractory cardiogenic shock and septic cardiomyopathy, she was placed on VA-ECMO and CRRT.

After 5 days, her heart function improved (EF 55%), and renal function was restored. Antibiotics were adjusted based on blood cultures, and after 9 days, she was extubated, transferred to the surgical ward, and later discharged home in good condition, continuing treatment with Praziquantel and Albendazole.

References:

https://www.who.int/news-room/fact-sheets/detail/ echinococcosis

Learning Points: This clinical case demonstrates that timely started ECMO has been used successfully for the treatment of patients with severe refractory cardiogenic shock caused by Echinococcus sepsis in the early postoperative period.

51AP01-9

A fulminant immune hemolytic anemia induced by contrast medium was successfully treated with eculizumab

A.M. Bernard¹, K. Althaus², H. Haeberle¹, P. Rosenberger¹, S. Hermann¹

¹University Hospital Tuebingen, Department of Anesthesiology and Intensive Care Medicine, Tuebingen, Germany, ²University Hospital Tuebingen, Department of Clinical and Experimental Transfusion Medicine, Tuebingen, Germany

Background: Contrast media (CM) is frequently associated with allergic reaction and kidney dysfunction. It can, however, also induce hemolytic anemia with a broad spectrum of hemolytic manifestation.

Case Report: We report of a 38-year-old male patient with a life-threatening intravascular immune hemolytic anemia after application of lomeprol due to a CT scan of thorax/abdomen. In our report, we illustrate the diagnostics and treatment of a lifethreatening hemolytic anemia induced by contrast medium that was successfully treated with eculizumab, a recombinant humanized monoclonal antibody used to treat paroxysmal nocturnal hemoglobinuria, and atypical hemolytic uremic syndrome among others.

Discussion: In literature, four case reports of CM-induced hemolysis of varying degree can be found [1-4]. We were confronted with a massive life-threatening intravascular hemolysis. To our knowledge, no drug-induced hemolysis with this magnitude and successful therapy has been published. Before knowing the serological findings, we chose a double-barreled therapy with eculizumab as the patient's critical condition didn't allow any delay of therapy. Four weeks later, the patient could be transferred to a rehabilitation unit and was back into full employment after one year.

Fig. 1: Skin efflorescences of hemolysis from a comparable case.

Learning Points: There are different mechanisms and serological findings underlying immune hemolytic anemia.

Beside eculizumab, plasma exchange/plasmapheresis, steroids, immunosuppression, and i.v. immunoglobulins are therapeutic options.

51AP01-10

Thyrotoxicosis induced coronary vasospasm as a rare cause of cardiorespiratory collaps: case report

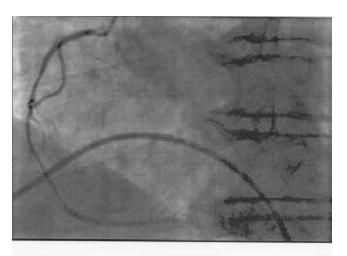

S. De Deckere¹, P. Jorens¹, R. De Paep¹, F. Lahaye¹, J. Van Herck¹, F. De Roeck² ¹Universital Hospital Antwerp, Intensive Care Unit, Edegem, Belgium, 2Universital Hospital Antwerp, Cardiology, Edegem, Belgium

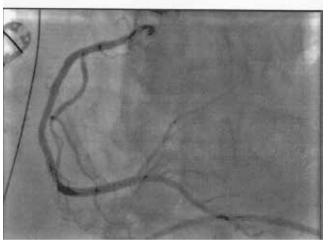

Background: Cardiac complications in patients with thyrotoxicosis are rather common and varied, including atrial fibrillation, heart failure or myocardial ischemia due to coronary spasm, but severe complications resulting in cardiac arrest are rare.

Case Report: We present a case of cardiac arrest in a 63 years old male with severe coronary vasospasm of the right coronary artery due to thyrotoxicosis. Diagnosis was made after coronarography and laboratory tests. The coronarography showed a severe spasm of the right coronary artery resolving after nitrate administration.

The patient fully recovered after treatment with intravenous nitrates and thyrostatic agents. Before discharge an internal defibrillator was implanted.

Discussion: To the best of our knowledge, this is the first case of cardiac arrest due to coronary vasospasm in a patient with thyrotoxicosis. Several cases in recent literature describes cardiac arrest in patient with profound heart failure due to thyrotoxicosis, but none of the case reports with coronary vasospasms results in cardiorespiratory collaps. In this case, the patient's cardiac function remained intact.

References:

Širvys A, Baranauskas A, Budrys P. A Rare Encounter: Unstable Vasospastic Angina Induced by Thyrotoxicosis. J Clin Med. 2024 May 27:13(11):3130

Zayour M, Yasmin FA, Baydoun A, Tawk M, Sleiman D, Shatila W, Chamoun C. Cardiac Arrest as First Presentation of Thyroid Storm. Cureus. 2023 Apr 3;15(4):e37057

Anjum R, Virk HUH, Goyfman M, Lee A, John G. Thyrotoxicosis-Related Left Main Coronary Artery Spasm Presenting As Acute Coronary Syndrome. Cureus. 2022 Jun 28;14(6):e26408 Brown J, Cham MD, Huang GS. Storm and STEMI: a case report of unexpected cardiac complications of thyrotoxicosis. Eur Heart J Case Rep. 2020 Nov 12;4(6):1-5.

Learning Points: When a patient presents with coronary vasospasm, it is crucial to consider a hyperthyroid state, whether it presents as subclinical recurring angina or as severe cardiac arrest, as in our case. Only through a correct diagnosis, a rapid and targeted therapy with thyrostatic agents be initiated to resolve the recurring vasospasm.

A case of using mesenchymal stem cells in a patient with post-intensive care syndrome

D. Martsinkevich¹, <u>V. Estryna</u>¹, A. Barbulat¹, S. Korotkov², A. Dzianisava¹

¹Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Anesthesiology and Intensive Care Unit No. 2, Minsk, Belarus, ²Minsk Scientific and Practical Center for Surgery, Transplantology and Hematology, Head of the Department of Transplantology (Liver Transplantation and Hepatobiliary Surgery), Minsk, Belarus

Background: Regenerative medicine today offers innovative approaches to treating diseases using cellular technologies [1]. Cellular therapy, through various mechanisms including mitochondrial transfer, represents a new frontier in managing patients with high risks of comorbidity, including those associated with neurological status. Mesenchymal stem cells (MSCs) possess great potential due to their ability to self-renew, differentiate into tissue-specific cells, and their significant immunomodulatory and anti-inflammatory properties.

Case Report: Patient A., a 65-year-old person underwent orthotopic liver transplantation. The postoperative period was complicated by infectious complications, the development of septic shock, and multiple organ dysfunction syndrome. We were dealing with a patient who had multiple severe systemic disorders, including neurological (hemorrhagic brain infarction), infectious, and organ-related complications, including impaired liver graft function. The duration and intensity of the treatment contributed to the development of post-intensive care syndrome [2].

Neurological rehabilitation, physiotherapy, and the maintenance of adequate nutritional and metabolic status did not yield significant improvements. Therefore, on the 30th, 32nd, and 34th days of intensive care, mesenchymal stem cells were administered intravenously at a dose of 4 million units per kilogram. Seven days after the transplantation of stem cells, alongside nutritional and metabolic correction, the patient demonstrated improvement in physical, cognitive, and psychological well-being. By the 57th day of hospitalization, the patient was discharged in satisfactory condition to continue treatment on an outpatient basis.

Discussion: The practical use of mesenchymal stem cells shows significant potential in clinical applications, demonstrating the ability to improve clinical outcomes in patients with neurological deficits.

 Renner C, Jeitziner M. Guideline on multimodal rehabilitation for patients with post-intensive care syndrome. Crit Care. 2023 Jul 31;27(1):301.

Learning Points: The transplantation of mesenchymal stem cells represents a promising new treatment approach. The precise mechanisms by which mesenchymal stem cell therapy promotes recovery require further investigation.

51AP01-12

The herald bleed: a severe complication secondary to an aortoenteric fistula

A. Plaza Saura¹, B. García Iniesta¹, M. Cano Castellote¹, A.I. Mateos Hernández¹, C.M. López López¹, R. González Celdrán¹

'Hospital General Universitario Beina Sofía.

¹Hospital General Universitario Reina Sofía, Anaesthesiology and Intensive Care, Murcia, Spain

Background: Aortoenteric fistula (AEF) is a rare but life-threatening condition that can result from a variety of causes although abdominal aortic aneurysm is the most common risk factor. The diagnosis can be challenging, and it usually requires urgent and aggressive treatment.

Case report: A 63-year-old male with a history of hypertension, type 2 diabetes, former smoker and mycotic aneurysm of the infrarenal aorta first treated in 2022 with an endograft and then, with an aorto-aortic bypass due to the graft's infection.

He presented with upper gastrointestinal bleeding associated with hemodynamic instability, so an urgent gastroscopy revealed a pulsatile lesion in the third and fourth portions of duodenum, elevated but without active bleeding. Suspecting an aneurysm, an CT angiography was conducted, demonstrating intimate contact between the aorto-aortic bypass and the posterior wall of the duodenum.

The patient's condition rapidly worsened, developing refractory hemorrhagic shock and pulseless ventricular tachycardia so cardiopulmonary resuscitation as well as the insertion of a distal intra-aortic balloon pump were performed which enabled radiological definitive treatment: the placement of a prosthesis in the left common iliac artery due to significant contrast extravasation in the ileum.

However, the patient decompensated once again, necessitating urgent reintervention via laparotomy but it was impossible to reach the source of bleeding. The patient deceased a few hours later due to refractory hemorrhagic shock and multiple organ failure.

Discussion: AEFs can be classified in primary, mostly due to aneurysm and in secondary, more common but nevertheless rare (less than 2%), following any aortic reconstruction, especially grafts.

There is a variety of clinical manifestations, but it must be kept in mind as a potential cause of massive gastrointestinal bleeding in patients with prior aortic interventions, no matter how long since it (herald bleed).

Resuscitative Endovascular Balloon Occlusion of the Aorta (RE-BOA) has been proposed as a method to control aortic hemorrhage, providing a temporary window for resuscitation or a bridge to definitive care.

Learning points: AEF is rare but potentially lethal.

Its diagnosis relies on a high index of suspicion.

It must be kept in mind in any patient with known aortic aneurysm or prior intervention and gastrointestinal bleeding.

Without treatment, AEF is nearly uniformly fatal.

51AP02-1 Use of intravenous Vitamin K in rodenticide poisoning

C.-H.E. Wong¹, D.J.A. Tan¹, Z. Yahaya¹, C.-F. Yim¹ 1KK Women's and Children's Hospital, Department of Women's Anaesthesia, Singapore, Singapore

Background: Management of bromadiolone poisoning complicated by hemorrhagic shock with vitamin K.

Case Report: A previously well 19-year-old female presented with hypotension, 4 days of abdominal pain, 1 day of hematuria. She had extensive laboratory abnormalities (Table) that normalised with addition of control plasma suggesting underlying coagulation factor deficiency.

Factor assays revealed a warfarin-like effect - markedly reduced serum levels of Factors II (prothombin), VII, IX, X. Liver function was unremarkable. CT of the abdomen and pelvis showed extensive hemoperitoneum with bleeding from a ruptured left ovarian corpus luteal cyst. Coagulopathy was managed with replacement therapy guided by ROTEM by administering 6 units of packed red cells, 5 units of fresh frozen plasma, 1 unit of pooled platelets, 10 units of cryoprecipitate and IV tranexamic acid 1g 8 hourly. IV vitamin K 10mg was started 8 hourly.

An emergency laparoscopic cystectomy done after coagulopathy correction confirmed a ruptured corpus luteal cyst with 3L of hemoperitoneum. IV vitamin K was switched to oral vitamin K 30mg thrice daily postoperatively. She was discharged well after 13 days. Serum toxicology confirmed bromadiolone poisoning.

Discussion: Bromadiolone, a 2nd generation 4-hydroxycoumarin rodenticide, follows a 2-compartment model elimination kinetics with a rapid decline phase (t/12 3.5 days) and slower termination phase (t1/2 24 days)1. Treatment mainstay is vitamin K. While vitamin K can rapidly correct coagulopathy, premature termination may result in a return of clotting derangements. There are currently no guidelines for duration of vitamin K therapy. Serial measurement of coagulation function is recommended even post vitamin K cessation.

References:

1. Lo VM, Ching CK, Chan AY, Mak TW. Bromadiolone toxicokinetics: diagnosis and treatment implications. Clin Toxicol (Phila). 2008;46:703-10.

Learning Points: Bromadiolone poisoning should be suspected in patients with disproportionately extensive coagulopathy with normal levels of platelets and unremarkable liver enzymes and confirmed with toxicology. Its prolonged half-life warrants extended vitamin K duration with coagulation profile monitoring for possible coagulopathy resurgence after correction of initial coagulopathy.

Thirst gone too far: symptomatic hyponatremia due to water intoxication - a case report

A.B. Tahir¹, V. Sudhir¹, E.I. Konthalloor¹ ¹Portiuncula University Hospital, Anaesthesiology, Ballinasloe, Ireland

Background: Hyponatremia is defined as a serum sodium <135 mEg/L, is severe at levels <125 mEg/L. Dilutional hyponatremia occurs when excessive water intake overwhelms renal excretion capacity. Water intoxication is a rare cause, typically seen in specific scenarios. This report highlights a rare case of severe hyponatremia due to excessive water intake during exercise/endurance training.

Case Report: A 40-year-old male presented with acute confusion after drinking 10 litres of water over 4 hours post-exercise. He was vitally stable (GCS 13/15) with unremarkable systemic examination. Investigations showed severe hyponatremia (serum sodium 112 mmol/L), hypo-osmolarity (235 mOsm/kg), and dilute urine (urine sodium <10 mmol/L, osmolarity 117 mOsm/kg). Imaging studies, including chest X-ray and brain CT, were normal. The patient was admitted to the ICU, where sodium levels were corrected gradually with 200 mL of 3% hypertonic saline. Sodium was monitored every 4 hours, and water restriction with isotonic fluids was implemented. His sodium improved to 133 mmol/L, and he was discharged in stable condition.

Discussion: Hyponatremia is a common electrolyte disorder. Several reports have documented cases of hyponatremia in psychiatric patients or with underlying co-morbidities, but it rarely occurs in healthy individuals without underlying comorbidities^{1,2}. The kidneys are capable of excreting up to 28 litres/day, but can only excrete 0.8-1.0 litres/hour, making rapid water intake dangerous. Symptoms of severe hyponatremia range from headache, confusion, nausea, and vomiting to seizures, coma, and death in severe cases. Diagnosis requires serum osmolarity, urine osmolarity, and urinary sodium tests. Guidelines recommend infusing 150 mL of 3% saline over 20 minutes or until symptoms resolve, with a sodium correction limit of 10 mmol/L in 24 hours to avoid osmotic demyelination syndrome3.

- 1. Clinical characteristics and outcomes of hyponatremia associated with oral water intake in adults: a systematic review. BMJ open. 2021 Dec
- 2. Severe hyponatremia due to surreptitious water intoxication in a hospitalized patient. CEN Case Reports. 2023 May.
- 3. Clinical practice guideline on diagnosis and treatment of hyponatremia. Eur J Endocrinol. 2014

Learning Points:

- 1. Early recognition and appropriate management of hyponatremia is critical to prevent complications.
- 2. Fluid intake should be limited to 1-1.5 litres/hour during heavy sweating to avoid water intoxication.

51AP02-3

External transcutaneous pacemaker in cardiogenic shock caused by 2nd degree mobitz II AV block – case report

T. Sisianu^{1,2}, C. Gutium¹, I. Cotorcea¹, A. Botizatu¹, V. Maevschi¹, V. Axentiuc¹

¹Timofei Moșneaga Republican Clinical Hospital, Anesthesia and Intensive Care, Chisinau, Moldova, Republic of, ²Nicolae Testemițanu State University of Medicine and Pharmacy, Anesthesiology and Reanimatology Nr.2, Chisinau, Moldova, Republic of

Background: Cardiogenic shock caused by severe bradycardia, such as in the 2nd degree type 2 and the 3rd degree AV block, represents a medical emergency where immediate intervention with a pacemaker is crucial. In the absence of an implantable pacemaker, the external defibrillator's pacemaker module can serve as a life-saving alternative [1].

Case Report: A 65-year-old woman with stage 5 CKD was admitted to the ICU following acute cardiac and respiratory failure during a colonoscopy. Initial clinical findings included a BP of 60/40 mmHg, heart rate of 30-42 bpm, SpO2 at 50%, and respiratory rate of 45/min. Emergency intubation and mechanical ventilation were initiated, alongside norepinephrine at 0.3 mcg/kg/min. Arterial blood gas analysis revealed metabolic acidosis (pH 7.30, lactate 3.6 mmol/L), severe hypoxia (DO2=206 ml/min, VO2=56.1 ml/min), and pulmonary edema on chest X-ray. ECG identified a second-degree AV block type 2 (Mobitz II). Transthoracic echocardiography showed severe pulmonary hypertension, preserved left ventricular (LV) contractile function (EF=61%), and significant tricuspid and mitral valve regurgitation. Advanced hemodynamic monitoring using PiCCO revealed high preload (GEDI=1330 ml/ m²), reduced cardiac contractility (GEF=13%, CFI=2.7), and elevated extravascular lung water (ELWI=19 ml/kg). Pulmonary CT angiography excluded pulmonary thromboembolism. Diagnosis of cardiogenic shock was established.

An external transcutaneous cardiac pacemaker was set in demand mode at 90 bpm, leading to significant hemodynamic improvement (HR 90 bpm, BP 105/64 mmHg).

Over subsequent days, external pacing combined with intensive care led to clinical improvement, resolution of vasopressor dependence, and successful ventilator weaning.

Discussion: This case demonstrates the efficacy of an external transcutaneous pacemaker in managing cardiogenic shock due to Mobitz II AV block, stabilizing cardiac function and facilitating discussions for implantable pacemaker placement.

References:

1. Wung SF. Bradyarrhythmias: Clinical Presentation, Diagnosis, and Management. *Crit Care Nurs Clin North Am.* 2016;28(3):297-308. doi:10.1016/j.cnc.2016.04.003

Learning Points: External defibrillator pacemaker modules can be critical in managing severe bradyarrhythmias in ICU settings, providing a bridge to more definitive treatments.

51AP02-5

Use of 2b/3a inhibitors in patients with stroke due to internal carotid artery oclusion

<u>A. Gritsan</u>¹, M. Kishinevskiy^{2,1}, O. Starikova², A. Suchkov², A. Starikova²

¹V.F. Voino-Yasenetsky Krasnoyarsk State Medical University, Anaesthesiology and Intensive Care, Krasnoyarsk, Russian Federation, ²I.S. Berzon Krasnoyarsk Interdistrict Clinical Hospital No. 20, Anaesthesiology and Intensive Care #2, Krasnoyarsk, Russian Federation

Background and Goal of Study: When performing thromboextraction in patients with ischemic stroke (IS) caused by thrombosis of the internal carotid artery (ICA), there is periodically a need for emergency endoprosthetics of the ICA, one of the complications is rethrombosis in the stent. The use of thrombolytic therapy alone does not solve the problem.

Objective: to evaluate the efficacy and safety of 2b/3a inhibitors (Aggrastat) in patients with IS in the therapeutic window for emergency ICA stenting.

Materials and Methods: A retrospective analysis was performed, which included 10 patients with IS with ICA occlusion. The average age was 59.6 years (48 – 74). Severity of the condition: Rankin 4-5 points, NIHSS 10-18, ASPECT 7-10. Before stenting, i.v. administration of Aggrastat was started at a dose of 50% of the cardiac dose, without bolus.

The duration of infusion was 18-24 hours. After stopping the Aggrastat infusion, patients immediately received loading doses of antiplatelet agents (50% of the cardiological dose): clopidogrel 300 mg, aspirin 150 mg, followed by a transition to dual antiplatelet therapy (Aspirin 100 mg/day indefinitely + Clopidogrel 75 mg/day for 3 months). All patients underwent ultrasound of the brachiocephalic arteries upon admission to the intensive care unit after reperfusion.

Evaluation of effectiveness: CT dynamics 12 and 24 hours after stenting, assessment according to Rankin and NIHSS scales after 24-48 hours.

Results and Discussion: According to CT data, a formed ischemic zone, remote hemorrhagic transformation and positive dynamics in the neurological status - 6 patients; a formed ischemic zone, hemorrhagic transformation and no dynamics in the neurological status - 1 patient; a formed ischemic zone, hemorrhagic transformation and negative dynamics in the neurological status - 2 patients. The Rankin scale score is 3-4 points, NIHSS 6-12 points. The mortality rate was 2 patients (20%).

Conclusion: The use of 2b/3a inhibitors is acceptable for emergency ICA stenting in patients with acute ischemic stroke. The use of Aggrastat is safe and effective, including in combination with systemic thrombolytic drugs.

After discontinuation of Aggrastat infusion, it is safe to switch to dual antiplatelet therapy by administering 50% of the cardiac loading dose.

The silent attack by streptococcus pyogenes by an unusual route

Z. Xia Qiu¹, E. Garcia Hernandez¹, D. Benguría Puebla¹, Z.A. Calderon Barajas¹, C. Armesto Castro¹, E. Conesa Lopez1

¹Hospital 12 de Octubre, Anesthesiology, Madrid, Spain

Background: Peritonitis, often secondary to abdominal organ perforation, can rarely manifest as primary peritonitis without a clear source. This uncommon condition may rapidly progress to septic shock, requiring timely diagnosis and management.

Case Report: A 32-year-old woman presented with left iliac fossa pain, peritoneal irritation, neutrophilia and elevated lactate. Gynecological ultrasound ruled out significant findings, but CT revealed pelvic free fluid and a subacute splenic laceration. Due to clinical deterioration, exploratory laparoscopy revealed purulent fluid without an clear infectious focus. A prophylactic appendectomy was performed.

The patient developed severe septic shock requiring ICU admission, intubation, and hemodynamic support with norepinephrine and vasopressin. Initial antibiotics included ceftriaxone, metronidazole, linezolid, and doxycycline. Streptococcus pyogenes isolated from blood cultures prompted a switch to penicillin, clindamycin, and metronidazole, supplemented with immunoglobulin (2g/kg). Detection of ESBL-producing E. coli in bronchial aspirates led to escalation to ertapenem and clindamycin. The patient improved, achieving extubation by postoperative day 8, ICU transfer on day 13, and full recovery with discharge on day 18.

Discussion: Primary peritonitis due to S. pyogenes is extremely rare but highly lethal, often linked to pharyngitis or genitourinary inoculation. In this case, menstrual cup use and household contact with streptococcal pharyngitis were likely predisposing factors, resulting in advice to avoid menstrual cups post-discharge. Management of streptoccocal toxic shock syndrome involved resuscitation, vasopressor support, and targeted antibiotics.

Clindamycin or linezolid is recommended for their anti-toxin properties, with immunoglobulin added in refractory cases despite limited evidence. Peritoneal lavage and drainage were crucial to reduce bacterial load.

Learning Points:

- 1. Primary peritonitis should be considered in cases without a clear source.
- 2. Rapid microbiological diagnosis enables tailored antibiotic ther-
- 3. Multidrug resistance requires careful antimicrobial regimen se-
- 4. Intensive care and addressing risk factors are essential for recovery.
- 5. Multidisciplinary collaboration ensures optimal management of complex infections.

Unveiling the shadows: candida glabrata-driven endophthalmitis and its clinical dilemma

D. Yiqit¹, E. Kilic Cakmak¹, M. Davioqlu¹ ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Bilateral endogenous endophthalmitis is a rare but severe vision-threatening entity. Candida species are the most common causes of endogenous endophthalmitis, particularly in immunocompromised individuals, those with uncontrolled diabetes mellitus or intravenous drug use. Timely diagnosis and therapy are crucial to improve visual outcomes. In this case report, we aimed to discuss a patient with bilateral visual impairment caused

Case Report: A 47-year-old female patient with a history of diabetes mellitus(DM) and hypertension presented to the hospital with a complaint of bilateral visual impairment. In the last 2 weeks, she was diagnosed with urinary tract infection and vaginitis.

Candida Glabrata was isolated from both the vaginal and blood cultures. No microbial growth was observed in the anterior chamber specimen of the patient, however gram-positive cocci were seen.

Antibiotic treatment with a combination of meropenem, vancomycin and fluconazole was initiated. Intravitreal voriconazole and amphotericin-B was also administered by the ophthalmologist. In order to identify the source of infection, with a known history of vaginitis, abdominal computed tomography (CT) was performed and intra-abdominal abscess was detected. Transthoracic Echocardiography (TTE) performed after candida glabrata growth in blood culture, revealed valvular vegetations. The patient underwent both abscess drainage and atriotomy operation.

Discussion: Predisposing conditions like diabetes, sepsis, immunosuppression or trauma are the probable causes of bilateral endophthalmitis. In patients presenting with bilateral endophthalmitis, eye trauma should be investigated, a focus scan to detect infection site should be conducted, and fundus examination, abdominal CT, TEE should be strongly considered. It should be taken into consideration that the patient may have systemic candidiasis, especially if there is a predisposing factor.

Yamamoto, Shinya, et al. "Bilateral Candida endophthalmitis accompanying Candida lusitaniae bloodstream infection: a case report." Journal of Infection and Chemotherapy 24.2 (2018):147-149.

Learning Points: In patients with bilateral endophthalmitis caused by candida, it should be taken into consideration that the patient may have systemic candidiasis, especially if there is a predisposing factor like DM.

51AP02-9

The diagnostic accuracy of the right ventricular outflow tract velocity-time integral in assessing fluid responsiveness with the passive leg-raising

S. Dehbi¹, B. El Ahmadi¹, A. Ghannam¹, Z. Belkhadir¹, A. El Fassi¹, O. Ssouni¹

¹The National Institute of Oncology in Rabat, Department of Anesthesiology and Intensive Care Medicine, Rabat, Morocco

Background and Goal of Study: Excessive fluid administration is harmful during patient resuscitation, making fluid responsiveness tests essential [1,2]. Passive leg raising (PLR) is well-established for assessing fluid responsiveness by measuring the left ventricular outflow tract velocity-time integral (LVOT VTI) in the apical 5-chamber view [3]. However, obtaining this measurement in the intensive care setting can be challenging. Therefore, this study aimed to evaluate the diagnostic accuracy of the right ventricular outflow tract velocity-time integral (RVOT VTI) variability during passive leg raising as a potentially reliable alternative for predicting fluid responsiveness.

Materials and Methods: This prospective observational study was conducted in the intensive care unit of the National Institute of Oncology of RABAT. We included patients with arterial hypotension. Ultrasound measurements of LVOT VTI and RVOT VTI were performed before and after PLR. Patients with LVOT VTI variability ≥ 13% received fluid resuscitation with 250 cc of 0.9% saline over 2 minutes. Then, a second transthoracic ultrasound was performed to measure the cardiac output variability. If it is ≥ 10%, the patient is considered a fluid responder.

Results: RVOT VTI measurements were obtained in all 55 patients. Of these, 71.4% were not intubated and 47.6% were receiving vasoactive drugs. The RVOT VTI variability after PLR showed a strong correlation with LVOT VTI variability (r = 0.85; p < 0.001). as well as with cardiac output variability after fluid resuscitation (r = 0.49; p < 0.012). The area under the ROC curve for RVOT VTI variability during PLR was 0.93. An increase of RVOT VTI ≥ 13.04% during PLR predicted fluid responsiveness with a sensitivity of 94.44% and a specificity of 86.36%.

Conclusion: RVOT VTI variability measurement during PLR is reliable for predicting fluid responsiveness and guiding fluid resuscitation for critically ill patients, particularly those with difficult LVOT VTI measurements.

51AP02-10

Risk of underdiagnosis of factor XIII deficiency in patients on ECMO: lessons from a complex

C. Armesto Castro¹, O. González González¹, L. del Río Prieto¹, Z. Xia Qiu¹, E. García Hernández¹, E. López López¹

¹Hospital Universitario 12 de Octubre, Anaesthesiology, Madrid, Spain

Background: Managing patients on ECMO is one of the most challenging aspects of intensive care. Achieving a balance between thrombosis and bleeding is often difficult. Hemostatic complications, particularly bleeding, are the most frequent during this therapy, despite normal results on conventional coagulation tests. In this context, several studies have explored potential causes. identifying acquired deficiencies of critical coagulation factors. such as FXIII, which can lead to ineffective management if left undiagnosed.

Case report: We report a case of a 68-year-old female with a history of diabetes and rheumatoid arthritis who underwent an urgent laparoscopic appendectomy for acute appendicitis. In the early postoperative period, she developed biphasic acute respiratory distress syndrome (ARDS) with possible superimposed acute interstitial pneumonia, requiring veno-venous ECMO support. During her ECMO course, she experienced airway hemorrhages and melena, necessitating blood transfusions, despite normal hemostasis test results. An acquired coagulation disorder was suspected, and factor quantification revealed deficiencies in Factor XIII, VII, and fibrinogen. After administration of Factor XIII and fibrinogen, bleeding was controlled. Factor VII was withheld due to its prothrombotic effects.

Discussion: This case highlights the complexity of coagulation disorders in ECMO patients and the risk of failing to detect acquired deficiencies of essential factors such as factor XIII, a fibrin stabilizer, even when conventional test results appear normal. The absence of established protocols for identifying these deficiencies contributes to the risk of underdiagnosis and suboptimal management.

References:

1. McMichael, A., Ryerson, L. et al. ELSO Adult and Pediatric Anticoagulation Guidelines. ASAIO Journal 68: p 303-310, March 2022.(2) Noitz M, Szasz J. et al. Acquired Factor XIII Deficiency Is Common during ECMO Therapy and Associated with Major Bleeding Events and Transfusion Requirements. J Clin Med. 2023 Jun 18;12(12):4115.

Learning points: It is crucial to suspect and assess for acquired coagulation factor deficiencies in ECMO patients, particularly when conventional tests show no abnormalities. Early identification of these deficiencies, such as factor XIII deficiency, can improve prognosis and prevent severe complications. Continued research and case collection are necessary to develop more precise and standardized diagnostic and treatment strategies.

51AP02-12 Use of LUS for early diagnosis of pneumonia in critically ill patients

A. Casado Iglesias¹, C. Garau Zaforteza¹, E. De Nalda Suarez-Barcena¹, S. Jebril Ortega¹, D. Paz Martin¹, M. Vives Santacana¹ ¹Clinica Universidad de Navarra, Anaesthesiology and Intensive Care, Pamplona, Spain

Background: Septic shock or pneumonia sepsis is a health problem associated with critical care units. Pneumonia associated with mechanical ventilation, according to cohorts, affects up to 10% of mechanically ventilated patients and has a mortality of up to 30%. The use of POCUS in acutely deteriorating IMV patients allows the identification of possible foci of pulmonary condensation associated with infection. This, in addition to the patient's clinical signs such as hypotension, increased inflammatory parameters or fever, allows early initiation of targeted antimicrobial therapy, shortening the time from clinical deterioration to initiation of treatment.

Case report: We present three patients admitted to the ICU who required intubation and connection to mechanical ventilation during admission for reasons unrelated to respiratory infection. The mean age of the patients was 56 years, two of them were female and one male. In all three patients, 72-96h after the start of IMV, there was acute clinical deterioration with the need to increase vasopressors, increased CRP and PCT, with no identifiable infectious focus at the start and with a normal chest X-ray. In the LUS, consolidation focus were identified at lung level, with a positive doppler pattern in the image, suggestive of infection. Sputum cultures and blood cultures were taken and empirical antibiotic treatment was started until the results of the cultures were obtained. Chest X-ray, performed 48 hours after the onset of the symptoms, identified (by an expert radiologist) infiltration with air bronchogram in the image suggestive of pneumonia.

Discussion: The use of POCUS is becoming increasingly common in intensive care units. Regular ultrasound examinations of admitted patients allow early diagnosis of possible foci of infection such as pulmonary infiltrates or abscesses and the differential diagnosis of haemodynamic alterations. In addition to the daily physical examination of patients, a protocolised ultrasound examination including cardiac, pulmonary, abdominal and VEXUS assessment should be considered.

References:

1. Demi L, Wolfram F, Klersy C, De Silvestri A, Ferretti VV, Muller M, et al. New International Guidelines and Consensus on the Use of Lung Ultrasound. J Ultrasound Med. 2023 Feb;42(2):309-344. doi: 10.1002/jum.16088. Epub 2022 Aug 22.

Learning points:

Using POCUS as a daily protocol in ICUs allows early diagnosis and early identification of complications as well as early targeted treatment.

51AP03-1

MicroRNA profiling in lung tissues of a murine aspiration pneumonia model

C.-J. Huang^{1,2}, C.-Y. Chang³, C.-W. Chuang^{1,2} ¹Taipei Medical University, Department of Anaesthesiology, School of Medicine, College of Medicine, Taipei, Taiwan, ²Taipei Medical University, Graduate Institute of Clinical Medicine, College of Medicine, Taipei, Taiwan, ³Taipei Medical University, Wan Fang Hospital, Department of Medical Research, Taipei, Taiwan

Background and Goal of Study: Acute lung injury resulting from aspiration pneumonia is a serious complication of anaesthesia, for which no effective therapy is currently available. MicroRNAs, known for their role in post-transcriptional gene regulation, have emerged as promising therapeutic targets. To explore their expression in aspiration pneumonia, microRNA profiling of lung tissues was conducted using a murine model.

Materials and Methods: Adult male C57BL/6 mice in the AP group (n = 3) were oropharyngeally administered 50 µL of a gastric content mimic containing a xanthan gum-based thickener, pepsin, and lipopolysaccharide (pH 1.6). The Sham group (n = 3) received 50 µL of normal saline. After 48 hours, the mice were euthanized, and lung tissues were collected for injury assessment and microRNA profiling. Small RNA sequencing was performed, followed by bioinformatic analyses, including Gene Ontology (GO) analysis and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis.

Results and Discussion: Lung injury in the AP group was characterized by histopathological changes, elevated injury scores, impaired lung function, increased leukocyte infiltration, and tissue oedema, all significantly different from the Sham group (p < 0.05). Small RNA sequencing identified 54 differentially expressed microRNAs, including 11 upregulated and 15 downregulated (fold change > 2, adjusted p < 0.05), GO analysis revealed active roles for cell migration and immune regulation in the observed lung injury. KEGG pathway enrichment analysis highlighted the MAPK and PI3K/Akt pathways as key mechanisms. Notably, miR-206-3p was the most significantly downregulated and miR-29c-3p the most significantly upregulated, suggesting their potential involvement in inflammation through MAPK and PI3K/Akt pathway dysregulation.

Conclusion(s): MicroRNA profiling and bioinformatic analysis identified the MAPK and PI3K/Akt pathways as key mechanisms underlying acute lung injury induced by aspiration pneumonia. Notably, the differential expression of miR-206-3p and miR-29c-3p highlighted their potential as therapeutic targets for the treatment of aspiration pneumonia.

Did long-term mortality of very old intensive care patients change between 2005-2009 and 2015-2019? A retrospective cohort study with propensity score matching

L.L.J De Pauw¹, E. De Keukeleere², M. Quisquater³, J. Pauwels⁴, W. Swinnen⁴ ¹KU Leuven, Anesthesiology, Leuven, Belgium, ²Ghent, Anesthesiology, Ghent, Belgium, 3Onze Lieve Vrouw Ziekenhuis, Anesthesiology & Critical Care, Aalst, Belgium, ⁴AZ Sint-Blasius, Anesthesiology & Critical Care, Dendermonde, Belgium

Background and Goal of Study: Progress in medical science and technology has had a huge impact on the treatment of patients in ICU the last fifteen years. This progress should ideally ensure better survival of patients during their stay in the ICU as well as after discharge. Our most vulnerable Very oldIntensive care Patients (VIP), over 80 years old, represent an expanding population in ICU. Comorbidity, polypharmacy and frailty are some extra challenges to handle in VIPs. Goals: To examine the survival of VIPs after ICU admission and to compare the survival for up to 12 months of 2005-2009 (0509) and 2015-2019 (1519).

Materials and Methods: Single-center retrospective cohort study with propensity score matching (PSM) at Sint Blasius General Hospital, Dendermonde, Belgium with a 12 beds mixed medicalchirurgical ICU. An ICU database query identified all VIPs admitted between 0509 and 1519. Crossmatching to the Belgian national register showed the actual vital status or date of death. To adjust for confounding factors (sample size, age, gender, SAPS II, APACHE IV admission diagnosis), PSM was used. Outcomes: Length of Stay (LOS) ICU, in-hospital mortality. Statistics: Chisquare, MannWhitney U-tests. To assess survival rates up to 12 months after ICU admission, Kaplan-Meier survival analysis with log-rank test was performed; significance; p < 0.05.

Results and Discussion: After PSM, two groups of 506 patients who were comparable were obtained. Demographic and outcome data are shown in Figure 1. PSM removed bias by sample size, age, sex, APACHE IV admission diagnosis, and SAPS II score. LOS ICU was significantly shorter in 1519. Hospital mortality did not differ. Kaplan-Meier survival analysis showed no changes in mortality up to 12 months after ICU admission.

Conclusion(s): After correcting for biases with PSM, in-hospital mortality and mortality up to 12 months after ICU admission did not differ significantly. In both study periods, most VIPs died within the first month after ICU admission. The assumption that 15 years of advancements in medicine would enhance the survival rates of this population proved unfounded.

51AP03-4

Methemoglobinemia in a patient with iatrogenic colonic perforation and bilateral pneumothorax: case report

B. Kozlu¹, C. Balci²

¹Sbu Evliya Celebi Training and Research Hospital, Anesthesiology and Reanimation, Kütahya, Turkey, 2Sbu Umraniye Training and Research Hospital, Anesthesiology and Reanimation, Istanbul, Turkey

Background: We aim to present a case of iatrogenic colonic perforation during colonoscopy, which was subsequently followed by methemoglobinemia.

Case report: A 75-year-old female patient was scheduled for endoscopy and colonoscopy.colonoscopy, colonic perforation occurred/maging revealed pneumoperitoneum and bilateral pneumothorax, necessitating transfer to the emergency department (ED). Hypoxia continued after the patient had a chest tube inserted. Methemoglobinemia was observed to have developed. Blood gas analysis showed pH: 7.45, pCO2: 34 mmHg, pO2: 21.9 mmHg, SpO2: 43.1%, and MetHb: 28.9%. Methemoglobinemia was diagnosed, and 300 mg/kg ascorbic acid was administered, with no improvement in MetHb levels. The patient, now hypotensive, was admitted to the intensive care unit (ICU) on low-dose inotropic support and mechanical ventilation. Repeat blood gas analysis revealed worsening MetHb (31%), prompting methylene blue administration at 1 mg/kg after ruling out G6PD deficiency. Three hours post-methylene blue, blood gas values improved significantly MetHb:3.1%.Postoperatively, the patient recovered without requiring further inotropic support. By day 6, chest tubes were removed, and she was transferred to the ward in stable condition. **Discussion:** Treatment involves discontinuing the offending agent. MetHb levels below 20% usually resolve spontaneously, but levels above 20% require intervention with ascorbic acid or methylene blue. Methylene blue facilitates MetHb reduction via the NADPH methemoglobin reductase system, but its efficacy depends on the absence of G6PD deficiency. Ascorbic acid provides a non-enzymatic alternative. In this case, methylene blue was effective after ascorbic acid failed.

https://pubmed.ncbi.nlm.nih.gov/32193811/ https://pubmed.ncbi.nlm.nih.gov/22024786/ https://pubmed.ncbi.nlm.nih.gov/15226289/

Learning points: Methemoglobinemia, though more common in early life, can occur in adults, particularly during procedures involving local anesthetics. Prilocaine is frequently used during chest tube placement for pneumothorax. Persistent desaturation in such cases should prompt suspicion of MetHb, and blood gas monitoring should continue until the diagnosis is confirmed or excluded.

Epidemiological insights into postoperative acute kidney injury: risk factors and outcomes in cardiac surgery

M. Alonso-Pérez¹, P. Martínez Jiménez¹, A. de Abreu González¹, P. Ruiz Bueno¹, M.S. Espinoza Fernández¹, P. Jorge-Monjas¹ ¹Hospital clínico Universitario de Valladolid, Anesthesia, Valladolid, Spain

Background: Acute kidney injury (AKI) is a frequent and severe complication after cardiac surgery, being this kind of surgery the second From skin to airway: employing ultrasonography in the prediction of difficult laryngoscopy and ventilationFrom skin to airway: employing ultrasonography in the prediction of difficult laryngoscopy and ventilationmost common cause of AKI in the intensive care unit (ICU).Patients developing AKI have increased morbidity and worse surviving rates than those with normal renal function. The aim of this study is to review the epidemiology of AKI on postcardiac surgery patients at ICU as well as the preoperative risk factors and morbimortality.

Materials and Methods: A prospective cohort study was conducted including 251 patients from a single center, over the age of 18, who underwent cardiac surgery with extracorporeal circulation. Patients were excluded if they explicity refused consent, were on chronic hemodialysis treatment or were in the terminal phase.

Results and Discussion: The overall incidence of AKI was 32%: stage 1 AKI 22,5%, stage 2 AKI 2,7% and stage 3 6,7 % there was a 15,5 % of all AKI cases progressed to persistent AKI and 12,4 % progressed to chronic kidney disease. The preoperative quantitative risk factors were significant (p<0,05) included: age, left ventricular ejection fraction, prior creatinine clearance ,previous urea levels and baseline creatinine. The significant qualitative risk factors were: NYHA functional class, insulin-dependent diabetes mellitus, extracardiac peripheral artery disease, pulmonary hypertension, arterial hypertension, prior diuretic treatment and diuretic treatment. Additionally, patients with renal damage had a higher infection rate (76,96%) a greater need for polytransfusion (70,835 %), higher mortality (81,23%) and a longer hospital stay; all with p-value of <0,001. The results confirm that there is a statistically significant association between patients with preexisting renal dysfunction with extracorporeal circulation and the development of AKI.

Conclusion(s): This study demonstrates a significant association between pre-existing renal dysfunction and the development of AKI in patients undergoing cardiac surgery with extracorporeal circulation. Patients with renal impairment experienced higher infection rates, increased need of polytransfusion, greater mortality, and longer hospital stays. These findings align with expected AKI incidence rates in cardiac surgery as reported in previous literature.

51AP03-6

Management of Lercanidipine-induced Lyell's syndrome

D. Henriques¹, J.P. dos Santos Caldeira¹, P. Silva¹, J. Aires¹, L. Ferreira¹, I. Tourais¹ ¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background: Toxic Epidermal Necrolysis (TEN) or Lyell's syndrome is characterized by mucocutaneous erosion, epidermal necrosis and detachment, vesicle formation and systemic inflammation. It is primarily triggered by medications¹. Although a rare disease, with an incidence of 1-2 per 1,000,000 people, it has a high degree of morbidity, and mortality can reach up to 48%¹. TEN patients require a high level of medical and surgical care, often requiring hospitalization in a Burn Unit (BU).

Case report: We present the case of a 38-year-old male who developed TEN 10 days after starting an antihypertensive medication, Lercanidipine. Initially, the patient presented with macular, bullous lesions and positive Nikolsky sign in 2% of his body surface area (BSA). He was diagnosed with Stevens-Johnson Syndrome. After 4 days the lesions affected more than 30% BSA. The diagnosis was updated to TEN, and the patient transferred to the BU. A SCORTEN score of 3 was calculated (mortality rate of 35%).

After 48 hours, the lesions had spread to over 70% BSA, sparing only the head. The therapeutic plan encompassed intensive support and monitoring, daily hydrotherapy and wound care. Strict aseptic techniques were maintained during patient contact. Goal-directed fluid therapy, daily complete laboratory assessments, bacteriological screening and chest radiographs were performed. Pain was managed with patient-controlled analgesia of Morphine, Ketamine and Droperidol plus peripheral analgesia. Hydrotherapy sessions were provided with a combination of Propofol, Ketamine, Dexmedetomidine, and Fentanyl, allowing effective wound care. Patient care involved daily ophthalmology evaluation, pulmonary rehabilitation and oxygen therapy. By the 24th day of hospitalization, the patient showed over 90% healing of the affected skin areas and was discharged home.

Discussion: This case underscores the critical importance of intensive and rigorous care in the management of TEN, particularly in a specialized BU. Rapid disease progression shows the unpredictable nature of this severe drug-induced reaction.

References. 1- Paulmann M, Mockenhaupt M. Allergo J Int. 2019;28:311–326.

Learning points: Timely diagnosis, close monitoring, aggressive supportive measures and wound care were essential to prevent complications and improve the patient's outcome. Moreover, it serves as a crucial reminder of the need for vigilance in prescribing common medications, especially when initiating new treatments.

Actinomyces odontolyticus sepsis in the ICU: an unexpected enemy lurking in the shadows!

S. Stojanovic Stipic1, S. Pavicic Perkovic1, A.M. Mitar1, F. Peris¹, A. Bego¹, G. Prizmic¹ ¹University Hospital Split, Department of Anesthesiology and Intensive Care, Split, Croatia

Background: Actinomyces odontolyticus infections in the ICU setting are rare and typically occur in the context of severe, invasive infections (sepsis, abscess formation) or secondary complications (mastoiditis).

Case Report: A previously healthy 30 years old was admitted to the hospital due to high fever, confusion, hypotension, and dyspnea. A month before admission, he was treated for otitis media.Brain MSCT revealed thrombosis of the right internal jugular vein.right sigmoid, and transverse sinuses with inflammatory changes in the right ear and mastoid cells.Lumbar puncture was not performed due to thrombocytopenia(25). Neither neurosurgical nor otosurgical treatment was indicated. Broad-spectrum antibiotics were initiated. After he developed respiratory insufficiency, was transferred to the ICU and mechanically ventilated due to severe pneumonia, sepsis, mastoiditis, thrombosis, and meningism. A thoracic drain was inserted for pneumothorax. Actinomyces odontolyticus was isolated from blood cultures. Treatment included intravenous penicillin 24 MIU for 6 weeks, vasopressors, bronchoaspiration and surgical procedures:myringotomy, mastoidectomy, antrotomy. He developed HIT, and was treated with fondaparinux. The patient experienced massive hemoptysis with hemorrhagic shock and was stabilized with transfusions, plasma, and tranexamic acid. He was extubated after 10 days. After 20 days in the ICU he was discharged to pulmonology and later home. He continued oral penicillin for one year. He made a full recovery.

Discussion: Managing Actinomyces odontolyticus sepsis in the ICU involves diagnostic challenges.prolonged treatment reguirements, and potential complications. The slow-growing nature of the organism and its nonspecific symptoms often delay diagnosis, emphasizing the need for multimodal diagnostics. Treatment requires extended antibiotic therapy, typically high-dose IV Penicillin for 6 weeks followed by months of oral antibiotics. A multidisciplinary approach,including various specialists is essential. Complications such as HIT, venous thrombosis, and dissemination require prompt recognition and management. ICU clinicians should maintain a broad differential diagnosis and leverage microbiology to guide therapy, sepsis protocols, and treatment to avoid unnecessary broad-spectrum antibiotics.

Learning points: Timely diagnosis, aggressive antibiotic therapy and coordinated care are critical to improving survival and reducing long-term complications in Actinomyces odontolyticus sepsis.

51AP03-9

Treatment algorithm for acute pancreatitis caused by hypertriglyceridemia and lipid apheresis

G. Kilicarslan¹, S. Ozozan¹, A. Evgit², C. Balci² ¹Umraniye Research Hospital, Anaesthesiology and Intensive Care, Istanbul, Turkey, Istanbul Health Science UN., Anaesthesiology and Intensive Care, İstanbul, Turkey

Background: Acute pancreatitis (AP) can result from various etiological factors, including alcohol consumption, medications and hyperlipidemia. Hypertriglyceridemia (HTG) is the third most common cause of acute pancreatitis, due to global changes in dietary habits incidence of hyperlipidemia and its association with acute pancreatitis has been increasing.

Regardless of the etiology, the management of acute pancreatitis focuses on maintaining perfusion, providing hemodynamic support, infection control. Lipid apheresis is a medical procedure that involves the removal of lipoproteins, including triglycerides, from the bloodstream.

Case Report: A 32-year-old, 120 kg male patient with a medical history of type 2 diabetes mellitus (DM) and HTG presented to the emergency department with complains of nausea and vomiting. Laboratory findings were as follows: Amylase: 487 U/L, Lipase: 1680 U/L, Triglycerides: 2668 mg/dL. CT scan revealed a Balthazar C stage. Upon admission to the ICU, the patient was hypoxemic and had metabolic acidosis, and therefore he was intubated and placed on mechanical ventilation. The patient was started on insulin therapy and fenofibrate, along with lipid apheresis on the same day.

Four sessions of lipid apheresis were performed, with triglyceride levels gradually decreasing from 2668, 1351, 538 mg/dL. On the fourth day of mechanical ventilation support, the patient developed severe ARDS, and inhaled NO therapy was initiated.

As sepsis developed, adsorbent treatment (MG 350 - Biosky) was administered for two days. The patient was extubated on the 16th day of hospitalization and was transferred to the general ward on the 21st day.

Discussion: A 32-year-old, 120 kg male patient with a medical history of type 2 diabetes mellitus (DM), hypertension (HT), and hypertriglyceridemia presented to the emergency department with complains of nausea and vomiting. Patient's medical history, revealed that he used matofin, lustral, beneday and lipanthyl. In his family there was a history of coronary artery disease related death (father) and hypertriglyceridemia/hypercholesterolemia.

References:

1. Loveday BP, Srinivasa S. High quantity and variable quality of guidelines for acute pancreatitis: a systematic review. Am J Gastroenterol. 2010;105(7):1466-1476.

Learning points: AP: A life-threatening condition that can result from various causes, including hypertriglyceridemia.

Lipid Apheresis:Lipid apheresis is important in the treatment of HTG.

Correlation between cardiac output determined by echocardiography and indirect calorimetry in critically ill patients in cardiogenic shock treated with extracorporeal circulatory support - a computational model

H. Booke¹, C. Ertmer¹, S. Krone¹, C. Strauß¹, T. von Groote¹, M. Sadjadi¹

¹University Hospital Muenster, University of Muenster, Department of Anesthesiology, Intensive Care and Pain Medicine, Münster, Germany

Background and Goal of Study: Assessment of cardiac function in patients receiving extracorporeal cardiovascular support via venoarterial extracorporeal life support (VA-ECLS) is challenging. Pulse contour analyses are not applicable for technical reasons. thus sonography is usually performed to estimate cardiac output (CO). Since the assessment of CO function is of great interest in VA-ECLS weaning, additional methods for CO measurement are appreciated. Therefore, this study investigates whether CO can be determined by indirect calorimetry.

Materials and Methods: ECLS oxygen uptake (VO_{2-ECLS}) is calculated by blood gas analysis whereas oxygen uptake of the heartlung circulation (VO_{2-lung}) is measured by indirect calorimetry. For similar post-oxygenator and arterial oxygen saturations and partial pressures as well as similar oxygen extraction, it is assumed that CO divided by VO_{2-lung} equals ECLS blood flow (BF_{ECLS}) divided by VO_{2-ECLS}. Thus, CO may be estimated as follows: CO = BF_{ECLS}/VO_{2-ECLS} x VO_{2-lung}

We applied this technique and formula in a male patient with central VA-ECLS cannulation and compared the CO measured by the above mentioned formula with CO measured by echocardiography.

Results and Discussion: CO determined by echocardiographic measurement of the velocity-time integral (VTI) in the left ventricular outflow tract (LVOT) in the apical five-chamber view (Heart rate 60/min, VTI 13cm, LVOT diameter 23mm) was 3.24L/min. Post-oxygenator pO₂ and radial arterial pO₂ were both 129mmHg. Taking into account pre- and postoxygenator values of hemoglobin, oxygen saturation and $\mathrm{BF}_{\mathrm{ECLS}},\,\mathrm{VO}_{\mathrm{2-ECLS}}$ was calculated as 124mL/min. Indirect calorimetry indicates a VO_{2-lung} of 131mL/ min. Applying the above mentioned equation gives a CO value of 3.26L/min. The deviation from echocardiography derived CO is less than one percent.

Conclusion(s): Indirect calorimetry might be a promising non-invasive method for evaluation of CO in VA-ECLS patients. Further research is needed to validate this method of CO assessment.

51AP03-11

Reactive airway dysfunctional syndrome (RADS) in pediatric inhalational burns: A case report

R. Ramkumar¹, V. Rajagopalan¹, B. Yalla¹, S. Singh¹, S. Guptha¹

¹All India Institute of Medical Sciences, New Delhi, Anesthesiology, Pain Medicine and Critical Care, New Delhi. India

Background:

Pediatric inhalational injury is a significant predictor of morbidity and mortality in pediatric burns.

This case report describes the successful management of a patient with RADS and his ICU course, highlighting the importance of a multidisciplinary approach.

Case report:

A 10-year-old boy was rushed to emergency after he sustained thermal burns following a firecracker explosion and getting trapped inside the room for around 15 to 20 min. On arrival resuscitation with IV fluids done followed by dressing of the burn wounds and intubated i/v/o facial burns and inhalational injury with respiratory distress. Bronchoscopy showed mild edema with congestion of the bronchus.

Started on broad-spectrum antibiotics, nebulization with heparin, NAC, bronchodilators, and steroids. Later reintubated I/v/o increased work of breathing, respiratory fatigue, persistent hypercarbia with metabolic acidosis, and tracheostomised. A weaning trial was done but failed and RADS was diagnosed. Kept on CPAP later to BIPAP machine. Weaned off from the ventilator to room air and decannulated and discharged.

Discussion:

RADS was first described by Brooks et al to designate an asthmalike condition that may develop following exposure to toxic gases. Criteria of RADS diagnosis include 1) Asthma-like symptoms such as cough, wheezing, and dyspnoea, 2) occurring within a few hours after exposure, with persistence for at least 3 months.3) Absence of previous respiratory symptoms.4) No evidence of other pulmonary diseases.5) High-level exposure to gas/smoke/ fumes.6) Pulmonary function tests that usually show airflow ob-

Management protocol of RADS begins with suspected inhalational injury in pediatric burns including a primary burn care survey, If the patient is stable, fluid management and dressings are done. Followed by a bronchoscopy if it is normal standard burn care management is done. If the patient is unstable or Bronchoscopy shows vocal cord edema or mucosal erosions then the patient is intubated and started on fluid Management, intravenous steroids, inhalational bronchodilators/steroids, Empirical antibiotics, and Nutritional supplements. The weaning trial is conducted and extubated or decannulated after performing the cuff leak test. A multidisciplinary approach including Critical care medicine, Plastic and reconstructive surgery, Paediatric pulmonologist, Radiologist, ENT, and Dietician is required

Management of severe blunt thoracic trauma with veno-venous ECMO and concurrent cardiac surgery requiring extracorporeal circulation

V. Perez Mari¹, E. Pereda Gonzalez¹, J. Moreno Pachon¹, C. Reina¹, M.B. Perolada Beaus¹, J. De Andres Ibañez¹¹Consorcio Hospital General Universitario de Valencia, Anaesthesiology and Intensive Care, Valencia, Spain

Background: Veno-venous extracorporeal membrane oxygenation (VV-ECMO) in trauma patients is controversial but critical when lung damage is severe, and treatments fail. Though rare, trauma-related injuries may require urgent cardiac surgery, posing significant anesthetic and surgical challenges.

Case Report: A 44-year-old male was admitted to the ICU after a traffic accident causing blunt trauma. He had left hemopneumothorax, rib fractures, a contained rupture of the posterior ascending aorta, cerebral contusions, and alveolar hemorrhage. Despite hemopneumothorax drainage and mechanical ventilation, severe hypoxemia persisted. Echocardiography confirmed normal cardiac function and ruled out tamponade. Refractory hypoxemia and alveolar hemorrhage led to heparin-free VV-ECMO, decided in an interdisciplinary manner. After lung contusion stabilization, the ascending aorta was replaced under extracorporeal circulation. Postoperatively, he was reconnected to heparin-free VV-ECMO. After 72 h, with no bleeding and stabilized cerebral contusions, heparin was reintroduced, and VV-ECMO weaning began. Persistent thrombocytopenia, initially linked to high ECMO flow rates, worsened after heparin was introduced. Anti-heparin antibody testing confirmed heparin-induced thrombocytopenia (HIT). VV-ECMO continued heparin-free with prophylactic fondaparinux during advanced weaning. The patient recovered without complications. VV-ECMO and mechanical ventilation were discontinued on days 8 and 15, respectively, with ICU discharge on day 20.

Discussion: This case highlights VV-ECMO's role as a lifesaving intervention in severe trauma. Hemorrhage is a critical concern, making heparin-free therapies essential in specific scenarios. Persistent thrombocytopenia required differentiating high ECMO flow-related platelet consumption, heparin-induced thrombocytopenia (HIT), and trauma-induced coagulopathy.

References:

1. Ried M, Bein T, Philipp A, et al. Extracorporeal lung support in trauma patients with severe chest injury and acute lung failure: a 10-year institutional experience. *Crit Care*. 2013;17(3):R110. Published 2013 Jun 20.

Learning Points:

- Heparin-free VV-ECMO is essential in managing severe blunt trauma with bleeding risks.
- Adhering to damage control principles (ABCD) is vital for life-threatening injuries.
- Prompt identification and tailored management of thrombocytopenia are critical for patient recovery.

51AP04-3

Hepato-pericardial fistula in a patient with hepatocarcinoma: a case report

C. Garau Zaforteza¹, Á. Casado Iglesias¹, E. De Nalda Suárez Bárcena¹, S. Jebril Ortega¹, J. Parreño Benito², C. Cara Gilabert¹ ¹Universidad de Navarra, Anesthesia and Intensive Care, Pamplona, Spain, ²Universidad de Navarra, Cardiology, Pamplona, Spain

Background: Hepato-pericardial fistula is a rare but serious complication in patients with hepatocarcinoma on cirrhotic liver, especially after treatments such as radiotherapy or tumor ablation. This condition is characterized by an abnormal communication between the liver and the pericardium, which can lead to serious infections, as in this case, where a pericardial effusion with bilious-purulent fluid was diagnosed after the development of a biliary sepsis and multiorgan complications.

Case Report: This is a 52-year-old patient with a history of hepatocarcinoma on cirrhotic liver due to hepatitis C virus (HCV, already eradicated, treated with microwave ablation and radiomebolization. One year later he presented with acute on chronic pancreatitis, complicated by septic shock due to purulent cholecystitis.

During his stay, he developed pericardial effusion with positive culture for S. anginosus, suggesting a hepatopericardial fistula. As a result, he developed renal failure, acute liver failure, ARDS, and gastrointestinal bleeding, which required intensive management. Despite ICU efforts, the patient died due to multiorgan failure.

Discussion: Purulent pericarditis is a rare clinical entity, characterized by pericardial effusion of a purulent nature that usually occurs by extension from a contiguous bacterial infectious focus or by hematic dissemination. In this case, the proximity of the tumor to the pericardium and the radiation received facilitated the formation of a fistula, which was confirmed by the finding of bilious-purulent fluid in the pericardium.

This condition requires targeted treatment, with hemodynamic support and control of the focus by pericardiocentesis and antibiotherapy. Echocardiography allows us to evaluate signs of cardiac tamponade and, above all, to perform a guided pericardiocentesis.

Reference:

Thiemann M, Benhidjeb T, Anders S, Gebauer B, Strik MW. Hepato-pericardial fistula following radiofrequency ablation (RFA) for liver metastasis: a case report and review of the literature. Langenbecks Arch Surg. 2008 Nov;393(6):1013-6. doi: 10.1007/s00423-008-0293-7. Epub 2008 Feb 12. PMID: 18266001.

Learning points: It is important to have a clinical suspicion of the main complications that can occur in patients deteriorating in the intensive care unit. But we should underestimate the clinical examination, monitoring and bedside tools such as ultrasound, which can help us to consider alternative diagnoses such as this one.

51AP04-4 Are arterial lines properly setup for hemodynamic monitoring in the ICU?

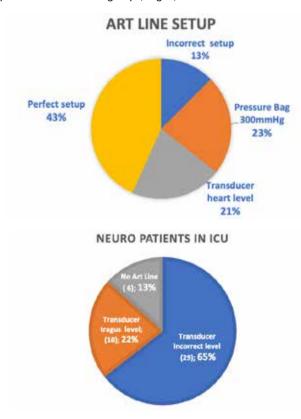

M.G. Bianchi¹, M. Bianchin¹, F. Gkioulos¹, A. Wong¹ ¹King's College Hospital, Intensive care, London, United Kingdom

Background and Goal of Study: An arterial line, correctly set up, is vital in the ICU for respiratory and cardiovascular management. However, issues like proper zeroing and damping are often overlooked. This project aims to evaluate the accuracy of arterial lines in ICU patients, particularly in neurotrauma, assessing for overdamping/underdamping and correct zeroing.

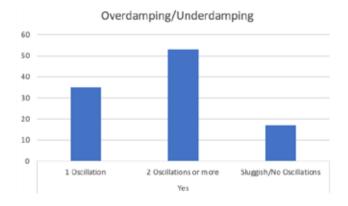

Additionally, we will record the use of vasoactive drugs and cardiac output monitors (e.g., PiCCO) across our ICUs.

Materials and Methods: We analyzed data from 142 patients admitted to the 5 ICUs (90 beds) at a tertiary-level hospital, evaluating the correct setup of arterial lines.

Furthermore, we assessed the subset of patients admitted for neurological conditions (TBI, SAH, ICH, IVH) to determine the proportion with arterial monitoring and the accuracy of transducer placement within this group (tragus).

Results and Discussion: 105 patients have arterial line inserted, 57% of them has imperfect setup and only 43% with the correct one: 65% of Neurotrauma patients had arterial line incorrectly levelled. 66% patients have no PiCCO line inserted but Noradrenaline infusion > 0.3 mcg/kg/min and damping is not correct most of the times.

Conclusion(s): Most ICU arterial setups are incorrect, requiring regular shift checks, comparison with non-invasive methods, and evaluation of PiCCO's appropriate use to improve monitoring accuracy. The use of PiCCO varies and lacks consistency. This may be worth addressing in the upcoming updates to vasopressor guidelines currently under review.

51AP04-5 Al and echocardiography in ICU: Are we really ready?

M.G. Bianchii, M. Nasr, M. Bianchin, E. Ambrasas,

¹King's College Hospital, Intensive care, London, United Kingdom

Background and Goal of Study: The integration of Al (artificial intelligency) in critical care ultrasound enhances accuracy, efficiency, and effectiveness in complex, time-sensitive settings. This study evaluates AI tools embedded in ultrasound machines by comparing their performance to an expert practitioner, using FUSIC (Focused ultrasound in Intensive care) heart-qualified practitioners as a benchmark.

It also investigates whether AI can help novices achieve accurate and comprehensive scan results.

Materials and Methods: The study compared echocardiographic measurements by an expert and six non-expert trainees using Al tools on six patients and two healthy volunteers.

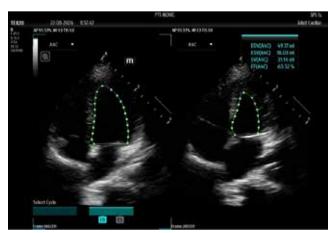

Figure 1. Ultrasound image of AI tool used for automated Ejection Fraction.

Parameters assessed included EDV(end diastolic volume), ESV (end sistolic volume), EF (ejection fraction) (Figure 1), DMIN (diameter mininum). DMAX (diameter maximum). VTI (Velocity time integral), and TIME. The expert performed manual measurements, while non-experts used automated AI tools . Both groups evaluated each patient.

Results and Discussion: Al significantly reduced the time required for exams. While end-diastolic volume measurements and VTI differed between experts and non-experts, other parameters. including ejection fraction (EF), end-systolic volume (ESV), and maximum inferior vena cava diameter, showed no significant differences (Table 1).

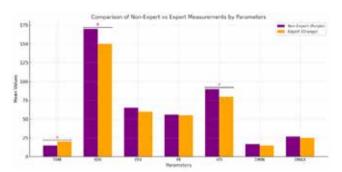

Table 1: The table shows the results for each parameter studied between the two groups: Expert (Gold Standard) and (Non-Experts).

Conclusion(s): Al tools enhance novice performance in cardiac evaluations, offering faster and reliable results, but still require expert supervision to ensure diagnostic accuracy and address limitations.

51AP04-6

Trends in dexmedetomidine use and its impact on delirium management in a surgical ICU: a sevenyear retrospective study

¹Yonsei University College of Medicine, Department of Anesthesiology and Pain Medicine, Seoul, Republic of Korea

Background and Goal of Study: Dexmedetomidine, a selective □2-adrenergic receptor agonist, is widely used for sedation in critically ill patients. This study examines seven-year trends in dexmedetomidine use in a South Korean surgical ICU and its impact on delirium incidence and severity using the ICDSC.

Materials and Methods: This retrospective study analyzed 6,140 patients admitted to an 18-bed surgical ICU from 2017 to 2023. Exclusions included duplicate admissions, cognitive impairments, and insufficient records. Data from the Severance Open Big Data Portal included demographics, ICDSC scores, and clinical outcomes. Statistical analyses evaluated risk factors, survival, and dosina.

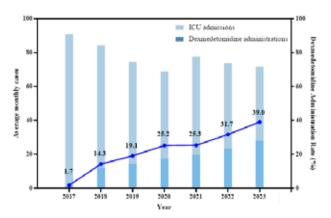

Results and Discussion:

Trends: Dexmedetomidine usage increased from 1.7% in 2017 to

Delirium and Risk: Dexmedetomidine recipients had higher ICD-SC scores (≥4: 46.1% vs. 13.9%, p<0.001). Risk factors included older age, psychiatric medication use, and prolonged ICU stays.

Dosing and Outcomes: Severe delirium cases required higher doses (0.147 mcg/kg/hour) and longer administration (3.84 days). Survival rates were lower in the Dex group (89.1% vs. 92.6%. p=0.014), attributed to the severity of underlying conditions rather than drug effects.

Implications: Dexmedetomidine serves as a symptom-focused treatment for severe delirium, emphasizing the need for tailored dosing protocols.

Conclusion(s): Dexmedetomidine plays a key role in ICU sedation, especially for high-risk delirium patients. While associated with greater delirium severity and longer ICU stays, it is essential for symptom management. Low-dose regimens for non-intubated patients warrant further study.

51AP04-7

Extracellular vesicles miRNA: searching for new biomarkers to enhance diagnostic accuracy of septic shock

M. Espinoza Fernandez¹, L. Suárez Pérez¹, A. García Concejo², A.W. Vega Harwood¹, M. Lorenzo López¹, E. Gómez Sánchez¹ ¹Hospital Clínico de Valladolid, Anesthesiology and Surgical Critical Care, Valladolid, Spain, 2Institute of Health Sciences of Castile and Leon, Research Unit, Soria, Spain

Background and Objectives: Sepsis is a severe condition marked by life-threatening organ dysfunction due to a dysregulated host response to infection. The aim of this study is to enhance the diagnostic accuracy of septic shock versus non-septic shock in postsurgical patients by identifying miRNAs derived from EVs that serve as specific biomarkers

Materials and Methods: a multicentric, prospective study that involved two distinct cohorts of adult patients undergoing surgery: (I) a discovery cohort from the Intensive Care Units (ICU) at "Hospital Clínico Universitario de Valladolid" and "Hospital Universitario de Toledo" in Spain, including 109 patients, 58 with septic shock and 51 with non-septic shock; (ii) a validation cohort from the same ICUs, consisting of 53 patients, 27 diagnosed with septic shock and 26 with non-septic shock. Predictive performance of miRNAs, along with sensitivity and specificity, was evaluated through area under curve (AUC) values using receiver operating curves (ROC).

Results: A total of 2880 miRNAs from miRbase were aligned. leading to the detection of 728 miRNAs, of which 426 plasma EV-derived miRNAs had sufficiently large counts for differential expression analysis. We selected the miRNAs with an area under the curve (AUC) over 0.7 and to assess the reliability of the selected genes as potential biomarkers, we tested them by gPCR in a separate study cohort (validation cohort). miR-100-5p showed the highest predictive value with an AUC of 0.921 (CI: 0.757-1.000), followed by miR-148a-3p (AUC: 0.889, Cl: 0.721-1.000) and miR-451a (AUC: 0.841, CI: 0.640-1.000).

Conclusion: Our study reveals a unique miRNA profile derived from EVs between post-surgical patients with septic shock and those with non-septic shock. Through differential analysis, we identified six that could serve as potential biomarkers for the early diagnosis of septic shock. Notably, the combination of these three miRNAs shows great promise as specific and complementary biomarkers for accurately diagnosing sepsis in post-surgical patients experiencing shock.

51AP04-8

Checking out the checklist - does introducing a checklist to test patient eligibility for ICU discharge improve patient outcomes?

V. Vončina¹, K. Medved¹, P. Ožegović Zuljan¹, J. Pavičić Šarić¹, A. Makovšek², H. Brborović³ ¹University Hospital Merkur, Department of Anesthesiology, Intensive Care Medicine and Pain Management, Zagreb, Croatia, ²University Hospital Center Zagreb, Department of Anesthesiology, Reanimation, Intensive Care Medicine and Pain Management, Zagreb, Croatia, 3University of Zagreb, School of Medicine, Andrija Štampar School of Public Health, Department of Environmental and Occupational Health and Sports Medicine, Zagreb, Croatia

Background and Goal of Study: Untimely discharges increase the risk of readmission and mortality and can lead to capacity strain. Checklists were stipulated as tools to assess ICU patients' discharge readiness. In 2022, Hiller proposed a set of 28 criteria as an adult Intensive Care Unit-Discharge Readiness Checklist (ICU-DRC).

The goal of this study is to assess how applying the ICU-DRC affects patient outcomes: ICU length of stay (ICU-LOS), ICU readmissions, and ICU mortality.

Materials and Methods: The ICU-DRC was implemented into the standard discharge process of one of two distinct ICUs in a clinical hospital. We evaluated patient outcomes in the year prior to introducing the ICU-DRC, 2022, and in the first year of using the ICU-DRC, 2023. The outcomes were evaluated for both the Surgical ICU - Intervention group (IG) and the Medical ICU - Control group (CG). We extracted the data from hospital electronic records. As the data is not normally distributed, it is described by median (M), minimum (min), and maximum values (max) and has been analysed using a Mann-Whitney U test. Distributions of qualitative data were analysed using the χ^2 test.

Results and Discussion: In 2022, a total of 1,567 and 882 patients were treated in the IG and the CG, respectively; in 2023, the numbers of patients treated were 1.663 and 867. Fidelity in the application of the ICU-DRC was 65.7%. We found that in IG, ICU-LOS paradoxically increased significantly in 2023 as compared to 2022 (2022: M 1, min 0, max 80, vs.; 2023: M9, min 0, max 103, Mann-Whitney U test p<0.001).

When analysing the number of ICU readmissions within the same hospitalization, there was a significant difference in favour of those treated in the ICU only once in IG in 2023 (γ^2 (9)=51.99, P<0.001). Mortality rates were significantly lower in the IG in 2023 (2.4%) as compared to IG in 2022 (2.6%) and CG in both 2022 (14.5%) and 2023 (15.5%) (χ^2 (3)=275.71, P<0.001).

Conclusion(s): We found that the ICU-DRC had a positive effect on two out of three outcome measures, as it was associated with fewer ICU readmissions and lower ICU mortality. Due to the complexity of the ICU discharge process, it is unrealistic to expect a simple checklist to ameliorate all patient outcomes; however, our results justify the additional administrative burden on healthcare

Further stratification of data in relation to admitting diagnoses might better clarify the role that the ICU-DRC plays in changing patient outcomes.

51AP04-9

Asystole as a result of dysautonomia in Guillain-Barré syndrome: a case report

X. Spahillari¹, J. Fitzgibbon¹, A. Mikor¹ ¹University Hospital Limerick, Department of Anaesthesia and Intensive Care, Limerick, Ireland

Background: Dysautonomia can be a common finding in patients with Guillain-Barre Syndrome (GBS), present in up to 36%1 of cases. These phenomena can be life-threatening when they involve the cardiovascular system.

Case Report: We present the case of a 44 year old woman who developed loss of power in both lower limbs over two days, followed by paraesthesia in the upper limbs. Her past medical history included Covid-19 virus infection with prolonged symptoms two years ago and recent influenza vaccination ten days prior to presentation.

Other findings on examination included facial diplegia, voice changes, globally diminished reflexes, shortness of breath and dysautonomia as showed by urinary retention. A lumbar puncture was done which showed raised proteins (0.83g/L) and leukocytes (15/µI).

The patient was diagnosed with GBS variant and admitted to Intensive Care Unit (ICU) where intravenous immunoglobulin treatment was initiated. Due to increased work of breathing and inability to clear secretions, she was intubated two days after hospital presentation.

On day nine of admission the patient had an episode of unprovoked asystole lasting 45 seconds, treated with chest compressions over 1.5 minutes, returning to sinus rhythm without any need for adrenaline administration. Another episode of asystole followed 18 hours later, which resolved with chest compressions lasting around 30 seconds. After these two episodes the patient was referred to the cardiology service and temporary pacing wires were inserted.

Discussion: The risk of dysautonomia is higher in patients with tetraplegia, respiratory failure and bulbar symptoms². While cardiovascular symptoms can be variable, bradycardia is one of the most risky complications. It is difficult to identify patients at risk but studies have described volatile blood pressure, eyeball pressure testing and 24-hour heart rate power spectrum as indices of instability. While these patients are usually admitted to the ICU due to respiratory failure, the risk of cardiac arrest has to be noted during their care.

References:

- 1. Chakraborty T et al. Dysautonomia in Guillain-Barré Syndrome: Prevalence, Clinical Spectrum, and Outcomes.
- 2. Pfeiffer, G., et al. Indicators of dysautonomia in severe Guillain-Barré syndrome.

Learning Points: Asystole can be a possible complication in GBS with autonomic dysfunction and these cases would require close cardiac monitoring. A temporary pacemaker might be a necessary intervention.

51AP04-10

The role of eculizumab in acute antibody-mediated lung transplant rejection treatment

L. Tisner Yagüe¹, J. Vigo Garay¹, F. López Lence¹, M.C. Puigserver Martorell¹, R. García Álvarez¹, M. González Serrano¹ ¹Hospital Universitario 12 de Octubre, Anestesiología y Reanimación, Madrid, Spain

Background: The post-operative management of patients undergoing lung transplantation presents significant challenges for intensive care units. Acute antibody-mediated rejection (AMR) is one of the most critical complications to consider. Conventional treatment consists of corticosteroids, plasmapheresis, immunoglobulins and monoclonal antibodies (1).

Case Report: We present the case of a woman whom after undergoing bilateral lung transplantation, she was diagnosed with AMR. She experienced respiratory deterioration, necessitating extracorporeal membrane oxygenation (ECMO) support for 23 days. Conventional treatment was iniciated. However, due to lack of clinical improvement and persistence of positive antibodies, we added Eculizumab to the regimen.

Subsequently, the patient showed significant respiratory improvement, enabling weaning from ECMO support and from invasive mechanical ventilation.

Discussion: A significant proportion of patients undergoing lung transplantation experience acute rejection within the first year of post-operation. Presently, there is no standardized treatment protocol for AMR. Nonetheless, advancements in understanding how to optimize immunosuppression and manage AMR have been made in recent years.

Treatment often involves a combination of antibody-lowering agents. While some patients respond favorably, others remain refractory to conventional therapies. Eculizumab, a monoclonal antibody that inhibits the C5 complement protein, offers a unique mechanism of action. By blocking the formation of the membrane attack complex, it disrupts complement-mediated intravascular hemolysis and prevents antibody binding to the graft, thereby mitigating severe tissue injury.

Currently, while there are multiple studies on the use of Eculizumab in kidney transplantation, further research is needed to provide solid scientific evidence supporting its use in lung transplantation. References:

1. Yannick D. Muller, et al. Acute Antibody-mediated Rejection 1 Week after Lung Transplantation Successfully Treated With Eculizumab, Intravenous Immunoglobulins, and Rituximab.

Transplantation 2018; 102: 301-03.

Learning Points: Acute antibody-mediated allograft rejection is a serious complication associated with poor prognosis, for which no standardized treatment currently exists. This case highlights an interesting path for further research into optimal treatment strategies for AMR in lung transplantation.

51AP04-11

Adding new paradigms to percutaneous dilatational tracheostomy - assessing the safety and feasibility of conventional, ultrasound guided and hybrid percutaneous tracheostomy techniques

¹Davanand Medical College & Hospital, Critical Care Medicine, Ludhiana, India

Background and Goal of Study: With increasing expertise, difficult percutaneous dilatational tracheostomies(PDT) with contraindications are being performed with adequate caution including Ultrasound Guided PDT (USGPDT) at bedside or minimally invasive Hybrid PDT (HPDT) in operation theatre (OT).

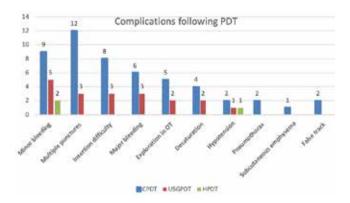

We hereby are presenting our experience regarding conventional, hybrid and ultrasound guided techniques of PDT and compare the procedure related complications and outcome of difficult tracheostomies in 285 critically ill patients done in our intensive care units retrospectively.

Materials and Methods: This retrospective observational study was done in the ICUs of a tertiary care hospital after ethical approval. High risk patient for tracheostomy was defined as patient with coagulopathy with INR>1.5, platelets < 100,000/cc, cervical spine injury, distorted neck anatomy, morbidly obese BMI >35, redo tracheostomy, post radiation, thyroid pathology, post cervical spine fixation surgery, high PEEP requirement.

Data was collected from a post tracheostomy pre-filled performa and data regarding complications and outcome was collected. The data generated was analysed using percentages, proportion and Chi square test for qualitative variables. A p-value of less than 0.05 was considered as statistically significant.

Results and Discussion: In high-risk group patients either UGP-DT or HPDT was mostly performed. The mean duration of the procedure was longer in UGPDT and HPDT group than conventional PDT. Common complications observed in patient population were minor bleeding (n=16,22%), multiple punctures (n=15,21%) and insertion difficulty (n=11, 15%).

Major bleeding was seen in 9 patients and 7 patients needed exploration in Operation Theater. Overall complication rate was highest in CPDT (n=51) followed by USGPDT (n=19) (figure 1). Hybrid percutaneous dilatational tracheostomy had the least complications was performed in 12 patients with visible pulsations and thyroid enlargement and none of the patients had any procedural and post procedural complications.

Conclusion(s): UGPDT is a safer bedside procedure especially in high-risk groups and HPDT in OT can be performed in patients with bleeding tendencies and difficult neck anatomy.

51AP04-12

Impact of continuous renal replacement therapy using the oXiris hemofilter on acute decompensated chronic heart failure secondary to infection

A. Ibrahimi¹, S. Kuci¹, R. Teliti², O. Shurdha³, M. Goga¹, D. Dhimitri4

¹University Hospital Mother Teresa, Anesthesiology and Reanimation, Tirane, Albania, 2German Hospital International, Cardiology, Tirane, Albania, 3University Hospital Mother Teresa, Cardiology, Tirane, Albania, ⁴German Hospital International, Radiology, Tirane, Albania

Background and Goal of Study: Infections represent an important emerging clinical problem that cause decompensation of heart failure (HF). It is reported a high hospital infection rate (45.8%) and relevant mortality (21,5%) among patients with decompensated HF[1].

Our aim is to assess the impact of oXiris filter on acute decompensated HF caused by infection.

Materials and Methods: This study included 10 patients with heart failure with reduced ejection fraction (HFrEF), all of whom had cardiac resynchronization therapy defibrillators (CRTDs) implanted for dilated cardiomyopathy. These patients were managed in intensive care units (ICU) of two hospitals for decompensated heart failure and concomitant infection.

They were divided into two groups: one group underwent intermittent haemodialysis (IHD) using a polysulfone membrane filter, while the other group was treated with the oXiris filter, all at the Risk (R) stage of the RIFLE classification.

The study monitored heart rate (HR), blood pressure (BP), and ICU mortality outcomes.

Results and Discussion: The oXiris group demonstrated an increase in BP (30±3/10±2 mmHg) and a greater reduction in HR (25±6 bpm) 36 hours post-continuous renal replacement therapy (CRRT) compared to the IHD group, which exhibited a decrease in BP (10/5±2 mmHg) and a smaller reduction in HR (10±2 bpm). Mortality was lower in the oXiris group (1/5) compared to the IHD group (3/5). oXiris, a high-adsorption membrane designed to simplify the delivery of blood purification therapy for patients requiring simultaneous removal of inflammatory mediators, endotoxins. and CRRT [2], has demonstrated improved outcomes in patients.

	oXiris group (n =5)	IHD group (n=5)
Age/years	67±6	65±7
EF (ejection fraction) %	27±7	29±6
CRT-D	5	5
AF (atrial fibrillation)	5	5
Procalcitonin ng/ml	1±0,4	1±0,3
Mechanic ventilation (n)	5	4
HR before CRRT/IHD	120±15	125±10
HR 36 hour after CRRT/IHD	95±9	115±8
BP(mm Hg) hour before CRRT/IHD	90±15/50±10	95±15/55±10
BP(mm Hg) 36 hour after CRRT/IHD	120±12/60±12	90±10/50±8
Death	1	3

Conclusion(s): Initiating oXiris treatment at the R stage of the RIFLE classification in patients with decompensated HF secondary to infection significantly improved hemodynamics, decreased the need for vasoactive drugs, and enhanced survival outcomes. References:

Small-volume blood sample collection tubes to reduce iatrogenic anemia in stroke patients admitted to intensive care: the difficulties we faced in preliminary study; importance of education in all sites

A.G. Bakkal¹, D. Güzelkaya¹, M.M. Sayin¹, D.A. Sağlam¹, B. Tezcan¹

¹Etlik City Hospital, Intensive Care, Ankara, Turkey

Background and Goal of Study: Anemia is a common problem in intensive care patients (ICUp). The cause of anemia is multifactorial and frequent phlebotomy has been reported as a contributing factor. The aim of our study is to investigate the effect of SvVT on reducing iatrogenic anemia in stroke patients admitted to intensive care(SP-ICU).

	SvVT (n=1500)	SVT (n=545)	р
Hemolysisl	1	0	N/A
Insufficient sample volume	2	0	N/A
Inappropriate sample volume	15	0	N/A
Clotted sample	52	16	0,55
TOTAL	68	16	0,11

SvVT:Small volume tubes;SVT:Standart volume tubes N/A:not applicable

Table 1: Distribution of error types in small volume and standard volume EDTA containing tubes (n=2045).

Materials and Methods: SP-ICU were randomly assigned to two groups. SvVT were used in the first group, while standard volume tubes (SVT) were used in the second between 5.5.2024 and 5.6.2024 as a preliminary study. Patients hospitalized >7 days were included. Hemoglobin values (HgV) at 10 and 30 days of admission, major-minor bleeding events, transfusions, the rejection rates and causes of blood collection tubes were planned to be recorded.

	SvVT (n=984)	SVT (n=485)	р
Hemolysis	6	8	0.05
Insufficient sample volume	71	44	0,21
Inappropriate sample volume	6	0	N/A
Clotted sample	6	0	N/A
TOTAL	89	52	0,3

Table 2: Distribution of error types in small volume and standard volume coagulation tubes (n=1469)

Results: 5531 tubes from 348 patients (SvVT:264;SVT:84) were examined. The rejection rate in SvVT was 4,5%; while it was 2,9% in SVT for EDTA containing tubes (Table 1). These rates were 9% and 11,5% respectively in coagulation tubes and 2,4% and 2% respectively in chemistry tubes (Table 2-3).

Noticeably; up to a difference of 10 g/dL were determined in HgV between consecutive two days and the study was suspended to investigate this problem.

	SvVT (n=1384)	SVT (n=633)	р
Hemolysis	18	6	0,46
Insufficient sample volume	11	5	0,99
Inappropriate sample volume	4	2	0,92
Clotted sample	0	0	N/A
TOTAL	33	13	0,65

Table 3: Distribution of error types in small volume and standard volume chemistry tubes (n=2017).

Discussion:SvVT have been found effective in reducing iatrogenic anemia prevalance in ICUp. We focused on pre-analytical laboratory errors associated with SvVT in this preliminary study and observe that there were no significant differences between the SvVT ve SVT in terms of rejection rates and rejection types.

When we investigated the reason of inconsistency in consecutive hemoglobin values, we witnessed improper phlebotomy techniques and determined nurses' avoidance of using evacuated blood collection tubes in ICUp. We provided education sessions to nurses before our main study.

Conclusion: We observed that; correct phlebotomy techniques and improving nurses' phlebotomy skills gain more importance in the use of SvVT, probably because of difficulty in optimizing the blood volume.

51AP05-2 ICU tales: the bumpy road from airway chaos to hospital discharge

B. Fraga¹, B. Couto¹, C. Silva Dias¹, J. Lameirão Gaspar¹, F. Faria1

¹Instituto Português de Oncologia do Porto Francisco Gentil, Anaesthesiology and Intensive Care, Porto, **Portugal**

Background: Tracheostomy is often required in critically ill patients, especially following extensive head and neck surgeries, to secure the airway and facilitate ventilation. Complications such as tube obstruction and malposition can arise, necessitating a multidisciplinary approach for effective management.

Case Report: A 61-year-old male underwent anterior pelviglossectomy with marginal mandibulectomy and bilateral neck dissection, reconstructed with a free forearm flap. An intraoperative tracheostomy was performed. On postoperative day one, a tracheostomy tube obstruction led to patient distress and self-removal of the tube, causing wound dehiscence and false passages in the trachea during attempted reinsertion. Immediate stabilization involved intubation via bronchoscopy through the tracheostomy stoma, albeit with initial right main bronchus placement. causing left lung atelectasis.

Subsequent management included wound revision, bronchoscopic clearance and adjustment of the airway devices. On day nine, the orotracheal tube was exchanged for a laryngectomy tube using a Frova introducer with bronchoscopy support through the tube. Later, the tracheal tube was replaced with a fenestrated tracheostomy tube (8.0) with pneumology support, who performed bronchoscopy for direct visualization. The patient was subsequently weaned from mechanical ventilation, transferred to the surgical ward, and discharged without further complications. Discussion: This case highlights the complexities involved in managing the airway after tracheostomy, such as tube obstruction, false tract formation, and malposition.(1) Bronchoscopic guidance ensured accurate airway device placement and minimized further trauma. The Frova introducer proved invaluable in navigating compromised airways. Multidisciplinary collaboration was critical for successful resolution and highlights best practices for tracheostomy care in complex surgical cases.(2)

- 1. Morris, L. et al. Critical Care Nurse, 2013
- 2. Rosero, E. et al, Anesthesia & Analgesia 132(4):p 1003-1011 Learning points:
- 1. Patients with a tracheostomy in a ward environment need special standardized care.
- 2. False tract formation during tracheostomy tube reinsertion underscores the need for immediate bronchoscopy to guide repositioning.
- 3. A multidisciplinary approach ensures optimal outcomes in managing complex airway complications.
- 4. The timing of the interface changes was fundamental to the positive outcome of the patient.

51AP05-3

The effect of NRF2 on the attenuation of biotrauma in ventilator-induced lung injury

Y. Takei¹, K. Taguchi², M. Yamada³, M. Yamauchi¹, M. Yamamoto4

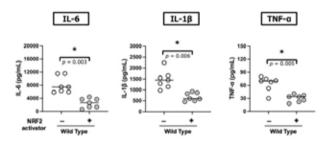

¹Tohoku University School of Medicine, Anesthesiology and Perioperative Medicine, Sendai, Japan, 2Tokyo University Graduate School, Agricultual and Life Science, Tokyo, Japan, ³Tohoku University School of Medicine. Respiratory Medicine, Sendai, Japan, ⁴Tohoku University, Tohoku Medical Megabank Organization, Sendai, Japan

Background and Goal of Study: To prevent ventilator-induced lung injury (VILI), it is important to attenuate biotrauma, an inflammatory response induced by alveolar hyperextension, and repeated collapse and re-expansion. NRF2 is an important transcription factor responsible for biological defense against stress responses due to the induction of antioxidant proteins, detoxifying enzymes, and glutathione synthase and suppression of the expression of inflammatory cytokines. We hypothesised that the administration of NRF2 activators would reduce biotrauma in a VILI rat model.

Materials and Methods: We created a two-hit VILI rat model by intratracheally administration of LPS (100 ng/kg), followed by a 210-min high tidal volume ventilation (20 mL/kg) after 24 h. Rats were intraperitoneally administered an NRF2 activator or PBS during LPS administration and upon mechanical ventilation (treatment and control groups). After 210 min of mechanical ventilation, the rats were euthanised by whole blood collection. Histological examination of the lungs was performed based on alveolar wall thickening, haemorrhage, and neutrophil infiltration into the alveoli, and the modified VILI score was calculated. The wet-to-dry lung ratio was used as a pulmonary permeability marker. The concentrations of inflammatory cytokines (IL-6, TNF- α , IL-1 β) in plasma and alveolar lavage fluid (BALF) were measured. All experimental protocols were approved by the Animal Care Committee of To-hoku University School of Medicine (2023-018-01)

Results and Discussion: NRF2 activators significantly reduced the modified VILI score on histological examination and wet-to-dry lung weight ratio. The concentration of IL-6, IL-1 β , and TNF- α in BALF significantly decreased in the treatment group compared to the control group (Figure 1). The concentration of IL-6 and IL-1 β in plasma also significantly decreased in the treatment group.

Figure 1. The concentration of IL-6, IL-1 β and TNF- α in BALF of VILI model rats

Conclusion(s): High tidal volume ventilation following LPS intratracheal administration induced strong lung injury; however, biotrauma was alleviated by NRF2 activator administration, suggesting NRF2 as a potential therapeutic target of VILI.

51AP05-4

Indirect calorimetry reveals malnutrition in an ICU-patient with super-refractory status epilepticus

<u>A. Holzhausen</u>¹, M. Zinggl¹, S. Heil¹, A. Parak², W. Pirker^{2,3}, B. Gustorff^{1,3,4}

¹Klinik Ottakring, Department of Anaesthesia, Intensive Care and Pain Medicine, Vienna, Austria, ²Klinik Ottakring, Department of Neurology, Vienna, Austria, ³Klinik Ottakring, Association for Scientific Research at Wilhelminenspital, Vienna, Austria, ⁴Sigmund Freud Private University, Sigmund Freud Private University Vienna & Association for Scientific Research at Wilhelminenspital, Vienna, Austria

Background: Although nutrition is a crucial component of intensive care therapy, it underlies uncertainties. This may result in an unrecognized malnutrition or even starvation.

Ensuring adequate caloric provision for a patient with super-refractory status epilepticus over weeks is such a particularly challenging situation, in which indirect calorimetry can provide valuable assistance.

Case Report: A 42-year-old male with Crohn's disease presented with acute disorientation, imaging showed a stroke in the right posterior cerebral artery territory. Generalized tonic-clonic seizures followed, requiring ICU admission due to refractory focal seizures. The patient had a weight of 64.5 kg, a height of 175 cm, and a BMI of 21.1. Initial caloric requirements were calculated at 1,550 kcal/day, increased to 1,700 kcal/day to account for heightened demand.

Despite adjustments, he lost 12.5 kg over 7 weeks. Indirect calorimetry revealed an actual caloric deficit of 400 kcal/day, prompting further adjustments that halted weight loss. Three indirect calorimetry measurements were conducted. On day 49, his resting energy expenditure (REE) was 1,956 kcal/day at a RASS score of -2. With no movement (RASS -4), REE dropped to 1,670 kcal/day. During weaning (RASS -1), REE rose to 2,155 kcal/day.

Persistent seizures led to the implantation of a vagus nerve stimulator (VNS). Twenty-three days post-implantation, under multimodal antiepileptic therapy, seizures ceased. The status epilepticus lasted 77 days. The patient was discharged without further seizures

Discussion: Malnutrition during an intensive care stay is a high risk in patients presenting conditions with high caloric consumption, such as persistent focal status epilepticus. We revealed malnutrition over weeks by application of indirect calorimetry and a nutritional deficit of more than 25% of assumed need. We recommend early and regular use of calorimetry in such cases.

Reference:

1. ESPEN - Guidelines

Pironi, L. et al. (2023) 'ESPEN guideline on chronic intestinal failure in adults – Update 2023', *Clinical Nutrition*, 42(10), pp. 1940–2021. Available at: https://doi.org/10.1016/j. clnu.2023.07.019.

Learning points: Especially in patients with complex conditions like a super-refractory status epilepticus nutrition with simple weight-based equations may lead to malnutrition. In such cases, indirect calorimetry can provide a valuable asset to ensure adequate caloric provision.

51AP05-5

Comparison between surgical and percutaneous dilatational tracheostomy and their effect on mortality of patients in Intensive care unit: a retrospective study

S. Stojanovic Stipic¹, J. Vicic¹, <u>N. Krolo</u>¹, F. Peris¹, G. Prizmic¹, A.M. Mitar¹ ¹University Hospital Split, Department of Anaesthesiology and Intensive Care, Split, Croatia

Background and Goal of Study: Tracheostomy is well defined and acknowledged technique which is essential in the process of weaning from mechanical ventilation and clinical outcome for patients treated in the ICU.Surgical tracheostomy(ST) is done by otorhinolaryngologist while percutaneous dilatational tracheostomy(PDT) is performed by a trained anesthesiologist and intensive care specialist.Our goal was to compare the effects of both types of tracheostomy on time needed for the patient to be

weaned from respirator and their mortality after 30 days. We took into account the period in which tracheostomy was done(early if it was before the 10th day of intubation, and late if it was after). We didn't focus on other factors because our patients were admitted to ICU and treated by mechanical ventilation for various reasons. We aimed to establish a positive connection between percutaneous tracheostomy and an early weaning period(defined as a period of 2 days from tracheostomy).

Materials and Methods: Our retrospective study was done on all the ICU patients that were tracheostomised in the period of two years. We did a bivariate analysis and compared two types of tracheostomy, time of tracheostomy, subsequent weaning period and one month mortality.

Results and Discussion: Total of 94 patients were tracheostomized,58 (62%) of which were being done by percutaneous dilatational tracheostomy, and 36 (38%) by surgical tracheostomy. Late tracheostomies were done on 57 patients (61%), and early ones on 37 patients (39%). There were 30 (32%) patients who were weaned early and 64 (68%) patients were weaned late, after 2 days from tracheostomy. Overall one month mortality was 11%. Percutaneous tracheostomy positively related to earlier weaning time (p 0.05, r 0.211, 64%). Surgical tracheostomy was associated with a higher mortality rate (p 0,01, r 0,296, 14% of all ST compared to 4% of all PDT). Late tracheostomy (done after the 10th day of intubation) was also associated with a higher mortality, independent of the type of tracheostomy (p 0,05, r 0,207, 90%).

Conclusion(s): Results of our study indicate that percutaneous tracheostomy is associated with earlier weaning period and lower mortality rate. Late tracheostomy is associated with higher mortality rate no matter the type of tracheostomy. Various comorbidities could also be included in the future study to determine stronger connection between tracheostomy, mechanical ventilation time and clinical outcome for patients treated in the ICU.

51AP05-6 Von Willebrand's late-life surprise in the ICU!

S. Stojanovic Stipic¹, A.M. Mitar¹, A. Bego¹, J. Vicic¹, F. Peris¹, G. Prizmic¹

University Hospital Split, Department of Anaesthesiology and Intensive Care, Split, Croatia

Background: One of the most common inherited bleeding disorder is Von Willebrand Disease (VWD) and 1% of the population is

The cause of vWD is deffected or defficient von Willebrand factor (vWF), a protein which has a role in blood coagulation. It is VWD classified in 3 types. Type 1 and 3 defines quantitative deficiency and type 2 qualitative disorder.

Case Report: After evacuation of acute subdural hematoma, a 69-years old male was admitted in ICU. Control CT-scan showed a satisfactory result and he was weaned from ventilator. He was presented with left-sided hemiparesis. After 2 days he became agitated with reduced responsiveness. An urgent CT scan showed epidural hematoma. He was reoperated. In his past medical documentation we found about his previous abnormal bleeding, potential spondilopathy and elevated levels of M-protein which indicate myelodisplastic syndrome. Diagnosis showed reduced vWF levels (0.26), normal prothrombin time (PT) and activated partial thromboplastin time (aPTT). A treatment with vWF concentrate was started in initial dose of 50 IU/kg, followed with 25 IU/kg every 12 hours until hemostasis was achieved along with intravenous tranexamic acid. Levels of vWF and factor VIII were monitored. After 8 days, a follow-up CT scan showed satisfactory findings, and patient was weaned from respirator. He was alert, oriented and left with mild residual left-sided hemiparesis and was discharged to the neurosurgery.

Discussion: Diagnose of VWD in ICU can be challenging, as tests like PT and aPTT often fail to reflect disease severity. Our patient was 69-year old when he was diagnosed with vWD. Management of VWD in the ICU demands a multifaceted approach. It includes hemostatic therapies like desmopressin (DDAVP) or vWF concentrates (Wilate) for more severe cases. Antifibrinolytics are essential for controlling mucosal bleeding, a common complication in VWD. Blood product support, including red blood cell or platelet transfusions, is often required. It is necessary to collaborate with hematologists to optimize therapy and minimize complications.

Learning points:

- 1. VWD in the ICU presents significant challenge due to interaction with critical illnesses and coagulopathies.
- 2. Early diagnosis, targeted therapy, and a multidisciplinary approach are important in reducing bleeding risks and improving outcomes.
- 3. Balancing effective hemostasis with minimizing thromboembolic risks remains a key aspect of care for these vulnerable patients.

51AP05-7 TUR syndrome isn't dead

M.I. Silva¹, J. Sousa Gomes¹, R. Araújo¹, A.R. Costa² ¹Centro Hospitalar Universitário de Santo António, ULS de Santo António, Serviço de Anestesiologia, Clinica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal, 2Centro Hospitalar Universitário de Santo António, ULS de Santo António, Serviço de Medicina Intensiva, Clinica de Anestesiologia, Medicina Intensiva, Emergência e Urgência, Porto, Portugal

Background: Transurethral resection (TUR) syndrome is characterized by hyponatremia and volume overload following TUR surgery. Depending on the severity of the electrolyte imbalance, clinical manifestations can go from mild to severe neurological symptoms and acute volume overload clinic. The use of bipolar electrosurgical devices that are compatible with electrolytecontaining irrigation solutions came to reduce the incidence TUR syndrome but not to obliviate it.

Case Report: A 72 years old male patient was admitted in the ICU due to respiratory insufficiency related to sudden onset pulmonary edema with the need of noninvasive ventilation.

Previous medical history included arterial hypertension, ischemic cardiomyopathy with midrange LVEF, type 2 diabetes mellitus and a previous smoking history.

Three days before, he was admitted in the hospital for an elective bladder TUR due to hematuria related to papillary bladder lesions. A general anesthesia was performed, and the procedure went uneventful. In the postoperatory period, the patient reported some visual alterations, confusion and

tinnitus that were interpretated as hallucinosis. Two days after surgery, the patient developed acute dyspnea with SpO2 88% in room air, confusion, tachycardia and hypertension. The first BGA revealed a type 1 respiratory insufficiency and a severe hyponatremia of 106 mEq/L (confirmed by laboratory tests).

The patient was admitted in the ICU where continuous monitoring, diuretic therapy and ventilatory support with noninvasive ventilation were provided and clinical improvement was achieved. Revisiting the history, the clinical suspicion of hyponatremia with fluid overload related to the transurethral resection of the bladder was made. Although confirmed the use of

bipolar surgery device and an electrolyte- containing irrigation solute, the volume of saline solution was unknown and with no other cause identified. TUR syndrome was assumed as the most likely hypothesis.

The patient had an overall improvement with no sequelae left and was discharged from the ICU within 24h and from the hospital within three days.

Discussion: Hyponatremia following TUR surgery is an increasingly uncommon condition with the use of new surgical techniques and devices. However, the risk is still real and a low threshold of suspicion is required, otherwise serious clinical conditions may go unnoticed.

Learning Points: TUR syndrome is a rare entity nowadays but is not extinguished.

51AP05-8 Successful management of a highly allosensitized heart transplant recipient

A. Vuksic¹, S. Konosić^{1,2}, I. Vučić¹, M. Mirčić¹, Ž. Čolak^{1,2}, S. Mihaliević¹

¹University Hospital Centre Zagreb, Department of Anesthesiology, Reanimatology, Intensive Medicine and Pain Therapy, Zagreb, Croatia, ²University of Zagreb, School of Medicine, Zagreb, Croatia

Background: Allosensitization, marked by elevated pre-transplant anti-HLA antibodies, is linked to longer waitlist times and increased risk of graft dysfunction or rejection. Sensitization can occur due to prior pregnancy, blood transfusion, or organ transplantation. Desensitization protocols, targeting various immune components, are mainly based on kidney transplant regimens, but no consensus exists on the optimal approach for cardiac transplant patients.

Case Report: A 49-year-old woman developed end-stage chemotherapy-induced cardiomyopathy. Due to recent malignancy, transplantation was initially contraindicated, and a ventricular assist device was implanted as bridge-to-transplant therapy. The procedure was complicated by severe bleeding, requiring a massive transfusion. After five years of complete remission, the patient was eligible for waitlist registration. The pre-transplant evaluation revealed elevated anti-HLA antibody levels. It took three years for a compatible donor to be matched. A preoperative desensitization protocol strategy included immunoadsorption for antibody removal and rituximab administration. During the transplantation, severe initial graft dysfunction required the implantation of an extracorporeal membrane oxygenator. Postoperatively, standard immunosuppressive therapy (anti-thymocyte globulin, methylprednisolone, mycophenolate mofetil, tacrolimus) was introduced. Nine additional immunoadsorption sessions were required, along with eculizumab and intravenous immunoglobulins, until anti-HLA antibody titers decreased to acceptable levels and cardiac function improved. The patient was discharged on postoperative day 18 with normal graft function. A subsequent myocardial biopsy showed insignificant cellular and humoral rejection. Discussion: There are no large-scale studies to guide desensitization protocols for heart transplant candidates and small-scale studies show variable efficacy. This case contributes valuable insights into the evolving field of desensitization protocols for heart transplant patients.

References:

1. DeFilippis EM, Kransdorf EP, Jaiswal A, et al. Detection and management of HLA sensitization in heart transplant candidates. J Heart Lung Transplant, 2023 Apr:42(4):409-422.

Learning Points: Multimodal desensitization strategies in highly sensitized solid organ transplant recipients has been shown to improve outcomes. Further research and standardization of protocols in cardiac transplant patients are necessary.

51AP05-9

Bioelectrical impedance analysis, fluid balance, and Capillary Leak Index in critically ill patients

H. Abdul Ghafour¹, A. Wong¹ ¹King's College Hospital, Critical Care, London, United Kinadom

Background: Fluid management is crucial in critically ill patients. Bioelectrical Impedance Analysis (BIA) measures Total Body Water (TBW), Intracellular Water (ICW), and Extracellular Water (ECW). The Capillary Leak Index (CLI), derived from CRP and albumin, reflects endothelial permeability. This study examines their relationship with fluid balance.

Materials and Methods: 15 critically ill patients were included with 62 BIA measurements over three days. BIA metrics were obtained at the bedside, and cumulative fluid balances were retrieved from electronic health records. CLI and BIA parameters were analyzed using Spearman's rank correlation.

Results and Discussion: Significant correlations were found between CLI and both TBW ([] = 0.431, p < 0.001) and ECW ([] = 0.435, p < 0.001), indicating that higher CLI values are associated with extracellular fluid accumulation. CLI did not significantly correlate with the ECW/ICW ratio (□ = 0.089, p = 0.489) or ECW percentage (\square = 0.089, p = 0.489).

Cumulative Net Fluid Balance, recorded since ICU admission, positively correlated with TBW (\square = 0.506, p < 0.001), ICW (\square = 0.442, p < 0.001), and ECW (\square = 0.495, p < 0.001). Delta changes in cumulative fluid balance and body water compartments showed weak, non-significant correlations, likely due to the challenges of detecting short-term fluid shifts with BIA or limitations in fluid balance data accuracy.

Parameter	Spearman's ρ	p-value
1. TBW (L)	0.431	<0.001
2. ECW (L)	0.435	< 0.001
3. ECW (%)	0.089	0.489
4. ECW/ICW Ratio	0.089	0.489
5. TBW (L)	0.506	< 0.001
6. ICW (L)	0.442	< 0.001
7 FCW(L)	0 495	<0.001

Table A: Correlation Capillary Leak Index (CLI) and BIA-Derived Metrics (1 - 4), Correlation Cumulative Fluid Balance and BIA Metrics (5 - 7)

CLI is calculated as (CRP [mg/dL] / Albumin [g/L]) × 100; - Cumulative fluid balance represents total intake minus total output recorded since ICU admission.

Conclusion(s): BIA-derived parameters, including TBW, ICW, and ECW, correlated with cumulative fluid balance, confirming their role in assessing fluid status and extracellular shifts in critically ill patients. Associations with CLI highlight BIA's ability to capture systemic fluid changes linked to endothelial dysfunction. However, weaker correlations for changes in fluid balance and body water compartments reflect the complexity of short-term fluid dynamics. Unlike previous BIA studies, this research integrates CLI to enhance understanding of fluid shifts and systemic inflammation, offering new insights into fluid management and endothelial permeability in critical care.

51AP05-10

Critical care victory: saving a life from multi-organ failure in a life-threatening case of thrombothic thrombocytopenic purpura (TTP)

S. Yildiz¹, N. Kalkan¹, B. Tunay¹, H. Öz¹ 1Istanbul Medipol University, Department of Anesthesiology and Reanimation, Istanbul, Turkey

Background: TTP is a clinical condition identified by microangiopathic hemolytic anemia, thrombocytopenia, neurological symptoms, often fatal outcome(1). TTP is a medical emergency. If treatment is not initiated rapidly, it leads to mortality.

Case Report: A 40-year-old female patient presented to the emergency department with fever, nausea-vomiting, diarrhea onset 3 days ago. She had no chronic diseases. She was somnolent. Widespread petechial rashes were on her body. Lab tests showed anemia, thrombocytopenia, hyperbilirubinemia, elevated liver enzymes and creatinine. Coagulation tests, fibrinogen levels were normal. The patient was in multi-organ failure, and admitted to the ICU. Further lab results showed reticulocytosis, low haptoglobin, negative direct Coombs test, schizocytes on peripheral smear. Intravascular hemolysis was diagnosed. ADAMTS-13 activity test was ordered. Simultaneously, rituximab, pulse steroids, plasmapheresis (PEX) (twice daily) were started. On the 3rd day, she was comatose, and intubated. Cranial imaging was normal. Vasopressors were started for shock. On the 6th day, hemodialysis was started for acidosis. ADAMTS-13 activity <5%, confirming TTP. On the 10th day, caplacizumab could only be administered in 3 doses. Then, hemodynamic and metabolic parameters began to improve. She was extubated on the 20th day. Meanwhile, a catheter-associated infection was detected, treatment was adjusted. Later, massive lower rectal bleeding occurred. Rectoscopy revealed a rectal ulcer. Sclerotherapy failed. The superior rectal artery was embolized angiographically. On the 25th day, the patient developed thrombocytopenia again. Resistance was suspected. Splenectomy was performed. After a month of ICU, she was discharged without sequelae.

Discussion: Infectious, autoimmune causes can lead to TTP. Organ failures may occur together due to hemolysis and microthrombi causing tissue ischemia. Coma and cardiac affection indicate poor prognosis(1). Rituximab, PEX, corticosteroids may be useful in treatment. In resistant cases, caplacizumab can be life-saving(1).

References:

1. Scully, M. et al. A British Society for Haematology Guideline: Diagnosis and management of thrombotic thrombocytopenic purpura and thrombotic microangiopathies. Br J Haematol 203, (2023).

Learning Points: TTP is an acute clinical condition with up to 90% mortality. The management of this complex process can challenge clinicians. Correct treatment can save lives, even in severe cases.

51AP05-11

Thorax volume of ARDS patients elevated by mechanical ventilation

J. van Egmond¹, J.P. Mulier² ¹Radboud University Medical Centre, Anesthesiology, Nijmegen, Netherlands, ²University Gent, Anesthesiology, Gent, Belgium

Background and Goal of Study: The diseased lung loses compliance, reducing lung volume and pleural pressure (Por more negative than the standard P_{a}). Several authors [i]. [ii] report high positive P_{nl} in mechanically ventilated (MV) ARDS patients. Positive P_{nl} is indicative of a high thoracic volume ($V_{\it thor}$) because the transthoracic pressure equals P_{pl} , V_{thor} is increased by the product of P_{pl} and thoracic wall compliance (Table 1). Therefore: V_{thor} increases during MV in ARDS patients.

Materials and Methods:

Author	Series	N	TV	EE Ppl	El Ppl	PEEP	Plateau	Compliance	Extra V>FRC
Talmor	Pes guided (base)	30	484	17.2	21.2	14.0	29	121	2807
	Conventional (base)	30	491	16.9	20.7	15.0	29	129	2959
	Pes guided (72 h)	30	472	18.4	21.7	18.0	28	143	3490
	Conventional (72 h)	30	418	14.3	17.9	12.0	25	116	2357
Beitler Pes guided	Pes guided	102	396	16.0	19.0	14.0	28	132	2905
	Emperical PEEP	98	362	15.0	18.0	12.5	27	121	2531
Kassis	Day 1	40	360	13.7	16.1	13.5	25	150	2955
	Day 3	38	390	13.0	15.9	13.0	24	134	2546
	1 week	35	380	12.1	15.8	13.0	25.5	103	1864

Table 1. Pleural pressure (Pes) measurements in mechanically ventilated ARDS patients.

Results and Discussion: Alveolar pressure in the end-expiratory conditions for ARDS patients must be at least P_{nl} +6 cmH₂O. Talmor[i] reports an end-expiratory P_{pl} of 17.2 cmH₂O (first row of Table 1), so alveolar pressure of 23 cmH₂O. Airway pressure equals PEEP at 14 cmH₂O, indicating complete airway closure. This finding is consistent across all rows in Table 1.

Hypothesized mechanism.

- · At the initiation of MV, expiratory volume is smaller than inspiratory tidal volume, leading to an increase in V_{thor} and P_{ol} .
- Driving expiration pressure rises.
- Equilibrium when expiratory volume equals inspiratory volume. Imaging studies (X-ray and CT scans) show that the V_{thor} increase is significantly due to edema. This edema may result from the altered hydrostatic component in the Starling equation.

Normally, airway pressure exceeds P_{nl} throughout the respiratory cycle. In MV-ARDS patients, however, mean P_{nl} often exceeds mean airway pressure, reversing this gradient and causing fluid to move from the pleural space into the lungs.

Conclusion(s): Clinical studies have shown that lowering tidal volume reduces mortality in ARDS patients. This can be explained by the fact that lungs are forcibly pressed against the thoracic wall during MV, stressing the underlying parenchyma.

The extent of this stress is proportional to the lung expansion, tidal volume.

The abundance of edema in the thorax aligns with the altered direction of the hydrostatic component in the Starling equation.

51AP05-12

Gavet-Wernicke encephalopathy following caustic ingestion: a case report from the surgical

S. Haddady¹, S. Bellaftouh², A. Erragh¹, S. Chaabi¹, A. Nsiri¹, R. Al Harrar¹

¹Ibn Rochd University Hospital Center, surgical intensive care unit, Anesthesiology-intensive care medicine department, Casablanca, Morocco, 2lbn Rochd University Hospital Center, Anesthesiology-intensive care medicine department, Casablanca, Morocco

Background: Gayet-Wernicke encephalopathy (GWE) is a neurological emergency caused by thiamine deficiency. Although rare, with a prevalence of 1.3%, it is often underdiagnosed, especially in high-risk populations such as elderly, malnourished, or polymorbid patients with gastrointestinal or renal disorders. Magnetic resonance imaging (MRI) is the key diagnostic tool, revealing specific thiamine deficiency lesions. Prompt recognition and treatment are critical to prevent progression to Korsakoff syndrome, coma, or death. This case illustrates the clinical and radiological presentation of GWE and emphasizes the importance of early

Case Report: A 63-year-old man was admitted to the surgical ICU with altered mental status following a two-month hospitalization for caustic ingestion. His clinical course was complicated by chronic vomiting, leading to apyretic encephalopathy. On examination, the patient was cachectic, hypothermic, and had a Glasgow Coma Scale score of 13/15. Oculomotor evaluation revealed nystagmus.Laboratory findings showed hypoalbuminemia (20 mg/L) and hypokalemia (3 mmol/L).Brain MRI revealed T2 hyperintensities in the periventricular regions of the thalamus, mammillary bodies, and floor of the fourth ventricle, consistent with GWE.

Discussion: Gayet-Wernicke encephalopathy is frequently overlooked due to its non-specific symptoms and varied presentations, particularly in malnourished surgical patients. MRI findings are critical for diagnosis, as the lesions identified are pathognomonic for thiamine deficiency(1). Chronic vomiting and nutritional deficiencies are common risk factors in surgical settings(2). Immediate administration of thiamine is the cornerstone of treatment and should ideally begin within 48-72 hours of symptom onset to reverse the condition and prevent irreversible seguelae(3). Delayed diagnosis or treatment can lead to permanent cognitive impairments or death, emphasizing the need for heightened awareness in at-risk populations.

Recurrent paroxysmal sympathetic hyperactivity following hypoxic brain injury after cardiac arrest: a case report

M. Dayioglu¹, E. Kilic Cakmak¹ ¹Ankara Etlik City Hospital, Anesthesiology and Reanimation, Ankara, Turkey

Background: Paroxysmal sympathetic hyperactivity (PSH) is a syndrome characterized by paroxysmal, transient increases in sympathetic activity and motor (posturing) activity following acquired brain injury (ABI). Early diagnosis is challenging but equally

Case Report: A 31-year-old man was admitted to our intensive care unit following a cardiac arrest associated with pregabalin and unknown drugs. CT on admission showed acute infarct and edema in the periventricular white matter, caudate nucleus. and basal ganglia. During sedation cessations, he experienced tachycardia, tachypnea, and hypertension. He was extubated on the 10th day of admission while receiving dexmedetomidine infusion. He was sedated for tonic seizures and treated for aspiration pneumonia-related sepsis. However, despite negative infectious findings, the patient developed fever, tachycardia, hypertension, diaphoresis, extensor posturing, and diarrhea during respiratory therapy. He was subsequently re-intubated and sedated. EEG evaluated as normal. Upon cessation of sedation, the same sympathetic features reappeared. A diagnosis of paroxysmal sympathetic hyperactivity (PSH) was made with a PSH assessment score of 24. Following the administration of propranolol and clonazepam, the patient was extubated on the 14th day, with a Glasgow Coma Scale of 15 and cognitive impairments. Baclofen was initiated for chronic muscle contractions. Two weeks later, symptoms recurred with a PSH score of 18, prompting a revision of medications. No new episodes occurred during the 90-day follow-up.

Discussion: PSH is indicative of disease severity but does not affect prognosis. Early diagnosis remains challenging. However, understanding the risk factors and considering them in the differential diagnosis can lead to earlier recognition, potentially reducing the duration of mechanical ventilation, hospital stay, and related complications.

References:

- 1. Baguley, Ian J., et al." Paroxysmal sympathetic hyperactivity after acquired brain injury: consensus on conceptual definition, nomenclature, and diagnostic criteria." Journal of neurotrauma31.17 (2014):1515-1520.
- 2. Xu SY, Zhang Q, Li CX. Paroxysmal Sympathetic Hyperactivity After Acquired Brain Injury: An Integrative Review of Diagnostic and Management Challenges. Neurol Ther. Şubat 2024;13(1):11-20.

Learning Points: Due to overlapping clinical presentations, PSH should be considered in cases of fever, shivering, and tachycardia, especially along with brain injury.

51AP06-2

When skin and system fail: a critical care perspective on Stevens-Johnson syndrome

S. Yildiz¹, N. Kalkan¹, B. Tunay¹, H. Öz¹ ¹Istanbul Medipol University, Department of Anesthesiology and Reanimation, Istanbul, Turkey

Background: Stevens-Johnson Syndrome (SJS) are severe mucocutaneous reactions, with high mortality in systemic cases. Survivors may have long-term sequelae affecting quality of life. Case Report: A 22-year-old female with type 1 diabetes presented with fever and rash lasting 2 weeks. She had been prescribed levetiracetam for suspected seizures 5 months prior, but developed widespread skin rashes, prompting a switch to valproate. Over the last two weeks, the rash worsened. She had been receiving intravenous piperacillin-tazobactam for 4 days for a urinary tract infection. Physical examination revealed an obese, icteric patient with widespread truncal skin rashes, hepatosplenomegaly, oral erosions with seborrheic crusts around the lips. Lab results showed leukocytosis, eosinopenia, elevated liver enzymes, hyperglycemia, ketonuria. She was admitted to the ICU, treatment for diabetic ketoacidosis and infection began. On day 2, she developed somnolence and hypoxemia, refusing oral intake due to painful oral lesions. EEG showed no epileptic activity. Drug reaction was suspected. Valproate was discontinued. All tests for autoantibodies and infections were negative. Skin biopsy confirmed SJS. Plasmapheresis (PEX) and corticosteroid therapy were initiated. On day 5, the patient developed ARDS, was intubated, and later had acute kidney injury and cardiogenic shock, requiring hemodiafiltration and vasopressors. Despite aggressive treatment, she died on day 14 from multi-organ failure.

Discussion: SJS has a 22% mortality rate. The skin barrier disruption causes fluid loss, thermoregulation issues, hemodynamic instability. Complications include pancytopenia, sepsis, acute liver failure, acute kidney injury, multi-organ failure. Corticosteroids, cyclosporine, PEX may enhance outcomes(1).

References:

1. Creamer, D. et al. UK guidelines for the management of Stevens-Johnson syndrome/toxic epidermal necrolysis in adults 2016. Journal of Plastic, Reconstructive and Aesthetic Surgery

Learning points: SJS requires a multidisciplinary approach and can be fatal if untreated. Long-term sequelae like corneal scarring and airway strictures can severely affect life quality.

51AP06-3

Bacteremia in the intensive care unit. Incidence and antimicrobial resistance in critical ill patients

M.D. Serrano Merlín¹, R. Millán Martínez¹, D. Arizpe Bravo² ¹Hospital Angeles Puebla, Anesthesia, Puebla, Mexico, ²Hospital Angeles Puebla, Anesthesia & Critical Care, Puebla, Mexico

Background and Goal of Study: Bloodstream infections (BSIs) remain a significant cause of morbidity and mortality in intensive care units (ICUs) worldwide. Studies estimate that the incidence of BSIs in ICUs ranges from 5 to 25 cases per 1,000 patient-days, depending on the region and healthcare setting. Timely and targeted antimicrobial therapy is essential for improving survival rates and reducing complications associated with BSIs.

In this study, we aimed to evaluate the incidence of positive bacterial blood cultures in the ICU of a hospital in Puebla, Mexico, and to analyze the antibiotic resistance profiles of these isolates.

Materials and Methods: This retrospective observational study was conducted in the intensive care unit (ICU) of a hospital in Puebla, Mexico. We analyzed data from all positive blood cultures obtained from ICU patients during the study period from August 2023 to August 2024. A total of 742 blood cultures were collected from 248 patients. Upon identification of a positive blood culture, the isolated microorganism underwent further testing to determine its antimicrobial resistance profile.

Results and Discussion: A total of 742 positive blood cultures were analyzed from 248 patients in the intensive care unit (ICU). Antibiogram testing revealed a wide range of antibiotic resistance profiles among the isolates. 49 patients were male and 34 women. The age range of the patients in the study was from 20 to 86, with a mean age of 58.2 years. The analysis of 742 positive blood cultures identified a diverse array of microbial isolates, with Gram-positive organisms being the most frequently detected. Staphylococcus species accounted for the highest proportion, representing 27.71% of all isolates. Escherichia coli was the most common Gram-negative isolate, comprising 24.10% of the total. The incidence of bacteremia in our study was 33%.

Our findings align with previous research showing that patients over the age of 55 years are more prone to develop bacteremia. The microbial spectrum in our ICU revealed a predominance of Staphylococcus species (27.71%) and Escherichia coli (24.10%), consistent with global trends where these pathogens are frequently implicated in BSIs.

Conclusion(s): These findings highlight the predominance of Staphylococcus and Escherichia coli in bloodstream infections within the ICU, underscoring the importance of targeted antimicrobial strategies to manage these common pathogens effectively.

51AP06-4

Exploring anemia in critically III patients: a retrospective observational analysis

R. Szabo¹, G. Mitru¹, R. Streza¹ ¹Iuliu Hatieganu University of Medicine and Pharmacy, Anesthesia and Intensive Care 2, Cluj-Napoca, Romania

Background and Goal of Study: Anemia is a frequent and multifactorial complication in critically ill patients, contributing to an increase in blood transfusions. This study aims to explore the type of anemia on admission as well as the type of anemia which arises during hospitalization.

Materials and Methods: This retrospective observational study included a number of 38 critically ill patients admitted to ICU for non-surgical pathologies. Two cohorts were defined: patients presenting with anemia on admission and non-anemic patients. but who developed anemia during hospitalisation. Anemia was defined as Hb < 13 g/dL in males and <12 g/dL in females.

Results and Discussion: 11 (29%) patients were diagnosed with anemia on admission and a further 19 (50%) developed anemia after admission. On admission, anemic patients exhibited a mean hepcidin level of 207.9 ng/mL, ferritin of 998 ng/mL and C-reactive protein of 8.8 mg/dL.

These findings suggests that inflammatory anemia is dominant in critically ill patients where inflammation induces hepcidin upregulation and iron trapping in the form of ferritin.

Conclusion(s): This study highlights the type of anemia in critically ill patients where iron metabolism is dysregulated by inflammation. These patients do not benefit from iron administration for the treatment of anemia.

Most often patients are transfused as means of treatment. Efforts in ICU should focus on strategies to reduce unnecessary blood loss such as frequent blood sampling. Monitoring hepcidin may offer valuable insights for timely interventions and improved management of anemia in critically ill patients.

These results indicate the need for future research exploring targeted therapies for iron metabolism disturbances in critically ill patients.

51AP06-5 Vertebral Artery Dissection: a leading cause of stroke in young patients

M. Bagci¹, S. Akbaş¹, A. Saylan¹, E. Kilic Cakmak¹, M. Dayioglu1 ¹Ankara Etlik City Hospital, Anesthesiology and

Reanimation, Ankara, Turkey

Background: The overall incidence of vertebral artery dissection (VAD) is approximately 1-1.5 per100,000, but VAD is a leading cause of stroke in young patients. It is usually associated with neck distortion caused by chiropractic manipulation, bending of the neck, or blunt trauma, although it can also occur spontaneously (1,2).

Case Report: A 30-year-old man was admitted to the emergency department with headache, nausea, and dizziness half an hour after he had self-manipulated his neck. The initial computed tomography angiography (CTA) was assessed as normal, but he was intubated due to the Glasgow Coma Scale(GCS) score worsening and transported to our hospital.

Control CTA revealed a right-sided vertebral artery dissection and Magnetic Resonance Imaging(MRI) showed a right-sided lateral medullary and cerebellar infarction. Anti-platelet and anticoagulant therapy was initiated in intensive care unit (ICU).

After extubation on the 4th hour of admission, he was found to have Wallenberg's Syndrome, which manifested as dysphonia, dysarthria, dysphagia, hiccups and hoarseness. The symptoms progressively diminished throughout the course of treatment.

On the day 5, only hoarseness and dysphagia continued to persist, albeit with an improvement compared to the initial presentation. Then, he transferred to the ward.

Discussion: Although rare, vertebral artery dissection should always be included in the differential diagnosis of nausea and dizziness and it should be kept in mind that activities such as cracking the neck, yoga, or painting the ceiling could lead to this condition.

Additionally, even if the initial imaging results are normal, if there is clinical suspicion, the imaging should be repeated.

References:

- 2. Albuquerque, Felipe C., et al. "Craniocervical arterial dissections as sequelae of chiropractic manipulation: patterns of injury and management." Journal of neurosurgery 115.6 (2011): 1197-1205.

Learning points: Even if the imaging results are normal, it should be repeated in the presence of clinical suspicion related to dissection and stroke.

51AP06-6

Post-surgical euglycemic diabetic ketoacidosis due to SGLT2i: a case report

A.I. Mateos Hernández¹, A. Plaza Saura¹, M. Cano Castellote¹, B. García Iniesta¹, M. Escribano Jiménez¹, R. González Celdrán¹ ¹Hospital General Universitario Reina Sofía, Anesthesiology, Murcia, Spain

Background: Diabetic ketoacidosis is an endocrine emergency characterized by hyperglycemia, metabolic acidosis with an elevated anion gap, and ketosis. There is a group of patients with diabetic ketoacidosis who present normal blood glucose levels, known as euglycemic diabetic ketoacidosis (EDKA), which is defined by relative euglycemia (serum glucose <250 mg/dl) with metabolic acidosis (HCO3- <18 mEq/l and pH <7.3) and ketosis. The incidence of EDKA has increased in recent years with the use of sodium-glucose cotransporter-2 inhibitors (SGLT2i), which include canagliflozin, empagliflozin, and dapagliflozin.

Case Report: A 76-year-old woman needs to undergo urgent laparotomy for incarcerated right inguinal hernia under general anesthesia. Of note, the patient has no known allergies and has type 2 diabetes, being treated with Sinjardy (Metformin and Empagliflozin), which she took that morning.

After the surgery, the patient is hemodynamically stable and no symptoms. However, her lab results stand out: pH 7.12, pCO2 27 mmHg, pO2 107 mmHg, HCO3- 8.1 mmol/L, Base Excess: -19, Lactate level of 1.4, Anion Gap of 22, and Blood Glucose of 180 mg/dL. Also, ketone bodies are measured in the urine, which are elevated.

A central line is inserted for the administration of HCO3- and treatment is started with an insulin pump and 10% glucose solution, resulting in improvement of the condition, and the patient is able to be discharged after 6 days.

Discussion: SGLT2i act on the kidney increasing urinary glucose excretion and blocking glucose reabsorption. Thus, they are associated with EDKA due to reduced glucose availability and production during fasting in diabetic patients who have an underlying absolute or relative insulin deficiency with insulin resistance.

All of this, combined with a stressor such as surgery, leads to an increase in counterregulatory hormones like glucagon and contributes to the production of free fatty acids, which results in ketogenesis and acidosis.

Learning Points: The incidence of EDKA is increasing due to the emergence of medications such as SGLT2i. This condition should be considered in postoperative patients where the recommended discontinuation times for these drugs have not been followed.

Diagnostic tests include blood gas analysis with measurement of pH, bicarbonate, and ketone body determination. Treatment involves resuscitation with intravenous fluids, insulin, glucose, and addressing the underlying etiology.

51AP06-7

Humanisation in intensive care units: evaluation of basic good practices

J.Á. Rodenas Rubio¹

¹Complejo Hospitalario Universitario de Albacete, Anesthesiology, Reanimation and Pain Therapy, Albacete, Spain

Background and Goal of Study: Advances in intensive care mean that more and more patients are surviving. However, the experience of patients and their families during their stay has been described as traumatic. In response to this situation, the HU-CI project¹ has been launched in Spain with the aim of promoting humanised care through the implementation of good practices divided into seven strategic lines².

This study aims to evaluate the implementation of good practices and to identify the deficient factors that contribute to the dehumanisation of the ICU.

Materials and Methods: A survey was designed for the study using the Google Forms tool. Only those good practices that were considered essential were included in the questionnaire. The survey was distributed to health professionals in intensive care units in Spain. The responses received were analysed to identify areas for improvement.

Results and Discussion: Responses from 29 centres were entered into an Excel database. Descriptive analysis of the data was performed using SPSS statistics. Significant deficiencies were found in the provision of continuing education, in the implementation of standardised protocols, especially in aspects such as the management of delirium, the involvement of families in care, and the prevention and management of post-intensive care syndrome (*Table*).

Conclusion(s): The study highlights the urgent need to implement continuous training programmes and standardised protocols. Although progress has been made, more training in non-technical skills, emotional support for staff, family involvement and addressing post-intensive care syndrome is essential.

GOOD PRACTICES	YES	NO
Continuous training in non-technical skills for the healthcare team is carried out to enable family presence and involvement.	19%	81%
There is a healthcare protocol available regarding family involvement in basic care (food, hygiene and moving) for critical patients.	24%	76%
Training activities are carried out on non-technical and relationship skills that include giving bad news, difficult situation and grief.	29%	71%
Training activities are carried out on understanding and managing stress, occupational burnout, as well as promoting engagement, emotional competences and psychosocial skills at work.	14%	86%
Newly incorporated staff: a welcome programme is offered to all ICU healthcare staff.	38%	62%
Training on end-of-life accompaniment with and grief support is provided to professionals involved in caring for patient/family.	33%	67%
There is a protocol in place to favour communication with patients who have difficulties to communicate.	14%	86%
There is an updated protocol on preventing and managing delirium.	48%	52%
There is an interprofessional protocol in place to prevent and deal with post intensive care syndrome for patients and families.	33%	67%

Establishment of the family school in the ICU: a new approach to understanding medicine based on humanization

C. Palau Martí¹, M.A. Pajares Moncho¹, M. Granero Cervera¹, E. Monte Pérez¹, C. Julia Romero¹, M.A. Pérez Solaz¹, Humanization Team of the Surgical ICU at La Fe Hospital in Valencia ¹Hospital Universitari I Politècnic La Fe, Anaesthesiology, Valencia, Spain

Background and Goal of Study: The illness in the critically ill patient causes a significant family crisis. As an excellent measure, the creation of the family school in the Intensive Care Unit (ICU) aims to integrate and involve family members in the care of the patient. This seeks to end the sense of helplessness that families experience, promoting their well-being. The main objective of this project is to enhance the care process for patients admitted to the ICU.

Materials and Methods: For the implementation of this project, two basic pillars are required:

- 1. Individual and family counseling. Identification and recruitment of primary caregivers.
- 2. Training program in skills and activities for the improvement of care and recovery. Theoretical sessions offered by the nursing team on topics of interest for family members (management of ostomies, positional changes for the prevention of pressure ulcers, aspiration of secretions through tracheostomy, etc.).

Results and Discussion: The results are very promising. 100% of family members find the training very useful and 100% of attendees would recommend it to other caregivers.

Conclusion(s):

- The unity of the team and the support from management is a guarantee for the successful functioning of the project.

- The family school has managed to reduce the stress and anxiety of the family members.
- The satisfaction and acceptance rate of the project is 100%. References:

Acknowledgements: I would like to express my gratitude for the involvement and great professionalism of the entire multidisciplinary team working on humanization.

51AP06-9

Prospective evaluation of bioelectrical impedance analysis metrics and correlations with clinical parameters in critically ill patients

H. Abdul Ghafour¹, A. Wong¹ ¹King's College Hospital, Critical Care, London, United Kinadom

Background and Goal of Study: Assessing fluid and cellular status is critical in managing critically ill patients, where traditional tools may not provide real-time insights. Bioelectrical Impedance Analysis (BIA) offers a non-invasive way to measure total body water (TBW), intracellular water (ICW), extracellular water (ECW), and phase angle, a marker of cellular integrity. This study evaluated the relationship between BIA-derived parameters, including phase angle, and clinical markers such as lactate, urea, and creatinine.

Materials and Methods: A prospective evaluation involved six critically ill patients over five days, with 50 BIA measurements using the InBody S10. Data on TBW, ICW, ECW, and phase angle were analyzed alongside clinical parameters from electronic records. Spearman's rank correlation assessed relationships between BIA metrics, lactate, urea, creatinine, and net fluid balance. Results and Discussion: Significant negative correlations were observed between serum lactate levels and TBW (Spearman's ρ = -0.541, p < 0.001), ICW (ρ = -0.536, p < 0.001), and ECW (ρ = -0.541, p < 0.001), indicating that elevated lactate levels were associated with reduced hydration. Phase angle also demonstrated a significant negative relationship with the urea-to-creatinine ratio (ρ = -0.475, p < 0.001), supporting its role as a marker of cellular health. Similar patterns were observed with urea, which correlated negatively with TBW (ρ = -0.429, p = 0.002), ICW (ρ = -0.428, p = 0.002), and ECW (ρ = -0.433, p = 0.002). Although net fluid balance did not correlate significantly with TBW or ICW, it was strongly associated with the ECW/TBW ratio (ρ = 0.671, p < 0.001).

Conclusion(s): This evaluation highlights the potential of BIA, including phase angle, in providing real-time insights into fluid and cellular status in critically ill patients. Elevated lactate, a marker of tissue hypoperfusion and metabolic stress, was associated with reduced hydration metrics, emphasizing the importance of monitoring fluid status. The urea-to-creatinine ratio, a marker of kidney function and protein breakdown, was negatively correlated with BIA parameters, reflecting hydration and cellular health changes linked to kidney dysfunction. Phase angle offered additional insights by associating fluid balance with cellular integrity and overall patient condition. Further research is needed to validate these correlations and assess their prognostic value.

51AP06-10

The efficacy of ceftazidime/avibactam combination therapy vs. colistin/polymyxin B in critically ill patients: A systematic review and meta-analysis

H. Binu¹, A. Kalonia¹, S. Sarkar², P. Khanna¹ ¹All India Institute of Medical Sciences. Anesthesiology, Pain Medicine and Critical Care, New Delhi, India, ²All India Institute of Medical Sciences, Anesthesiology, Pain Medicine and Critical Care, Kalvani. India

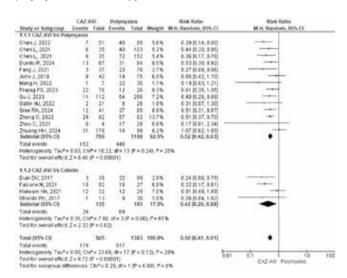

Background: Ceftazidime/avibactam (CAZ-AVI) and Colistin/polymyxin B-based therapy are current treatment options for critically ill patients with sepsis; however, few studies have contrasted the relative efficacy of the two antibiotics regimens.

We aimed to compare the clinical efficacy and safety of CAZ-AVI therapy in combination with other antibiotics and Colistin/polymyxin-based therapy (either alone or in combination with other antibacterial drugs) in treating sepsis.

Materials and Methods: Electronic databases including PubMed, MEDLINE, Embase, and the Cochrane Library were searched from January 2017 to December 2024 using the following search terms: "Ceftazidime/avibactam" AND ("polymyxin B" OR "Colistimethate" OR "Colistin") AND ("Sepsis" OR "Pneumonia" OR "VAP" OR "Bloodstream Infection").

Prospective and retrospective cohort studies comparing ICU mortality, clinical success, bacterial eradication, and adverse complications after the use of CAZ-AVI and polymyxins in critically ill patients were included. Risk ratio (RR) was used as the effect size for evaluating outcomes, using the generic inverse variance method and random effects meta analysis.

Results and discussion: Eighteen studies with 2308 patients were included (CAZ-AVI: 925, polymyxins: 1383). The pooled data showed that in patients treated with CAZ-AVI therapy had significantly lower risk of mortality [Risk ratio (RR) 0.50; 95% Confidence Interval (CI): 0.41, 0.61; I² = 29%; p < 0.00001], better clinical improvement [RR 1.82; 95% CI: 1.45, 2.29; I² = 65%; p < 0.00001], better bacterial eradication[RR 2.20; 95% Cl: 1.57, 3.07; $I^2 = 80\%$; p < 0.00001], lower risk of acute kidney injury [RR 0.46; 95% CI: 0.30, 0.71; $I^2 = 7\%$; p = 0.0005) than patients treated with polymyxin-based therapy.

Conclusion: Ceftazidime/avibactam combination therapy has a superior clinical efficacy in treating sepsis, in terms of better bacterial eradication, clinical improvement, lesser acute kidney injury, and lower risk of ICU mortality compared to Colistin/polymvxin B.

51AP06-11

postoperative choreoathetosis: anesthesiologic management of an unusual complication in cardiac anesthesia

A.V. Espinosa¹, Y.A. Shadad², M. Jain³, A. Shaaban⁴, S.K. Motwani⁵, M. Khayat⁴

¹King Salman Specialist Hospital, Department of Anesthesia, Hail, Saudi Arabia, 2Mohammed Bin Khalifa Bin Salman Al Khalifa Specialist Cardiac Centre, Department of Perfusion Sciences, Awali, Bahrain, 3Royal Brompton Hospital, Department of Critical Care, London, United Kingdom, 4Mohammed Bin Khalifa Bin Salman Al Khalifa Specialist Cardiac Centre, Department of Cardiac Surgery, Awali, Bahrain, 5 Eternal Hospital of Jaipur, Department of Cardiac Anesthesia, Jaipur, Rajashtan, India

Background: Postoperative choreoathetosis ("post-pump chorea," PPC) is common in pediatric cardiac surgery but rare in adults. We report a 68-year-old male with no neurological history who developed PPC after elective double valve surgery (mitral valve repair, tricuspid ring, atrial fibrillation ablation, and left atrial appendage closure). Forty-eight hours post-surgery, the patient exhibited abnormal limb and facial movements. Neurological imaging (CT, EEG, MRI) revealed no abnormalities.

Case Report: A 68-year-old man with dyspnea underwent elective double valve surgery. He had no prior neurological or familial history. Anesthesia included midazolam, ketamine, remifentanil, cisatracurium, and low-dose propofol, maintained with sevoflurane. One unit of blood was transfused during cardiopulmonary bypass (CPB) for hemoglobin of 8.1 g/dL. Stable hemodynamics and cerebral oximetry were maintained, with norepinephrine (max 0.05 µg/kg/min) used briefly post-CPB. Aortic clamp time was 134 minutes, CPB time 154 minutes, with no hypothermia or hyperglycemia.

Forty-eight hours postoperatively, the patient developed choreoathetoid limb and facial movements, dyskinesia, blepharospasm, bradylalia, dysphagia, and psychomotor impairment. PPC was diagnosed based on clinical presentation. Tetrabenazine and clonazepam were initiated, and levetiracetam was added to prevent seizures. The patient was extubated three days later and discharged from the ICU on chorea management therapy.

Discussion: Choreoathetosis affects the limbs and orofacial regions, causing dyskinesia, hypotonia, dysphagia, and speech impairment. PPC typically occurs 2-14 days post-surgery and is associated with prolonged aortic clamp/CPB times, cyanosis, hypothermia, and lactic acidosis. Medlock et al. linked PPC to hypothermia and circulatory arrest but noted cases without these factors. This case highlights PPC in valve surgery without hypothermia or arrest, likely related to prolonged CPB, surgical complexity, and lactic acidosis.

References:

1. Park KW, Choi N et al. Post-Pump Chorea and Progressive Supranuclear Palsy-Like Syndrome Following Major Cardiac Surgery. Mov Disord Clin Pract. 2019;7(1):78-82.

2. Medlock MD et al. A 10-year experience with postpump chorea. Ann Neurol. 1993;34:820-826.

Learning Points

- Recognize PPC in patients with new movement disorders post-cardiac surgery.
- · Early identification and treatment improve outcomes and rehabilitation.

51AP06-12

Management of refractory shock: exploring the role of methylene blue

M.D. Soto Guanotasiq¹, F.J. Cañas Perea¹, E. Samsó², A.J. Navarro¹, C. Farré¹, G.E. Mansilla¹ ¹Althaia - Xarxa Assistencial de Manresa, Anestesiologia, Manresa, Spain, ²Parc Salut Del Mar. Hospital Del Mar, Anestesiología y Reanimación, Barcelona, Spain

Background: Refractory septic shock is a life-threatening condition characterized by profound vasoplegia and resistance to standard therapies, including fluid resuscitation, vasopressors, and corticosteroids. This case highlights the use of methylene blue intraoperative as a tool in a scenario of severe refractory shock secondary. Its importance lies in the patient's hemodynamic stabilization despite escalating vasopressor requirements, showcasing a potential alternative for patients unresponsive to conventional treatments.

Case Reporte: A 52-year-old male patient presented with intestinal perforation one week after undergoing a right hemicolectomy. Upon arrival in the operating room, he exhibited signs of septic shock, including tachycardia (HR 140 bpm), hypotension (MAP < 50 mmHg), and profuse sweating. During exploratory laparotomy, fecaloid peritonitis was identified. Despite aggressive management with fluid resuscitation and vasopressors (norepinephrine at 0.6 µg/kg/min and vasopressin infusion), the patient's hemodynamics remained unstable. A single dose of methylene blue (2 mg/kg over 10 minutes) was administered intraoperatively. Hemodynamic improvement was observed within 15 minutes, with stabilized blood pressure (MAP > 65 mmHg) and a reduced need for vasopressors. The patient was successfully transferred to the ICU for postoperative management.

Discussion: This case underscores the potential of methylene blue in managing refractory vasoplegic shock. Methylene blue inhibits inducible nitric oxide synthase (iNOS), reducing excessive nitric oxide production - a key factor in persistent vasodilation. Prior studies have demonstrated its efficacy in restoring systemic vascular resistance and decreasing vasopressor dependency. For example, Bassi et al. described methylene blue as a valuable adjunct in high-dose vasopressor-dependent shock. Despite promising results, its use is limited by a lack of standardized dosing protocols and potential adverse effects, such as rebound hypertension or methemoglobinemia. This case contributes to the growing body of evidence supporting methylene blue as a viable option for refractory shock, especially when administered early.

References:

- 1. Vincent J-L, De Backer D. Circulatory shock. N Engl J Med. 2013;369:1726-34.
- 2. Bassi E, Park M, Azevedo LC. Therapeutic strategies for highdose vasopressor-dependent shock. Crit Care Res Pract. 3. Rubio SG, Ezquerra PG. Introducción a la práctica clínica. 2022.

Learning Points:

- Methylene blue offers a promising alternative for refractory vasoplegic shock, particularly in patients unresponsive to conventional therapies.
- Early administration of methylene blue may enhance hemodynamic stabilization and reduce vasopressor dependency.
- Further research is required to establish standardized protocols and evaluate its long-term safety in critically ill patients

51AP07-1

Exploration of the degree of interprofessional collaboration (IPC) in the intensive care setting

S. Mifsud¹, S.C. Buttigieg²

¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care and Pain Management, Msida, Malta, ²University of Malta, Department of Health Systems Management and Leadership, Msida, Malta

Background and Goal of Study: Interprofessional collaboration (IPC) involves healthcare professionals (HCPs) from diverse disciplines and specialities working together with patients, their families, carers, and communities to provide the highest standard of care. Research has identified several advantages of IPC, such as better quality of care, greater patient safety, higher job satisfaction, and reduced staff burnout and turnover.

Materials and Methods: A retrospective, cross-sectional research design was utilised. A self-administered structured questionnaire, composed of the Collaborative Practice Assessment Tool (CPAT) and Assessment of Interprofessional Team Collaboration Scale (AITCS-II) was distributed to 169 eligible HCPs working in the twenty-bedded mixed ICU in a general university hospital, between December 2022 and January 2023. Descriptive and inferential statistics were performed on the quantitative data utilising S.P.S.S. (version 28) with a one-way analysis of variance (ANOVA).

Results and Discussion: 110 (65.1%) eligible HCPs participated in the study. Statistically significant differences were observed between team leadership and employment status (p = .035); team leadership and respondents' profession and grade (p = .002) and the overall CPAT score and level of education (p = .029). The AITCS-II mean item score obtained was 3.443. The findings suggest that participants employed full-time and occupying senior positions, who are more likely to be in charge of the team, tend to rate IPC higher, reflecting their perceived leadership. Higher levels of education may also contribute to greater exposure to interprofessional education (IPE) experiences, which are fundamental to IPC. Also, it appears that a traditional hierarchal structural divide is present in the Maltese intensive care setting with physicians still holding the role of team leaders. The AITCS-II score of 3.443 indicates that currently the interprofessional team in the ICU is on the way to collaboration. This finding provides a baseline for future research and allows comparisons with other settings and populations.

Conclusion(s): The study indicates that Maltese ICU practice is progressing toward interprofessional collaboration, with communication being the main area needing improvement. Addressing areas like communication and team processes can inform the design and implementation of focused interventions to strengthen IPC such as interprofessional simulation training.

51AP07-2

Adherence to adult sepsis guidelines recommendation on the use of Vasopressin in patients with septic shock

E.X. Monsalve Ortiz¹, L.S. Chiscano Camon², M. De-Miguel Negro¹, A.J. Ruiz Sanmartin², J.C. Ruiz Rodriguez², M. De Nadal¹.³ ¹Hospital Universitario Vall d'Hebron, Anesthesia, Barcelona, Spain, ²Hospital Universitario Vall d'Hebron, Intensive Care, Barcelona, Spain, ³Universitat Autonoma de Barcelona, Department of surgery associated professor, Barcelona, Spain

Background and Goal of Study: Threshold for adding vasopressin remains unclear in septic shock patients. If mean arterial pressure is inadequate despite low-to-moderate norepinephrine (NE), updated adult sepsis guidelines suggest adding vasopressin as a second-line vasoactive agent.

We designed this study to evaluate adherence to Surviving Sepsis Campaign (SSC) Guidelines 2021 on vasoactive agent management.

Materials and Methods: Retrospective observational cohort study in 155 adult patients with septic shock (Sepsis-3 definition) admitted to ICUs in a single University hospital from January through December 2023. Patients were divided into two groups according to NE dose at the time of vasopressin initiation (<0.25 or ≥0.25 μg/kg/min).

Primary endpoint was physician prescriptive practice over study period.

Secondary outcomes included the duration and maximal doses of NE and vasopressin, adverse effects (digital ischemia, arrhythmias) and in hospital mortality.

Results and Discussion: From 155 eligible patients, 90 (58%) received high dose NE (≥0.25 μg/kg/min). Of those, 54 patients (58%) started vasopressin infusion. When comparing vasopressin prescription during first and second semester, no differences were found (31 vs 39%, p= 0.29). In the low dose NE (<0.25 μg/kg/min) group, only two patients received vasopressin.

Mean dose of vasopressin was 0.05 UI/min (CI 95% 0.03-0.07) and mean duration of vasopressin infusion was 0.7 days (IC 95% 0.5-0.9). Patients who received NE + vasopressin showed more digital ischemia compared to patients who only received NE (20% vs 1%, p< 0.001).

No differences were found in hospital mortality (55.8%in NE + vasopressin group and 47.4% in NE group; p=0.4).

Conclusion(s): In our study, the overall percentage of patients who were treated with the last guideline-recommended therapy was low at 58% and didn't increase over the study period.

The digital ischemia was a common side effect observed in the group of vasopressin+ NE, but that can be affected by the NE doses and any pre-existing comorbidities.

51AP07-3

Evaluation of microcirculation in septic shock patients during vasopressor therapy using remote photoplethysmography parameters. Pilot study

V. Serova¹, M. Klibus¹, Z. Marcinkevics², U. Rubins³, A. Grabovskis³, O. Sabelnikovs¹¹Riga Stradins University, Department of Clinical Skills and Medical Technology, Riga, Latvia, ²University of Latvia, Department of Human and Animal Physiology, Riga, Latvia, ³University of Latvia, Institute of Atomic Physics and Spectroscopy, Riga, Latvia

Background and Goal of Study: Septic shock is a life-threatening condition associated with high mortality. In the intensive care unit, resuscitation therapy typically includes fluid administration and vasopressor infusion, with the primary goal of improving tissue microcirculation. However, high doses of vasopressors can lead to excessive vasoconstriction, potentially impairing tissue perfusion. Remote photoplethysmography (rPPG) is a non-invasive, low-cost optical technique for monitoring tissue perfusion that could provide valuable insights during vasopressor therapy. The aim of this study was to evaluate changes in rPPG signal parameters and the microvascular bed during vasopressor treatment.

Materials and Methods: This single-center, prospective observational pilot study included six patients diagnosed with septic shock. During the study, varying doses of noradrenaline were administered as part of vasopressor therapy. Continuous arterial blood pressure was monitored using a bedside monitor, and remote photoplethysmography (rPPG) signals were collected from the skin on the palm and foot. Single-period rPPG waveforms were extracted and averaged.

Six hemodynamic parameters were calculated from the averaged rPPG waveform: Perfusion Index (PI); Incisura amplitude (Inc); Amplitude of the diastolic wave (Dia); Dia/Inc ratio; Incisura curvature; Diastolic curvature.

Results: Our study results show, that during increased vasopressor dosage comparing patients palm vs foot skin - MAP increased by 20 % vs 16 %, PI increased by 67% vs 38 % [0.21-0.63 vs 0.16-0.22], Inc increased by 24% vs 3% [0.67-0.83 vs. 0.67-0.69], Dia increased by 40% vs 26% [0.41-0.684 vs 0.43-0.54], Dia/Inc ratio increased by 43% vs 17 % and incisura curvature decreased by 50% vs 50% [med 0.00186 vs 0.0046], diastolic curvature decreased by 43% vs 67 % [med 0.00292 vs 0.0038].

Discussion: In our study, we observed that during vasopressor therapy in septic shock patients, rPPG signal parameters in the palms increased more significantly than in the feet and demonstrated a notable sensitivity to hemodynamic changes.

Conclusion(s): Our findings suggest that rPPG signal parameters undergo significant changes during vasopressor therapy in septic shock patients and may serve as reliable indicators for assessing tissue perfusion and responsiveness to resuscitation interventions

Assessment of microcirculation blood flow during venous occlusion test using remote photoplethysmography in septic shock patients

V. Serova¹, <u>M. Klibus</u>¹, D. Smirnova¹, U. Rubins², O. Sabelnikovs¹

¹Riga Stradins University, Department of Clinical Skills and Medical Technology, Riga, Latvia, ²University of Latvia, Institute of Atomic Physics and Spectroscopy, Riga, Latvia

Background: Septic shock can lead to alterations in microcirculatory perfusion. Remote photoplethysmography, a non-invasive bedside method, allows for the assessment of microcirculatory perfusion. Evaluating perfusion during a venous occlusion test has been proposed to assess venous perfusion parameters, reflecting the capacity of microvessels to dilate and/or be recruited

The aim of our study was to evaluate changes in microcirculatory blood flow during venous occlusion tests using remote photoplethysmography in patients with septic shock.

Materials and Methods: This prospective observational study included 11 healthy volunteers and 13 septic shock patients. Perfusion and pulse wave parameters were measured using remote photoplethysmography during a 9-minute venous occlusion test (3 minutes baseline, 3 minutes occlusion, and 3 minutes release). Data were analyzed using non-parametric Mann-Whitney tests.

Results: Our study demonstrated that healthy volunteers had a higher perfusion index after release compared to septic shock patients (1.996 \pm 0.795 vs. 1.437 \pm 0.519). Conversely, the septic shock group showed higher incisura amplitude (0.993 \pm 0.0064 vs. 1.025 \pm 0.0072) and diastolic amplitude (0.98 \pm 0.076 vs. 1.002 \pm 0.165) after release.

Discussion: In our study, septic shock patients exhibited stiffer blood vessels, likely due to vasopressor use and altered microcirculation.

Conclusion(s): Our findings indicate that remote photoplethysmography holds potential as a reliable method for assessing venous perfusion in septic shock patients during venous occlusion tests. Furthermore, septic shock patients were observed to have increased vascular stiffness, likely reflecting the pathophysiological impact of their condition.

51AP07-6

Analysis of the implementation of an early detection system for complications with a rapid response team in surgical wards at a tertiary care hospital

G. Muñoz¹, A. Carramiñana Dominguez¹, L. Zattera¹, C. Fernandez-Barceló², L. Sampietro-Colom³, L. Martinez Faneca⁴¹Clinic Hospital, Anesthesiology and Critical Care, Barcelona, Spain, ²Coreva Scientific GmbH & Co. KG, Health Economics, Koenigswinter, Germany, ³Clinic Hospital, Research and Innovation Directorate, Barcelona, Spain, ⁴Clinic Hospital, Rapid Response Team Nursing, Barcelona, Spain

Background and Goal of Study: Patients admitted to hospital wards frequently experience complications associated with increased mortality, longer hospital stays, and higher healthcare costs. Rapid response systems (RRS) are structures designed to address patients who may develop these events, with the goal of early detection. This resource was implemented at the Hospital Clínic de Barcelona (HCB) in 2021.

Hypothesis: The implementation of RRS at HCB reduces mortality, hospital stays, and the severity of complications, while being cost-effective and optimizing healthcare resources.

Materials and Methods: A comparative study of effectiveness and costs was conducted. Data from patients admitted to the surgical wards were collected for two one-year periods, retrospectively and prospectively (2019 and 2022).

Effectiveness was measured in terms of mortality, complications, and life-years gained (LYG). Data on the length of stay (LoS) in conventional wards and ICU, as well as readmission rates, were collected to assess resource utilization. The chi-square test was used to compare categorical variables, and t-tests and Wilcoxon tests were applied for continuous variables with normal and non-normal distributions, respectively.

Results and Discussion: A total of 7,892 patients were included in the pre-implementation period and 7,257 in the post-implementation period. Both populations were comparable in terms of age, sex, and type of admission (scheduled vs. emergency).

A significant reduction in the average LoS was observed in both conventional wards (4.12 vs. 3.89 days) and ICU (2.29 vs. 2.09 days) (p<0,001), accompanied by actual savings of €681,432, even after accounting for the costs of implementing and maintaining the RRS. A significant difference was also observed in the severity of complications upon ICU admission.

Additionally, there was a 33.5% reduction in hospital arrest team activations. No significant differences were found in the number of ICU admissions, mortality rates, or life-years gained (LYG).

Conclusion(s): The implementation of the RRS is beneficial and cost-effective, as it significantly reduces hospital stays in both conventional wards and UCIs, without increasing patient mortality. All of this results in significant economic savings. Additionally, it leads to a notable reduction in the activation of the hospital arrest team.

51AP07-7

Examination of the effects of chromium levels on glucose metabolism, lipid metabolism, morbidity, and mortality rates in intensive care patients

O. Kahveci¹, B. Kilicaslan¹, S.B. Akinci¹, N. Islak², B.E. Kaya³, Y. Er Oztas²

¹Hacettepe University, Department of Anaesthesiology and Intensive Care, Ankara, Turkey, ²Hacettepe University, Department of Biochemistry, Ankara, Turkey, ³Hacettepe University, School of Pharmacy, Ankara, Turkey

Background and Aim: Monitoring and managing chromium levels in critically ill patients are crucial for optimizing metabolic control, preventing complications and supporting overall recovery.

This study aims to evaluate the effects of blood chromium levels on glucose metabolism, lipid metabolism, morbidity and mortality rates in the intensive care unit (ICU) patients.

Materials and Methods: Patient demographics, comorbidities, reasons for ICU admission, APACHE-II and SOFA scores, nutritional status, and ICU and hospital lengths of stay were prospectively documented. Blood samples were collected on the day of ICU admission and weekly thereafter during the ICU stay. HbA1c, lipid panel, blood chromium levels and daily blood glucose levels were measured. Glycemic coefficients of variation of patients were calculated. Chromium levels were measured using ICP-MS. Mann-Whitney U and Spearman's Rho tests were applied for non-normally distributed data. Associations between variables and outcomes were evaluated using Chi-square tests with Bonferroni correction for multiple comparisons.

Results and Discussion: A total of 309 patients were included in this study. No statistically significant association was found between chromium levels and glucose or lipid metabolism indicators. This finding may be attributed to the complex interplay of critical illness factors that could overshadow chromium's metabolic effects. However, plasma chromium levels measured on the 7th ICU day were significantly associated with mortality (p=0.017). Plasma chromium levels were significantly lower in deceased patients.

Additionally, plasma chromium levels and mortality rates were higher in patients with greater glycemic CV, though this was not statistically significant. Mortality rates were also significantly associated with male gender, higher SOFA and APACHE-II scores, high triglyceride and VLDL levels, and low HDL, LDL and total cholesterol levels.

Conclusion: Based on the data that chromium deficiency is associated with increased mortality and prolonged hospital stay by causing hyperglycemia and dyslipidemia, this study aimed to provide a novel perspective to the existing literature in terms of reducing morbidity and mortality rates in critical care settings according to chromium levels.

Although plasma levels measured on day 7 in the ICU were significantly associated with mortality, this study did not find a direct effect of chromium levels on glucose and lipid metabolism in ICU patients.

51AP07-8

Descending necrotizing mediastinitis: a retrospective analysis of 13 cases

C. Martinez Garcia¹, A. Parera Ruiz¹, M. Giné Serven¹, I. Millán Moreno¹, M. Sneyers Closa¹, S. Sabaté i Tenas¹ 'Hospital de la Santa Creu i Sant Pau, Anesthesiology, Barcelona, Spain

Background: Descending necrotizing mediastinitis (DNM) is a rare but serious infection with high mortality. We aimed to describe 13 patients treated in our center.

Materials and Methods: A retrospective review was performed of patients diagnosed with DNM and treated at our center between 2020 and 2024. Variables analyzed included: epidemiology, clinical presentation, classification, microbiology, treatment, complications, and outcome. Qualitative variables are presented as absolute numbers and percentages, and quantitative variables as median and interquartile range (IQR 25-75).

Results: Most patients were men (92%) with a median age of 50 years (IQR 45-63). Common comorbidities were smoking (69%), hypertension (38%), diabetes (38%), corticosteroid use (15%) and hypoperfusion diseases (15%). Symptoms before diagnosis lasted 6.5 days (IQR 4-7). Fever (77%) and odynophagia (62%) were the most common symptoms.

Other symptoms were dysphagia (38%), dyspnea (31%), trismus (23%), and chest pain (8%). The infectious focus was pharyngeal in 62% of cases, odontogenic in 23%, and cervical in 15%. Classification according to Endo: Endo I (31%), IIA (62%), and IIB (8%). Most DNM were polymicrobial (69%).

Gram-positive bacteria were found in 83% of the samples, gramnegative in 50%, and anaerobes in 67%. S. constellatus and Prevotella spp were the most common species.

All patients received surgery. The time from diagnosis to surgery was 2 hours (IQR 2-3). The most common surgical approach was transcervical (92%), followed by VATS (77%). Seven patients (54%) required tracheostomy. The antibiotic treatment duration was 42 days (IQR 28-52).

Most frequent complications were: respiratory failure (85%), pleural effusion (69%), septic shock (69%), and airway obstruction (62%)

Other complications included pneumonia (38%), renal failure (31%) and pericardial effusion (23%). The hospital stay was 39 days (IQR 26-56), with 18 days (IQR 6-27) spent in critical care. One in-hospital death was recorded, but no mortality was reported at one year.

Conclusions: The clinical presentation of DNM is unspecific, so a high index of suspicion is required for diagnosis. Treatment includes broad-spectrum antibiotics and early, sometimes repeated, surgical intervention. Despite severe complications, early combined treatment significantly reduce mortality.

51AP07-10 Delirium in ICU patients with noninvasive mechanical ventilation

P. Martinez Martinez¹, J. Fernández Molina¹, I. Garmendia Rufo¹, A. Olalquiaga de Dios¹, P. Lafita Aniel-Quiroga², F. Hidalgo Martínez¹ ¹Clínica Universidad de Navarra, Anesthesiology, Pamplona (Navarra), Spain, ²Universidad de Navarra, Medicine student, Pamplona (Navarra), Spain

Background and Goal of Study: delirium is a disorder characterized by a fluctuating alteration of consciousness, with changes in attention and perception of the environment. There are three subtypes: hyperactive, mixed and hypoactive. The most common form of presentation in ICU is the hypoactive subtype (1). The appearance of delirium is associated with longer stay in the ICU, complications and mortality.

The aim of this study was to assess whether noninvasive mechanical ventilation (NIV) is a risk factor for delirium. A secondary objective was to determine whether COVID infection is a risk factor for delirium.

Materials and Methods: through a single-center retrospective observational analysis of 145 patients submitted to NIV in ICU, we performed a multivariate analysis of the risk factors for delirium. Neurocritical patients and those who had previously received invasive mechanical ventilation were excluded.

Results and Discussion: the incidence of delirium in the sample (4.14%) was lower than that described in the literature (22%) (1). The most frequent subtype found in this sample was the hyperactive subtype.

We found a higher incidence in the group that spent more time with NIV, although this was not statistically significant.

We did not find a statistically significant association between risk factors and the appearance of delirium, neither with COVID infection.

Limitations of the study were low statistical power, a single-center study, and few cases of delirium collected in the sample.

Conclusion(s): we have found associations between the use of NIV and delirium that, although not statistically significant, are worth analyzing in future studies.

Predicting non-invasive ventilation failure: Insights from the MIMIC-IV large-scale dataset

<u>D. Stranic</u>¹, M. Grzelja¹, L. Lijović¹, T. Radočaj¹
¹University hospital clinic Sisters of Charity, Department of Anesthesiology and Intensive care, Zagreb, Croatia

Background and Goal of Study: Background and Goal: Non-invasive ventilation (NIV) and high-flow nasal cannula (HFNC) are common critical interventions to prevent intubation in intensive care unit (ICU) patients with respiratory failure. Despite their prevalence, both modalities exhibit high failure rates. Delayed intubation after NIV/HFNC failure increases mortality, underscoring the need for better prediction tools. The ROX index and other methods show limited predictive ability. This study utilises the MIMIC-IV database to explore variables improving NIV failure prediction using machine learning models.

Materials and Methods: We conducted a retrospective analysis using data from 73,181 ICU admissions of 50,920 patients in the MIMIC-IV database (2008–2019). Patients undergoing their first NIV episode in pressure support or continuous positive airways pressure modes were included, excluding those with prior invasive mechanical ventilation or intubation more than 24 hours after NIV initiation. NIV failure was defined as the need for intubation, return to NIV, or death, all within 24 hours of NIV termination. We extracted demographic data, admission SOFA scores, laboratory and ventilatory data (mean values over the first two hours). These measures were used in logistic regression, XGBoost, and random forest models to assess feature importance and predict NIV failure.

Results and Discussion: Among 2312 NIV-ventilated patients, 987 (42.7%) experienced NIV failure. In prediction of NIV failure, logistic regression achieved the highest AUROC (0.66), followed by random forest (0.63) and XGBoost (0.58) (Figure 1).

Feature importance analysis revealed SOFA score as the strongest predictor across all models, followed by respiratory rate, SpO_2 and PaO_2 .

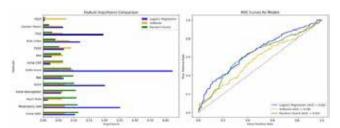

Figure 1.

Conclusion(s): Our study highlights the challenges of accurately predicting NIV failure using machine learning models, even when applied to a large, high-quality ICU dataset such as MIMIC-IV. Although predictive models provide valuable insights, the complexity of assessing NIV failure still requires the judgment and experience of clinicians.

51AP08-2

Perioperative complications in simultaneous heart and kidney transplantation: a range of possibilities

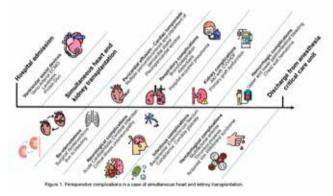

H.R. Hernández Durán¹, A. Moral Bonet¹, I. Zarragoikoetxea Jáuregui¹, M.A. Pajares Moncho¹, M.P. Argente Navarro¹

¹Hospital Universitari i Politècnic La Fe, Anaesthesiology and Reanimation, Valencia, Spain

Background: Ischemic dilated cardiomyopathy (IDC) is a serious condition that frequently leads to advanced heart failure. These patients often require circulatory support devices and, in critical cases, an urgent heart transplant.

We present a case of simultaneous heart and kidney transplant in which multiple complications developed. This case illustrates the wide range of possible complications and the absolute need for multidisciplinary management.

Case report: A 56-year-old man with ischemic dilated cardiomyopathy (IDC), atrial fibrillation, pulmonary hypertension (PH), severe ventricular dysfunction (LVEF 23%) and a single-functioning kidney (renal artery thrombosis) was admitted for congestive heart failure (CHF), requiring ICU admission due to hemodynamic instability, with successive placement of Veno-Arterial Extracorporeal Membrane Oxygenation (V-A ECMO), Levitronix, and Protek-Duo. A simultaneous heart and kidney transplantation was performed. Perioperative complications can be seen in Figure 1.

Discussion: This case exemplifies the vast range of complications that can arise in simultaneous heart and kidney transplantation. While circulatory support devices are lifesaving, they add layers of complexity to perioperative care. Ultimately, continuous monitoring, early intervention, and a well-coordinated multidisciplinary approach remain the cornerstones of improving patient survival and postoperative quality of life.

van den Hoogen MW, et al. (2021). Care for the organ transplant recipient on the ICU. *J Crit Care*, 64, 37–44. https://doi. org/10.1016/j.jcrc.2021.03.003

Sampaio NZ, et al. (2024). Simultaneous heart and kidney transplantation: A systematic review and meta-analysis. *Transpl Int*, 37. https://doi.org/10.3389/ti.2024.12750

Learning points: This case highlights the complexity of perioperative management in transplant patients especially in those using circulatory support devices, emphasizing the importance of continuous monitoring and interdisciplinary management.

Tricuspid valve repair following an electric scooter accident: a case report

C. González Fernández¹, V. Mayor Coll¹,
A. Cariñena Amigo¹, S. Veiras del Río¹, A. Calvo Rey¹,
J.M. Martínez Cereijo²
¹Santiago de Compostela, Anesthesiologist, Santiago de
Compostela, Spain, ²Santiago de Compostela, Cardiac
surgeon, Santiago de Compostela, Spain

Background: Tricuspid valve repair surgery in the immediate postoperative period of a polytraumatized patient: yes or no? We present the case of an 18-year-old patient who, after severe polytrauma, was diagnosed with severe tricuspid regurgitation and urgent surgical repair was decided.

Case Report: A male, with no relevant medical history, polytraumatized after an electric scooter accident was diagnosed with hemoperitoneum due to a splenic rupture and right hemothorax with severe anemia. After a splenectomy and thoracic drainage, the patient was transferred to our center for postoperative intensive care. Despite hemodynamic and volume resuscitation, an increase of vasoactive drugs was required. A transthoracic echocardiogram revealed a severely dilated right ventricle and free tricuspid regurgitation caused by papillary muscle rupture. An angio-CT scan ruled out active bleeding, and urgent surgical intervention was carried out with systemic heparinization for extracorporeal circulation. The surgical procedures included papillary muscle reimplantation, neochord insertion, and tricuspid ring implantation. The patient was discharged from the unit 15 days later in stable condition. A follow-up transesophageal echocardiogram showed moderate tricuspid regurgitation and no signs of heart failure.

Discussion: Tricuspid regurgitation due to trauma is an extremely rare complication, and to our knowledge, this is the first reported case involving an electric scooter accident. Typically diagnosed months or years later due to arrhythmias or heart failure, this case was identified in the immediate postoperative period, and surgical intervention was decided within 24 hours of the accident and the initial surgery. A review of previous case reports suggests that early surgery reduces the risk of heart failure and the need for valve replacement.

References:

- Karaca O. Tricuspid valve chordal rupture after a motorbike accident. Turk Kardiyoloji Dernegi Arsivi-Archives of the Turkish Society of Cardiology. 2016;
- 2. Enomoto M, Takashima N, Kamiya K, Lee J, Hachiro K, Wakisaka H, et al. Surgical repair for primary tricuspid regurgitation related to trauma. Journal of Cardiology Cases. June 1, 2024; 29(6):251-3.

Learning points: Tricuspid rupture should be considered in traumatized patients. In this case, the involvement of an electric scooter is particularly relevant, as this is a rapidly growing mode of transportation used by millions of people worldwide.

51AP08-4

The critical appraisal of the predictive power of substances with antioxidant properties in patients with COVID-19: a journey towards cure and hope in severe cases

A. Djurdjevic Svraka¹, D.S. Svraka¹, B. Pejakovic¹, D. Vuruna¹, T. Radulovic¹, M. Garaca¹ ¹General Hospital Gradiska, Dep. of anaesthesia, resuscitation and intensive care, Gradiska, Bosnia and Herzegovina

Background and Goal of Study: This study provides a comprehensive critical review of various predictor variables known for their antioxidant properties, specifically on albumin, ferritin, urea, and bilirubin. It aims to evaluate how these substances influence the health outcomes of critically ill patients diagnosed with COVID-19. By analysing these variables, the research seeks to enhance our understanding of their roles in the progression and management of the disease in this vulnerable patient population. Materials and Methods: From Jan 1, 2021, to Jan 1, 2023, a prospective observational study was conducted involving 275 critically ill patients who tested positive for COVID-19 through polymerase chain reaction (PCR) testing. At the time of a patient's admission to the ICU, a comprehensive set of laboratory tests is performed to gather essential information about their health status. For clinical prediction models, we employed receiver operating characteristic (ROC) curves, which are used to predict the risk of occurrence (diagnostic research) or development (prognostic research). These models provide individual risk predictions based on the values of the predictors included in the model. One of the key aspects of performance is discrimination, the ability to separate parameters that could be a predictive factor. We used albumin, ferritin, urea, and bilirubin as independent quantitative variables, while the adverse outcome of critically ill COVID-19 patients served as the dependent variable.

Results and Discussion: The p-value of less than 0.001 for the Area Under the Curve (AUC) of the Receiver Operating Characteristic (ROC) curve demonstrates statistically solid significance in evaluating the model's serum albumin and BAL albumin performance. In comparison, the AUC ROC for ferritin, urea, and bilirubin does not exhibit any statistical significance within our model. While various substances in the body possess antioxidant properties, an important avenue for further research is whether these properties diminish in cases of organ dysfunction, such as multiorgan failure.

Conclusion(s): Our results show that specific sensitivity and specificity values are only clinically relevant for the comparison. In this comparison between albumin, ferritin, urea, and bilirubin, we can only rely on the albumin values in both serum and BAL and consider them relevant outcome-predictive factors.

Intensivist approach to the treatment of gynecological-obstetrical complications - necrotizing fascitis

A. Sekulic¹, O. Marinkovic², <u>N. Nikolic</u>², T. Aleksijevic³, V. Denda², M. Zdravkovic⁴

¹CHC Bezaniska kosa, Anaesthesyologi and intensive care, Belgrade, Serbia, ²CHC Bezaniska kosa, Anaesthesyiologi and intensive care, Belgrade, Serbia, ³CHC Bezaniska kosa, Anaestehesyiologi and intensive care, Belgrade, Serbia, ⁴UHC Bezaniska Kosa, Anesthesiology and Intensive Care, Belgrade, Serbia

Background: Necrotizing fascitis is a fulminant infection that involves large areas of soft tissue necrosis, most often affecting the limbs, perineum and abdominal wall.

Case Report: A 27-year-old patient was hospitalized in the Intensive Care Unit of KBC Bežanijska Kosa due to a wound infection and developed necrotizing fasciitis after an emergency caesarean section 7 days earlier.

A month before the caesarean section, COVID pneumonia was diagnosed and treated. Patient with accompanying comorbidities: systemic lupus since 11 years of age, rheumatoid arthritis on therapy with prednisone, azatrioprin and hidroxicloroquina. With a fracture of six thoracic vertebrae as a result of osteoporosis and corticosteroid therapy.

On the lungs, auscultatory bilateral audible breathing, basally weakened. Chest CT: Diffuse reticular interstitial changes in the lungs, non-COVID, according to the LE type, bilateral pleural effusions. SOFA 5, APACHE II 11. Enterococcus spp isolated from the operative wound, vancomycin resistant (VRE).

Treated with antibiotic therapy based on antibiogram. Surgical treatment carried out by necrosectomy and implantation of the "Abthera VAC System". After 12 days and 4 changes of the sponge membrane, the VAC system was successfully removed and the wound closed.

The surgical recovery was accompanied by an improvement in the clinical, laboratory and radiological parameters of the infection. She was treated with a multidisciplinary approach throughout her hospitalization. After 18 days of treatment in our institution, the patient was released for home treatment in a stable general condition.

Discussion: Infections can be intra-abdominal or around the surgical wound; these sometimes dangerous infections can increase morbidity and mortality, prolong hospital stays, and increase treatment costs. Females undergoing cesarean section have a 5 to 20 times higher chance of infection compared to those who gave birth vaginally.

Risk factors associated with necrotizing fascitis: diabetes mellitus, intravenous drug abuse, age over 50 years, immunodeficiency states, hypertension and malnutrition/obesity. Group A Streptococcus is the most common monomicrobial isolate, polymicrobial infections with various gram positive, gram negative, aerobic and anaerobic isolates.

51AP08-6

Assessment of the clinical significance of scoring systems for assessing severity and outcome in patients with acute pancreatitis

A. Sekulic¹, O. Marinkovic¹, T. Aleksijevic¹, <u>N. Nikolic</u>¹, M. Zdravkovic², S. Trpkovic³

¹UHC Bezaniska Kosa, Anesthesiology and Intensive Care, Belgrade, Serbia, ²UHC Bezaniska Kosa, Cardiology, Belgrade, Serbia, ³Faculty of Medicine University of Pristina, Seat in Mitrovica, Anesthesiology and Intensive care, Kosovska Mitrovica, Serbia

Background and Goal of Study: Acute pancreatitis (AP) is a sudden inflammation of the pancreas with an unpredictable course and uncertain outcome. Early diagnosis of AP, in the first 24 - 48 hours, especially in fudrujant forms, can be very difficult. We use laboratory tests, imaging diagnostics and scoring systems to predict the severity and outcome of AP.

The aim of this study is to examine the factors that are the simplest to apply and most objective for assessing the severity of AP, predicting the development of complications, and the outcome of patient treatment in our conditions.

Materials and Methods: The research was conducted as a prospective study and included patients admitted to the surgical department or to the Intensive Care Unit level II and III with a diagnosis of AP. The research was conducted in several phases: on admission (zero day), 48, 72 hours, 7 days and 12 months after admission.

Results and Discussion: In our study, there were 50 patients, of whom 84% survived to discharge from the hospital and 16% died. The most common cause of AP was gallstones, slightly more common in women than in men, while alcoholism was the cause of AP only in men. Severe pancreatitis was statistically significantly more common in younger patients and patients with a higher body mass index (BMI). Patients with severe AP were on mechanical ventilation (MV) for longer and were treated in the intensive care unit (ICU) for longer. Patients with sepsis/septic shock as a complication were on MV for significantly longer.

The best prognostic value for predicting the outcome of treatment of patients with AP on the day of admission (day zero) was shown by MEWS $_0$, APACHE II $_0$ and BISAP $_0$ scoring systems. After 48 hours, APACHE II $_{48}$ and MEWS $_{48}$.

Compared to other scoring systems, MEWS $_{72}$ and 7d showed a slightly better prognostic value in predicting the outcome of treatment 72 hours and 7 days after admission compared to BISAP $_{72}$ and 7d scoring systems. Of the biochemical markers of inflammation, PCT determined on day 7 had the best degree of discrimination.

Conclusion(s): The application of scoring systems and biomarkers of inflammation in different phases of treatment is important in assessing the prediction of the final outcome, severity of AP, occurrence of complications, length of stay in the ICU, and length of MV. The prognostic value of the scoring system for treatment outcome 48 hours after admission was better than that of CRP and PCT.

Rhabdomyolysis following acute right mastitis in a postpartum woman: a case report

L. Nunci^{1,2}, O. Ajasllari¹, D. Nunci³, A. Ajasllari⁴
¹University Hospital Center "Mother Teresa", Anaesthesia and Intensive Care, Tirana, Albania, ²University Hospital Center "Mother Teresa, Anesthesia and Intesive Care, Tirana, Albania, ³University Hospital Center "Mother Teresa", Department of Imaging and Nuclear Medicine, "Mother Teresa" University, Tirana, Albania, ⁴Health Center No. 9 / Polyclinics, Nephrology Service, Tirana, Albania

Background: Rhabdomyolysis, characterized by the breakdown of skeletal muscle fibers and the release of intracellular contents into the bloodstream, is a rare but serious complication in the postpartum period.

This case report presents a unique instance of rhabdomyolysis following acute right-sided mastitis in a postpartum woman.

Case Report: The patient, a 29-year-old woman, developed sudden-onset muscle pain, weakness, and dark-colored urine after being diagnosed with right mastitis. Blood tests confirmed rhabdomyolysis with elevated CK and myoglobin levels.

Treatment included aggressive IV isotonic saline to prevent acute kidney injury (AKI). By day three, urine output decreased to 1700 mL/24 hours, though renal function remained slightly impaired. CRRT was considered but avoided in favor of diuretic therapy and fluid resuscitation, guided by CVP monitoring. Sodium bicarbonate was trialed for urine alkalinization despite limited evidence of its efficacy.

Discussion: This case underscores the importance of early recognition and management of rhabdomyolysis in postpartum patients with unusual infection-related complications. It highlights the challenges in therapeutic decision-making, including the role of CRRT and urine alkalinization, and emphasizes the need for individualized, evidence-informed approaches to prevent renal complications.

Further research is warranted to clarify the relationship between postpartum infection and rhabdomyolysis and to establish optimal management strategies in similar cases.

References:

Bosch X, Poch E, Grau JM. Rhabdomyolysis and acute kidney injury. *N Engl J Med.* 2009;361:62–72. Safari S, Yousefifard M, Hashemi B, et al. The value of serum creatine kinase in predicting the risk of rhabdomyolysis-induced acute kidney injury: A systematic review and meta-analysis. *Clin Exp Nephrol.* 2016;20:153–61.

Learning Points:

- Clinicians should consider rhabdomyolysis in postpartum women presenting with systemic symptoms and muscle pain following infections.
- 2. Early diagnosis and aggressive fluid resuscitation are essential to prevent complications such as AKI.
- 3. Postpartum physiological and inflammatory changes may predispose to unusual complications, requiring a high index of suspicion
- Individualized management strategies, including decisions on CRRT and supportive therapies, are crucial in uncertain scenarios.

51AP08-8

Compound 21, a non-peptide agonist of angiotensin II type 2 receptor, attenuates organ injury and survival in septic rats

C.-M. Tsao^{1,2}, C.-C. Wu³, C.-C. Shih³
¹Taipei Veterans General Hospital, Anesthesiology, Taipei, Taiwan, ²National Yang Ming Chiao Tung University, Anesthesiology, Taipei, Taiwan, ³National Defense Medical Center, Department and Graduate Institute of Pharmacology, Taipei, Taiwan

Background and Goal of Study: Sepsis is complicated by a variety of conditions such as septic shock, vascular hyporeactivity to inotropics and immune disturbance, contributing to poor organ perfusion and then multiple organ dysfunction syndrome. Previous studies revealed that the angiotensin II type 2 receptor (AT2R) agonist could reduce inflammatory response and ischemia injuries in brain and heart. We found that CGP42112, a peptide AT2R agonist, significantly attenuated hypotension, organ dysfunction and mortality in rats with polymicrobial sepsis.

The purpose of this study is to evaluate whether non-peptide AT2R agonist, compound 21 (C21), can protect rats from septic shock and organ injury induced by cecum ligation puncture (CLP).

Materials and Methods: In this study, male Wistar rats received CLP or sham operation followed by the intravenous administration of saline or C21 at 3 hours after sham operation or CLP. The changes in biochemical and hemodynamics variables as well as plasma chemokine and nitric oxide levels were detected during the 24-hour observation. Rats were then euthanized for subsequent histological examination.

In addition, we used LPS and nigericin-stimulated cell model to examine the effects of C21 on sepsis-induced macrophage pyroptosis. J774A.1 cells were pretreated with different doses of C21 for 30 minutes, then incubated with LPS (100 μ g/ml) for 4 hours and nigericin (10 mM) for 3 hours to induce pyroptosis.

Results and Discussion: CLP lead to multiple organ injuries, characterized by elevated plasma biochemical parameters and histopathological changes, which were attenuated by C21 administration.

Furthermore, C21 significantly attenuated plasma production of chemokines and nitric oxide, but also reduced lung expressions of inducible nitric oxide synthase, cytochrome c and caspase-3 in CLP rats.

Meanwhile, C21 significantly decreased the protein expression of IL-1 β , cleaved-caspase1, and gasdermin-D in J774A.1 cells. More importantly, C21 improved the survival of rats with sepsis.

Conclusion(s): In this animal model of polymicrobial sepsis, C21 protected against organ dysfunction at 24 hours following CLP possibly through anti-inflammatory response and anti-apoptosis. Moreover, C21 inhibited the activation of inflammasome-stimulated pyroptosis in macrophages. It suggests that the treatment of AT2R stimulation provides a promising therapeutic candidate for sepsis.

ACE inhibitors and calcium channel blockers concomitant poisoning: multimodal approach

O. Smékalová^{1,2,3}, V. Rozumova^{1,2}, J. Benes^{1,2,3,4}
¹Faculty of Medicine in Pilsen, Charles University,
Department of Anesthesiology and Intensive Care
Medicine, Pilsen, Czech Republic, ²University Hospital
Pilsen, Department of Anesthesiology and Intensive Care
Medicine, Pilsen, Czech Republic, ³Faculty of Medicine
in Pilsen, Charles University, Simulation Centre, Pilsen,
Czech Republic, ⁴Faculty of Medicine in Pilsen, Charles
University, Biomedical Centre, Pilsen, Czech Republic

Background: Calcium channel blockers (CCBs) and angiotensinconverting enzyme inhibitors (ACEI) are widely used antihypertensives. Overdoses can lead to severe vasodilatory shock and cardiodepression, resulting in life-threatening hemodynamic instability. Treatment is supportive due to the absence of a specific antidote. This case details a patient's survival after ingesting lethal doses of both drug classes through multimodal therapy.

Case Report: A 51-year-old female with a history of hypertension and schizophrenia was admitted after ingesting 90 tablets of perindopril/amlodipine and 30 tablets of perindopril in a suicidal attempt.

On presentation, she was hemodynamically stable but quickly developed severe vasoplegic shock with escalating doses of vasopressors (norepinephrine up to 4.5 μ g/kg/min, vasopressin 0.06 IU/min). Hemodynamic monitoring revealed high cardiac output with low systemic vascular resistance index.

The treatment included calcium supplementation, hyperinsuline-mic-euglycemic therapy (HIET), intravenous lipid emulsion (ILE), and continuous hemodialysis due to anuria. The patient was intubated and ventilated following a decrease in consciousness. Methylene blue (MB) was administered as a third vasopressor, and naloxone was introduced at high doses as a last-resort therapy. After 48 hours, vasopressor doses could be tapered, urine production resumed by Day 3, and the patient was extubated on Day 10 with full neurological recovery. She was discharged on Day 41.

Discussion: Mixed CCB and ACEI overdoses are rare but pose significant therapeutic challenges due to amplified vasodilatory effects. Current literature supports using HIET, ILE, and MB in refractory shock, but their combination in severe cases is rarely reported.

This case also highlights the application of high-dose naloxone for antagonizing endogenous opioids. Survival in such cases is rare, highlighting the importance of aggressive multimodal therapy and advanced monitoring. This report contributes to evidence supporting innovative approaches to life-threatening drug overdoses.

References:

Robert M, De Bels D, Chaumont M, Honoré PM, Gottignies P. Angiotensin converting enzyme inhibitor intoxication: Naloxone to the rescue? Naloxone for ACE inhibitor intoxication. Am J Emerg Med. 2019;37(6):1217.e1-1217.e2.

Learning Points:

Early multimodal therapy is crucial in managing severe CCB and ACEI intoxication.

Prompt intervention and advanced monitoring improve neurological outcome.

51AP08-10

Transfusion confusion. Diagnostic difficulties in critically ill patient with acquired hemophilia A due to blood product transfusions

M. Saulite^{1,2}, R. Stašinskis^{1,3}, I. Sujete^{1,3}, S. Nemme-Rubene¹, A. Andrianovs¹, I. Būce-Šatoba^{1,3} ¹Rīga Eastern University Hospital, Intensive Care Unit, Rīga, Latvia, ²Rīga Stradiņš University, Department of Residency (Anaesthesiology and Intensive Care), Rīga, Latvia, ³Rīga Stradiņš University, Department of Anaesthesiology and Intensive Care, Rīga, Latvia

Background: Acquired hemophilia A (AHA) is a rare coagulopathy with incidence of 1.5 cases per million per year.¹ Although diagnostic criteria for AHA are clearly defined, treatment of an acutely bleeding critically ill patient with blood products may interfere with laboratory studies, which can cause misdiagnosis and delay of proper treatment. The aim of this case report is to highlight the importance of correct timing of blood sampling.

Case Report: Female, 65 years old, was admitted in district hospital with shortness of breath and lower extremity oedema. Symptoms developed over several months after acute viral respiratory infection. X-ray showed right sided hydrothorax and pleural puncture was performed. Haemoglobin decreased from 12.9 to 7.0 g/dL in 5 days after puncture and right sided haemothorax was detected. Bleeding occurred from all blood vessel puncture sites and patient received regular life-saving blood product transfusions. Coagulation studies showed extremely prolonged APTT. Patient was transferred to ICU of Riga Eastern University Hospital. Prolonged clotting time (531 sec.) and clot formation time (132 sec.) were detected in ROTEM intrinsic pathway. While receiving blood product transfusions coagulation study showed high F VIII activity >150% (N=70-150%). After one week of targeted treatment with human plasma products, coagulation study was repeated.

Results shoved low F VIII activity (0.9%) and high F VIII inhibitor level - 55 BU(N<0.5 BU). Treatment with recombinant F VIIa was initiated and bleeding mitigated. Specific immunosuppressive therapy was started and patient was able to be transferred.

Discussion: The diagnosis of AHA itself is challenging due to the rare occurrence. Transfusion of blood products can lead to significant errors in coagulation studies and may delay targeted treatment. Thanks to multi-disciplinary teamwork repeated coagulation studies were repeated in correct time.

References:

1. Autoimmune (Acquired) Hemophilia: Updates in Diagnosis and Therapy. Meera Sridharan; Rajiv K. Pruthi. *The Hematologist.* (2022)19(2).

Learning Points:

- Intensivists must have in-depth understanding of coagulation, coagulopathy diagnostics and treatment.
- Multi-disciplinary team is an essential part of successful and timely management of critical care patients with rare diseases.
- Correct timing of blood sample collection is crucial in the diagnosis of coagulopathies because blood product transfusions can affect the results.

A systematic review on the long-term outcomes of atrial fibrillation in critical care patients

N.A. Canagarajah^{1,2}, J. Chae¹, H. Essa^{1,2}, B. Johnston^{1,2}, I. Welters^{1,2}

¹University of Liverpool, Institute of Life Course and Medical Sciences, Liverpool, United Kingdom, ²Liverpool University Hospitals Group, Royal Liverpool University Hospital, Liverpool, United Kingdom

Background and Goal of Study: Atrial fibrillation (AF) is an arrhythmia with a lifetime risk of up to 33% after 45 years old and is often managed with medication including anticoagulation. Newonset atrial fibrillation (NOAF) develops in 4.5% to 15% of patients in critical care, and it is linked to additional risk factors such as infection, electrolyte abnormalities, pain, and inotropic support. As a result, NOAF is commonly not treated as it may resolve alongside illness resolution.

However, growing evidence suggests that NOAF in critical care is associated with increased long-term mortality and morbidity from stroke, heart failure, and recurrent hospitalisations with AF. There is a need to compare the outcomes of NOAF, pre-existing atrial fibrillation (PEAF), and those without AF in critical care to inform management plans.

Methods: This systematic review has been registered with PROSPERO (CRD42024593912). Ovid MEDLINE, EMBASE, and Ovid Emcare were systematically searched on 23rd July 2024 using relevant medical subject headings and keywords. Studies with patients who were 16 years and older in critical care or high dependency units who developed NOAF or with PEAF and had any reported ≥30-day mortality or thromboembolic outcome were included.

Two reviewers (NAC, JC) independently performed title and abstract screening, full-text screening, data extraction, Newcastle Ottawa Scale risk of bias and quality assessment in Covidence. All conflicts were discussed with support from a senior third reviewer (BWJ).

Trial and patient characteristics, outcomes, and risk of bias in tables and forest plots were extracted. Where appropriate, forest plots show pooled analysis using a random-effects model.

Results and Discussion: The literature search identified 3357 studies. After screening, 25 studies were included for full-text analysis including 11 prospective and 14 retrospective observational studies.

Results suggest heterogeneity between studies and no standardised outcomes, limiting opportunities to compare studies and continue with meta-analysis.

Conclusion: This systematic review investigates the long-term mortality and thromboembolic outcomes of NOAF and PEAF in adults hospitalised in critical care to help direct management. Significant variation in outcomes reported, study design chosen and patient populations studied limit generalisability of results. Core outcome sets are needed to allow comparison of studies in the future.

51AP08-12

Early postoperative albumin replacement after colorectal surgery: is it beneficial?

D. Yaylak¹, E. Şentürk¹, Y. Sincer¹, F. Yurdakul², E. Aygün¹, I. Ozata³, E. Balik⁴, M. Veznikli⁴, N. Cakar⁴ ¹Koc University Hospital, Anesthesiology, Istanbul, Turkey, ²Koc University Hospital, Anesthesiology, Istanbul, Turkey, ³Koc University Hospital, General Surgery, Istanbul, Turkey, ⁴Koc University Hospital, Istanbul, Turkey

Background and Goal of Study: Hypoalbuminemia is a known predictor of postoperative complications, including infections, delayed wound healing, and prolonged recovery in colorectal surgery patients. While albumin replacement is commonly used to address low postoperative albumin levels, its clinical efficacy remains controversial.

This study aimed to evaluate the impact of early postoperative albumin replacement on complication rates, ICU length of stay, and 90-day mortality in patients undergoing elective colorectal surgery.

Materials and Methods: This retrospective study included 164 patients who underwent elective colorectal surgery at Koc University Hospital between January 2018 and December 2023. Patients aged ≥18 years requiring at least 24 hours of ICU care postoperatively were included. Serum albumin levels were assessed preoperatively and immediately postoperatively, with patients categorized into groups based on serum albumin levels (<3.5 g/ dL or ≥3.5 g/dL) and whether they received albumin replacement. Patients receiving albumin were administered 100 mL of 20% albumin solution three times daily.

Outcomes assessed included postoperative complications, ICU length of stay, and 90-day mortality. Data were analyzed using Mann-Whitney U, Pearson Chi-Square, and multivariate logistic

Results and Discussion: Patients with hypoalbuminemia were significantly older and had shorter operative durations but showed no significant association with complication rates, ICU stays, or 90-day mortality. Albumin replacement was associated with significantly higher complication rates (56.5% vs. 17.9%) and longer ICU stays (p<0.001).

The findings suggest that albumin replacement is often employed in patients with greater clinical severity, potentially confounding its association with adverse outcomes. These results align with prior studies questioning the routine use of albumin in critically ill postoperative patients.

Conclusion(s): Early postoperative albumin replacement was not associated with improved clinical outcomes in colorectal surgery patients requiring ICU care.

On the contrary, its use correlated with higher complication rates and prolonged ICU stays. These findings emphasize the importance of individualized decision-making when considering albumin replacement therapy.

Future prospective studies are needed to clarify its role and identify patient subgroups that may benefit from its use.

Patient Safety

52AP01-1

Strange complications of long-term catheters insertion and maintenance

A. Abdyli¹, D. Hoxha¹, R. Domi², G. Huti¹, K. Lilai². F. Conialione¹

¹American Hospital Tirana, Anesthesia and Intensive Care, Tirana, Albania, ²University of Medicine Tirana, Anesthesia and Intensive Care, Tirana, Albania

Background: Central venous catheters are preferred in patients receiving medications that can potentially damage peripheral veins, require vasopressors, need large volumes of fluids, require long-term use, chemotherapy or renal replacement therapy.

Case Report:

Case 1: A 24-year-old male, who has been undergoing hemodialysis for two years, was scheduled for the insertion of a long-term catheter. This procedure is routine in our institution. The left subclavian approach was selected. The procedure was uneventful, and the catheter functioned properly. However, a routine chest X-ray revealed an unexpected finding, leading to the performance of an Angio CT scan. It was determined that selective cannulation of the brachiocephalic vein was required due to a congenital abnormality.

Case 2: A 50-year-old female, following a right hemicolectomy. was referred to our institution for the insertion of a Port-a-Cath. The procedure was successfully performed, and she underwent chemotherapy for six weeks. After this period, the catheter suddenly became blocked and ceased to function. An Angio X-ray revealed that the catheter had completely ruptured, with the distal portion having migrated to the right ventricle.

The proximal part was surgically removed. Echocardiography confirmed that the distal part had not embedded into the ventricular wall. The distal portion was subsequently removed in the Cath Lab using an endovascular snare. The procedure was un-

Discussion: Physicians must consider the importance of individualizing patient care and should have a comprehensive understanding of insertion techniques and potential complications. Ultrasound-guided techniques are the preferred method today, especially for inserting intermediate long-term venous cannulas.

- 1. Moir D, Bodenham A. A narrative review of long-term central venous access devices for the intensivist. J Intensive Care Soc. 2018:19(3):236-246.
- 2. Lenz H, Myre K, Draegni T, Dorph E. A Five-Year Data Report of Long-Term Central Venous Catheters Focusing on Early Complications. Anesthesiol Res Pract. 2019; 2019:6769506.

Learning Points:

- 1. Ultrasound-quided insertion followed by diagnostic Angio CT enhances the success of this procedure.
- 2. Knowledge about maintenance and careful usage protocols is crucial to prolong the duration of catheter use.

52AP01-2

From facilitating practician to perioperative clinician: the importance of multi-speciality input and shared decision making for optimal patient-centred outcomes in anaesthesia

R.M. Thompson¹, A.R. Randall¹, S. Bains², T. Torlinski^{1,3} ¹Queen Elizabeth Hospitals Birmingham, Department of Anaesthethesia and Intensive Care Medicine, Birmingham, United Kingdom, ²Queen Elizabeth Hospitals Birmingham, Department of Breast Surgery, Birmingham, United Kingdom, ³Aston University, Aston Medical School, Birmingham, United Kingdom

Background: Multi-speciality input (MDT) and shared decisionmaking (SDM) are crucial for safe anaesthesia. This case exemplifies such approach in delivering patient-centred care in frail patient with retrosternal goitre and associated tracheal deviation. Case Report: Staging CT revealed incidental large retrosternal goitre with tracheal deviation. Risk stratification for potential airway obstruction on administration of anaesthesia was identified via surgical & anaesthetic MDT. Extensive discussions with patient & family were had regarding risk vs benefit.

Worst-case outcomes discussed- challenging intubation/extubation, ICU admission, Patient-centred quality of life outcomes acknowledged. As identified by surgical MDT, the patient showed an obstructive breathing pattern on induction due to goitre, which resolved on intubation.

For extubation, patient was in Fowler's position, neuromuscular block fully reversed, awoken under propofol cover. Additional consultant anaesthetist present to assist, team briefed on rapid sequence induction (RSI) in case of airway collapse.

Discussion: Knowledge of airway risk and patient priorities, identified via MDT & SDM, enabled a successful procedure and sameday discharge. Collaborative, patient-centred decision-making empowered the anaesthetic and surgical teams to proceed, with patient-acceptable risk-mitigation strategies and outcomes. It is essential to highlight the impact that effective SDM could have if applied ubiquitously(1).

While several communication models support SDM(2), complex patient pathways with varied clinician buy-in mean that effective SDM is inconsistent in practice(3).

The anaesthetist has unique overview of medical and surgical risks; by reorienting the anaesthetic role from 'facilitating practician' to 'perioperative-clinician,' the true impact of anaesthetic expertise on enabling meaningful SDM & MDT working can be realised.

References:

- 1. NICE CG197;
- 2. cpoc.org.uk/shared-decision-making:
- 3. pubmed.ncbi.nlm.nih.gov/30144968/

Learning Points: Importance of multidisciplinary teamwork and shared decision-making for risk stratification in complex cases for optimal surgical and anaesthetic outcomes; Recognition of the Anaesthetists' unique opportunity to deliver effective, shared decision-making in complex surgical care pathways; Consideration of system-wide ripple-effects of effective patient-centred care: better use of resources, better patient outcomes, higher patient and staff satisfaction.

A long-term change management program to improve compliance with the Safe Surgery Checklist in a Belgian regional hospital

W. Swinnen¹, J. Suykens¹, C. Bellens², D. Verhelst², T. De Grauwe¹, J. Pauwels¹

¹az Sint-Blasius, Anesthesia, Dendermonde, Belgium, ²az Sint-Blasius, Operating Theater, Dendermonde, Belgium

Background and Goal of Study: The Safe Surgery Checklist (SSC) enhanced patient safety. However, research shows ongoing challenges among OR professionals in using the SSC, with literature reporting low compliance rates. Goals: Improve compliance, identify causes of suboptimal adherence.

Materials and Methods:

Setting: Surgical Day Care Center, 4 ORs, az Sint-Blasius, Dendermonde. Belgium. Closed-record review during 5 study periods (SP). Only end-of-SP results were analyzed. Evaluation of Sign in by surgeon (SI SURG), anesthesiologist (SI ANE), and Time out (TO) and Sign out (SO) by circulating OR nurse.

Inclusion: surgeries under general anesthesia, sedation, or regional anesthesia. Exclusion: emergency surgery, surgeries under local anesthesia, absence of SSC.

Interventions: communication of results to all OR staff; post-baseline survey of nurses on SO issues and improvement suggestions; SP2: PACU-nurses recall circulating OR nurse if SSC is incomplete; SP3: halt communication of results and recall to study compliance decline; SP4: resume communication. Statistical tests: Fisher's exact test at the end of each SP; significance: P<0.05.

Results and Discussion: Baseline TO and SO were suboptimal. Nurses cited lack of time (90.5%), forgetting during replacement (52.4%), and distraction (38.1%) as reasons for poor SO. Improvement suggestions included anonymous reporting (42.9%), selfcontrol (33.3%), and public reporting (23.8%). SI ANE, TO, and SO significantly improved during SP1. During SP2. TO and SO continued improving despite circulation nurses' poor recall. PACU nurses reported aggressive behavior and social pressure, leading to recall omission in subsequent SP. SP3, with halted communication, resulted in non-significant declines in SI SURG, TO, and SO. Resuming communication in SP4 slightly improved SI SURG, TO, and SO.

Disable period -	Timing	Intervention	N	Sign in	Sign in.	Tiese Out .	Tigh Out
Sexcine	Feb 2029	Compliance milliouriment Communication of results Survey numes: why is Sign Dut the problem, improvement suggestions	128	11.7%	91.29	826	800
W1	iun 2019 to kine 2020, morthly	Compliance measurement Communication of results	304	36.7%	\$6-0.000	9735 9-5.0003	9-36
M.S.	Jen 2021 to June 2023, months	Compliance measurement Communication of resurts Receil crossiting nurse when SVC not DX.	171	95.4%	102%	(p-0004)	17.15 pressi
593	Apr 2022 to 0ct 2021, semestrial	Compliance measurement Step communication Step receil	255	91.54	99.2%	1100	54.3%
10-4	Apr 2008 to Apr 2024, secreptive	Compliance measurement Resignet commercianism of results	261	THE	00.2%	3676	36.7%

Conclusion(s): Repetitive measurement and communication can enhance compliance with the SCC beyond published outcomes. Interrupting communication leads to decline. SO is the hardest to optimize, often due to time constraints or being overlooked, particularly when replaced. Some interventions failed due to resistance and social pressures.

52AP01-4

Association between patient safety culture and incidence of patient falls in postoperative period

D.I. Vachnadze¹, G. Rovtberg¹, N. Kondratova¹, E. Galanina¹ ¹JSC "Medicina", Inpatient Department, Moscow, Russian Federation

Background and Goal of Study: Patient falls in the postoperative period is a significant problem, often leading to restricted mobility, anxiety, and depression, as well as increased healthcare costs for treatment and rehabilitation of fall-related injuries. Although prevention programs are implemented, their effectiveness largely depends on the level of patient safety culture among healthcare staff.

This study aimed to assess the correlation between safety culture levels and the frequency of postoperative patient falls.

Materials and Methods: The study was conducted in ICU and surgical departments of a multidisciplinary hospital, JSC "Medicina" in Moscow, Russia, from 2014 to 2020. Patient safety culture was assessed using the SOPS Hospital Survey 1.0 (HSPSC), and fall frequency was measured from online staff reports.

Correlation analysis was used to examine associations between fall frequency and safety culture composites, with significance set at p < 0.05.

Results and Discussion: The analysis included fall rate per 1,000 bed days, categorized by injury severity. Significant correlations were found between fall frequency and several safety culture composites: teamwork (-0.826, p=0.022), learning from errors (-0.747, p=0.049), leadership support (-0.760, p=0.047), overall perception of safety (-0.821, p=0.024), incident reporting frequency (0.782, p=0.038), communication openness (-0.846, p=0.017), inter-unit collaboration (-0.867, p=0.012), handoffs and transitions (-0.791, p=0.034), nonpunitive response to errors (0.838, p=0.019), and overall safety culture score (-0.809, p=0.027).

The correlation between teamwork and fall rate may reflect the importance of collaborative efforts in fall prevention. Studies underscore teamwork as essential to patient safety, with training on communication shown to reduce adverse events.

Additionally, the inverse correlation with handoffs emphasizes the role of implementation of different safety instruments such as bedside shift reports in identifying safety risks, with evidence suggesting that this practice reduces fall rates.

Conclusion(s): This study confirms that evaluating safety culture is vital to fall prevention in postoperative period. Higher safety culture levels correlate with fewer falls and injuries, suggesting that safety culture could be an indicator of effective fall prevention measures in healthcare. These findings are valuable for professionals focused on enhancing patient safety.

When tranexamic acid goes intrathecal: understanding the impact and solutions

V. Eckardt¹, L. Freixo¹, P. Freire², L. Lêdo² ¹Unidade Local de Saúde Lisboa Ocidental. Anesthesiology, Lisbon, Portugal, 2Unidade Local de Saúde Lisboa Ocidental, Intensive Care, Lisbon, **Portugal**

Background: An alarming number of cases involving inadvertent intrathecal administration of tranexamic acid (TXA) have been reported. The management of this life-threatening emergency largely relies on evidence from published case reports. Here, we present our experience and discuss preventive strategies to mitigate such errors.

Case report: A 59-year-old man was scheduled for total knee replacement under combined spinal-epidural anesthesia. After administration of the local anesthetic (LA), the patient reported perineal discomfort and developed generalized myoclonic movements. A look-alike error occurred, where the ampoule of TXA was mistaken for LA, leading to the intrathecal administration of TXA. Despite the use of three anticonvulsants, seizures only partially abated, necessitating mechanical ventilation. The surgical procedure was canceled, and the patient was transferred to the neuro-intensive care unit (ICU) with persistent light refractory tonic-clonic thoracic jerks and electrical instability.

Management included sedation with propofol and dexmedetomidine, optimization of anticonvulsant dosages, and the addition of dexamethasone and lacosamide. The patient developed nosocomial pneumonia, which delayed extubation by four days. He was discharged from the ICU after six days. Six months later, he reported persistent shoulder pain but no other complications.

The management approach was primarily supportive, focusing on controlling refractory seizures, arrhythmias, and pneumonia. Dexmedetomidine was used to manage tachycardia, while lacosamide served as an additional anticonvulsant, and dexamethasone was administered to reduce potential edema.

Discussion: Preventing such errors is critical. Double-checking medications should remain a standard practice, while manufacturers should prioritize redesigning ampoules to prevent lookalike errors.

Additionally, TXA should be stored separately from LA. This case adds to the growing body of literature on intrathecal TXA management, highlighting the importance of awareness and preventive measures to avoid this potentially fatal drug error.

Impact of ozempic use on preoperative assessment: role of gastric ultrasound in risk stratification for bronchoaspiration

M.D. Soto Guanotasig¹, A.J. Navarro González¹, C. Farré¹, M. Cazorla¹, H. Contreras¹

¹Althaia - Xarxa Assistencial de Manresa, Anestesiologia, Manresa, Spain

Introduction: Semaglutide (Ozempic), a GLP-1 receptor agonist, slows gastric emptying, increasing the risk of residual gastric content and, consequently, aspiration – a perioperative complication with high mortality. While the ASA recommends stopping semaglutide 7 days before elective surgery, recent evidence questions the adequacy of this interval. Gastric ultrasound emerges as a vital tool to assess gastric content in real-time, enabling personalized risk evaluation for aspiration and improving anesthetic decision-making in high-risk patients.

Case Report: A 64-year-old male with HTA and type 2 diabetes (on Ozempic, last dose 10 days ago) presents with renal colic. Diagnosed with left renal lithiasis requiring double-J-stent placement. Despite fasting for 10 hours, we performed a gastric ultrasound, showing significant gastric content. Because of this, we decided to perform rapid sequence intubation instead of sedation.

Discussion: This case challenges the adequacy of fasting guidelines in semaglutide-treated patients, suggesting a literature revi-

- 1. Risks of Semaglutide Use: Up to 40% of patients on semaglutide exhibit elevated residual gastric contents, significantly increasing aspiration risk even after proper fasting.
- 2. Current Recommendations' Limitations: A 7-day discontinuation may be insufficient for optimal gastric emptying, However, this statement cannot be generalized to all patients, as there is no solid evidence, which may lead to unnecessary delays.
- 3. Role of Gastric Ultrasound: Ultrasound enables identification of gastric content, personalizing aspiration risk stratification in perioperative management. Ultrasound-Based Strategies:
 - 1. Elevated Residual Gastric Content: Delay elective surgery, use prokinetics, or perform rapid sequence intubation in emergencies.
 - 2. No Elevated Residual Gastric Content: Use standard anesthesia without delays.

Conclusion: This case underscores the need for personalized perioperative risk assessment in patients treated with semaglutide or other GLP-1 agonists, due to the increased risk of aspiration even after recommended fasting periods.

Gastric ultrasound stands out as a fundamental tool for guiding critical anesthetic decisions, suggesting that discontinuation of semaglutide for more than 7 days may be necessary in high-risk patients

Promoting its use in the perioperative setting could enhance patient safety and optimize surgical outcomes.

Improving clarity in summoning emergency assistance to theatres at the Royal Bournemouth Hospital: a quality improvement project

A. Yeoman¹, L. Charig¹, R. McCormick¹, T. Longstaffe¹
¹Royal Bournemouth Hospital, Anaesthetics, Bournemouth, United Kingdom

Background: Effective response to emergencies in theatres is critical for patient safety. The importance of having a standard procedure to call for help in emergencies, that is understood by all staff and clearly displayed, has been highlighted by the Royal College Of Anaesthetists in the 7th National Audit Project and their Guidelines for the Provision of Anaesthetic Services^{1,2}. A recent change in the hospital's communication system, including the removal of the 'fast bleep' functionality, created confusion among theatre staff regarding how to summon emergency assistance.

Objective: To improve clarity and knowledge of the escalation policy during emergencies in theatres both in and out of hours at RBH.

Methods: A questionnaire was distributed to all theatre staff to assess their understanding of emergency escalation protocols.

Results: 85 responses were obtained from a range of theatre staff. Results revealed that 60% of staff relied on the obsolete 'fast bleep' system during hours, and only 40% knew to activate a medical emergency call out of hours, with 6% of staff unsure how to summon help.

Discussion: This questionnaire highlighted significant knowledge gaps, with many staff relying on outdated methods or being unsure how to call for help, particularly out-of-hours. Educational posters detailing correct emergency procedures for in-hours and out-of-hours emergencies were developed and prominently displayed in all theatres and anaesthetic rooms.

Two weeks post-intervention, the original questionnaire will be redistributed to assess improvement in staff knowledge. It is hypothesised that the intervention will result in a higher percentage of correct responses, indicating improved understanding of emergency protocols.

Conclusion: This project aims to address a critical gap in emergency response readiness within theatres by standardising communication procedures, thereby reducing response times, minimising cognitive load for staff, and by proxy improving outcomes for patients in emergencies.

Process management in renal transplantation for a case series at Hospital La Fe

C. Docampo¹, F.V. Tomás Rios¹, A. Tur Alonso¹, B. García Rivas¹, A. García Navarro¹, M.P. Argente Navarro¹ ¹Hospital Universitario y Politécnico La Fe, Anestesiología, Valencia, Spain

Background and Goal of Study: Spain is the country in the world where most transplants are performed, with renal transplantation being the most frequent. Process management in anesthesia refers to the organized and systematic approach to managing all phases of anesthetic care. This management involves coordinating resources, personnel, tools and clinical practices in a way that optimizes patient safety, minimizes risks and ensures efficiency in each phase of the anesthetic process.

Materials and Methods: Our study included 70 renal transplant patients over a period of 6 months. After the implementation of the protocol, all patients on the Surgical Waiting List are scheduled for anesthesia consultation, with an average delay of one month

Results and Discussion: Thanks to the organization system developed, the patient no longer comes to the hospital as an emergency patient without preoperative tests. An appointment is made when the patient enters the surgical waiting list, making it possible to carry out an adequate pre-anesthetic assessment, which allows, among other things, the evaluation of the airway and identification of possible risks derived from the underlying pathology, as well as a detailed explanation of the process to the patient.

As regards intraoperative procedures, protocols have been developed on standard monitoring, management of the most frequent complications, such as difficult airway, complications related to vascular access, hemorrhage, hyperkalemia or arrhythmias, and acute postoperative pain, with patients being followed up by the hospital's acute postoperative pain unit.

Conclusion(s): Thanks to a pre-anesthetic assessment, it was possible to foresee a difficult airway in 50% of the intubations. Ninety-three percent of the patients were referred to the PACU and 7% to Resuscitation, with an average stay of 3h in the PACU and 2.5 days in Resuscitation, thus guaranteeing exhaustive surveillance in the immediate postoperative period. All this guarantees patient safety and reduces the incidence of adverse events related to the anesthetic procedure.

52AP01-10

Factors for the occurrence of postoperative respiratory pauses: prospective observational study

T. Hambach¹, L. Ullmann¹, M. Czaplik¹, A. Follmann¹, C. Pereira¹

¹University Hospital RWTH Aachen, Clinic for Anaesthesiology, Aachen, Germany

Background and Goal of Study: Respiratory depression is a significant cause of morbidity and mortality after surgery. Typically, only oxygen saturation (SpO2) is measured to monitor respiration in the post-anaesthesia care unit (PACU). A drop in SpO2 is a late indicator of respiratory depression and can be masked by oxygen

administration (1), potentially causing further dangerous respiratory pauses after transfer to a general ward and discontinuation of oxygen therapy. This study aimed to record respiratory pauses in the post-operative phase and identify risk factors.

Materials and Methods: We observed 80 non-critically ill patients (ASA ≤ 3, median age 61.5 years) after elective surgery under general anaesthesia (40 patients underwent total intravenous anaesthesia (TIVA) with propofol, 40 had balanced anaesthesia with propofol/sevoflurane). Upon arrival in the PACU, thoracic excursions were recorded for 25 minutes using a chest strap. Patient characteristics and medications were extracted from anaesthesia records.

Results and Discussion: In 33 of 80 patients, respiratory pauses lasting more than 10 seconds occurred (17 balanced group, 16 TIVA group). Both the number (p=0.004) and total duration of respiratory pauses (p=0.011) were significantly increased after TIVA (Fig. 1). No significant correlation was found between frequency or duration of respiratory pauses and postoperative opiates, mean MAC of sevoflurane (balanced group) or weight-adjusted propofol rate (TIVA group). The amount of opiates as morphine equivalent per body weight and time also did not correlate significantly with respiratory pauses.

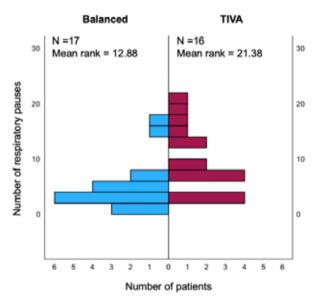

Fig.1: Frequency of respiratory pauses after TIVA and balanced

Conclusions: Relevant respiratory pauses were recorded in about 40% of patients. These often remain undetected and do not necessarily cause a sharp drop in SpO2. Respiratory pauses could not be reliably predicted based on anaesthetic medication. Monitoring respiratory function beyond SpO2 in the PACU may be essential for identifying postoperative respiratory pauses and improving patient safety.

Medication errors, a preventable patient harm cause?

M. Mas¹, A. Garrido Sanchez², J.A. Campoy Moreno¹, I. Merino Santana¹, J. Silva¹, D. Benguria Puebla¹ ¹HU 12 De Octubre, Anaesthesiology, Madrid, Spain, ²HGU Gregorio Marañon, Anaesthesiology, Madrid, Spain

Background: Medication errors are a leading preventable cause of patient harm, often involving incorrect drug selection, dosing, administration routes, or patient identification. These errors affect approximately 6.5 per 100 hospital admissions. Reporting incidents and implementing prevention strategies are critical to minimizing their occurrence.

Case Report: We describe the case of a 55-year-old heart transplant recipient who was approaching extubation, managed without hypnotics or neuromuscular blockers, while receiving norepinephrine, dobutamine, and morphine for pain control.

Just post-extubation, he became unresponsive, desaturated to 60%, and required reintubation, not needing any induction drugs. Suspecting a medication error, naloxone was administered without effect, but sugammadex restored movement and responsiveness.

Further investigation revealed an unlabelled syringe and an empty rocuronium vial, supporting the idea of a medication error. The patient reported being conscious during the event but unable to

Discussion: Medication errors rank among the top causes of patient harm globally. They often occur during prescribing, ordering, or administration, exacerbated by factors like age, polypharmacy, comorbidities, and system inefficiencies. These errors lead to adverse outcomes such as increased hospitalizations, extended stays, elevated costs, and higher mortality rates. Healthcare professionals face legal, ethical, and disciplinary repercussions for errors, emphasizing the need for vigilance and interprofessional collaboration. Strategies such as surgical checklists, medication reconciliation, and verifying verbal orders are effective when supported by a culture of safety and error reporting. Tools like root cause and failure mode effect analysis are pivotal in identifying and addressing systemic weaknesses, ultimately reducing the risk of future errors.

Tariq RA et al. Medication Dispensing Errors and Prevention. [Internet]. StatPearls Publishing; 2024. Available: https://www. ncbi.nlm.nih.gov/books/NBK519065/

Rodziewicz TL et al. Medical Error Reduction and Prevention [Internet]. StatPearls Publishing; 2024 Available: https://www. ncbi.nlm.nih.gov/books/NBK499956/

Learning Points: Safety culture, teamwork, and proactive tools like root cause analysis are key to reducing medication errors. Prevention strategies, including medication reconciliation, checklists, and verification, emphasize a systematic approach to patient safety.

52AP02-2

The mini morbidity and mortality conference. A small conference with a big effect on patient safety and staff well-being

A.L. Leibold¹, V.L.M. Kimmerling¹, J. Rosenberger¹, S. Weigert¹, N. Zech¹ ¹University Hospital Regensburg, Anesthesiology, Regensburg, Germany

Background and Goal of Study: Health care systems currently suffer from staff shortages and financial pressure while facing an increasing workload. This poses a possible threat to patient safety and staff's health.

We want to present a new and simple method of improving safety culture. Our format, the so-called Mini-M&M-Conferences (mMMC), in comparison to traditional M&M-Conferences, poses a low-threshold and an easy to organize alternative. We postulate the mMMCs can contribute to patient safety and to staff well-being.

Materials and Methods: We implemented the mMMC in the department of anesthesiology in a major University Hospital in Germany. They are an abbreviated version of the classic M&M, where residents, specialists and nurses can report an adverse event (AE) they witnessed or were involved in, in a safe and human space.

The hosts use a shortened London-Protocol to analyze the AEs for organizational factors and the reasons that led to the event. The participants can learn about safety culture, occurrence of AE, human factors and simple CRM-Methods. We accompanied the conferences with a feedback questionnaire. We measured the emotional response of participants with the Self-Assessment-Manikin-Model (SAM), a nonverbal pictorial assessment tool.

Results and Discussion: Over a period of 18 months we held 21 mMMCs with 125 participants. We collected and analyzed 89 cases, 76 of them severe or life threatening. Most common cognitive errors were anchoring, omission and commission bias. There was statistically relevant correlation between anchoring and life-threatening AEs.

We proposed and implemented several security-relevant improvements in the department. E.g. we will change labeling of our syringes to the German standard since 38% of reported AEs were medication errors. We developed a SOP concerning documentation of pediatric cases with continued informed consent, after the same incident with the same patient happened twice. So far, six participants reported they avoided an AE because they attended an mMMC.

SAM-Model-Analysis results indicated significant increases (p<0.0001) across all three variables (Pleasure, Arousal and Dominance). These findings suggest a measurable positive impact on participants' emotional and psychological states.

Conclusion(s): We therefor conclude mMMCs improve patient safety, safety culture and staff well-being. Our concept also might have a positive influence on peer support, for which further research is planned.

Patient perspectives of Al-based vital sign prediction on general wards: a qualitative study

A. Weigel¹, M.A. Feufel¹, F. Balzer², N. Hecht³,
D. Fürstenau²⁴, L. Mosch²⁵
¹Technische Universität Berlin, Fachgebiet
Arbeitswissenschaft, Berlin, Germany, ²Charité Universitätsmedizin Berlin, Institut für Medizinische
Informatik, Berlin, Germany, ³Charité - Universitätsmedizin
Berlin, Klinik für Neurochirurgie, Berlin, Germany, ⁴Freie
Universität Berlin, Department Wirtschaftsinformatik, Berlin,
Germany, ⁵Charité - Universitätsmedizin Berlin, Klinik für
Anästhesiologie und Intensivmedizin, Berlin, Germany

Background and Goal of Study: Artificial intelligence (Al)-based prediction of vital sign trends from continuous monitoring data has the potential to improve postoperative patient safety in general wards by enabling early detection of deterioration [1]. This study aimed to gain insights into patients' perspectives on prospective Al-based vital sign prediction, to develop recommendations for future implementation aligned with their needs.

Materials and Methods: Sixteen postoperative patients on a neurosurgical general ward of a German university hospital were included after IRB approval. All patients underwent moderate to severe head or spine surgery and were continuously monitored with a wireless pulse oximeter. Semi-structured interviews were conducted using a guideline developed through literature review, expert focus groups, and test interviews. With an inductive approach, interview transcripts were analyzed by qualitative content analysis in MAXQDA.

Results and Discussion: Patients' acceptance of Al-based vital sign prediction was positively influenced by a perceived increase in quality of care and safety (cf. Figure 1).

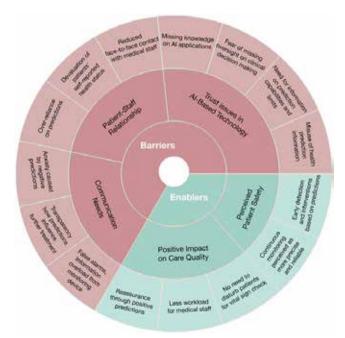

Figure 1: Patient-related barriers and enablers for Al-based vital sign prediction.

Their trust was negatively affected by concerns about the accuracy of predicting individual health conditions, potential misuse of patient data, and the loss of face-to-face interaction with medi-

cal staff. Patients emphasized the need for health professional oversight and accountability in clinical decision-making. Successful implementation of an Al-based vital sign prediction model requires clear communication about prediction consequences. alongside reassurance about data safety and transparency in clinical decision-making.

Our study is limited to neurosurgical patients and a hypothetical vital sign prediction scenario.

Conclusion: The results offer valuable initial insights to engage patients in clinical technology implementation.

52AP02-4

The incidence and risk factors for post-induction hypotension in obese patients

M. Katsin¹, M. Glebov¹, M. Katsin¹, H. Berkenstadt¹, D. Orkin¹

Sheba Medical Center, Anesthesiology, Tel Hashomer, Israel

Background and Goal of Study: Post-induction hypotension (PIH) is a common complication associated with an increased postoperative risk. The incidence and severity of PIH in obese patients varies owing to unique physiological and pharmacokinetic factors. This study aimed to determine the predictors of PIH in obese patients.

Materials and Methods: This single-center retrospective cohort study included the medical records of 4,973 patients with a BMI >30 who underwent non-cardiac surgery between September 1, 2018, and September 1, 2023. PIH was defined as a mean arterial pressure (MAP) <60 mmHg within 10 min of induction. Multivariable logistic regression was used to assess risk factors for PIH.

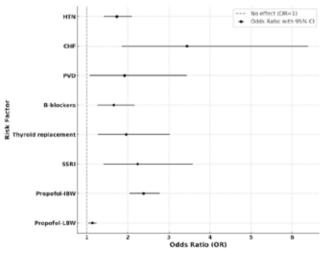

Figure 1. Risk factors of PIH.

Results and Discussion: The study included 3090 (60.3%) patients with class I, 1286 (25.1%) with class II, and 752 (14.6%) with class III obesity, with PIH incidence rates of 25.4%, 25.9%, and 22.5%, respectively. There were no statistically significant differences between obesity classes; therefore, risk factor analysis was performed across all groups combined. The significant predictors of PIH included hypertension (odds ratio [OR] 1.73, p<0.001), congestive heart failure (OR 3.44, p<0.001), and peripheral vascular diseases (OR 1.92, p=0.028). Medication-related risks included the use of beta-blockers (OR 1.66, p<0.001), thyroid-replacement therapy (OR 1.96, p=0.002), and selective serotonin reuptake inhibitors (OR 2.24, p<0.001).

Across anesthesia-related factors, propofol dose for anesthesia induction according to ideal body weight (OR 2.38, p<0.001) and lean body weight (OR 1.14, p=0.003) were significantly associated with PIH.

Propofol dose, mg/kg	no PIH	PIH	P-value
TBW	1.38 (0.53)	1.56 (0.58)	<0.001
IBW	2.07 (1.01)	2.4 (1.21)	<0.001
LBW	2.19 (1.66)	2.61 (1.91)	< 0.001

Table 1. Propofol dose for induction in anesthesia

Conclusion(s): Several perioperative and medication-related factors were significant predictors of PIH in obese patients, emphasizing the need for tailored hemodynamic strategies to minimize PIH risk in this group.

52AP02-5

Surgical productivity change after workstyle reform for doctors in Japan

Y. Nakata¹, Y. Watanabe², A. Ozaki³ ¹Teikyo University Hospital, Department of Anesthesia, Tokyo, Japan, ²Japan External Trade Organization, Institute of Developing Economies, Tokyo, Japan, ³Jyoban Hospital, Department of Surgery, Fukushima, Japan

Background and Goal of Study: Workstyle reform for doctors is a priority of Japanese labor policy, which capped the legal overtime of doctors. New regulations for workstyle reform were applied to all fully licensed physicians in Japan on April 1, 2024 (Ref 1). The long work hours of doctors adversely affect their health and increase the risk of medical errors (Ref 2, 3). The goal of this study is to determine the surgical productivity change before and after the implementation of the workstyle reform using a Malmquist index (MI) model. We hypothesized that the workstyle reform for doctors would significantly increase their surgical total factor productivity by reducing the risk of medical errors and by improving doctors' health.

Materials and Methods: We collected data from the surgical procedures performed at Teikyo University Hospital from April 1 through May 31 in 2023 and in 2024.

MI represents the dynamic productivity change of a decisionmaking unit (DMU) between two time periods; it is an example of comparative statics analysis. MI can be used to divide the productivity change into two components: efficiency change (EC) and technical change (TC). We used a non-radial and non-oriented Malmquist model under variable return-to-scale assumptions. A DMU was defined as a surgeon with the highest academic rank in surgery. The inputs were the number of medical doctors who assisted the surgery, as well as the duration of the surgery from skin incision to closure. The output was the surgical fee. We defined in this study 2023 as "before workstyle reform" and 2024 as "after workstyle reform."

All surgeons in the sample were assigned MI, EC, and TC values; their natural logarithms were calculated to allow interpretation as percent changes. The natural logarithms of MIs, ECs, and TCs for surgeons were compared against 0 using t-tests. P-values < 0.05 were considered statistically significant.

Results and Discussion: We analyzed 1,557 surgical procedures performed by 72 surgeons from April 1 through May 31 in 2023 and in 2024. There was no statistically significant difference from 0 in productivity, efficiency and technical changes (TABLE).

Conclusion(s): No evidence was found to suggest that the workstyle reform for doctors increased their surgical total factor productivity in Japan.

Intraoperative migration and entrapment of an esophageal temperature probe during laparoscopic sleeve gastrectomy: a case report

C. Pereira¹, A. Ferreira², J. Teixeira¹, B. Matias¹, I. Ferreira¹

¹Unidade Local de Saúde da Arrábida, Anesthesiology,
Setúbal, Portugal, ²Unidade Local de Saúde da Arrábida,
General Surgery, Setúbal, Portugal

Background: Laparoscopic sleeve gastrectomy (LSG) is a prevalent bariatric surgery for managing obesity. Despite its efficacy, complications can arise from intraoperative devices such as esophageal thermometers, nasogastric and orogastric tubes. (1) We report a case where the temperature probe migrated intraoperatively into the stomach and was inadvertently stapled across while performing this type of surgery.

Case report: A 45-year-old female, ASA III, with obesity (BMI: 35.54 kg/m2) and undifferentiated connective tissue disease presented for elective LSG. Standard ASA monitoring was used, including the placement of a reusable thermometer in the proximal esophagus through the mouth. During the procedure, this device migrated into the stomach and was inadvertently stapled across the gastric sleeve. This required additional surgical intervention to remove the severed device segments and repair the damage with manual sutures. A methylene blue leak test confirmed the absence of leakage. The patient's postoperative recovery was uneventful, leading to discharge without further complications.

Discussion: The case presented involves the migration and section of an esophageal thermometer during LSG, highlighting a preventable complication. This situation is contrasted with similar cases reported in the literature to underscore the importance of

ensuring the effective communication between surgical and anesthetic teams, proper placement and continuous monitoring of intraoperative devices, to prevent similar complications. (2) Reporting this avoidable incident aims to raise awareness of the appropriate precautions needed when positioning intraoperative devices.

- 2. Guru GK, et al. Temperature probe entrapment during laparoscopic sleeve gastrectomy: a preventable complication. Clin Surg J. 2021;2(4):1–4

Learning points: Complications from intraoperative device migration and entrapment during bariatric surgery, while rare, are significant and preventable.

52AP02-7

Impact of a novel Electronic Health Recordintegrated Ward Round proforma on documentation completeness and clinician experience in the intensive care unit

<u>A. Chang</u>^{1,2}, F. Gallop¹, S. Harrington¹, R. Nabeel², M.A. Shabbir², A. Wong¹

¹King's College Hospital NHS Foundation Trust, Department of Critical Care, London, United Kingdom, ²King's College Hospital NHS Foundation Trust, Department of Haematology, London, United Kingdom

Background and Goal of Study: The ICU ward round (WR) is central to promoting safe and timely decision-making in intensive care units (ICUs). Consensus statements from Royal Colleges emphasise the importance of structured WR documentation. Inconsistencies in documentation present clinical and medicolegal challenges.

Electronic health records (EHRs) enhance documentation efficiency through proformas. We implemented a novel EHR-integrated WR template in a tertiary ICU in the UK, evaluating its impact on WR documentation completeness, and surveying clinician experience.

Materials and Methods: A single-centre audit of ICU WR documentation across three, one-month cycles between January - September 2024 (where cycle 1 is pre-implementation). The proforma utilised automated data population for vitals, organ support, key medications and blood test results and a FLATCH-

UGs checklist. We identified poorly-documented areas (bowel opening, glycaemic control, line assessment) and dynamically designed electronic prompts within our proforma. Parameters analysed were based on international guidelines and validated by senior intensivists.

Surveys of ICU clinicians before and after template implementation evaluated user satisfaction and time efficiency.

Results and Discussion: 86 WR notes were audited (Cycle 1: n=29: Cycle 2: n=30: Cycle 3: n=27). The proforma significantly improved documentation completeness across above interventions; confirmed by a paired t-test, t(5) = 4.31, p<0.0077, mean difference of -45.117 (95% CI; -72.1 to -18.2). Documentation of the following improved:

- Bowel opening (from 55% to 90%).
- Glycaemic control (from 3% to 50%).
- Line review (from 7% to 27%).
- FLATCHUGS checklist completion (from 14% to 100%).

Surveys from ICU clinicians (5-point Lickert) revealed improved satisfaction (2.6 to 4.5, where 5 is most satisfied), ease of use (2.6 to 4.33, where 5 is easiest to use), and reduced documentation time (23.7 to 17.5 minutes per review).

Conclusion: We demonstrate the utility of structured EHR proformas with automated data population, prompts, and checklists, in significantly enhancing completeness of WR documentation. Real-time data entry reduces "cut/paste" practices often seen in EHRs, improving patient safety, medicolegal robustness, and addressing ICU-specific needs e.g. CAM-ICU, FLATCHUGS. Future research should explore the role of EHR-proformas on other important aspects of ICU documentation.

52AP02-8

The role of respiratory rate monitoring: a scoping review of early detection of clinical deterioration and mortality

S.A.S. Aglen¹, H.F. Simonsen², I. Jammer³ ¹University of Bergen, Faculty of Medicine, Bergen, Norway, ²University of Bergen, Faculty of Medicine, Bergennorway, Norway, 3Haukeland University Hospital. Department of Anesthesia and Intensive Care, Bergen, Norway

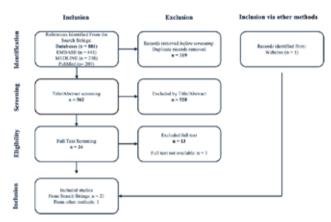

Background and Goal of Study: Respiratory rate (RR) is a key vital sign to assess patient health and predict clinical deterioration. Despite its importance, RR is often underutilised. This scoping review aims to examine the existing evidence on intermittent and continuous RR monitoring in hospitalised adults.

Materials and Methods: A systematic search was conducted using Medline Ovid, EMBASE Ovid, and PubMed. Studies focusing on the impact of RR monitoring compared to either no measurement or less frequent manual measurements in adult patients were included.

The primary outcomes were clinical deterioration and mortality. RR monitoring was compared with early warning systems, organ dysfunction scores, and standard care. Thematic synthesis was used to map the available evidence.

Results and Discussion: Twenty-one studies met the inclusion criteria. Elevated RR, particularly when sustained over time, was associated with severe outcomes such as ICU admission and mortality.

All studies reported a significant correlation between RR and deterioration, but no single vital sign consistently excelled across all patient populations or conditions. The predictive utility of RR improves when combined with other physiological measures. Continuous RR monitoring was found to enhance the detection of tachypnea and respiratory abnormalities compared to intermittent assessments, facilitating earlier identification of deterioration and potentially improving patient outcomes. However, proper implementation is needed to adjust alarm thresholds, minimizing alarm fatigue from false positives.

References:

Sol Agnete Stene Aglen, University of Bergen Henriette Flesland Simonsen, University of Bergen Supervisor: Ib Jammer, Haukeland University Hospital

Conclusion(s): RR monitoring is essential for early detection of clinical deterioration and mortality, particularly when integrated into early warning systems. Continuous RR monitoring proved more effective than intermittent methods in predicting worsening condition. Furthermore, emerging technologies that enable continuous monitoring could contribute to more sustainable healthcare by improving efficiency and patient safety.

52AP02-9

One-year outcome in patients undergoing postponed elective surgery during the COVID-19 pandemic (TRACE II)

A.C. Werger¹, J.S. Breel², B.A. In 'T Veld¹, M.W. Hollmann², W.F. Buhre³, D. de Korte-de Boer⁴ ¹Haaglanden Medical Centre. Department of Anaesthesiology & Pain Medicine, The Hague, Netherlands, ²Amsterdam University Medical Centres, location AMC, Department of Anaesthesiology, Amsterdam, Netherlands, 3University Medical Centre Utrecht (UMCU), Department of Anaesthesiology, Division of Vital Functions, Utrecht, Netherlands, 4Maastricht University Medical Centre+ (MUMC+), Department of Anaesthesiology & Pain Medicine, Maastricht, Netherlands

Background and Goal of Study: The COVID-19 pandemic greatly impacted the capacity of elective surgery, which resulted in the delay of elective surgical procedures. It was hypothesized that this would result in worse outcome. The TRACE II studied the effects of delayed surgery on clinical and patient reported outcome measures until 1 year after surgery.

Materials and Methods: TRACE II, an observational, multi-centre, prospective cohort study among surgical patients with postponed elective surgery due to COVID-19, was performed in seven academic and non-academic hospitals in the Netherlands between September 2020 and February 2023 (1).

Results were compared with the control group of the pre-COVID TRACE study (2).

Clinical outcome measures included one-year mortality, hospital readmission and re-operation. Functional recovery measures included patient reported Global Surgical Recovery (GSR) and Activities of Daily Living (ADL). Pain was measured using the NRS (Numeric Rating Scale) and Quality of Life (QoL) using the EQ-5D-5L. We used Fisher's exact tests to check for differences in distribution of categorical variables between the two cohorts, and Mann-Whitney U tests for comparison of non-normally distributed continuous variables.

Results and Discussion: A total of 1479 patients were included in TRACE II and compared to 2490 control patients from TRACE. One-year mortality was lower in TRACE II compared to TRACE (33 (2.5%) vs 133 (5.4%); p<0.001). There was no significant difference in readmission or re-operation between the cohorts. Patient reported recovery and ADL scores were lower in TRACE II, and median pain scores were higher. The median quality of life using the EQ-5D-5L at 1 year was 0.82 (IQR 0.70-1.0) in TRACE II patients compared to 0.86 (IQR 0.75-1.0) for patients in TRACE; p<0.001. Multivariate regression analyses and subgroup analyses will be presented at Euroanaesthesia 2025.

Conclusion(s): In contrast to our hypothesis, patients undergoing delayed elective surgery in the COVID-19 pandemic had a decreased one-year mortality. No other differences in clinical outcome were observed. These patients did, however, have significantly poorer patient reported outcomes in functional recovery, pain and QoL.

Intraoperative mortality, a five years analysis at a Tertiary University Hospital

<u>I. Leon</u>¹, N. Fábregas¹, M. Agustí², P. De Santos¹

'Hospital Clinic, Anesthesiology and Critical Care,
Barcelona, Spain, ²Hospital Clínic, Anesthesiology,
Barcelona, Spain

Background and Goal of Study: Intraoperative mortality has decreased in recent decades and is now rare, and hard to quantify, 0.5–1 per 100,000 operation (1). Nevertheless it remains a robust indicator of patient safety in the surgical environment. Analyzing each event should be mandatory to review factors that could be modified or optimized to assure that deaths in the operating room are only those unavoidable.

Materials and Methods: Since 2019, the Surgical Area "safety commission" of our Spanish tertiary University Hospital, prospectively review and analyze any reported intraoperative death. The review is done as soon as possible. The surgical and anesthetic charts, patient past and actual pathologies are obtained from the

electronic records. Interviews with the involved health care professionals are done with a debriefing technique. Opportunities for improvement are sought.

Results and Discussion:Intraoperative deaths are scarce, and the majority occur during urgent surgeries. But one scheduled patient per year, at our institution, can have a non-expected severe intraoperative complication. Hemorrhagic shock is the leading ultimate cause.

Year	Scheduled surgery	Intraoperative Death	Urgent surgery	Intraoperative death
2019	17129	2 (0.01%)	6318	8 (0.13%)
2020	14236	0	5834	10 (0.17%)
2021	18637	1 (0.01%)	10161	5 (0.05%)
2022	15032	1 (0.04%)	5052	9 (0.19%)
2023	15748	1 (0.01%)	6116	3 (0.01%)

Multidisciplinary analyzed as sentinel cases, the intraoperative deaths triggers several actions to improve. Some examples are: Increase the accomplishment of the safety surgery check list; to avoid overlapping of vascular surgeries that may require specific instrumentation; improve hand over and the coordinate performance of explorations in polytrauma patients; consider not operating as an option in severely fragile; Standardizing access to aid for any suspect second victim.

Conclusion(s): Safety committees help to detect situations that may have led to non-resolution of avoidable intraoperative complications.

52AP02-11Patient positioning matters

M. Laires¹, D. Cachão¹, M. Miranda² ¹CUF Tejo, Anesthesiology, Lisboa, Portugal, ²CUF Tejo, Anesthesiology, Lisbon, Portugal

Background:

Anesthesiologists have the duty of checking patient positioning during surgery as malpositioning is associated with neural, vascular, joint or bone lesions. There are several reports concerning this situation but this abstract describes an unusual and rare situation.

Case Report:

We describe a 48 yo male obese patient (125 Kg, 170 cm, BMI 42 Kg/m², ASA III) with past history of uncontrolled hypertension and type 2 diabetes, submitted to an elective robotic bariatric surgery (gastric bypass) that lasted 6 hours in extreme reverse Trendelenburg position under general anesthesia. The legs were positioned on a specific support with an intermittent pneumatic compression system and a ligature securing both limbs. The surgery, although laborious, went uneventful. Twelve hours later the patient complained with intense acute pain in both legs.

Examination findings revealed swell and tense legs. After clinical observation it was ruled out DVT and compartment (well leg) syndrome was diagnosed with creatine phosphokinase, myoglobin and serum potassium elevation. The patient was transferred

immediately to OR and fasciotomies were done under general anesthesia. The post-operative period in the ICU was markedly characterized by hemodynamic instability, acute kidney disease. hepatic failure, electrolyte imbalances, hyperactive delirium/encephalopathy, anemia and thrombocytopenia. Fasciotomies were closed 14 days after the first surgery.

During the ICU stay that lasted 30 days, the patient went through continuous hemodiafiltration and even after discharge to the nursery the patient remained under intermittent dialytic replacement therapy with persistent elevated CK myoglobin and creatinine measurements. Thirty-nine days after the elective procedure the patient was discharged.

Discussion:

Measures to decrease the likelihood of developing well-leg syndrome must be implemented: relieving excessive pressure on the lower leg contact area, horizontally repositioning the operating table every 3 hours, decompressing the contact area of the lower leg during the operation and maintaining normal blood pressure during surgery. This case highlights the importance of patient positioning before but mostly during prolonged surgeries as serious consequences can emerge after the anesthetic period (1,2).

Improvement of treatment quality through cognitive aid eGENA in in-situ case simulations

M. Pfefferer¹, V. Truxa¹, P. Dussmann^{1,2}, L. Mülder³, R. Wiczorek³, F. Rückert^{1,2}

¹Ernst von Bergmann Medical Center, Department of Anaesthesia, Intensive Care, OR-Management and Pain Thearapy, Potsdam, Germany, 2Ernst von Bergmann Medical Center, Medical Simulation Center, Potsdam, Germany, 3Health and Medical University Potsdam, Workand Organizational Psychology, Potsdam, Germany

Background: Since the introduction of the electronic memory and decision aid for emergencies in anaesthesia (eGENA) by the DGAI and the BDA 2020 [1], there has been little data available that demonstrates possible changes in treatment through its use. The aim of this study is to further analyze and describe the quality of treatment with and without the support of eGENA in the context of in-situ case simulations in a pilot clinic.

Methods: 28 cases were processed in 14 training groups, each with 4 participants. The order of the two scenarios, the release of eGENA during the scenarios and allocation of participants were randomized. 37 doctors (10 specialists and 27 residents) and 19 nurses (7 ATAs, 7 specialized nurses and 5 nursing staff) took part in the simulations. The scenarios were standardized in terms of case progression. The quality of treatment in the simulations was assessed using a previously defined 20-point evaluation form, which was divided into 10 resuscitation-related and 10 caserelated points. Statistical analysis was performed using paired Ttests or Wilcoxon tests depending on the normal distribution, with a significance level of p < 0.05.

Results and Discussion: Both scenarios showed comparable case complexity (14.86 vs. 15.36 pts. out of 20, n.s.). Physicians used eGENA ten times, nurses twice and twice jointly by both professional groups. The use of eGENA resulted in higher caserelated scores (7.43 vs. 5.14 of 10, p=0.004) and higher total score (16.36 vs. 13.86 of 20. p=0.008). There were no significant differences in CPR-related scores (8.93 vs. 8.71 of 10). The use of eGENA led neither to delays nor to acceleration of resuscitation measures. With eGENA, differential diagnoses were discussed significantly more frequent and extended therapeutic and diagnostic measures were used more often, including optimisation of positioning, consideration of contraindications and extended medication.

Conclusions: In this study, eGENA was primarily used by physicians. The use of eGENA led to comparable resuscitation quality without a time delay. With use of eGENA, better case-related results were achieved. In complex emergency situations, extended diagnostic and therapeutic measures were implemented more frequently, thereby increasing the overall quality of treatment. Further studies with larger case numbers are required to confirm the observed effects.

52AP03-4

Improving safety in local anaesthetic dosing for elective lower limb joint replacements

P. Kamath¹, K. Amin¹, S. Kaial¹ ¹Hillingdon Hospital NHS Foundation Trust. Anaesthetics, London, United Kingdom

Background and Goal of Study: Local anaesthetics(LA) are integral to elective lower limb joint replacements. However,a recent Coroner's report(1)uncovered a fatal case of Local Anaesthetic Systemic Toxicity(LAST) linked to LA dosing miscalculation. This study aims to review current practices in LA dosing and documentation during elective lower limb joint replacement surgeries, identify areas for improvement, and propose strategies to enhance patient safety.

Materials and Methods: After clinical audit registration, a departmental survey was conducted to evaluate practices in LA usage for elective lower limb joint replacements. A retrospective audit also reviewed 87 elective total hip(THR) and knee replacements(TKR) across two hospitals between June-July 2024. The audit collected data on LA volumes used for anaesthetic blocks and surgical infiltration,documentation accuracy,and compliance with safety guidelines. Statistical analysis included descriptive statistics for practice patterns and deviations from safe limits.

Results and Discussion:

- Correct documentation of LA dosing was found in 32% of cases.
- · In one incident, LA dosing exceeded the recommended maximum by 135%, raising concerns about the risk of LAST.
- · 69% of respondents did not use standardised tools for dose calculations, resulting in notable variability in practices.
- · Team communication about LA dosing was inconsistent, with only 54% of respondents reporting that LA doses were always discussed before administration.

Conclusion(s): This study underscores the critical need for clear documentation and standardised practices to prevent LAST. In response, we developed user-friendly LA dosing charts(Figure 1),to calculate the maximum LA dose and determine the safe dose after anaesthetic nerve blocks. Key recommendations inrecommendations.

clude using LA dosing charts, adhering to lean body weight calculations for obese patients⁽²⁾,and implementing mandatory twoperson checks for LA preparation. These findings emphasise the importance of strong communication between anaesthetic and surgical teams to ensure consistent practices,vital for improving safety. Future studies should assess the effectiveness of these

Spinal anesthesia in high risk patients: technical complications and management of an accidentally retained needle fragment

I. López-Puertas Bermejo¹, M.B. Rodríguez Campoó¹, M. Bacigalupo Ribera¹, E. Alarcón Aramburo¹, J. Olarra

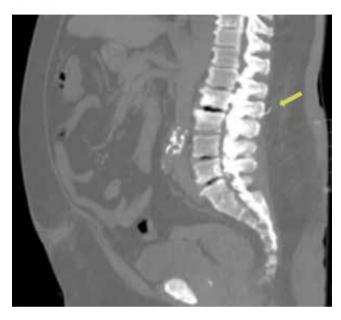

¹Hospital Universitario de Fuenlabrada, Anesthestiology, Fuenlabrada, Spain

Background: Intradural anesthesia is commonly used not only as a first choice type of anesthesia in certain surgical procedures but as an alternative to general anesthesia in those patients whose comorbidities imply a higher risk for certain complications associated with the latter.

Case Report: A 54 years old and 250kg male patient was scheduled for perianal abscess drainage. Considering the higher risk for complications associated with general anesthesia, intradural anesthesia was chosen as the best aproach. During the first attempt, the spinal needle fractured (1), and part of it was retained in the muscular and subcutaneous tissue. It was not until after

the second attempt, which was successful, that the surgery was completed without any further complications. Postoperatively, a lumbar CT scan confirmed the exact needle location, and conservative management was decided by a multidisciplinary consensus (2) with the neurosurgical team.

Discussion: This case highlights the dual role of spinal anesthesia, considered a safer option in certain patients and procedures, but not exempt from risk and complications. It, likewise, emphasizes the importance of technical expertise, and collaborative decission making in managing complications during regional anesthesia.

- 2. Benham M. Spinal needle damage during routine clinical practice. Anaesthesia. septiembre de 1996;51(9):843-5. **Learning points:** Spinal anesthesia is not exempt from complications other than the typical ones such as hypotension, but more technical ones which we have to consider too when assessing a patient.

52AP03-6

Ensuring patient safety during sedoanalgesia for bidirectional endoscopy in a patient with severe ankylosing spondylitis: a case report

C. Genç¹, H. Erzurun², B. Ciftci¹, S. Tulgar¹¹Samsun University, Faculty of Medicine, Department of Anesthesiology and Reanimation, Samsun, Turkey, ²Samsun Educational and Research Hospital, Department of Internal Medicine, Division of Gastroenterology, Samsun, Turkey

Background: Patients with severe ankylosing spondylitis (AS) pose significant challenges in non-operating room anesthesia. Ensuring patient safety can be difficult due to limited mobility, potential airway complications, and comorbidities like osteoporosis.

This case report presents our experience in managing a patient with severe AS undergoing bidirectional endoscopy under procedural sedation, emphasizing critical considerations, including patient positioning and safety.

Case Report: The patient was a 64-year-old male with a history of coronary artery disease, chronic hypertension, anemia, and severe ankylosing spondylitis. The patient was evaluated preoperatively and diagnosed with a difficult airway due to significant spinal stiffness and limited mobility. The indication for bidirectional endoscopy was his elderly age and anemia, aiming to clarify the underlying etiology. Standard ASA and non-invasive end-tidal CO2 monitoring were supplied.

The patient was carefully positioned to minimize strain on his joints, particularly the spine, due to the severe stiffness from ankylosing spondylitis. A total of 2 mg midazolam, 90 mg propofol, and 100 mcg fentanyl were administered for sedation. The team collaborated to tailor the endoscopy and sedation to the patient's needs.

Discussion: Routine patient positioning during endoscopic procedures can be challenging due to spinal rigidity. In this case, an individualized position was chosen to minimize strain on the joints and spine. Airway management was addressed with preoperative assessment and non-invasive monitoring, including end-tidal CO2. Successful outcomes in such patients require careful sedation and positioning, with close collaboration between the procedural and anesthesia teams.

Learning points: Positioning Considerations in Patients with Severe Ankylosing Spondylitis, Individualized Anesthesia Manage-

52AP03-7

Accidental intrathecal administration of 1,500 micrograms of morphine - any side effects?: a case report

R. Albergaria Lima¹, P. Frias¹, C. Fortuna Soares¹, J. Borges¹, A. Machado Borges¹, C. Dias¹ ¹Hospital do Divino Espírito Santo de Ponta Delgada, EPER, Anesthesiology, Ponta Delgada, Portugal

Background: The intrathecal administration of a toxic dose of morphine can lead to life-threatening side effects. This case highlights a critical medication dosing error in which a 10-fold overdose was unexpectedly tolerated without any adverse outcomes, challenging our understanding of opioid pharmacodynamics and underscoring the importance of precise medication management.

Case Report: A 68-year-old male patient, ASA II, was admitted for an elective retropubic radical prostatectomy. Before induction, a subarachnoid injection of morphine was performed for analgesia. The morphine vials at 10 mg/mL required a 100-fold dilution, but only a 10-fold dilution was performed.

Consequently, the anesthesiologist inadvertently administered 1,500 mcg of morphine instead of 150 mcg. This medication dosing error was not recognized immediately, and the procedure continued with a general anesthesia.

The surgery was completed without complications, and the patient remained stable. In the postoperative anesthetic care unit, the team recognized the mistake and implemented appropriate monitoring. The patient was later transferred to a level 2 care unit, where he stayed 24 hours, before being transferred to the ward and then discharged two days later. Remarkably, he did not show respiratory depression, remained pain-free, and normotensive.

Discussion: This case reveals a significant medication dosing error involving a 10-fold morphine overdose administered without adverse outcomes. Research indicates intrathecal morphine overdose can cause severe respiratory depression with delayed onset, particularly above 300 mcg[1].

Despite these risks, the patient remained stable, highlighting individual variability in opioid response. The error was identified postoperatively during team debriefing. This event emphasizes the critical role of closed-loop communication and safety protocols to minimize medication dosing errors. We attribute this error mainly to unclear communication and the absence of a specific intrathecal morphine protocol at the institution.

References:

1. Gehling M, et al. Risks and side-effects of intrathecal morphine combined with spinal anaesthesia: a meta-analysis. Anaesthesia. 2009;64(6):643-651

Learning Points: Medication dosing precision is critical in anesthesia. Individual drug responses vary dramatically. Error recognition, thorough monitoring, and prevention protocols are essential to patient safety and mitigating potential risks during medical procedures.

52AP03-8

The Cappuccini Test: an aspirational standard for anaesthesia supervision

H. Kaur¹, I. Sharieff², S. Seeburuth³, A. Barry²
¹Queen Elizabeth Hospital, Lewisham and Greenwich
Trust, Anaesthetics, London, United Kingdom, ²Queen
Elizabeth Hospital, Anaesthetics, London, United Kingdom,
³Queen Elizabeth Hospital, Clinical Site Management
Team, London, United Kingdom

Background and Goal of Study: Frances Cappuccini, a young mother who passed away following a routine caesarean section, highlighted deficiencies in the supervision of anaesthetists. The Cappuccini Test was developed as a direct response to the coroner's inquest which revealed that the supervision arrangements for the Anaesthetist involved were "undefined and inadequate," with no clear awareness of who was supervising or their availability.

It is a simple, six-question audit tool designed to assess and improve supervision practices in line with the Guidelines for the Provision of Anaesthesia Services (GPAS).

Materials and Methods: The Cappuccini Test was conducted over 6 weeks in 2023 in the anaesthetics department at QEH Woolwich. The test included questions for supervisees regarding identification of their supervisor, the method of contact, and success in reaching them using the method provided by them. Supervisors were also asked to name their supervisees, describe their activities, and confirm availability to attend.

Data from 77 Supervision episodes was collected out of which 90% were on-call activities and 10% theatre lists and analysed descriptively.

Results and Discussion: A total of 77 supervision episodes were recorded. Supervisees demonstrated 99% ability to identify their supervisor, and 90% of supervisors were aware of their supervisee's identity and could describe nature of their work. Successful contact rates were 99%. However, variability was noted across shifts, with gaps in availability during peak hours.

Comparison with a 2020–2021 audit highlighted a marked improvement in supervision practices due to enhanced communication protocols

Conclusion: The Cappuccini Test is a straightforward safety and quality improvement tool, ensuring trainees work in a safe environment with full access to their supervising consultant. It serves as a valuable measure of supervision quality and training standards, representing an aspirational benchmark for enhancing patient safety and care quality in anaesthesia services.

52AP03-9

Operating room fire during carotid endarterectomy: an anesthesia perspective

J. Lin¹, <u>F. Ramos¹</u>, R. Moço¹ ¹Western Lisbon Local Health Unit, Anesthesiology, Lisbon, Portugal

Background: Operating room (OR) fires are extremely dangerous and are considered a "never" event, however very rarely they still are reported. We present a case of an OR fire in a patient during carotid endarterectomy, its management and causes.

Case Report: A 72-year-old female, ASA III, was proposed for right carotid endarterectomy due to recent ischemic stroke. After an uneventful induction of intravenous general anesthesia with orotracheal intubation, the surgical incision with an electrosurgical knife started. Few minutes later, a fire was detected below the surgical drapes, involving the patient's ear, hair, and shoulder. The surgical drapes were immediately removed and the fire was extinguished with abundant saline solution. After replacing the electrosurgical knife with a lower intensity and applying gauze pad to the wounds, the surgery was concluded without further incidents. She was awakened and later evaluated by Plastic Surgery and Otorhinolaryngology, which identified second-degree burns which recovered completely with conservative treatment. A debriefing meeting followed to review the incident and reinforce safety protocols.

Discussion: OR fires occur when the "fire triangle" elements are present:

- Fuel: Surgical drapes, alcohol-based antiseptics and patient hair
- Ignition Source: Electrosurgical devices, lasers, or light sources
- Oxidizer: Oxygen and nitrous oxide

The culprits of the fire in this case were presumably insufficient drying of alcohol-based antiseptics, inadequate protection of hair, and proximity of the electrosurgical knife. surgical field not fully applied. The surgical field may not have been fully applied, increasing exposure to ignition sources. Anesthesia considerations for fire prevention include adequate oxygen and fuel management and ignition control. Immediate actions are critical in managing a surgical fire by extinguishing the flames, halting the use of ignition sources, and protecting the patient.

References: Teresa S. Jones, Ian H. Black, Thomas N. Robinson, Edward L. Jones; OperatingRoomFires. Anesthesiology 2019; 130:492–501

Learning points: Despite being uncommon, OR fires are still a constant threat. Insufficient drying of alcohol-based antiseptics can produce a fire. Vigilance is essential in controlling oxygen levels, managing flammable materials, and mitigating ignition risks.

52AP03-12

Error in medication administration: anectine instead of fentanyl

M. Bacigalupo¹, C. Gil Lapetra¹, I. Lopez-puertas Bermejo¹, M.I. Rodriguez Seguín¹, J. Olarra Nuel¹ ¹Hospital Universitario de Fuenlabrada, Anestesiología y Reanimación, Fuenlabrada, Spain

Background: Drug administration errors occur during the process of prescribing, dispensing or administering medication, and can have a major impact on patient safety. They, unfortunately, occur in 20% of medical administrations1. "To Err is Human: Building a Safer Health System", is a report published in the United States which positioned healthcare-related adverse effects as the seventh cause of death in the country2.

Case Report: A 27 year old male, with no medical history, who undergoes an appendectomy. After he is extubated and the monitoring is removed, he reports pain, so the anesthesiologist requests a vial of fentanyl.

Once administered, the patient seems disoriented and starts experiencing respiratory difficulty. Manual ventilation is needed. No miotic pupils were observed. Anesthesiologist's first thought was a possible error with drug administration, specifically suxamethonium instead of fentanyl, due to their vial's labeling resemblance. Indeed, an empty suxamethonium vial was found on the desk.

Discussion: Strategies like syringe labeling have decreased the incidence of healthcare-related errors. In emergencies, however, there is often no time to double check. In this case some determining factors were: the urgency of the situation, the labeling concealing (i.e. when charging the medication) and the omission of double-checking procedures.

Consequently, it is decided not to carry the succinylcholine vial along with other anesthesic drugs in order to avoid similar situations.

References:

1. Koyama AK, Maddox CS, Li L, et al. Effectiveness of double checking to reduce medication administration errors: a systematic reviewBMJ Quality & Safety 2020;29:595-603. 2. Institute of Medicine (US) Committee on Quality of Health Care in America. To Err is Human: Building a Safer Health System. Kohn LT, Corrigan JM, Donaldson MS, editors. Washington (DC): National Academies Press (US); 2000. PMID: 25077248.

Learning points: Errors related with medication administration are still very prevalent. These errors can reach the patient and can cause an adverse effect, especially in situations of vulnerability, such as in patients exposed to anesthesia.

52AP04-1

Learning from mistakes: an overview of injectable drug error practices in Portugal

C. Bastos Magalhães¹, B. Couto¹, H. Dutra Figueira¹ ¹IPO Porto, Anesthesiology, Porto, Portugal

Background and Goal of Study: Drug labeling errors in anesthesia are estimated to occur in 1-1.25% of cases, with drug swaps accounting for 0.2%.1 The Association of Anaesthetists emphasizes that ensuring the safety of injectable drug preparation is both an individual and institutional responsibility. This survey aims to assess errors observed by anesthesiologists in Portugal and their handling.

Materials and Methods: A national survey was conducted among anesthesiology residents and specialists through the Portuguese Society of Anesthesiology. Participants were emailed a questionnaire asking about their experience with drug errors, types of errors observed, reporting practices, reasons for non-reporting, consequences, and changes made to prevent recurrence. Data were collected over November 2024.

Results and Discussion: From 732 anesthesiologists surveyed, 103 responded (14%). All respondents agreed on the importance of addressing drug errors. Of these, 15 had not witnessed errors, while 68 had observed at least two. Syringe swaps were the most common errors, followed by ampoule swaps and dosage errors. Of the respondents that witnessed errors, 63% reported that all errors were communicated, but formal notification occurred in only 13%. Reasons for non-reporting: undervaluation of errors (38%), the complexity (20%) or absence (19%) of reporting systems, and fear of blame (15%). Only 22 participants stated that all errors were discussed and reflected upon with the involved team, after notification.

While most reported errors had no clinical consequences, three led to cardiopulmonary arrest. Following errors, 88% reported implementing individual changes, such as enhanced daily systematization (48%), syringe preparation standardization (44%), and closed-loop communication (45%). Institutional changes were reported by 67%, including the introduction of color-coded labeling (49%), promotion of error reporting (47%), and the creation of "Look-Alike, Sound-Alike" and "Alert Medicines" lists (31%).

Conclusion(s): Standardized practices in preparing injectable drugs are essential to reduce errors. Encouraging effective error reporting and fostering team discussions can promote institutional learning and improve safety protocols. Overcoming reporting barriers and adopting preventive measures may be the key to enhancing patient safety in anesthesia.

Relationship between depth of neuromuscular block and retroglossal airway area: a prospective clinical investigation

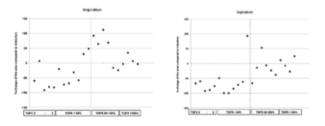

L. Asztalos¹, M. Boktor¹, M. Kukuly¹, D. Sólyom¹, A. Pongrácz¹, B. Fülesdi¹ ¹University of Debrecen, Department of Anesthesiology and Intensive Care, Debrecen, Hungary

Background and Goal of Study: We correlated the depth of neuromuscular block with changes in the retroglossal area induced by neuromuscular blocking agents (NMBAs).

Materials and Methods: The protocol was approved by local and national ethics committees and patients provided written informed consent. To compare the upper airway retroglossal areas before tracheal intubation and after extubation, 2 pharyngoscopic examinations were performed. The first was under propofol anaesthesia and spontaneous breathing using an Ambu® aScope™ (Ambu A/S, Denmark) placed nasally to visualize the vocal cords. Video images were recorded during inhalation and exhalation. Balanced anaesthesia included target-controlled propofol infusion and routine monitoring. A TetraGraph® (Senzime AB, Sweden) electromyograph recorded compound muscle action potentials (cMAPs) of adductor pollicis muscle. A second pharyngoscopy was performed immediately after tracheal extubation. A neuromuscular reversal agent was administered if quantitative post-extubation TOF ratio was <90%. Using the software Image J (Rasband WS, USA), the size of the airway was traced and the program calculated the area of interest.

Results and Discussion: Tracheal extubation based on traditional subjective means resulted in 12 of 21 (57%) patients being considered adequately recovered and received no antagonism. Seven (35%) of these patients had a TOF ratio below 90% at tracheal extubation.

Retroglossal areas in the TOF ratio ≤0.89 patient group (n=11) were lower (20-30% of baseline) both during inspiratory and expiratory phases compared to values measured after induction but before paralysis (baseline). In contrast, retroglossal areas in the TOF ratio ≥0.90 group (n=10) were only marginally lower (>80%) compared to induction values in both respiratory phases. (See Figure)

Conclusion(s): We recorded the retroglossal area at baseline and after administration of NMBA, allowing us to correlate change in glottic area as a function of depth of neuromuscular block. Our

data confirm that after neuromuscular block, a TOF ratio >0.90 is the minimal requirement for normalization of retroglossal area to prevent respiratory compromise.

52AP04-3

Improving safety in handover of surgical critical patients: Standard operating procedure and implementation of an admission checklist for the surgical ICU

E. Ferreres¹, L. Garcia Huete¹, S. Lopez Charcos¹, C. Santolaria Martinez¹, A. Palencia Sanchez¹, J. Saludes Serra¹

¹University Hospital Joan XXIII, Anesthesiology, Tarragona, Spain

Background and Goal of Study: Care transitions, especially from the operating theatre to the surgical ICU, are a crucial patient safety issue, as improper handover can delay treatment and increase patient risk. Following an analysis of a patient safety event, this study aimed to improve safety during the handover of critical patients from the operating theatre to the surgical ICU.

Materials and Methods: A safety incident involved a nurse admitting a patient from the ICU who had an abdominal drain closed. Upon opening it, 800 ml of blood drained, leading to hypotension and tachycardia. The patient had undergone major digestive surgery with three abdominal drains, but no clear instructions on the drains' management were provided on admission or reviewed during staff shift changes. One drain had not been draining during the ICU admission, and after transfer to the ward, the nurse discovered it was closed. The team analysed the incident, identified contributory factors, and developed improvement measures, including:

- 1. A Standard Operating Procedure (SOP) for patient transfers from the operating theatre to the ICU.
- An admission checklist for the ICU, detailing the transition process and ensuring all critical patient information is communicated.
 A multidisciplinary meeting involving key surgical and ICU staff to review the case, improve safety culture, and teach the use of the new SOP and checklist.

Results and Discussion: An audit conducted a year after check-list implementation showed it was used in 72.5% of admissions, with full adherence in 70% of cases. The checklist usage was higher after planned surgeries (82%) compared to emergency surgeries (33%). The main challenge identified was incomplete teams during 72% of the admissions. Despite this, the audit revealed improvements in team satisfaction with the new transfer procedures.

Conclusion(s): Critical incident notifications can enhance patient safety during perioperative transitions. Checklists, tailored to the specific needs of each institution, improve safety and teamwork, helping prevent issues during patient transfers.

52AP04-4

Vasopressor support through peripheral access: A case of hypoperfusion injury resolution

C. Garcia Sobral¹, J. Pacheco¹, A. Paulino¹ ¹Hospital Beatriz Ângelo, Anaesthesia, Lisboa, Portugal

Background: Vasopressor support is typically administered through central venous catheters. However, in specific cases, peripheral venous access may be used when therapy is expected to be of short-term. This practice is common in operating rooms and intensive care units, where it has been shown to be safe. Adverse effects, such as tissue necrosis, are rare, particularly at lower doses (below 0,15 mcg/kg/min) and concentrations (less than 60 mca/ml) (1,2).

Case Report: We present a case of a 69-year-old male who underwent left hepatectomy and resection of a peritoneal lesion due to cholangiocarcinoma. His medical history included Crohn's disease and COPD. Anesthesia was induced with a combined intravenous and thoracic epidural technique. During the intraoperative period, specifically during the liver resection, noradrenaline infusion was required to maintain a mean arterial pressure (MAP) > 65 mmHg, with a maximum dose of 50 mcg/min. Postoperatively, hypoperfusion-related injury was identified in the upper limb, associated with pain. The vasopressor infusion was discontinued, and with close monitoring, the injury showed almost complete recovery within less than a month, without the need for surgical intervention.

Discussion: The use of noradrenaline via peripheral access is recommended, and the doses in accordance with the literature were strictly followed in this case. While rare, adverse effects like tissue necrosis can still occur, even at low doses, highlighting the importance of clear monitoring protocols. Noradrenaline was essential for blood pressure maintenance during liver resection, critical in major abdominal surgeries. Although rare, complications like hypoperfusion-related injury can occur, especially with prolonged or higher-dose use. In this case, the injury was selflimited and resolved with conservative management, emphasizing the need for continuous monitoring and early vasopressor cessation. The recovery without surgical intervention underscores the positive outcome with close follow-up.

2)Stolz, A., et al. (2022). Safety and efficacy of peripheral versus centrally administered vasopressor infusion. Australian Critical Care, 506-511.

Learning points: Close monitoring is essential to identify and manage rare adverse effects, ensuring favorable outcomes.

52AP04-5

Preliminary results of the impact of GLP-1 analog use on gastric emptying following fasting prior to upper digestive endoscopy

A. Farreras Margenat¹, I. Diéguez¹, D.L. Leoz¹, E. Rivas¹, E. Castellanos¹, G. Martínez-Pallí¹

¹Hospital Clinic Barcelona, Department of Anaesthesia, Reanimation and Pain Management, Barcelona, Spain

Background and Goal of Study: Glucagon-like peptide-1 (GLP-1) receptor agonists were initially approved for the treatment of type 2 diabetes mellitus, and their use has since been extended to promote weight loss. One of the main mechanisms of action is a delayed gastric emptying, which may result in an increase in gastric residual volume (GRV), even when patients adhere to fasting guidelines.

This study aimed to quantify GRV in obese patients undergoing upper gastrointestinal endoscopy, following the current fasting guidelines, and to determine whether the use of GLP-1 analogs increases the incidence of complications due to GRV.

Materials and Methods: This is a prospective, observational, single-center study with an estimated sample size of 200 patients. The inclusion criteria were obese patients with a body mass index (BMI) >30 kg/m², who were scheduled for gastroscopy.

Demographic and clinical data were collected, including GLP-1 analog treatment status, fasting hours for liquids and solids, observed gastric content (liquids and solids) using the Barcelona Scale, and any procedural incidents.

Results and Discussion: A total of 18 patients (mean age 58 ± 18 years, BMI 41 ± 7 kg/m2) were included in the preliminary analysis: 5 patients (27%) were receiving GLP-1 analogs, and 13 patients (73%) were not. No significant differences were observed between the two groups regarding age, BMI, ASA classification, fasting hours, or procedure time.

However, patients on GLP-1 analogs had a significantly higher rate of observed GRV (100% vs. 46%; p < 0.05). Despite this, no complications related to the elevated GRV were recorded.

	GLP-1 analogs	No GLP-1 analogs	p-value
	(n=5)	(n=13)	
Sex (Male / Female) n (%)	0(0) /5(100)	2(12) /11(78)	0.015
Age, years	43 ±12	46 ±19	NS
BMI, kg/m²	38±6	41±7	NS
ASA III, n (%)	4(80)	10 (77)	NS
Fasting hours performed:			
Solids, hours	13.4 ±3.7	18.1± 9.3	NS
Liquids, hours	4.4 ±3.3	8 ± 8.5	NS
Presence of RGV n (%)	5 (100)	6 (46)	0.048
Time (min) mean ±SD	18.4±18.8	16.5±11.5	NS

Data expressed as mean±SD and n (%)

Conclusion(s): Preliminary results suggest that the use of GLP-1 analogs in obese patients is associated with an increased rate of GRV, which could potentially raise the risk of complications during anesthesia, such as regurgitation and aspiration. These findings highlight the need to revise fasting guidelines for patients taking GLP-1 analogs to enhance safety and reduce the risk of aspiration.

52AP04-6

Complications following transesophageal echocardiography at a multicenter academic tertiary referral center

C. Zak¹, K. Rehfeldt², M.R. Youssef³, J.J. Morales Behaine⁴, S.A. Buckner Petty⁵, B. Smith³ ¹University of Arizona College of Medicine, College of Medicine, Tucson, United States, ²Mayo Clinic, Anesthesiology and Perioperative Medicine, Rochester, United States, ³Mayo Clinic, Anesthesiology and Perioperative Medicine, Phoenix, United States, ⁴Mayo Clinic, Anesthesiology Department, Rochester, United States, ⁵Mayo Clinic, Quantitative Health Science Research, Phoenix, United States

Background and Goal of Study: Transesophageal Echocardiography (TEE) is a specialized form of cardiac ultrasound associated with rare but serious complications. Previous studies on complications related to TEE are outdated and focused on specific contexts, limiting the generalizability of their findings. Recent research suggests that TEE-related complications may be more common than previously recognized. As TEE becomes more widely used in clinical practice, there is a need to reassess its complications to ensure safe peri-procedural care.

Materials and Methods: A retrospective study of patients who underwent TEE between January 1, 2002, and March 1, 2022, was conducted at our large multicenter academic institution. Echocardiographic and medical records were manually reviewed for procedural complications. Post-procedural complications, consultation notes by gastroenterology, otolaryngology/ear, nose, throat, and/or thoracic surgery, and 30-day all-cause mortality were collected and manually reviewed.

True or potential TEE relat		lications	
distributio	n		
Complication		Overall	
Dysphagia within 24 hours		293 (12.5%)	
Dysphonia within 24 hours		244 (10.4%)	
Larynx or vocal cord injury			
Factors associated to TEE	OR	p value	
related complications			
Age	0.996	0.009	
Race	1.289	0.002	
Male	0.889	0.012	
BMI	0.985	<0.001	
Year of procedure	0.975	<0.001	
Intraoperative TEE cardioversion	0.571	<0.001	
TEE for catheter guidance	0.403	<0.001	
Steroid use within 90 days preop	1.129	0.035	
PPI use within 90 days preop	1.494	<0.01	
History of cerebrovascular	0.794	<0.001	
disease		2	
History of dysphagia	1.123	0.049	
History of esophageal surgery	1.412	<0.01	

Table 1. TEE related complications and associated factors.

Results and Discussion: 89,689 patients underwent 119,288 TEEs. Severe post-procedure complications directly attributable to TEE occurred in less than 0.5% of patients. Common complications included dysphagia (12.5%), dysphonia (10.4%), and larynx

or vocal cord injury (5.1%). The complication rate declined during the study period. Risk factors positively associated with periprocedural complications included age, BMI, gender, year of the procedure, type of TEE, steroids or PPI use within 90 days of procedure, and history of esophageal surgery (p<0.05). TEE-related complications were not significantly associated with an increased 30-day mortality.

Conclusion(s): This study is the largest to date evaluating TEE-related complications and provides more contemporary insights into peri-procedural complications. Serious complications were rare, though minor, self-limited effects occurred more commonly. Multiple risk factors were identified.

Of note, the rate of complications declined during the study period, possibly reflecting increased awareness, education, or procedural skill.

52AP04-8

Cardiac arrest during anesthesia induction for corneal transplantation in a Down syndrome patient

P.O. Barros junior¹, C.S. Goveia², R.S. Quirino², H.P. Castro², R.C.S. Machado², K.H.R. da Costa³ ¹University Of Brasilia, Anesthesiology, Brasilia, Brazil, ²University of Brasilia, Anesthesiology, Brasilia, Brazil, ³university of brasilia, anesthesiology, Brasilia, Brazil

Background: Down syndrome (DS) is associated with ocular conditions requiring surgery and intrinsic autonomic nervous system (ANS) dysfunction, ranging from transient bradycardia and hypotension to severe events such as cardiorespiratory arrest during anesthesia induction, as demonstrated in this case.

Case Report: A 70kg, 22-year-old woman with DS underwent corneal transplantation for keratoconus. Anticipating a difficult airway, diagnostic laryngoscopy was performed under sevoflurane with spontaneous ventilation, confirming a Cormack-Lehane grade 1 view. Induction was achieved with alfentanil (1.5 mg), propofol (30 mg), and succinylcholine (70 mg) for tracheal intubation

Shortly after induction, the patient developed severe hypotension, bradycardia, and asystole. Atropine and ephedrine were administered promptly, and cardiopulmonary resuscitation (CPR) restored spontaneous circulation after one cycle. The procedure proceeded without further complications, and the patient recovered fully in the ICU.

Discussion: DS patients often require general anesthesia for ophthalmic surgeries due to limited cooperation and potential airway challenges. However, DS-related ANS dysfunction complicates perioperative management. Heart rate variability (HRV), a proposed measure of autonomic stability, is not widely used in routine practice. In this case, autonomic imbalance likely contributed to cardiovascular collapse. Sevoflurane, combined with alfentanil, propofol and succinylcholine may have exacerbated parasympathetic dominance, leading to the event. The rapid recovery following CPR supports this hypothesis.

Anesthesiologists must be vigilant when managing DS patients, considering both anatomical and autonomic challenges. Tailored anesthetic strategies and heightened monitoring are critical to minimizing risks. The development of practical HRV tools could enhance risk stratification and guide perioperative management, reducing adverse outcomes in this population.

Learning Points: This case underscores the critical role of autonomic dysfunction in DS patients during anesthesia. Tools like HRV monitoring may improve risk assessment and guide tailored anesthetic plans. Meticulous preparation, vigilance, and awareness are essential to ensuring patient safety.

From chaos to checklist: creating a structured handover from anaesthetist to recovery staff

A. Kurani¹, K. Louly-Nathan¹, N. Gautam¹ ¹West Hertfordshire Teaching Hospitals NHS Trust, Anaesthesia, Watford, United Kingdom

Background and Goal of Study: Effective communication during patient handover between the anaesthetist and recovery staff is critical for patient safety, especially in managing postoperative care for vulnerable patients such as those with critical medications, as per RCoA guidelines [1].

The introduction of the WHO surgical safety checklist in 2009, promoted communication during surgery between team members and demonstrated a reduction in surgical mortality [2].

This study aimed to standardise the handover process between anaesthetists and recovery personnel and improve handover of critical information.

Materials and Methods: A service evaluation was registered with the local audit department and ethical approval was waived. A novel handover tool was created, modifying a universal handover tool used in the UK. In the first cycle, the handover of key parameters was assessed. The novel handover checklist was placed in each recovery bay and a re-audit of key parameters was completed.

Analysis compared pre and post intervention compliance rates across several categories using percentage change as a measure of improvement.

Results and Discussion: Post-intervention results showed significant improvements in several key areas. Compliance with handing over allergy status increased from 80% to 94%, whether antibiotics need to be continued from 53% to 94%, and reporting significant anaesthetic events from 23% to 100%.

Other improvements included need for postoperative fluids (+41%), target oxygen saturation (+65%), and requirement of special investigations (blood gas/haemacue/blood glucose) (+77%).

Despite these gains, 75% of cases still lacked a written postoperative care plan, highlighting an area for further improvement.

Conclusion: The introduction of a structured handover tool has led to marked improvements in communication between the anaesthetic and recovery staff and has led to enhanced patient safety.

However, challenges remain in ensuring written postoperative care plans. Future steps include expanding the handover format our satellite surgery site, re-auditing the tool to achieve 100% compliance in all areas.

Risk factors for failure to rescue in major non-cardiac non-neurological surgery: analysis of 48,720 patients from the UK **Peri-operative Quality Improvement Programme** (PQIP)

A. Putzu^{1,2}, R. Moonesinghe¹

¹University College London, Centre for Perioperative Medicine, Research Department for Targeted Intervention, London, United Kingdom, 2Geneva University Hospitals, Department of Anesthesiology, Pharmacology, Intensive Care and Emergency Medicine, Geneva, Switzerland

Background and Goal of Study: Failure to rescue (FTR) is defined as in-hospital death following a postoperative complication and is an important perioperative quality measure.

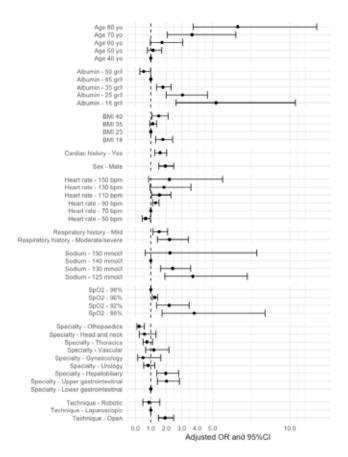

This study evaluated rates and risk factors for FTR in a large multicenter cohort from the UK's publicly funded national health service (NHS).

Materials and Methods: Data were analyzed from the UK Perioperative Quality Improvement Programme (PQIP), which includes prospective, patient-level data for adults undergoing elective major non-cardiac, non-neurological surgery in England and Wales. Postoperative complications were categorized using the Clavien-Dindo (CD) classification. FTR was defined as inpatient death following a postoperative complications of CD grade II or higher. Multivariate logistic regression was used to identify preoperative variables associated with FTR. Missing predictor data were addressed through multiple imputation. Ethical approval for PQIP was obtained from the UK Health Research Authority, and informed consent obtained from all participants.

Results and Discussion: Data from a total of 48.270 patients who underwent surgery in 173 hospitals between December 2016 and October 2023 were included in the analysis. Postoperative complications occurred in 23.8% of patients, with 360 in-hospital deaths (0.7%), resulting in an overall FTR rate of 3.1%. The median hospital stay was 6 days (interguartile range [IQR]: 3-9), increasing to 11 days (IQR: 7-18) among patients who developed complications.

Eleven variables were included in the final model (fig 1) and are presented as adjusted odds ratios (OR) with 95% confidence intervals (CI). These included fixed variables such as age and sex, body mass index, physiological variables, surgical factors and long-term conditions. A sensitivity analysis found no impact of the hospital site on FTR rates.

Conclusion(s): Postoperative complications are common, but FTR is uncommon after major non-cardiac surgery in the UK's NHS. Several preoperative factors were identified as being associated with FTR and could help identify higher risk patients, who could potentially benefit from enhanced postoperative monitoring and care.

52AP04-11 Glycaemia 99 mmol/I - case report

K. Nekvindová^{1,2,3}, T. Gabrhelík^{1,2,4}, J. Hůsková² ¹Tomas Bata Hospital, Anesthesiology and Intensive Care, Zlín, Czech Republic, 2Tomas Bata University in Zlín, Faculty of Humanities, Zlín, Czech Republic, 3Palacký University Olomouc, Department of Public Health, Olomouc, Czech Republic, 4Olomouc University Hospital, Anesthesiology and Intensive Care, Olomouc, Czech Republic

Background: Diabetic ketoacidosis and a hyperosmolar state are the most serious and life-threatening emergencies in individuals with diabetes and can occur in individuals with both type 1 and 2 diabetes mellitus [1,2].

Case report: A 26-year-old noncompliant male with type I diabetes mellitus was admitted to the emergency department after resuscitation (ROSC 28 minutes). He had been intubated in the field; his blood glucose level was 99 mmol/l, and his osmolality was 358 mmol/kg. The first correction of his blood glucose level resulted in a decrease to 64 mmol/l, but the mistake was immediately recognized.

Within the next 2 days, his hyperglycaemia was corrected by an approximately 3 mmol/I decrease per hour, and post-ROSC care was performed. The patient's family was informed about the uncertain prognosis.

On the third day, divergence of the eyes was detected, and head CT was repeated with no pathology identified. EEG monitoring revealed nonconvulsive status epilepticus without a reaction to standard treatment, necessitating treatment with thiopentone coma. The patient developed septic shock and underwent tracheostomy. On the 17th day, the patient woke up, with no neurological injury: on the 22nd day, decannulation was performed. On the 32nd day, the patient was discharged home.

Discussion: In this report, we wanted to demonstrate the mistake of quickly correcting hyperglycaemia. A correction of 26 mmol/l per hour could result in cerebral oedema, which could easily harm the patient or even become fatal. The incident was investigated within the hospital, and a patient safety protocol was implement-

Negative incidents and mistakes are rarely reported in our hospital. Changes in hospital culture and a nonjudgmental and nonpunitive environment can help increase the incidence of reporting.

Learning points: Establishing an effective safety culture and incident reporting system is crucial for good patient outcomes. In the USA, medical errors are the third leading cause of death [3].

52AP04-12

Acute pulmonary edema secondary to operative hysteroscopic intravascular absorption syndrome and/or anaphylaxis in a latex-allergic woman: case report

L. Viladrich¹, J. Azcarate Arrieta¹, P. Tarin¹, C. Garcia¹, B. Martinez¹, I. Pérez¹ ¹Hospital General de Granollers, Anesthesiology Department, Granollers, Spain

Background: Operative hysteroscopic intravascular absorption (OHIA) syndrome with an incidence of 0.1-6%, has fatal consequences. Monitoring the irrigation fluid balance is essential to rapidly detect signs of excessive fluid absorption.

We present the case of a patient who developed angioedema, initially oriented as anaphylaxis, and acute pulmonary edema (APE), which required admission to the ICU.

Case Report: A 43-year-old woman, allergic to latex, ASA 1, was scheduled for a hysteroscopic myomectomy. The procedure was carried out following a latex allergy protocol under sedation, maintaining spontaneous ventilation.

At minute 105, the patient presented desaturation, facial edema and chemosis. Anaphylaxis was suspected and appropriate treatment was administered. Orotracheal intubation was performed. Irrigation fluid balance was positive (+ 6L of 0.9% saline) and bilateral wet crackles were ausculted prompting the initiation of diuretic treatment and urine output monitoring.

Chest X-ray was consistent with APE. Bedside echocardiography revealed bilateral B-lines, no pleural effusion and good biventricular function. Arterial blood gas yielded mixed hyperchloremic acidosis. Patient was transferred to ICU, improved progressively and successfully extubated after 24 hours.

Discussion: OHIA is a rare complication with high morbimortality, preventable through proper management of key factors, such as irrigation fluid balance, which is crucial.

The initial diagnosis in this case was anaphylaxis, likely due to its more common recognition as an emergent situation. However, it underscores two key points: the need to consider OHIA syndrome, as well as the prioritization of patient stability over diagnosis in high-risk conditions.

References:

M.-T. Wang et al. Operative hysteroscopy intravascular absorption syndrome is more than just the gynecological transurethral resection of the prostate syndrome: A case series and literature review. Taiwanese Journal of Obstetrics & Gynecology (2020); 59 748-753.

Learning points: Proper management of fluid balance is crucial to prevent OHIA. The use of automated fluid management systems is recommended, and intravascular absorption should be limited based on the solution tonicity. It is essential to remain mindful that multiple severe events may coexist, each requiring immediate intervention.

Sustainability

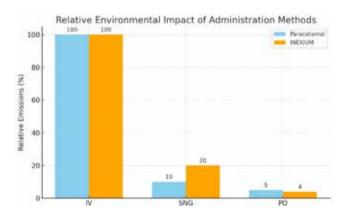

53AP01-1

Environmental impact of paracetamol and pantoprazole administration routes in intensive care: intravenous vs. enteral

C. Pernod¹, E. D'Aranda¹, P.-Y. Arnaud² ¹Military Teaching Hospital of Toulon, Intensive Care Unit. Toulon, France, 2Sainte Musse Hospital, Intensive Care Unit, Toulon, France

Background and Goal of Study: The healthcare sector is a significant contributor to greenhouse gas (GHG) emissions and environmental pollution. Medication use, particularly in decarbonized energy settings, constitutes a substantial portion of the healthcare sector's carbon footprint (1-2).

This study evaluates the environmental impacts of intravenous (IV), nasogastric (SNG), and per os (PO) administration of paracetamol and pantoprazole in intensive care units.

Materials and Methods: A Life Cycle Assessment (LCA) was conducted to compare the environmental impacts of administering standard doses of paracetamol (1000 mg) and pantoprazole (40 mg) through IV, SNG, and PO routes. Key outcomes included carbon footprint (kg CO₂ eq), toxicity (environmental and human), resource use, and water consumption. The analysis followed ISO 14044 guidelines and used the ReCiPe 2016 Midpoint (H) methodology.

Results and Discussion: The environmental impact of IV administration was significantly higher than enteral methods across all indicators. For paracetamol, the carbon footprint of IV administration was 10 times greater than SNG and 20 times higher than PO. For pantoprazole, IV administration resulted in 5 times the emissions of SNG and 25 times that of PO. PO administration consistently showed the lowest environmental impact. These findings are illustrated in the graph below, highlighting the relative emissions of the three routes.

Conclusion(s): Transitioning from IV to enteral administration, particularly PO, can substantially reduce the environmental footprint of intensive care practices. These findings support the systematic prioritization of enteral routes when clinically appropriate, aligning patient care with sustainability goals.

The environmental impact of coronary artery bypass grafting surgery and postoperative intensive care unit admission: a state-of-the-science life cycle assessment

E. van Bree^{1,2}, T. Stobernack¹, E.J. Kooistra¹, W. Li³,

F. McGain^{4,5}, H.R.W. Touw¹

¹Radboudumc, Department of Intensive Care Medicine, Nijmegen, Netherlands, 2Maastricht University, Department of Surgery, Maastricht, Netherlands, ³Radboudumc, Department of Cardiothoracic Surgery. Nijmegen, Netherlands, 4Western Health, Departments of Anaesthesia and Intensive Care, Melbourne, Australia, ⁵University of Melbourne, Department of Critical Care, Melbourne, Australia

Background: Healthcare faces an urgent challenge to reduce its negative environmental impact to contribute to the mitigation of human-induced environmental change. The operating room (OR) and intensive care unit (ICU) are known to be resource-intensive, yet understanding regarding the key focus areas for impact mitigation in individual patient trajectories is still limited. Therefore, we chose to focus on a common major surgery requiring postoperative ICU-admission: coronary artery bypass grafting (CABG). Goal of Study: To identify key areas for environmental impact mitigation.

Materials and Methods: We performed a state-of-the-science life cycle assessment following international ISO-14040/44 standards to quantify the environmental impacts per patient, from OR-admission to ICU-discharge. We investigated all products, processes, and services required for care delivery based on a sample of 12 patients in a Dutch academic hospital. Environmental impacts were quantified from cradle to grave using ReCiPe 2016 (H) methodology and studied using contribution, uncertainty, and sensitivity analysis. We reported medians and interquartile

Results and Discussion: A single patient trajectory primarily contributed to global warming, amounting to 314 [296-333] kgCO₂eq for the OR and 77 [68-93] kgCO₂eq for the ICU. Further notable environmental impacts were fine particulate matter, (non-) carcinogenic toxicity, land use, and terrestrial acidification. Highquality plastic disposables, energy use related to air handling, and employee commute contributed most of the OR's environmental impact. Anaesthesia's impact was relatively low due to predominant use of total intravenous anaesthesia - compared to use of inhalational anaesthesia, which are potent greenhouse gases. Key areas for environmental impact in the ICU are indicated in Figure 1.

Conclusion: Most impact mitigation could be achieved by avoiding/reducing disposable product use, optimising OR air handling systems, switching to renewable energy, and encouraging lowemission employee commute.

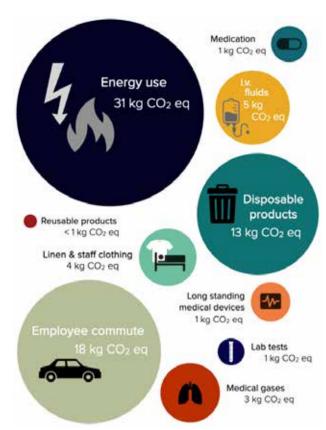

Figure 1. Overview of the carbon footprint of a CABG postoperative ICU-admission

53AP01-3 Climate impact of BIS sensor

J. Braem¹, A. Kalmar²

¹University Ghent, Medicine, Ghent, Belgium, ²AZ Sint Jan, Anaesthesia and Critical Care, Brugge, Belgium

Background and Goal of Study: Environmental concerns, especially with sevoflurane, support using Total Intravenous Anesthesia (TIVA) over inhalation methods¹. Volatile anesthetics allow for continuous monitoring of end-tidal concentrations, providing a reliable indication of anesthetic depth. TIVA, on the other hand, lacks an equivalent to end-tidal values, which can increase the risk of inadequate anesthesia depth due to various factors².

Target-Controlled Infusion (TCI) helps but doesn't fully address this. Guidelines recommend Bispectral Index (BIS) monitoring for real-time depth feedback. Despite TIVA's lower environmental impact, BIS's single-use electrodes raise concerns, requiring a comparison with sevoflurane's carbon footprint.

Materials and Methods: We calculated that the production and disposal of a single BIS electrode (from a box of 25 electrodes) emit approximately 79 grams of CO₂ equivalent emissions (CO₂EE) (Table 1).3

Results and Discussion: In contrast, even in minimal-flow settings, sevoflurane releases approximately 13 kilograms of CO2 equivalent emissions (CO₂EE) per hour, whereas TIVA anesthesia produces at most 1 kilogram of CO₂EE per hour.¹ The environmental impact of a BIS electrode is therefore minimal compared to sevoflurane, underscoring the environmental benefits of TIVA with BIS monitoring.

	weight (gr)	gr CO ₂ E			
	weight (gr)	production	incineration	total	
Pouch (laminated paper)	9,29	8,54	16,72	25,26	
release liner (LDPE)	3,59	9,29	11,28	20,57	
BIS sensor (mixed plastic)	3,42	10,61	10,75	21,36	
cardboard box (1/25)	3,70	2,97	6,67	9,63	
paper leaflet (1/25)	0,77	0,70	1,39	2,09	
sum	20,77	32,10	46,80	78,91	

Table 1: CO₂ equivalent emissions of a single BIS electrode

Conclusion(s): While sevoflurane offers simplicity in titration, its substantial environmental footprint remains a concern. TIVA with BIS monitoring not only addresses ecological considerations but also enhances clinical outcomes by ensuring precise anaesthesia

These findings underscore that ecological responsibility can be harmoniously aligned with clinical efficacy and patient safety in anaesthesia decision-making. Over a 20-year time horizon, only 1 ml sevoflurane has cradle-to-grave CO2EE of 2294 grams, which is as much as the CO2EE of 29 BIS sensors.

The impact of postoperative fasting on the length of hospital stay and healthcare sustainability: a meta-analysis

A.M. Camilleri Podesta'1, M.A. Zerafa Simler1, J. Elmawieh2, A. Nagrebetsky³, M. Dias Vaz⁴, F. Bilotta⁵, ESAIC Task Force on Perioperative Fasting in Adults ¹Mater Dei Hospital, Department of Anaesthesia, Intensive Care, and Pain Medicine, Msida, Malta, 2Gustave Roussy Cancer Campus, Department of Anaesthesia, Villejuif, France, 3Massachusetts General Hospital, Harvard Medical School, Anaesthesia and Intensive Care, Boston. United States, 4Unidade Local de Saúde de Gaia e Espinho, Department of Anaesthesiology, V.N. Gaia, Portugal, ⁵Policlinico Umberto I Hospital, La Sapienza University of Rome, Department of Anaesthesiology and Critical Care, Rome, Italy

Background and Goal of Study: International guidelines on the resumption of postoperative intake of liquids and solids remain scarce. Surgical patients are subjected to unnecessarily prolonged postoperative fasting times, resulting in increased postoperative morbidity. Reduced length of postoperative fasting has been shown to enhance postoperative recovery, improve rehabilitation, and alleviate the psychological burden of major surgery in such patients.

These benefits may result in decreased length of hospital stay. which in turn may benefit healthcare sustainability. Given these potential benefits, this meta-analysis aimed to quantitatively explore the relationship between the duration of postoperative fasting duration and length of hospital stay.

Materials and Methods: This is a meta-analysis, carried out as an adjunct of a literature review of clinical evidence by the ESAIC Task Force on Perioperative Fasting in Adults.

A systematic literature search was conducted between 1st January 2010 to 6th January 2023. Bibliographic databases were used, including MEDLINE (OVID), Enbase (OVID), CINAHL, Web of Science, the Cochrane Database of Systematic Reviews (CDSR) and the Cochrane Central Register of Controlled Trials (CENTRAL). Eligible manuscripts were original studies published in English between 1st January 2010 and 6th January 2023.

Results and Discussion: The results indicated a significant decrease in the length of hospital stay in all the stages of data analysis (p < 0.05). A mean difference of 0.9 days for patients with earlier postoperative intake of liquids (p < 0.05).

Conclusion(s): Shorter postoperative fasting times reduce the length of hospital stay, resulting in improved patient outcomes and enhanced healthcare sustainability.

53AP01-5 ECO-BQ Project: introduction to waste segregation in the surgical environment

C. Mestre Iniesta¹, L. Ricol¹, N. Alegret¹, L. Blasco¹, Á. Hernández Quintanilla¹

¹Consorsi Sanitari Parc Tauli, Anesthesiology and Intensive Care, Sabadell, Spain

Background and Goal of Study: The growing concern about the environmental impact of our activities has led to an increasing number of studies highlighting the importance of recycling in the surgical field. For this reason, an initiative to introduce waste segregation was launched at our center in 2020.

Hypothesis: The implementation of a waste segregation program in total knee prosthesis surgeries reduces the amount of health-care waste.

Objectives:

- To assess the amount of healthcare waste generated in total knee prosthesis surgeries before and after implementing segregation measures.
- To evaluate the proportion of recycled plastic and paper/cardboard in total knee prosthesis surgeries.

Materials and Methods: This study is a non-randomized, non-double-blind controlled clinical trial involving 20 cases of non-infectious total knee prosthesis replacements collected between October 2022 and March 2023.

Initially, non-hazardous healthcare waste (Groups I and II, general waste) and hazardous healthcare waste (Groups III and IV, sharps and biosanitary) generated per surgical procedure were measured by weight (kg) and volume (L). The same variables were then measured after segregating non-hazardous waste into paper/cardboard and plastic.

The primary variables were the weight and volume of healthcare waste generated during each procedure. Data collection was conducted using a data collection sheet, followed by the creation of a database for subsequent descriptive analysis using the Student's t-test.

	NO	CEODEOATION
	NO segregation (n=10)	SEGREGATION (n=10)
Total number of bags	7 (4-7)	6 (5-8)
Total number of general waste bags	5 (4-7)	2 (1-3)
Weight of general waste (kg)	11 (9.77-20)	5.19 (1.58-6.48)
Weight of paper (kg)	0	3.16 (2.42-3.70)
Weight of plastic (kg)	0	2.44 (1.50-3.40)

Results and Discussion: The median of the obtained results is presented. The duration of the surgeries was similar in both groups (110–120 minutes), as was the weight of sharps waste (0.02 kg).

Conclusion(s): Waste segregation in the surgical setting is an effective measure, as it reduces the amount of non-recyclable waste by more than half. Non-biosanitary paper and plastic constitute the main categories where this action can be implemented.

53AP01-6

Turning down the fans: how to save money and reduce CO₂ emissions in operating theatres

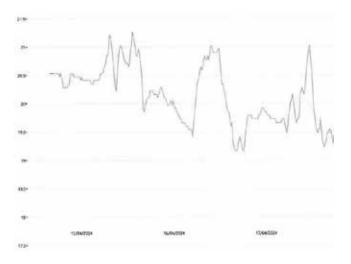

<u>G. Chivers</u>¹, D. Lake¹
¹Darent Valley Hospital, Anaesthetics Department, Dartford, United Kingdom

Background and Goal of Study: Operating theatres' ventilation require a minimum of 22 air changes per hour when in use¹. Most modern theatres, including at our hospital, have a set back function which is a control strategy that reduces air velocity to a minimum standard, well below the operationally required changes per hour. This set back function has not been utilised at our hospital since the COVID pandemic due to rule changes which have since been revoked. Concerns had been raised that using this set back function again would reduce theatre temperatures below that necessary of 18°C¹.

Our goal was to show that setting the ventilation back overnight did not significantly impact theatre temperature and that by implementing it, both environmental and financial gains could be made.

Materials and Methods: Over two consecutive nights a randomly chosen operating theatre's ventilation was set back between the hours of 23.00 and 08.00 and automatic temperature logs were analysed. Estimates of the reduction in tonnes of CO₂ equivalents [tCO₂e] and cost savings were calculated using the known 70% reduction in fan power during set back and the institution's power tariff.

Results and Discussion: Operating theatre temperature never fell below 19°C as shown in the graph.

A conservative estimate of $12.24 \text{tCO}_2\text{e}$ per annum were saved. The energy savings were estimated at 59,136kWh per annum giving a cost saving of £14,606 per annum.

This does not take into account savings achieved from reduced ventilation maintenance, longer filter life and increased longevity of the air handling unit all resulting from setting back of the ventilation system.

These calculations involved our hospital's 8 main operating theatres. There are a further 11 theatres across our trust which were not included in this study but could also be set back.

Conclusion(s): Utilising a ventilation set back system out of hours does allow safe operating temperatures to remain and has significant environmental and cost saving benefits.

53AP01-7

Towards a more sustainable operating theater: perspectives of Belgian surgeons, anesthesiologists, nurses, and other operating theater professionals

E. De Vos¹, W. Swinnen², C. Bellens³, D. Verhelst³, B. Crombez⁴, H. Peleman⁵ ¹University of Ghent, Anesthesiology and Perioperative Medicine, Ghent, Belgium, ²AZ Sint-Blasius, Anesthesiology and Perioperative Medicine, Dendermonde, Belgium, 3AZ Sint-Blasius, Operation Room, Dendermonde, Belgium, ⁴AZ Sint-Blasius, Quality and Process Optimisation. Dendermonde, Belgium, 5Belgian Federal Public Service Health, Quality of Care and Patient Safety, Brussels, Belgium

Background and Goal of Study: Hospitals generate significant amounts of waste, with operating rooms (ORs) being major contributors to pollution and carbon emissions. This study investigated the willingness and barriers of OR professionals in Belgium to act more sustainably, focusing on waste segregation and recycling within ORs.

Materials and Methods: We conducted a cross-sectional study using an online questionnaire targeting professionals in Belgian ORs, including anesthesiologists, surgeons, nurses, and other operating theater staff. The questionnaire was distributed in three languages (Dutch, French, and English) and included closed questions using Likert scales and multiple-choice questions. Statistical analysis was performed using Pearson's chi-squared and Fisher's exact tests for group comparisons.

Results and Discussion: Of the 673 participants, nurses formed the largest group. More than 60% had extensive experience (>10 years in OR). The vast majority segregated waste at home, but much less waste was segregated in ORs, despite high willingness. Unlike other waste categories, hazardous medical waste is universally segregated. Papers and plastics are often treated as nonhazardous waste.

The main perceived barriers are proper waste facilities and time and space constraints, indicating that effective implementation is hampered by structural deficiencies.

A sub-study showed most anesthesiologists used sevoflurane with low or very low fresh gas flow, contributing to lower CO2 emissions. Potent greenhouse gases like N2O and desflurane are infrequently used.

Conclusion(s): The study shows a gap between Belgian OR professionals' willingness to act sustainably and their actual implementation. Improving infrastructure and providing training and information are essential steps in promoting sustainable waste management within hospitals. These changes can lead to a more sustainable health care environment.

Figure.

53AP01-8

Safety of preanesthetic assessment by teleconsultation in digestive endoscopy procedures for patients ≤ 65 years: prospective qualitative study

M. Zouari1, T. Tuna1, C. Boudart1 ¹Hôpital Universitaire de Bruxelles (H.U.B) - Erasme, Anesthesiology, Intensive Care, Perioperative Medicine, and Algology, Anderlecht, Belgium

Background and Goal of Study: The transition to remote preanesthetic consultations was accelerated by the COVID-19 pandemic, raising questions about its safety. The department of Anesthesiology. Intensive Care. Perioperative Medicine, and Algology at Brussels' University Hospital - Erasmus adopted telephone consultations for young, healthy patients scheduled for minor procedures.

This study was conducted in the hospital's One-Day Clinic and aimed to evaluate the safety of this consultation method for gastrointestinal tract endoscopies. Additional assessed aspects included patient satisfaction, compliance with the Belgian Health Care Knowledge Centre (KCE) guidelines for preoperative exams, time spent on consultations, and the carbon footprint.

Materials and Methods: This study primarily aimed to evaluate the safety of the recently implemented preanesthetic teleconsultation compared to the in-person consultation conducted until 2023. A risk assessment questionnaire completed by the anesthesiologist was used for this purpose. Patient satisfaction was assessed through questionnaires based on the Likert scale, and the alignment of prescribed preoperative tests with the KCE guidelines was also evaluated.

Furthermore, the total time dedicated to the consultation and the associated carbon footprint were analyzed. The carbon footprint was calculated by multiplying the distance between the patients' residential addresses and the hospital by a ratio of 104.6 gCO₂/km, as established by the European Environment Agency (EEA).

Results and Discussion: Teleconsultation appears to be safe. Both groups expressed satisfaction with their consultation approach. However, patients who underwent a traditional in-person consultation were less receptive to teleconsultation (p = 0.001). Compliance with the KCE guidelines was higher in the teleconsultation group. Patients who attended in person spent more time on their consultation and generated a higher carbon footprint.

Conclusion(s): Teleconsultation is a safe method for pre-anesthetic evaluation in scheduled endoscopies at the One-Day Clinic of Erasmus Hospital. It ensures patient satisfaction, reduces unnecessary preoperative tests, and optimizes both time and the carbon footprint.

Acknowledgements: Professor Céline Boudart, Professor Turgay Tuna and the entire team of the One-Day Clinic at Brussels' University Hospital - Erasmus are gratefully acknowledged for their invaluable contributions to the success of this study.

53AP01-9 Sustainability in operating rooms

A. Nagarajan Thirumagal¹, F. Menezes¹, E. Divinney¹
¹Luton and Dunstable University Hospital (Bedfordshire NHS Trust), Anaesthetics and Intensive Care, Luton, United Kingdom

Background and Goal of Study: The biggest global health threat of the century arises from the accumulation of 'greenhouse' gases. H The healthcare sector is one of the biggest contributors of greenhouse gas emissions, with the NHS accounting for 4.6% of the UK's total carbon footprint. Operating theatres have a disproportionate environmental impact because of energy-intensive processes, consumption of resources, use of volatile anaesthetics and production of waste. They tend to produce approximately 50–70% of the total hospital waste. The NHS, supported by the UKHACC has pledged to meet a 'Net Zero' carbon target by 2040 through its Greener NHS campaign. Incorrect sorting of waste is often caused by a lack of understanding of the nuances of waste segregation, compounded by complex colour coding, lack of leadership and improper planning.

Materials and Methods: Our aim was to find out the knowledge, attitude and practice of theatre staffs (35 participants) on waste segregation at Luton & Dunstable Hospital. We surveyed surgeons (6%), anaesthetists (31%), ODP (29%) scrub team (29%) and recovery nurses (6%) using a questionnaire in person. Further, they were asked about the benefits of waste segregation and times when they would dispose wastes correctly and reasons for not doing.

Questions on cost of disposal of different type of wastes were also included and general opinion on waste disposal was collected. We inspected 17 theatres to see if green bags were used appropriately.

Results and Discussion: : 51% would dispose wastes appropriately every time vs 49% at most of the times. The reasons for inappropriate disposal were unavailability of bags (25.7%), inattention and more training (25.7%). 34.2% had no idea about the cost for disposal. 49% thought waste disposal is vital because of environmental impact, cost (27%), ease of recycling (11%) and infection risks (13%). Staffs with no idea of type of wastes going

into yellow, orange, green and clear bags were 9%,30%,17%,18% respectively. 67% staffs insisted on more training sessions and knowledge gap was highlighted.

Conclusion(s):): To educate staff on waste segregation and increase the availability of general waste bins. To use product coding to enable more accurate and efficient sorting of waste, more training sessions and workshops at regular intervals. Information about economics of waste disposal will improve compliance.

53AP01-10

Segregation of healthcare waste in the intensive care unit: a single-centre pilot study

J.C.B. Tan¹, Y.T.M. Chia¹, R. Cuttilan¹, Y.L. Wong¹ ¹Tan Tock Seng Hospital, Anaesthesiology, Intensive Care and Pain Medicine, Singapore, Singapore

Background and Goal of Study: Singapore's healthcare sector contributes 3.4% of total carbon emissions, ranking Singapore as second globally in healthcare per capita emissions. Locally, medical waste has increased over the past 5 years from 4400 tonnes to 5700 tonnes. However, recycling opportunities are often missed due to many perceived barriers. In our hospital, waste was previously only separated into biohazard, sharps and general wastes with no segregation for recyclables. We aimed to increase staff awareness and uptake of plastic waste segregation to facilitate recycling in Tan Tock Seng Hospital.

Materials and Methods: We conducted a 2-phase pilot study in 1 intensive care unit in a hospital in Singapore for the segregation and recycling of plastic wastes in collaboration with a recycling company. In phase I, we conducted a 1-day trial in a 16-bed ICU whereby a recycling bin was set up for segregating plastic waste. Nursing staff were educated on the types of plastics to be recycled according to the plastic resin identification codes, and the recycled waste was weighed. The data was used to design the second phase. In phase II, we conducted a 6-week trial in the same ICU whereby nursing staff were instructed to segregate specific plastic items into a recycling bin for which these bins were weighed daily. In both phases of the study, staff were given a questionnaire to fill in during the study period.

Results and Discussion: In phase I, the amount of plastic waste generated per patient per day was 0.35kg. 88.2% of nursing staff expressed interest in recycling and 61.7% were likely to actively segregate ICU waste.

Some barriers included perceived infectious risks, decreased work efficiency and lack of recycling infrastructure. In phase II, nurses were asked to segregate 3 specific plastic items – apron covers, water irrigation bottle and bottle caps. An average of 49.6kg of plastic waste was segregated per week, averaging 0.44kg of plastic waste per patient per day.

More than 68% of respondents were able to accurately detail the appropriate process for recycling these items. They also suggested including a greater variety of recyclable paper and metal wastes.

Conclusion(s): Our pilot study highlights the active interest in and feasibility of recycling healthcare waste. Ongoing efforts with our infectious disease department have highlighted more possibilities for recycling more healthcare waste. Recycling efforts can further be extended hospital wide.

Education

54AP01-1

A national advanced airway management course for moldovan anaesthesiology residents: initial results

O. Gherasim¹, C. Burlacu², S. Sandru¹, I. Chesov¹ ¹'Nicolae Testemiṭanu' State University of Medicine and Pharmacy from Republic of Moldova, Anaesthesia and Intensive Care, Chisinau, Moldova, Republic of, 2School of Medicine, University College Dublin, Division of Surgery and Surgical Specialties, Dublin, Ireland

Background and Goal of Study: Airway skills training and immersive simulation sessions incorporating social and cognitive (nontechnical) aptitudes have been long recognised as contributing to more effective and safer airway management [1], especially when training is backed up by the Difficult Airway Society (DAS) guidelines [2]. Our goal was to implement a mandatory National Advanced

Airway Management Course in the Moldovan anaesthesiology training (NAAM-M).

Materials and Methods: Under the leadership of the European Society of Anaesthesiology and Intensive Care and Society for Simulation in Europe, and with support from the Romanian and Moldovan

Societies in Anaesthesia and Intensive Care, a national pool of Moldovan instructors underwent a NAAM-M Train the Trainer course in March 2024. During June - September

2024, NAAM-M was rolled out to a cohort of Moldovan anaesthesiology residents. The course lasts 2 days, and the content was a combination of theory, stations skills,

and immersive simulation scenarios followed by debrief. The participants were asked to complete an online pre-and post-course MCQ test and an anonymous post course feedback form.

Results and Discussion: A total of forty-five 3 rd and 4 th year anaesthesiology residents took part in 2 courses. All participants completed the online MCQ and feedback form. The mean preand post-MCQ

scores were 50.4% and 94.0%. Most participants highly rated the course, mean score 4.81/5 (SD 0.66). Majority of participants found the course informative and reported new learning, mean score 4.67/5 (SD 0.78).

Participants reported significant learning in managing difficult airways and applying DAS protocols. The course appeared to improve participants' confidence and competence in handling emergency airway management. The course was considered relevant to participants' professional activities, mean score 4.84/5 (SD 0.65).

Most participants reported an 'adequate' balance between practical and theoretical activities. Participants appreciated the interactive nature of the course, like engaging clinical scenarios, simulation and hands-on skill stations.

Conclusion(s): Data suggests that NAAM-M has led to improvement in the knowledge, practical abilities and confidence in this small cohort of anaesthesiology residents. The authors find this reassuring and an initial step forward towards the implementation of advanced airway teaching methods and technologies in the Moldovan anaesthesiology training.

54AP01-2

Emergency Front of Neck Access (eFONA): a comparison of performance of consultants and non-consultants in simulated 'can't intubate. can't oxygenate' (CICO) scenarios

H. Porter¹, M.S.Y. Back¹, N. Barot¹, B. Gohil¹ ¹Barts Health NHS Trust, Newham University Hospital Anaesthetics Department, London, United Kingdom

Background and Goal of Study: Emergency Front of Neck Access (eFONA) technique is a vital part of training for clinicians involved in airway management as it forms the final life-saving step in the management of 'Can't Intubate, Can't Oxygenate' (CICO) scenarios to prevent hypoxaemic complications, forming Plan D in the Difficult Airways Society (DAS) guidelines1.

Our objective was to study the proficiency of clinicians in their management of simulated CICO scenarios using eFONA, comparing Consultant Clinicians (CCs) vs Non-Consultant Clinicians (NCCs).

Materials and Methods: We assessed the proficiency of 5 CCs (from anaesthesia) vs 10 NCCs (from anaesthesia, intensive care and emergency medicine) at Newham University Hospital in managing simulated CICO scenarios using scalpel cricothyroidotomy (scalpel-bougie-tube) technique. Data was gathered using scores to assess proficiency and time to completion. Mean values were compared using confidence intervals (CIs). All 5 of the CCs and 4 of the NCCs underwent CICO training over 12 months prior to assessment, 4 NCCs 6-12 months prior and 2 NCCs within the last 6 months. Clinicians had 2 attempts at the CICO scenario, receiving no prompts prior to attempt 1 (A1), then receiving guidelines before attempt 2 (A2). Individual points were given for completing a step of the eFONA algorithm, formed by modified DAS guidelines to produce a 14-step process.

Results and Discussion: NCCs scored higher than CCs in A1 (mean scores 9±2.02 vs 7±1.07). All clinicians showed a significant improvement in mean scores in A1 (8.33±1.45) vs A2 (12.73±0.59). Completion times (seconds) were lower in CCs (134.4±34.63 in A1; 102±29.25 in A2) than in NCCs (161.4±37.46 in A1; 114.3±34.76 in A2). Results are expressed with 95% Cl.

Conclusions: Trends show higher scores in A1 in NCCs, and faster completion in CCs, however these data lack statistical significance. Given the more recent CICO training in NCCs, and statistically significant score improvement of all clinicians after prompting, further research with larger sample sizes are required to analyse the correlation between training frequency and eFO-NA performance.

Development of a workplace-based assessment scale for nurse anesthetist students

P. Apidechakul¹, P. Vichitvejpaisal², N. Triyasunant², M. Permpolprasert², W. Punchuklang² Mahidol University, Undergraduate Program, Bangkok, Thailand, ²Mahidol University, Anesthesiology, Bangkok, Thailand

Background and Goal of Study: Assessing clinical competence is vital in nurse anesthesia education to ensure the development of safe and proficient practitioners¹. The increasing complexity of healthcare underscores the need for reliable and valid instruments to evaluate nurse anesthetist students' performance in workplace settings. A standardized workplace-based assessment (WBA) scale is essential for accurately measuring clinical and professional competencies in real-world practice environments².

This study aimed to develop and validate a skill assessment tool for evaluating the workplace performance of nurse anesthesia students through psychometric analysis of its reliability and validity.

Materials and Methods: The study was conducted in three sequential phases:

Scale Development: A comprehensive literature review and expert consultations were undertaken to construct the initial assessment items.

Content Validation: The draft scale was reviewed by three expert anesthetists for content validity.

Psychometric Testing: The final scale was evaluated using data from 40 nurse anesthetist student assessments.

Results and Discussion: The finalized WBA scale consisted of 24 items spanning three key domains: Patient and equipment preparation, technical skills and Non-technical skills.

Psychometric analysis demonstrated strong internal consistency (Cronbach's α = 0.93), high inter-rater reliability (ICC = 0.87), and moderate concurrent validity as evidenced by Pearson's correlation analysis. These findings affirm the scale's robustness in reliably assessing clinical performance.

Conclusion(s): The newly developed workplace-based assessment scale exhibits strong psychometric properties, providing a reliable and comprehensive tool for evaluating the clinical competencies of nurse anesthetist students in practice settings.

54AP01-5 Zooming down: incentivizing a return to in-person grand rounds

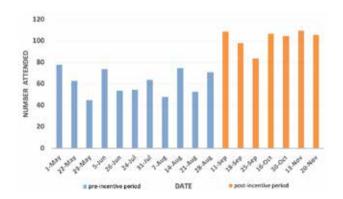

J. Soliz¹, J. Mani¹, T. Moon-Calderon¹
¹University of Texas MD Anderson Cancer Center,
Anesthesiology and Perioperative Medicine, Houston,
United States

Background and Goal of Study: When the worldwide COVID-19 pandemic led to lockdowns and travel restrictions, grand round lectures were transitioned to a virtual format. This change, while necessary, led to diminished engagement and attendance. In January 2023, our department resumed in-person grand rounds, yet attendance remained lower than pre-pandemic levels.

Recognizing the importance of these educational opportunities, departmental leadership sought strategies to improve in-person participation through the introduction of a targeted incentive program.

Materials and Methods: In September 2024, an incentive structure was implemented linking grand rounds attendance to a portion of a faculty incentive award. Specifically, in-person attendance was set to account for 5% of the incentive award amount. Faculty were expected to attend ≥ 80% of all grand rounds unless they were serving in an excused role. We compared attendance rates over the three months following the incentive's implementation to the four-month period preceding it.

Results and Discussion: The attendance for grand rounds during the study period is shown in Figure 1. Eleven of the grand rounds occurred in the pre-incentive period, with 7 occurring after incentive implementation. The attendance in the post-incentive period (102.7 \pm 9.1) was statistically greater than the pre-incentive period (61.8 \pm 11.6; p < 0.0001). The minimum attendance in the post incentive era (range: 45,78) was greater than the maximum attendance in the pre-incentive period (range: 84,110). Overall, attendance in the post-incentive period improved by 66% compared to the pre-incentive period.

Conclusion(s): The results of this study suggest that well-designed incentive programs can play a significant role in achieving departmental goals, such as enhancing educational experiences and fostering professional development. Encouraging in-person attendance through incentives may be a viable strategy for other departments facing similar challenges in the post-COVID era.

Online regional anesthesia resources - are they effective? Comparison between self-directed online educational material and conventional teaching in acquiring ultrasound-guided regional anesthesia skills for supraclavicular brachial plexus block by novice performers

H. dos Santos Fernandes¹, S. Peacock¹, Y. Gleicher¹, N. Siddiqui¹, <u>S. Andrade Santos¹</u>, Z. Friedman¹ ¹University of Toronto, Department of Anesthesiology and Pain Medicine, Toronto, Canada

Background and Goal of Study: Ultrasound is an important innovation in regional anesthesia (RA). The proper performance of ultrasound guided RA (UGRA) is a useful competency for any anesthesiologist. However, there are some obstacles to RA education. The increasing availability of UGRA-related online resources may have a value for trainees. The objective of this study is to assess the impact of using educational material from The New York School of Regional Anesthesia (NYSORA) and Ultrasound for Regional Anesthesia (USRA) websites on the learning process of novice trainees on ultrasound guided supraclavicular brachial plexus block (SBPB).

Materials and Methods: Randomized controlled trial comparing directed independent learning using NYSORA and USRA online educational material versus conventional in-person teaching, in acquiring UGRA skills for SBPB, among first year anesthesiology residents (PGY1s). The primary outcome was the performance when demonstrating ultrasound images for SBPB on live model, in a task specific checklist: the Sonographic Proficiency Assessment Score (SPAS).

Results and Discussion: Twenty-three PGY1s were enrolled. SPAS was statistically higher for the Online group [30.0 (26.0-31.0)] than for the In-person group [25.0 (22.0-26.0)], p=0.009.

	In-person group (n = 11)	Online group (n = 12)	P value
Gender			0.292ª
Female, n (%)	4 (36.36)	7 (58.33)	
Male, n (%)	7 (63.64)	5 (41.67)	
SPAS, median (IQR)	25.0 (22.0 – 26.0)	30.0 (26.0 – 31.0)	0.009 b
Quality of best acquired image			0.59 °
0 – completely inaccurate image, n (%)	1 (9.09)	0 (0.00)	
1 – poor quality, n (%)	0 (0.00)	1 (8.33)	
2 – moderate quality, n (%)	0 (0.00)	2 (16.67)	
3 – good quality, n (%)	8 (72.73)	8 (66.67)	
4 – excellent quality, n (%)	2 (18.18)	1 (8.33)	

SPAS: Sonographic Proficiency Assessment Score; IQR: interquartile range. a: Chi-square test. b: Wilcoxon rank sum test. c: Fisher exact test

Table 1. Comparison of participants` characteristics and outcomes between groups.

Conclusion(s): Online available educational material from NYSO-RA and USRA performed better for SBPB image acquisition and sonoanatomy interpretation learning skills, among PGY1s.

54AP01-7

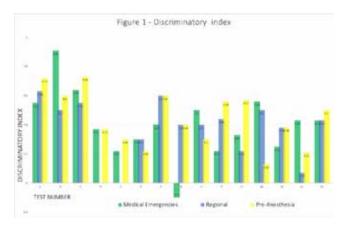

Simulated exam modules as a tool for summative evaluation of anesthesia residency graduates

N. Sheffy¹, A. Ronen², D. Sagi³, R. Hakim⁴, A. Raz⁵¹Rabin Medical Center, Department of Anestehsiology, Petah Tikva, Israel, ²Hebrew University-Hadassah Medical School, Department of Anesthesiology, Jerusalem, Israel, ³Chaim Sheba Medical Center Tel Hashomer, Israel Center for Medical Simulation (MSR), Tel-Hashomer, Israel, ⁴Emek Medical Center, Anesthesia Department, Afula, Israel, ⁵Rambam Health Care Campus, Department of Anesthesiology, Haifa, Israel

Background and Goal of Study: Oral boards entailing questions and discussion have traditionally been conducted for anesthesia residency graduation. Recently, testing methods evolved to include simulated components. The Israeli oral board examinations employ three types of simulated modules: simulated medical emergencies (SME), ultrasound based regional anesthesia stations (RA), and pre-anesthetic clinic visits (PAV). We examined the ability of simulated modules to predict the candidates' passing odds.

Materials and Methods: We reviewed results from 15 consecutive exams starting July 2020 onward. A total of 43 different stations were examined, including 15 SME, 15 PAV, and 13 RA. In addition to simulated stations, each exam had 4-5 "traditional" oral encounters. The weight of each station (oral and simulated) in the calculation of the final score was equal. We used Discriminatory index, based on the portion of high score candidates passing the station in comparison to low score candidates.

Results and Discussion: Records from 471 SME and PAV encounters, and 386 RA encounters were tested. Simulated stations showed a good (over 60%) predictive and negative value for exam passing and failing odds, respectively. Discriminatory index was almost always positive with an average of 0.4 for SME, 0.44 for PAV and 0.42 for RA (Figure 1).

Conclusion(s): Theoretical oral exams may not be sensitive enough to assess all crucial skills. We demonstrate that simulated exam modules are effective in distinguishing high scoring candidates from low scoring ones. Thus, simulated exams allow testing more than theoretical knowledge without losing data related to theoretical knowledge. However, more studies comparing theoretical and simulated exams are needed.

An evaluation of the Microsoft HoloLens2 in the clinical teaching of pain pathways for undergraduate medical students

K. Murphy¹, N. O'Brien², M. Connolly¹, G. Shorten¹
¹Cork University Hospital, Department of Anaesthesia and Intensive Care, Cork University Hospital, Cork, Ireland,
²University College Cork, Medical Education, Cork, Ireland

Background: In medical education, vertical integration refers to integration between the clinical and basic sciences. Mixed reality (MR) is a rendered experience in which virtual and "real" elements are perceived simultaneously. The Microsoft HoloLens2 (HL2) is a novel MR headset which can facilitate a live two-way broadcast to (a)remote environment(s). We present a mixed methods study which examines the feasibility, usability and efficacy of MR in the education of medical students, specifically teaching pain pathways in a clinical context.

Methods: A series of interactive bedside tutorials on pain pathways and their relevance to pain management was delivered using the HL2. Each tutorial included interaction with a patient during the postoperative period and a group of medical students who were situated in a remotely. The tutorial employed insertion of virtual artefacts, including examples of pain pathways often superimposed on or positioned adjacent to the patient. Student feedback was elicited using a modified Evaluation of Technology-Enhanced Learning Materials: Learner Perceptions (ETELM-LP) tool

Results: This was a prospective, observational study that used both qualitative and quantitative methods. Seven patients and 35 students participated across seven separate tutorials. The mean SUS score for medical students was 72.5 (IQR 62.5 – 80) and for the clinician was 70.5, indicating favourable usability. The mETELM Questionnaire using a 7-point Likert Scale demonstrated MR contributed to achieving the learning objectives of the tutorial (Median=6), and was superior to a traditional PowerPoint tutorial. There was disagreement among students regarding the value of the MR tutorial in comparison to a live patient encounter (Median=4). The patients' mETELM results showed that the HL2 created a safe environment during the session (Median=7), without affecting communication with the clinician (Median=7), and was favoured over small group bedside teaching (Median=7).

Conclusions: We demonstrated that bedside clinical teaching of pain pathways using the HL2 and MR is both feasible and effective, and could enhance vertical integration of basic and clinical material within a medical undergraduate curriculum. This study's collaborative application development model, involving tutors, facilitators, and curriculum experts, sets a precedent for future educational technology in healthcare. Further evaluation of the usability of the device in this context is planned.

54AP01-9

Hybrid 3D-printed manikin for lung isolation training of anesthesia residents: a randomized controlled trial

R. Eshel¹, S. Haim¹, E. Rahman¹, B. Cohen^{1,2}, O. Goren¹, R. Shaylor¹

¹Tel-Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel, ²Outcomes Research Consortium, Cleveland Clinic, Cleveland, United States

Background and Goal of Study: Lung isolation is an essential technique in thoracic anesthesia. Commercially available high-fidelity lung isolation manikins to teach lung are costly and scarce in most training programs. We developed a 3D-printed modification that integrates with a simple airway manikin to enhance anatomical fidelity.

This study examined whether teaching lung isolation techniques using the modified hybrid manikin enhances skill acquisition compared to a standard, non-modified manikin.

Materials and Methods: Anesthesia residents were randomly assigned to participate in a lung isolation workshop using either the hybrid manikin or the standard manikin. They were then assessed for time to insert a double lumen tube (DLT), time to insert a bronchial blocker, time to identify the right upper lobe bronchus, and overall bronchoscopy score. All skills were re-assessed after two weeks, two months, and six months.

Results and Discussion: In total, 29 residents were randomized (hybrid manikin N=14, standard manikin N=15). Immediately postworkshop, the hybrid manikin group demonstrated higher success in DLT placement (86% vs. 53%, p=0.068) and shorter procedure times (median 26 seconds, interquartile range [IQR] 13–48 vs. 54 seconds, IQR 35–90; p=0.04).

Superior performance persisted at two months for DLT placement success (86% vs. 47%, p=0.03). At six months post-work-shop, the groups' performance converged, with both demonstrating significant improvements from baseline.

Conclusions: Training lung isolation with a 3D-printed hybrid manikin shows sustained benefits in bronchoscopy performance and lobar anatomy, with an immediate performance enhancement after the initial workshop.

This cost-effective modification has the potential to increase accessibility and improve skill acquisition for thoracic anesthesia training.

Ward nurses use of epidural analgesia when treating breakthrough pain. A National survey of Denmark

T.E. Thomsen¹, C.C. Lamprecht¹.2,³, T. Thomsen¹.2, K. Wildgaard¹.2, M. Vester-Andersen¹.2
¹Copenhagen University Hospital, Herlev Hospital, ACES Anesthesia Critical and Emergency Care Science Unit, Department of Anesthesiology, Herlev, Denmark, ²University of Copenhagen, Department of Clinical Medicine, Copenhagen, Denmark, ³Copenhagen University Hospital, Herlev-Gentofte, Herlev, Department of Orthopedic Surgery, Herlevdend, Denmark

Introduction: Epidural analgesia is an effective postoperative pain treatment reducing the administration of systemic opioids improving postoperative outcomes.

Studies have shown ward nurses lack education in epidural pain treatment

Our study investigated ward nurses' use of in-situ epidural catheters for postoperative pain treatment during breakthrough pain. Furthermore, we explored if educational programs are available, and the barriers experienced by ward nurses when treating breakthrough pain.

Method: Danish Nationwide survey targeting all abdominal and orthopedic surgical wards in Denmark. Head nurses from each ward appointed two ward nurses to answer the questionnaire. The survey took place from March-July 2023.

Result: In all, 104 of 121 (86%) ward nurses completed the questionnaire. Seventy-five (72.1%) used epidural bolus as first-line treatment for breakthrough pain. Education in epidural analgesia was available at 98% of surgical wards. Further, 47% reported getting formalized education, with 37 (35.6%) receiving it from a nurse or doctor (anesthesiology department or pain-team). The most frequent barriers to using epidural bolus were lack of knowledge (36.9%) or missing guidelines and instructions (29.1%).

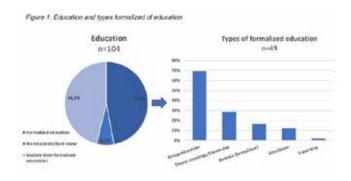

Conclusion: The majority of ward nurses administered epidural bolus as first line treatment for breakthrough pain. Only 47% of the nurses reported getting formalized education. Frequently reported barriers were lack of knowledge and missing guidelines and instructions.

	Gave bolus via epidural catheter		Didn't give epidural	
	n=75	95% CI	n=29	95% CI
Gave a systemic opioid (p.o, s.c/i.m/i.v)	42 (56.0%)	44.8-67.2	27 (93.1%)	83.9-100
Non-medical option (E.g. heating blanket or mobilization)	17 (22.7%)	13.2-32.1	10 (34.4%)	17.2-51.8
Gave non-opioid treatment (NSAID, paracetamol)	17 (22.7%)	13.2-32.1	7 (24.1%)	8.6-39.7
Contacted expert (E.g. doctor or nurse from the anesthesiology department or pain team)	17 (22.7%)	13.2-32.1	12 (41.4%)	23.5-59.3
Changed epidural infusion rate	12 (16.0%)	7.7-24.3	4 (13.8%)	1.2-26.3
Other (E.g. removal of catheter)	7 (9.3%)	2.7-15.9	6 (20.7%)	5.9-35.4

Table 1: First-line treatment for breakthrough pain, stratified for bolus via epidural catheter.

54AP01-11

An evaluation of peripheral intravenous cannulation training: insights from a UK-based survey of medical students and resident doctors

T. Saha¹

¹University College London, Medical Student, London, United Kingdom

Background and Goal of Study: Peripheral intravenous cannulation is the commonest procedure performed for inpatients and diagnostic investigations. Despite being low risk to patients, a range of cannulation related complications are still observed. The choice of insertion site is essential for the safe delivery of treatment (1).

Considerable variation exists in the approaches used to train medical students in cannulation.

Materials and Methods: To evaluate current clinical practice and university teaching methods, a survey was conducted amongst medical students from 14 different UK universities and resident doctors employed in UK hospitals, trained from 29 universities. A total of 250 invitations were distributed, yielding 104 responses - 64 from students and 40 from doctors.

Participants were asked to provide details on their venous cannulation training, including access sites emphasised during training compared to their current preference in clinical practice, as well as their experience with simulation and ultrasound techniques.

Results and Discussion: 95.2% of respondents received simulation-based cannulation training. Notably, 38.8% were trained to use the antecubital fossa and 37.9% the dorsum of the hand. However, clinically 42.3% preferred the dorsum and 26.9% the antecubital fossa. Some UK medical schools still emphasise the antecubital region, a site prone to flexion, risking mechanical obstruction, patient discomfort, brachial artery puncture, and arterial drug delivery (1).

Only 32.7% participants received ultrasound training for challenging cannulations, involving 8 students from 6 universities. Out of all resident doctors who had received ultrasound training, 38% were anaesthetists.

Conclusion: Students need comprehensive training in safe cannulation, including simulation-based teaching and site-specific risks and benefits. Guidelines should discourage flexor sites like the antecubital fossa as first-line options when better veins are available.

Ultrasound training must be integrated into curricula for difficult intravenous access. Anaesthetists can play a pivotal role in contributing to medical school initiatives or training medical students directly, ensuring the delivery of efficient and safe cannulation practices.

Case closed? A decade of case report publications in the field of anesthesiology: A focused review

R. Eshel¹, D. Arad¹, Y. Rajmilevich¹, O. Cohen-Rosenboim¹, L. lacubovici¹, C. Weiniger¹

¹Tel-Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel

Background and Goal of Study: Peer-reviewed medical journals tend to publish less case reports (CRs). We aimed to describe trends in publishing CRs in Anesthesiology peer-reviewed medical journals between January 2014 and August 2024.

Materials and Methods: We conducted a literature search using PubMed and Web of Science databases. Selection criteria involved identifying peer-reviewed CRs published within the last 10 years in the top 20 journals in Anesthesiology according to Journal Citation Reports (Clarivate, June 2024).

We identified published CRs adhering to "CARE reporting guidelines" for CRs, including the term "case report" or "case study" in their title.

Results and Discussion:: A total of 486 CRs were identified over the study period. Half of the top 20 Anesthesiology journals currently do not publish CRs, with 5 (25%) not publishing any CRs over the past decade. Two companion journals have been identified to provide a publication alternative for CRs.

Categorization of journals according to CR publication frequency established 5 (25%) journals did not publish any CRs; 7 (35%) published 1-19 CRs; 5 (25%) published 20-49 CRs, and 3 (15%) published >50 CRs during the investigated period. Obvious temporal trends were identified, with a continued downward trend in the number of published CRs.

Conclusions: Many leading peer-reviewed anesthesiology journals do not currently publish case reports CRs.

Nevertheless, the establishment of companion journals and the ongoing publication of CRs in various outlets indicate that they remain a valuable source of clinical information for both authors and readers.

54AP02-1

How smart is AI for EDAIC?: The success of artificial intelligence in the European diploma of anaesthesiology and intensive care exam

K.S. Elden¹, B. Kuvaki Balkan¹
¹Dokuz Eylul University, Anaesthesiology and Reanimation, Izmir, Turkey

Background and Goal of Study: Advancements in artificial intelligence (AI) have shown promise in medical applications, including standardized exams. The European Diploma of Anaesthesiology and Intensive Care (EDAIC) is a multilingual exam assessing

knowledge in anesthesiology and intensive care. This study evaluates the performance of ChatGPT 3.5, ChatGPT 4.0, Claude 3.5 Sonnet, and Gemini 1.5 Pro in EDAIC Part 1.

Materials and Methods: A total of 120 multiple-choice questions (MCQs) from the ESAIC official website were used. Each question included five true/false sub-questions, totaling 600 queries. The AI models were assessed across 9 basic and 6 clinical science subtopics. Correct response rates were calculated, and errors analyzed. No ethical approval was needed, as the study did not involve human participants or personal data.

Results and Discussion: On average, ChatGPT 3.5 answered 90.2%(541/600), ChatGPT 4.0 90.8%(545/600), Claude 3.5 Sonnet 90.8%(545/600), and Gemini 1.5 Pro 87.8% (527/600) correctly. Basic science scores (Paper A) were higher than clinical science scores (Paper B) across all models. ChatGPT 3.5 scored 92%(276/300) in Paper A and 88.3%(265/300) in Paper B, while ChatGPT 4.0 achieved 91.7%(275/300) and 90%(270/300), respectively.

The error rate was higher for clinical sciences, indicating limitations in handling experiential knowledge. Analysis revealed 22 questions consistently missed by all models, evenly split between basic and clinical sciences. Despite these challenges, the models surpassed the 2024 average pass rates for EDAIC Part 1 (65.66% for basic sciences and 68% for clinical sciences).

Chatbot	Correct Answers	Incorrect Answers	Total Questions	Success Rate (%)
ChatGPT 3.5	541	59	600	90.2
ChatGPT 4.0	545	55	600	90.8
Claude 3.5 Sonnet	545	55	600	90.8
Gemini 1.5 Pro	527	73	600	87.8

Chatbot	Paper A Correct	Paper A Incorrect	Success Rate (%)	Paper B Correct	Paper B Incorrect	Success Rate (%)
ChatGPT 3.5	276	24	92%	265	35	88.3%
ChatGPT 4.0	275	25	91.7%	270	30	90%
Claude 3.5 Sonnet	275	25	91.7%	270	30	90%
Gemini 1.5 Pro	267	33	89%	260	40	86.7%

Conclusion(s): Al models demonstrated strong performance in EDAIC Part 1, with ChatGPT 4.0 and Claude 3.5 Sonnet achieving the highest scores. However, limitations in interpreting experiential clinical scenarios remain. Integrating clinical case data into Al training could enhance their ability to support medical education and clinical reasoning.

54AP02-3

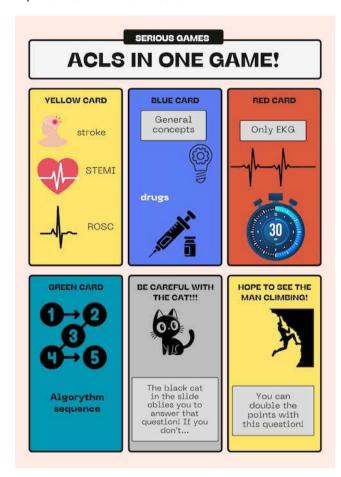

Serious games improve academic knowledge during ACLS simulation in medicine students

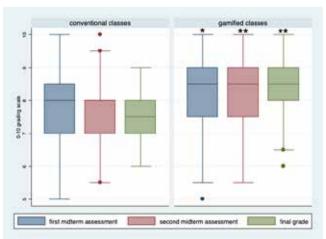

T. Bragateli Campos¹, J. de Moura Erbolato Melo¹, J. Lopes Ferraz¹, V. Ybrahim Ruiz¹, M. Balbino¹ ¹Centro Univessitário São Camilo, Medicine, São Paulo, Brazil

Background and Goal of Study: Serious Games are innovative teaching tools that improve efficiency in the learning process. Some studies show the role of serious games in medical teaching, but there are limited results on their use in ACLS courses with medical students. This study aims to evaluate the effectiveness of serious games in improving learning skills in ACLS theoretical preparation.

Materials and Methods: The two comparison groups are the fourth-grade medical students who took the ACLS course in 2024, with traditional classes in the first semester (traditional group – TG) and gamified classes in the second-semester classes (gamified group – GG). Before the class, all the students watched a 7-minute video and received a text with all the content based on AHA guidelines.

For the gamified class, each student of GG received 4-5 cards of the UNO game®, which has four colors of the cards (figure 1). Both groups of students answered a survey about their learning experience at the end of the course.

There was no difference between groups in self-sufficiency, knowledge retention, or the perceived importance of each team member's role in the resuscitation.

Conclusion(s): Our data showed that gamified ACLS classes increased students' exam performance and retention of critical subject points. Teachers should consider this strategy when teaching crucial medical learning subjects.

54AP02-4 Enhancing and Empowering Multi-Disciplinary Care in Tracheostomy Management

X.Y. Chin¹, L.S. Tay¹, X.L.L. Ng¹
¹Changi General Hospital, Department of Anaesthesiology, Singapore, Singapore

Background and Goal of Study: Tracheostomy is a surgical procedure commonly performed for patients requiring prolonged mechanical ventilation or as an alternative airway in certain head and neck surgeries. The number of patients with tracheostomies has increased over the past few decades. Consequently, there is a growing need for adequate training amongst healthcare professionals to manage tracheostomies. Unfortunately, only specific surgical specialties and nursing units are trained to do so. Therefore, the team has designed a course in Basic Tracheostomy Care and Management to bridge this knowledge gap.

Materials and Methods: This course is led by a multidisciplinary team comprising nurses, respiratory therapists, and specialists from various fields. It is designed to promote interdisciplinary interactions, teamwork, and enhance familiarity with tracheostomy management, with the ultimate aim for better patient outcomes. Participants of various healthcare backgrounds underwent a halfday course of Basic Tracheostomy Care and Management from April 2021 to April 2024 in Changi General Hospital, a 1000-bed tertiary hospital in the eastern part of Singapore. Participants were asked to complete a pre-course survey, after which seven sets of pre-reading material specially curated by trainers of various disciplines covering basic airway anatomy, to maintenance and weaning of tracheostomies were released to participants. Any gueries were addressed during the course, which included five interactive stations including two crisis-simulations. A postcourse survey was then administered, and both survey results were analysed.

Results and Discussion: A total of 197 and 198 participants completed the pre- and post-course surveys respectively. 60.9% of participants had no formal training in tracheostomy care. Questions regarding crisis management of tracheostomies scored the lowest (45.9% correct), as compared to those regarding clinical knowledge (70.6% correct) and nursing (60.4% correct).

After the tracheostomy course, there was an improvement across all domains; 23.3% for crisis management (69.2% correct), 14.7% for clinical knowledge (85.4% correct) and 20.0% for nursing domains (80.5% correct).

Conclusion(s): Many of our healthcare professionals have limited exposure to tracheostomy management. The tracheostomy course has shown to improve healthcare workers' knowledge and management of tracheostomies.

*Both authors contributed equally as first authors.

54AP02-5

The situation and constraints in simulation-based medical education in anesthesia in China: data analysis from West China Hospital of Sichuan University

Y. Zhou¹, C.-m. Wu¹, L.-q. Fang¹, Q. Li¹
¹West China Hospital, Sichuan University, Anesthesia And Operation Center, Chengdu, China

Background and Goal of Study: Simulation-based medical education plays a crucial role in the training of anesthesia practitioners. To explore the current situation and constraints in simulation-based medical education in anesthesia (SBMD-A) in China, we analyzed data from a survey through eight years of national-wide Train the Trainers Course in Anesthesia Simulation (TTTC-AS) at West China Hospital of Sichuan University.

Materials and Methods: Anesthesia educators participated in the national-wide TTTC-ASs held at West China Hospital and completed a questionnaire regarding SBME-A in their institutions. Results and Discussion: From 2014 to 2024, eight sessions of national-wide TTTC-ASs were held. Five hundred and seventynine anesthesia educators from 205 institutes or hospitals in China completed the survey. Results showed the number of dedicated simulation centers is increasing (2015: 59% vs. 2024: 68%). For simulation modalities and technologies, an increase was observed in task trainers (2015: 11% vs. 2024: 36%) and visual reality (VR) devices (2015: 6% vs. 2024: 13%), while high-fidelity simulation declined (2015: 83% vs. 2024: 30%). Biological resourcebased simulation remains low (6%-8%), and standardized patients have increased since 2016 (2016: 8% vs. 2024: 16%). In all SBME-A curricula conducted, the proportion of procedural skills ranks first (2015: 42% vs. 2024: 32%), and that of crisis resource management (2015: 11% vs. 2024: 26%), ultrasound-guided technigues (2015: 14% vs. 2024: 22%), VR (2%-6%) and computerbased simulations (1%-13%) are rising, while BLS/ACLS declined (2015: 33% vs. 2024: 11%). SBME-A activity frequency has increased from generally twice a year (2015: 92% vs. 2024: 29%) to more than once per month (2015: 45% vs. 2024: 44%). Systemization of integrating simulation in patient safety is on the rise (2015: 11% vs. 2024: 38%). Constraints include the dedicated time for teaching (2015: 28% vs. 2024: 15%), and lack of curriculum standards (2016: 9% vs. 2024: 11%). In the past decade, SBME-A in China has achieved great progress in simulation center construction, equipment availability, curriculum development, and educator training. However, dedicated time for teaching and lack of curriculum standards are still constraints for SBME-A in China. Conclusion(s): More attention should be paid to the lack of dedicated teaching time and curriculum standards for SBME-A in China in the future.

54AP02-6

Validation of metrics for midline catheter placement using modified Delphi methodology

H. Ahmed¹, M. Simpson¹, S. Howell²
¹Leeds Teaching Hospitals NHS Trust, Anaesthesia,
Leeds, United Kingdom, ²University of Leeds, Leeds
Institute of Medical Research, Leeds, United Kingdom

Background and Goal of Study: Midline catheters are peripherally inserted vascular devices that end inferior to axilla. Midline insertion failure rate has been reported to be as high as 12.5%. Proficiency based progression (PbP) training based on unambiguously defined metrics is an innovative methodology in which a trainee must attain certain proficiency level before performing the skill in clinical setting. It has been reported to improve performance in simulation and clinical settings. We are aiming in this study to validate the previously defined metrics for midline catheter placement (50 metrics and 30 errors of which 12 are critical and the rest are non-critical) using modified Delphi methodology. These validated metrics will be used as a core for PbP training.

Materials and Methods: Delphi methodology has been extensively used before to achieve consensus among a group of experts through multiple rounds and voting. This involved two electronic voting rounds via an online survey tool (Google Forms) followed by a virtual round table discussion (Microsoft Teams) to exchange views and finalise results. Collaborators are experts in the field of vascular access devices who are practicing midline placements regularly. They were invited to participate via the National Infusion and Vascular Access Society (NIVAS). In round 1 all items which achieved more than 50% of voting passed to round 2, any item achieved less than 50% was reworded and passed for voting in round 2. In round 2 all items which achieved more than 75% were included in the final list of metrics. Items which achieved between 50-74% were discussed in round 3. Items which achieved less than 50% were rephrased and included for voting in round 3.

Results and Discussion: 22 experts participated in round 1, 24 in round 2 and 6 in round 3. 12 metrics needed rephrasing in round 1 and 2. Only 7 metrics and 3 errors did not achieve consensus in the first two rounds and had to pass to round 3 in which they were rephrased and achieved consensus except one item which has been combined with another metric after round table discussion. (Table 1 and 2)

Conclusion(s): Using modified Delphi methodology, 49 metrics and 30 errors for midline catheter placement were validated.

- 1. Failure to identify arterial puncture (critical)
- 2. Pulling the wire through the needle (critical)
- 3. Repositioning the needle with the wire inside (critical)
- 4. Not confirming the guidewire inside the vein before dilatation (critical)

Table 1: Sample of validated errors.

- 1. Adjust ultrasound settings: high frequency probe selection, depth and gain
- 2. Check the orientation of the ultrasound probe
- 3. Hold the probe in a tripod grip (stable and anchored to the patient)
- 4. Identification of important structures: Median nerve, Brachial artery and Brachial vein
- 5. Vein selection: diameter of the vein is 3 times diameter of the line

Table 2: Sample of validated metrics.

In situ multidisciplinary simulation - an effective educational tool for management of operating room emergencies

L. lacubovici¹, O. Cohen-Rosenboim¹, R. Agur¹, R. Eshel¹, S. Zarour¹, Y. Brzezinski Sinai¹

¹Tel Aviv Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel

Background and Goal of Study: Operating room (OR) emergencies are rare, time sensitive events requiring a rapid and coordinated multidisciplinary team intervention. In-situ simulations provide a safe and effective learning environment. We used in-situ multidisciplinary simulations as an educational aid and evaluated relevant clinical knowledge, performance, and satisfaction of participants via surveys.

Our goal was to find significant gaps in knowledge, communication, or familiarity with a new operating room domain that may impact patient safety.

Materials and Methods: We simulated a cardiac arrest due to local anesthetic systemic toxicity (LAST) in a young patient. Each participating team included an anesthesia resident and staff, two surgeons, two OR nurses and one ancillary staff member.

Each simulation was overseen by a supervisor from each discipline and two additional simulation operators that operated and recorded mandatory actions via checklists. Simulations were also video-recorded for future analysis.

Results and Discussion: In total, 23 participants completed self-assessment surveys (26% surgery residents, 26% anesthesiologists, 35% nurses, and 13% others). Most participants reported improved confidence (95%), knowledge (78%), communication (91%), and wished to participate in future simulations (95%).

Supervisors reported that most teams (85%) rapidly requested and administrated intralipid, while only one team (14%) advanced management to extracorporeal membrane oxygenation.

When screening for theoretical knowledge, both anesthesiologists (90%) and surgeons (83%) scored well on differential diagnosis, though surgeons lacked knowledge regarding treatment options (20%). As for practical knowledge (location and usage of intralipid), anesthesiologists and OR nurses performed well (90 and 100% respectively).

Our survey results and the difficulty of finding the intralipid during simulation led to new OR signage of the location of intralipid with attached treatment checklist for LAST which was utilized during simulations.

Conclusions: In-situ multidisciplinary simulations captured as a positive learning experience by participants. In addition to increasing clinical knowledge and teamwork skills, we found an increase in confidence.

Performing in-situ simulations in real-life environments exposes latent challenges and safety issues which can then be addressed to improve future patient care.

54AP02-8

Perioperative nutritional support of patients with Inflammatory Bowel Disease in - screening, assessment and management of perioperative malnutrition in tertiary hospital in Serbia

N. Vico Katanic^{1,2}, G. Jovanovic^{1,2}

¹The University Clinical Center of Vojvodina, Clinic for Anesthesia, Intensive Care Therapy and Pain Treatment, Novi Sad, Serbia, ²University of Novi Sad, Faculty of medicine, Novi Sad, Serbia

Background and Goal of Study: Inflammatory bowel disease (IBD) is a group of intestinal disorders characterized by chronic digestive tract inflammation. While non-surgical management approaches have advanced, many patients still require surgical treatment. Optimizing preoperative patient care is crucial to achieving favorable surgical outcomes.

The goal of this work was on the awareness of preoperative nutritional therapy and the role of healthcare professionals in preoperative assessment, and management principles in patients with IBD in tertiary hospital in Serbia.

Materials and Methods: This research was conducted by filling out an anonymous questionnaire consisting of twenty-four questions online. The questionnaire was distributed online by professional associations, and the target were doctors specialized in anesthesiology, gastroenterology, and surgery. Statistical analysis was performed using SPSS 21.0.

Results and Discussion: The response rate was 72.9% among anesthesiologists and surgeons, 20.3% but very low among gastroenterologists. In our hospital, perioperative nutritional support is mainly performed by anesthesiologists (40.7%). Only 12.1% of respondents perform regular Nutritional support for patients with IBD. The most common screening tools used in clinical practice are Nutritional Risk Screening 2002 (55.9%) and Mini Nutritional Assessment (23.5%). The most used tools for nutritional assessment are anamnesis, physical exams and laboratory tests. 44.1% of respondents still determine how long Nutritional support should be done preoperatively.

Modern guidelines for preoperative starvation are performed in 54.2%. In the preoperative period, 90.1 percent of nutritional support combines enteral and parenteral nutrition.

Oral intake of liquid carbohydrates before surgery is done in 21.1%. All respondents agreed that the main challenges are knowledge, organizational support, time, and resources.

Conclusion(s): No specific preoperative nutritional support was used regularly, and methods and timing are still diverse. Further work on education, implementation, and identifying clinical needs and benefits for nutritional support in patients is vitally needed.

The effect of participation in Student-as-Teacher programs on feedback-seeking behaviour in the clinical life of the residents

<u>T. Prokopová</u>^{1,2}, T. Vafková^{3,2}, J. Hudec^{1,2}, R. Gál¹, M. Kosinová^{4,2}, P. Štourač^{4,2}

'University Hospital Brno, Faculty of Medicine, Masaryk University, Department of Anaesthesiology and Intensive Care Medicine, Brno, Czech Republic, ²Faculty of Medicine, Masaryk University, Department of Simulation Medicine, Brno, Czech Republic, ³Masaryk Memorial Cancer Institute and Faculty of Medicine, Masaryk University, Brno, Czech Republic, Department of Comprehensive Cancer Care, Brno, Czech Republic, ⁴Faculty of Medicine, Masaryk University, Department of Paediatric Anaesthesiology and Intensive Care Medicine, University Hospital Brno, Brno, Czech Republic

Background and Goal of Study: At Masaryk University in Brno, Czechia, General Medicine and Dentistry students could participate in the Student-as-Teacher program (SaT). In this program, students are trained in the basics of adult learning theories, simulation-based education, debriefing, and more profound training in theory and skills in the subject (e.g. first aid). After this training, students participate as assistant teachers during the practices. The positive effect of the peer-to-peer learning concept has already been proven.

In this study, we focus on the influence of this training on the student's perception of feedback and simulation training in their residency.

Materials and Methods: These data were obtained from an online questionnaire distributed by email, and its completion was strictly anonymous and voluntary. The study population consisted of students who finished the training in this program, actually taught during their studies, and have already graduated. 90 residents received the questionnaire, and 17 participants completed the survey in one week (21.11.2024-29.11.2024).

Results and Discussion: 100 % of participants claim that participation in the SaT program influenced their perception of feedback. 94.1 % of participants expect the feedback to be a normal part of their work life, 82.4 % are less afraid of feedback, 94.1 % expect feedback not only after major mistakes, and 95.0 % of participants expect feedback daily in a daily manner.

Improvement in giving feedback and working through receiving one constructively was stated in 88.2 % and 94.1 %. The participants are not satisfied with the frequency of receiving feedback (58,6 %), feedback culture (76,5 %) and constructiveness (64,7 %).

The approach to simulation postgraduate training was also altered. Participants feel more motivated to participate in optional training in 59.0 % and obligatory simulation training in 25.0 %. Their fear of simulation and debriefing was lessened (46.0 %), and their motivation for completing pre-learning was higher (21.0 %)

Conclusion(s): Participation in simulation education as a lector positively influences perceiving feedback and simulation training even after graduation. This kind of training promotes feedback-seeking behaviour and sets expectations on high standards of feedback culture.

Acknowledgements: Many thanks to Václav Vafek and Daniel Barvík for co-leading the SaT programs and our student lectors.

Implementation of simulation-based lectures to enhance knowledge retention in anesthesiology residents

O. Loskutov^{1,2}, Y. Markov¹, <u>S. Maruniak</u>^{1,3}
¹P.L. Shupyk National HealthCare University of Ukraine, Anesthesiology and Intensive Care, Kyiv, Ukraine, ²Heart Institute Ministry of Health of Ukraine, Department of Anesthesiology, Kyiv, Ukraine, ³Heart Institute Ministry of Health of Ukraine, Department of Kidney Transplantations and Hemodialysis, Kyiv, Ukraine

Background and Goal of Study: Improving the quality of training for medical residents is one of the primary goals of modern medical education. Among innovative approaches, simulation-based lectures stand out as a method that effectively integrates real-life clinical scenario modeling with theoretical training. This integration has the potential to facilitate deeper understanding and retention of material.

The aim of this study was to evaluate the effectiveness of simulation-based lectures compared to online learning in improving the knowledge of first-year anesthesiology residents.

Materials and Methods: The study involved 67 first-year anesthesiology residents (aged 23–27 years), including 32 men (47.8%) and 35 women (52.2%). The residents were divided into two groups based on the learning format for the topic "Preoperative Patient Assessment": 38 residents attended a simulation-based lecture at the department (Group 1), while 29 residents attended an online lecture (Group 2).

Learning effectiveness was assessed using initial test results (15 questions) and a follow-up test conducted one month later. The retention coefficient was calculated as the ratio of follow-up test results to baseline knowledge levels. Statistical analysis was performed using XL-STAT software.

Results and Discussion: Initial test scores showed no significant difference between the groups: 60.2±4.32% in Group 1 versus 62.4±5.27% in Group 2 (p=0.305). One month after the lectures, test scores in Group 1 significantly increased to 76.3±5.17% compared to baseline (p=0.001), while in Group 2, scores rose to 71.9±8.13%, also showing a significant improvement over baseline (p=0.011).

However, the test results in Group 1 were significantly higher than those in Group 2 after one month (p=0.033). The retention coefficient was also higher in Group 1 compared to Group 2 (1.28 (1.15;1.42) versus 1.16 (1.08;1.27), p=0.019).

Conclusion(s): Simulation-based lectures are an effective tool for improving the quality of anesthesiology residents training and provide higher levels of knowledge retention over time. A simulation-based lecture is a novel form of instruction that differs from traditional simulation exercises by better integrating theoretical knowledge into a practical context, thus enhancing learning effectiveness.

The results of this study support the incorporation of simulationbased approaches into educational programs for anesthesiology residents

54AP02-11

Feasibility study of a novel 5G-connected mobile video recording and review system for educational and research application in anaesthetic in-situ high-fidelity simulation training

O. Thomas^{1,2}, V. Carlund^{1,3}, M. Berg^{1,4}, C. Christensson^{5,3}, M. Flores Bjurström^{6,7}, L. Walther Sturesson^{1,3}

¹University of Lund, Department of Clinical Sciences, Lund, Medical Faculty, Lund, Sweden, ²Skåne University Hospital, Lund, Dept of Cardiothoracic Surgery, Lund, Sweden, ³Skåne University Hospital, Intensive and Perioperative Care, Lund, Lund, Sweden, ⁴Skåne University Hospital, Malmö, Department of Emergency Medicine, Malmö, Sweden, ⁵University of Lund, Department of Health Sciences, Lund, Sweden, ⁶Uppsala University, Department of Surgical Sciences, Uppsala, Sweden, ⁷Akademiska Sjukhuset, Anaesthesia and Intensive Care, Uppsala, Sweden

Background and Goal of Study: We aimed to develop, implement and evaluate a mobile system using off-the-shelf components, to record and review simulations and debriefings in four separate rooms during standardized simulation courses at multiple centres in Sweden. Our requirements were: high quality sound and video; easy to install, use and demount; suitable for transport by courier; no requirement to use personal mobile devices; not dependent on local intranet; GDPR compliant; automatic remote long-term storage.

Materials and Methods: Four sets of the components shown in Table 1 were acquired to record simulations and debriefings, each with its own 5G internet connection. The equipment fits in a standard transport case, total weight 25kg. Automatic storage is at a remote server (AXIS Camera Station S2208). Faculty access recordings during courses using the AXIS Camera Station® app on iPads.

1-2 AXIS M3086-V stationary wide-angle (120°) dome cameras mounted on 16x16cm electrical blanking plates

AXIS T8355-A microphone; AXIS T6101 MkII interface

AXIS S3008 Recording unit

Teltonica RUTX50 5G Router providing ethernet connection for recording unit and Wi-Fi for course faculty

Table 1. Components of each recording set.

Results and Discussion: The study ran during 7 courses at 5 centres in 2024 (1), comprising 100 full-scale simulations, both in-situ in the OR and ICU, and at simulation centres. Ease of installation, video-review, demounting and packing were acceptable, transport unproblematic. Sound and picture quality was generally good and participants did not appear to be perturbed by the cameras. Towards the end of the study, faculty were encouraged to show recordings of laudable debriefing techniques used by their peers, which resulted in lively and constructive discussion during faculty meetings.

Video review of simulations in medical education is widespread even though evidence of its superiority to non-video-assisted debriefing is sparse. Video-review of debriefings in facilitator development programmes is less well described (2): our group believes it is useful and should be formally evaluated. Future developments may include AI analysis of both simulations and debriefings.

Conclusion(s): A mobile recording system complying with our specifications is feasible.

Face and content validation of a 3D-printed, open-source anesthesia machine simulator

O. Bar-nathan^{1,2}, <u>O. Cohen-Rosenboim</u>^{1,2}, T. Talmy^{1,2}, C. Weiniger^{1,2}, R. Shaylor^{1,2}, Y. Brezezinski Sinai^{1,2}
¹Tel-Aviv Sourasky Medical Center, Division of Anesthesia, Intensive Care, and Pain, Tel Aviv, Israel, ²Tel-Aviv University, Faculty of Medicine and Health Sciences, Tel Aviv, Israel

Background and Goals: Medical simulation is essential for medical training, standardizing teaching and competency evaluation. Using anesthesia machines (AM) in simulation allows appropriate responses to clinical situations. AMs provide feedback that anesthetists rely on to diagnose clinical problems. However, their use is often limited to operating rooms or specialized centers, restricting availability. Additionally, AMs function poorly in simulations and lack operator control of display. We developed "The Drooler", a portable, cost-effective, and reproducible 3D-printed, open-source AM Simulator (AMS) (Figure 1).

This study aimed to evaluates the **face** and **content validity** of the AMS, focusing on its realism and suitability for anesthesia training.

Materials and Methods: We present preliminary data of a survey study including 15 participants (9 are simulation instructors). Participants engaged in **directed sessions** using the AMS and completed a survey for:

- · Face validity: Visual, tactile, and auditory Realism -assessed by anesthetists (>1 year experience)
- **Content validity**: Suitability for anesthesia simulation- assessed by simulation instructors (>10 simulations experience)
- · Likert Scale (1-5) evaluations were used for scoring.

Results and discussion: Preliminary results are presented in Figure 2.

Conclusions: We report consistent face validity of the AMS with excellent visual and tactile realism scoring, in dynamic clinical situations. We report content validity, as the AMS was highly appreciated as an educational and assessment tool by experienced simulation instructors. We plan to further evaluate the validity of the AMS in larger population of anesthetists including simulation instructors. In conclusion the Drooler AMS offers a novel, accessible solution for anesthesia training and skills assessment outside high-fidelity settings.

54AP03-1

Bottom-up feedback: Stress test for teams or key to enhancing education and team culture? How residents and faculty in an anesthesiology and intensive care department addressed this challenge

I. Marcolino¹, S. Schmelzer², R. Thomasin¹
¹Spital Limmattal, Institut für Anästhesie und
Intensivmedizin, Schlieren, Switzerland, ²Zürcher
Hochschule für Angewandte Wissenschaften,
Winterthurer Institut für Gesundheitsökonomie WIG,
Winterthur, Switzerland

Background and Goal of Study: Traditionally evaluation in medical education is executed top down where trainees are rated once a year by their consultants. However, it is increasingly recognized that the professional development of residents towards independent practice is significantly influenced by a supportive learning environment, the expertise and commitment of faculty, and the overall quality of educational practices.

Materials and Methods: With the aim of enhancing the skills of both trainees and educators, we strive to cultivate a positive feedback culture based on psychological safety. To attain this goal, we focused on faculty development by implementing a bottom-up feedback system in which consultants are evaluated by residents regarding their teaching competencies. For this purpose, the SwissSETQ-Questionnaire[1] was used.

Given that bottom-up feedback may challenge the traditional hierarchical structures prevalent in hospitals, we sought to identify potential concerns and expectations related to the use of Swiss-SETQ. Therefore, we evaluated the implementation of the Swiss-SETQ by conducting a pre- and post-survey. We assessed the attitudes of residents and faculty members towards bottom-up feedback, feedback practices in general, and their perceptions of the current working climate within our institution. The questionnaire was developed in collaboration with an occupational psychologist and incorporated adapted items from validated questionnaires previously utilized in similar contexts (e.g. student-teacher evaluations). Items were rated on a 5-point Likert scale.

Additionally, two open-ended questions addressed concerns and expectations. One month after the implementation of the Swiss-SETQ, the post-survey was conducted to re-evaluate whether initial concerns and expectations had been proven true.

Results and Discussion: This poster presents the findings from the pre- and post-evaluation, alongside insights and experiences gained from the first implementation of a bottom-up feedback using the SwissSETQ.

Conclusion(s): Based on our findings, we conclude that bottomup feedback represents a powerful tool to enhance the quality of education and to promote a positive team culture. We highly encourage other institutions to adopt bottom-up feedback to achieve similar benefits.

54AP03-3

Role-switching in internal jugular vein catheterization training on skill acquisition: a cognitive load theory-informed randomized controlled trial

S.-I. Li1, Y. Zhou1, Q. Li1

West China Hospital, Sichuan University, Anesthesia and Operation Center, Chengdu, China

Background and Goal of Study: Internal jugular vein catheterization (IJC) is a commonly used vascular access technique in clinical practice, yet it poses significant learning challenges for novices. We hypothesized that incorporating a role-switching component, where trainees design a skill assessment checklist of IJC during training, might improve the acquisition of IJC skills. Materials and Methods: Interns with no prior landmark-based IJC experience were invited to self-study theoretical knowledge materials of IJC, including PowerPoint presentations and IJC operation videos emphasizing the key points. Following a knowledge test, those who passed were randomly assigned to the control group (Group C) and the intervention group (Group I). Both groups then underwent an IJC skill pre-test. After that, Group C received one-hour simulation-based IJC skill training with an instructor-trainee ratio of 1:12, and feedback was given by an instructor. Group I was required to design an IJC skill assessment checklist in 20 minutes without the intervention of an instructor, using an endotracheal intubation skill assessment checklist as a reference. It was emphasized that the checklist should reflect the key points of IJC skills. Subsequently, Group I practiced IJC skills for 40 minutes and received feedback from the instructor. One week later, both groups underwent an IJC skill post-test and completed a cognitive load test. A separate IJC skill assessment checklist (with a full mark of 100) used in the pre and post-test was not exposed to the trainees.

Results and Discussion: Forty-eight interns were included, with 24 in each group. IJC skill pre-test scores were not significantly different (Group I vs. Group C: 55.3±6.1 vs. 54.3±7.9, P=0.64). Post-test scores were significantly higher in Group I (91.0±2.8 vs. 88.5±4.6 in Group C, P=0.03). There was no significant difference in total cognitive load (Group I: 334.7±63.6 vs. Group C: 311.1±57.8, P=0.82). Group I had significantly lower frustration scores (25.1±15.3 vs. 42.3±22.4, P=0.00). Incorporating role-

switching in IJC skill training, where students allocate some of the time originally used for skill practice to designing an IJC skill assessment checklist, switching their role from trainee to skill assessor, enhanced active learning, increased germane cognitive load, and reduced frustration.

Conclusion(s): Role-switching in IJC training improved skill acquisition.

54AP03-4

Cardiopulmonary resuscitation training in midlle school: start them young!

R. Góis¹, <u>M.J. Nascimento¹</u>, A. Bernardino¹, M. Pereira¹, M. Correia Silva¹

¹Unidade Local de Saúde de Coimbra, Anesthesiology, Coimbra, Portugal

Background and Goal of Study: Out-of-hospital cardiac arrest is the third leading cause of death in Europe [1]. Immediate initiation of Cardiopulmonary Resuscitation (CPR) can triple survival rates. Children's education is one way to improve health literacy and rationalize healthcare costs. Several organizations recommend mandatory annual CPR training of 2 hours for school-aged children, integrated into the school curriculum [2]. Investing in health literacy, starting from school age, can shorten the time to initiate proper CPR, reducing morbidity and mortality [3]. Our main goal was to assess the impact of CPR training (2 hours with simulation) for children aged 12-14 on promoting health literacy, comparing questionnaire results before and after the training. Secondary goal included comparing before training questionnaire results between children with previous CPR training and those without.

Materials and Methods: A diagnostic questionnaire, with eleven theoretical questions about CPR, was applied before and after the training. Informed consent was obtained from parents or guardians to administer the tests and analyze the data. Descriptive statistical analysis of demographic data was performed. The results were converted into dichotomous nominal variables "70% correct answers" and "not 70% correct answers" and inferential statistic was applied using the Chi-square test (p-value 0.05).

Results and Discussion: Questionnaires from 72 children attending the 8th grade were analyzed. The median age was 13 years old. Before the training, 34.7% of the children achieved "70% correct answers," increasing to 98.6% after training (p-value <0.001). Among the children with prior CPR training (29.2%), 33.3% achieved "70% correct answers" in the initial questionnaire, compared to 36% among those without prior training (p-value 0.82). Additionally, 95.7% of the children reported that learning about CPR was important.

Conclusion(s): The results demonstrate that middle school children can acquire basic CPR knowledge through adapted training sessions, which can contribute to improving health literacy. However, regular training is necessary to reinforce knowledge. This study highlights the importance of training children in CPR as a way to enhance health literacy.

Competency based medical education (CBME) in prehospital emergency medicine – curriculum development, validation and definition of core skills using Entrustable Professional Activities (EPAs)

A. Ganzhorn¹, P. Hilz¹, L.F.L. Kröger¹, <u>P. Moll-Khosrawi</u>¹ *'University Medical Center Hamburg-Eppendorf, Anaesthesia, Hamburg, Germany*

Background and Goal of Study: The implementation of competency based medical education (CBME) poses the challenge to evaluate competencies quantitively. ¹ Entrustable professional activities (EPAs) bridge this gap by combining theoretical and practical aspects of a broader task and allow a gradual entrustment to learners. ² Although challenging and practical disciplines like prehospital emergency medicine could benefit greatly from EPAs, such curricula have not been defined yet. To fill the gap, this study aimed to define and validate EPAs for core skills in prehospital emergency medicine.

Materials and Methods: The study was conducted at the department of Anesthesiology at the University Hospital Hamburg, Germany. A multi-step, modified delphitrial, combined with expert analysis and interviews was used to define and validate EPAs for prehospital emergency medicine. The EPAs were accepted for the final curriculum based on the consensual agreement (>80%) and sorted by relevance, reflected by the content validity index (CVI)

Results and Discussion: In the first delphi round 311 replies by 41 participants were analyzed by the expert group and 22 EPAs defined. Following, an adaptation process consisting of 11 individual expert interviews and an additional expert group analysis, led to a total of 18 EPAs. The mean agreement on the EPAs in the second delphi round with 70 participants was 95%. 17 EPAs met the criteria and were accepted in the final curriculum. EPAs were separated in a high (CVI>0.75) and low ranking (CVI<0.75) group, reflecting the importance inside the curriculum. The ranking differed significantly between participants with or without the prehospital emergency medicine certification (p=0.03). Implementing EPAs could lead to identifying overlapping competencies between different specialties and design a more efficient training. Furthermore, the results should be evaluated interdisciplinary in national and international approaches to reach a broad consensus on the future prehospital medical education.

Conclusion(s): This study defines and validates the first EPA based curriculum for prehospital emergency medicine in Europe. **References:**

54AP03-8

EDAIC certification and one step forward for anaesthesia and intensive care education in Bangladesh

A. Kazi Mahzabin¹, I. Md Shafiqul¹, A. Shadeda², B. Dilip Kumar¹, V. Frank³, <u>A. Akhtaruzzaman¹</u>
¹Bangabandhu Sheikh Mujib Medical University,
Department of Anaesthesia, Analgesia and Intensive Care Medicine, Dhaka, Bangladesh, ²Bangabandhu Sheikh Mujib Medical University, Department of Microbiology and Immunology, Dhaka, Bangladesh, ³Artemed Hospital Munich South, Department of Anaesthesiology and Intensive Care, Munich, Germany

Background and Goal of Study: The European Diploma in Anaesthesia and Intensive Care (EDAIC) certification is a recognised global standard for expertise in anaesthesia and intensive care. Professionals obtaining this certification gain better access to various career opportunities in multiple countries. This survey aims to assess the impact of EDAIC certification on professional development and educational standards in anaesthesia and intensive care of Bangladesh.

Materials and Methods: An online survey was done on anaesthesiologists and intensivists of Bangladesh who have passed the EDAIC Part 1 or 2 exams to evaluate the impact of EDAIC certification on anaesthesia and ICU education, along with feedback on its influence on professional development and clinical skills.

Results and Discussion: A total of seventy-seven participants responded to the survey. Most respondents were anaesthesiologists (87.01%), followed by intensivists (6.49%). Postgraduate qualifications include DA (61%), FCPS (19%), MD (13%), and MCPS (7%). About 37.6% have over 5 years of work experience. Most of the participants were from academic institutes (48.05%). and the rest were from private hospitals (22.8%), district Hospitals (12.9%), and sub-district hospitals (5.19%), Approximately 48.05% of respondents completed EDAIC part 1, and 7.58% passed part 2. Amongst the EDAIC achievers, 54.5% expressed advanced expertise in clinical reasoning, meanwhile 15% stated escalated dignity professionally. Upliftment in practicing safe anaesthesia (40.63%) and rendering better ICU services (15.6%) was also observed. About 94.3% acknowledged the implementation of the knowledge and skills acquired from the EDAIC exam in teaching and training programs for future anaesthesiologists and intensivists of Bangladesh.

Conclusion(s): EDAIC certification has significantly improved anaesthesia and ICU education in Bangladesh by strengthening clinical competencies, updating knowledge, and enhancing professionals' educational development and recognition.

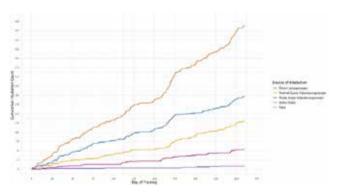

54AP03-9

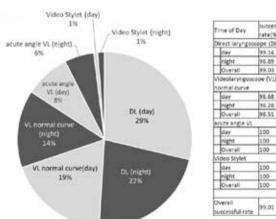

Assessing skill acquisition in a resident anesthesiologist over 260 days: impact of diverse intubation tools and night shift training on competency development

H. Chen¹, M.-L. Wang¹¹National Taiwan University Hospital, Department of Anesthesiology, Taipei, Taiwan

Background: Endotracheal intubation is a fundamental skill in anesthesiology, essential for airway security and patient safety during surgery. Proficiency is crucial for managing diverse clinical scenarios.

Case Report: A first-year anesthesiology resident completed a 260-day training program focusing on four intubation devices: direct laryngoscope(DL), normal curve video laryngoscope(VL), acute angle VL, and video stylet. Between August 4, 2023, and April 30, 2024, the resident attempted 447 intubations; 404 cases were analyzed after excluding incomplete data or double-lumen tube usage. The resident completed 206 intubations with DL, 134 with VL, and 56 and 8 with Acute angle VL and video stylet. Daytime intubations were more frequent, with DL and VL used in 29% and 19% of cases, while night shifts accounted for 22%(DL) and 14% (VL).

Discussion: The resident demonstrated steady skill acquisition across all devices, reflected in high success rates. Exposure to multiple tools enhanced adaptability and proficiency. Night shifts provided opportunities to handle complex cases, fostering resilience and aligning with Kolb's experiential learning theory, which emphasizes learning through experience. Ericsson's concept of deliberate practice also applies, as repeated practice with feedback is essential for mastery. Structured debriefing and mentor-

ship can enhance learning and mitigate burnout. Individual differences may affect skill acquisition rates, indicating that peer-level comparisons are needed to optimize training programs.

Reference:

Kolb DA. Experiential Learning. Prentice Hall; 1984.

Learning Points: Diverse exposure to intubation devices accelerates skill development, and night shifts enhance clinical competence through complex cases. Incorporating educational theories, such as experiential learning, improves training and resident well-being.

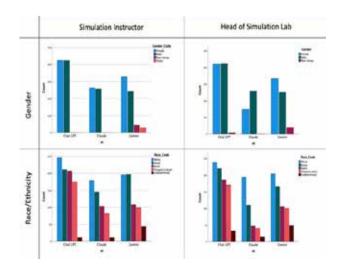

54AP03-10 Diversity in simulation: can Al pass the inclusion test?

M. Blesa¹, J. Berger-Estilita², P. Dieckmann³, M. Gisselbaek⁴, S. Saxena⁵ ¹Hospital Universitario y Politécnico La Fe, Anesthesiology, Valencia, Spain, 2University of Bern, Institute for Medical Education, Bern, Switzerland, 3Copenhagen Academy for Medical Education and Simulation. (CAMES), Copenhagen, Denmark, 4University of Geneva, Department of Anesthesiology, Clinical Pharmacology, Intensive Care and Emergency Medicine, Geneva University Hospitals and Faculty of Medicine, Geneva, Switzerland, 5Helora, Department of Anesthesiology, Mons. Belaium

Background and Goal of Study: Simulation-based medical education (SBME) plays a crucial role in healthcare training, with the workforce of simulation labs influencing curriculum development and inclusivity. While artificial intelligence (AI) introduces innovative tools for demographic analysis, it also has the potential to perpetuate systemic biases.

This study explores the capability of AI tools to assess demographic diversity among SBME leaders.

Materials and Methods: Three Al models - ChatGPT, Gemini, and Claude – were used to generate demographic data of simulation lab instructors and leaders across nine countries over five days in November 2024. Analysis focused on demographic patterns in age, gender, race, and specialty, aiming to evaluate inclusivity and identify trends or disparities in the data generated by these Al models.

Results and Discussion: We analysed 3894 entries. Claude emerged as the most inclusive tool, demonstrating a balanced distribution across gender and racial/ethnic groups, with a higher proportion of women and equitable representation of minorities (Fig 1.). ChatGPT showed the least diversity, with a pronounced overrepresentation of males and White individuals in leadership roles. The most frequently mentioned medical specialities associated with SBME were Anaesthesiology, Emergency Medicine, Surgery, Internal Medicine and Pediatrics, accounting for over 50% of all mentioned specialities.

Conclusion(s): Al tools offer significant potential for analyzing diversity among SBME leaders but also reflect inherent biases. Future efforts should focus on improving the diversity representation capabilities of AI tools to ensure unbiased insights that enhance SBME workforce inclusivity.

54AP03-12 Acute pain in Portugal and Europe – A long way to go

R. Santa Barbara¹, D. Martins¹, I. Flor de Lima¹, D. Henriques¹, M. Miranda¹ ¹Hospital Cuf Tejo, Serviço de Anestesiologia, Lisboa, **Portugal**

Background and Goal of Study: For several years, Anesthesiology has witnessed significant advancements in Acute Pain. The development of regional techniques and the diversity of adjuvant strategies available have contributed to this progress. However, postoperative pain management in Portugal and Europe remains ineffective, with "lack of organization" being widely recognized as one of the main obstacles.

Materials and Methods: The implementation of Acute Pain Units (APUs) in European hospitals began decades ago. In Portugal, the first recommendations from the Portuguese Society of Anesthesiology (SPA) were published in 2018. However, their applicability has fallen far short, with only about 37% full implementation nationwide. Across Europe, the situation is highly varied. In the United Kingdom, Germany, and Netherlands, the percentage of hospitals with available APUs is around 90%; in France and Austria it's approximately 50% and 40%, respectively. Other countries, like Hungary, have an implementation rate less than 10%. Despite this variability, all these countries recognize the importance of APU implementation to pain management improvement. In 2024, CUF Tejo Hospital, in Lisbon, Portugal, implemented an APU based on SPA recommendations. The project began in 2023 and follows a nurse-centered model, similar to most models implemented across Europe.

Results and Discussion: Although our patient sample is still insufficient for a comprehensive outcome analysis, we already perceive very positive feedback from users. We can highlight that our greatest challenge has been the lack of human resources, particularly nursing staff. This is a problem shared by other European countries, especially those with lower adherence rates. In countries with higher adherence rates, contrary to expectations, moderate to severe postoperative pain remains highly prevalent, suggesting that the lack of standardization across Europe and even within individual countries contributes to the inefficacy of pain management.

Conclusion(s): At a time when the focus is on quality, what are the main reasons hindering effective acute pain control in European hospitals? Is it merely a matter of human resources? Would the creation of European guidelines enabling standardized practices and improved outcomes be beneficial? The question remains...

Career and Wellbeing

55AP01-1

Comparison of in-simulation versus post-simulation debriefing in medical Simulation **Based Training (SBT)**

K. Ekelund¹, P. Dieckmann¹, R.V.B. Jacobsen¹, D. Østergaard1 ¹Herlev Hospital, Copenhagen Academy of Medical Education and Simulation, Herlev, Denmark

Background and Objective: Simulation-Based Training (SBT) is commonly used to train medical personnel in skills, knowledge, and teamwork within a realistic environment. Traditionally, postscenario debriefings are essential for reinforcing learning, allowing learners to understand the direct consequences of their actions. An alternative approach is in-scenario debriefing, which involves pausing the simulation to discuss specific events. However, pausing the scenario may affect both fidelity and learner engagement. This study investigates how learners perceive in-scenario debriefing compared to traditional post-scenario debriefing and examines perception differences among various learner populations in postgraduate medical education.

Materials and Methods: The study compared in-scenario debriefing with post-scenario debriefing among Certified Registered Nurse Anaesthetists. Postgraduate MDs (Year 1 and Year 3), and Certified Specialists in Anaesthesiology. During each pause, participants and facilitators temporarily left the manikin for a facilitator-led debriefing focused on the simulation, fostering reflection-in-action and reflection-on-action while addressing clinical, social, and cognitive skills. The pauses were kept under five minutes. Learners' perceptions were assessed using an adapted instrument and semi-structured interviews. Traditional post-debriefing scenarios were also included in the course day. Results and Discussion: Eighty-eight participants completed the

questionnaire, with scores ranging from 39 to 75 (mean of 57), and a median score of 4 per question (range 1-5), with a mean of 3.81. Twenty learners and seven facilitators participated in interviews (20-40 minutes). Participants reported that in-scenario debriefing effectively promoted engagement, learning, and reflection without diminishing the fidelity of the scenario. Reflection-inaction allowed participants to enhance their expertise by cycling between action and reflection. Learners indicated they had no difficulty re-engaging after the pauses, regardless of their professional background or experience level.

Conclusion: In-scenario debriefing is an effective tool in SBT and could serve as a viable alternative to traditional post-scenario debriefing. It supports active engagement, adaptability, and learning for individuals across diverse levels of medical education and simulation experience.

Virtual reality and simulation-based training in tracheal intubation competency

D. Sazhvn¹, I. Kuchvn¹, K. Bielka¹, O. Khomenko¹ ¹Bogomolet`s National Medical University, Dep. of Surgery, Anaesthesiology and IC, Kyiv, Ukraine

Background and Goal of Study: Tracheal intubation is a critical skill in anesthesiology and emergency medicine. While lecturebased learning remains essential, simulation techniques, including manikin training and virtual reality (VR), are increasingly used to enhance practical skills (1,2). This study compared the effectiveness of these three educational methods for tracheal intubation training.

Materials and Methods: 33 participants were divided into 3 groups: lecture-only, lecture plus manikin training, and lecture with VR simulations. The manikin group combined lectures with practical sessions, while the VR group used immersive simulations of intubation scenarios. This design allowed comparison of theoretical, tactile, and immersive approaches.

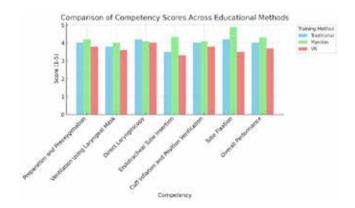

Results and Discussion: Competency was assessed across seven steps: preparation, preoxygenation, ventilation (LM), direct laryngoscopy, endotracheal tube (ETT) placement, cuff inflation, ETT fixation, and overall execution, scored on a 5-point scale (1 = unable to perform, 5 = independent).

The manikin group scored highest overall, particularly in ETT insertion (mean 4.33 \pm 0.71, p = 0.043). The VR group scored lower in tasks requiring tactile feedback, like ETT insertion. No significant differences were found in direct laryngoscopy (p = 0.433) or cuff inflation (p = 0.322).

Conclusion(s): Manikin-based training is more effective for developing tracheal intubation skills than lecture-only or VR-based methods, as tactile practice is crucial for manual procedures. While VR offers innovative potential, its current lack of tactile realism limits its utility. Future advancements in VR could improve its role in medical training.

Adaptive refinement of a critical incident debriefing and support program for anaesthetists at a major trauma centre informed by clinician stakeholder needs analysis

M. Allen¹, K. Allen¹, J. Wright¹ ¹The Royal Melbourne Hospital, Department of Anaesthesia and Pain Management, Melbourne, Australia

Background and Goal of Study: Clinical incident debriefing (CID) benefits patients, clinicians, and organisations[1]. We investigated psychological safety and experiences of CID to develop a feasible yet impactful program for our major trauma centre. Following implementation, we evaluated experiences of the program.

Materials and Methods: Anesthesiologists were invited to complete a baseline survey investigating psychological safety, past critical incident(CI) and CID experiences. After analysing the survey results, we recruited four focus group (FG) sessions. A bespoke program was designed for identified stakeholder needs and introduced into practice. The program was evaluated through a survey and three post-program FGs with anesthesiologists. Descriptive statistics were used to report survey data. The FGs were recorded, transcribed, and the content was thematically analysed. Results and Discussion: Baseline survey responses were obtained from 55/111 anesthesiologists (49.5%) and psychological safety was high. 38% of CIs occurred after hours, and relief from clinical duties was uncommon. Those who participated in CID found it useful(75%). From the FGs, CID was reported as important and acceptable. The main barrier to CID was logistics, and the purpose of the debrief was not always explicit (clinician wellbeing vs. incident review). The CID process was developed in partnership with our hospital Wellbeing team. The program evaluation survey received 54 responses(49%) - staff identified increasing availability of CID as a positive program outcome. Post-CI relief from duty was more common but future opportunitied included more training and overcoming logistic barriers to CID. CI's had adverse professional impact for 52% and adverse personal impact for 37% but 48% reported a positive professional impact.

Conclusion(s): CID is important, acceptable and feasible even in a busy trauma centre. By supporting anaesthetists post-CI through a targeted CID program adverse effects of Cis can be mitigated and positive impact achieved.

Implementing a well-being curriculum for anesthesiology residents: a pilot program experience in Brazil

C.M.R.P. Cavaliere¹, L.I.M. Carvalho², L. Azi³, E. Yugue¹, R.d.P. Lian¹, M.A.C. Albuquerque⁴, Núcleo do Eu ¹Pontifical Catholic University of Campinas, Anesthesiology, Campinas, Brazil, 2Hospital Unimed Primavera, Anesthesiology, Teresina, Brazil, ³Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil, 4Federal University of Sergipe, Anesthesiology, Aracaju, Brazil

Background and Goal of Study: Medical residency is a period marked by high stress demands, which can negatively impact residents' well-being and also the patient care. This study presents the implementation of a well-being curriculum at a Brazilian teaching hospital designed to reduce stress and promote selfcare both in staff and residents.

Materials and Methods: Launched in April 2022 at PUC-Campinas, Brazil, the Well-being Medical Residency Program (WMRP) involved 52 participants (29 staff and 23 residents). The program included modules on physician wellness, resilience, emotional well-being, financial management, and mindfulness. Data were collected using the Maslach Burnout Inventory (MBI) and a satisfaction questionnaire previous and after WMRP.

Results and Discussion: The MBI scale (44 respondents) indicated high emotional exhaustion (EE) and burnout risk, with 80% of residents and 57.9% of staff at high risk. These findings align with studies highlighting burnout in surgical specialties, including anesthesiology (Afonso et al., 2020). Social events and stress-coping strategies were well-received, with over 90% of participants reporting improvements in well-being. These results support previous research suggesting that wellness activities and team building reduce burnout and enhance resilience (Saadat et al., 2017). Challenges included initial resistance and logistical constraints, particularly related to scheduling and financial limitations, which hindered the full implementation of the program.

Conclusion(s): This pilot program introduced a culture of wellbeing within the anesthesiology residency program, but further research is needed to optimize which are the better interventions and evaluate their long-term effects.

Pregnancy and parenthood for female intensive care unit (ICU) physicians

G. Scarpati¹, M. Cascella¹, O. Piazza¹ ¹University of Salerno, Anaesthesia and Intensive Care, Baronissi (Salerno), Italy

Background and Goal of Study: Pregnancy for female intensivists is particularly challenging due to the high demands and the critical nature of their work environment. They often face unique stressors, including balancing their responsibilities as healthcare providers with their roles as expectant or new mothers. Illnesses among this workforce include sick leave due to work-related and pregnancy-related diseases, with very high absenteeism. The primary objective of this study was to review the available literature on gestational and occupational risks to which pregnant healthcare workers are exposed, causes of absenteeism, and issues related to maternity protection and ICU work.

Materials and Methods: The authors used online databases to identify articles published from 2015 to 2024, using the PRISMA extension for scoping reviews.

Results and Discussion: The study examined 18 peer-reviewed scientific articles addressing pregnancy, work, absenteeism and maternity protection. Most studies used a quantitative approach (12), particularly cohort studies (6). The use of sick or "precautionary" leave emerged in 11 papers as the emergency "solution" to the hospital administration's incapacity to readjust the work environment or reassign to other tasks. Thirteen articles analysed adverse gestational complications (spontaneous abortion, preterm birth, fetal abnormalities and intrauterine growth restriction). Ten articles recommended improving working conditions with social support and a proactive approach to support the working capacity of pregnant women and ensure a healthy and risk-free work environment.

Conclusion(s): This review findings, even if incomplete, report some inferences on pregnancy complications, associated occupational risk factors, significant causes of absenteeism, maternity protection measures and challenges for the careers and professional lives of pregnant workers in the ICU. Support systems, such as flexible work arrangements, access to child care, and mental health resources, are critical to helping these women navigate the complexities of pregnancy and parenthood while continuing to pursue their demanding careers.

55AP01-6

Evolution of female first authors in Anesthesia & Analgesia: a century of progress in anesthesiology

T.L. Dominguez¹, R.L. Alves², C.S. Goveia³, P.O. Barros Jr³, L. Azi²

¹Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil, 2Faculty of Medicine - Federal University of Bahia, Department of Anesthesiology and Surgery, Salvador, Brazil, 3University of Brasília, Department of Anesthesiology, Brasília, Brazil

Background and Goal of Study: The role of women in medicine has evolved significantly over the last century. This study aims to examine the historical participation of women as first authors in Anesthesia & Analgesia, the oldest journal in anesthesiology, and identify trends in their prevalence over the past 100 years. The study focuses on the analysis of the publication data from 1923 to 2023, marking the centennial history of the journal.

Materials and Methods: This observational, longitudinal retrospective study analyzes data from 2329 articles published between 1923 and 2023 in Anesthesia & Analgesia. A sample of articles from each decade was selected, excluding editorials, letters to the editor, and book reviews. The gender of the first author was identified using gender recognition tools and online resources. Statistical analysis was performed to determine trends in the representation of female authors over time.

Results and Discussion: The study revealed a steady increase in the number of female first authors throughout the century. In 1923, the percentage of women as first authors was negligible, but by 2023, it had risen to 34.5%. The 1970s saw a significant increase in female authorship, likely influenced by the feminist movement and initiatives promoting gender equality. However, disparities remain, with women representing only 18% of first authors across all decades studied. The analysis also highlighted the increasing involvement of women in academic leadership roles, correlating with the rise in first authorship. Despite these advancements, the study also noted that a significant gender gap remains, especially in leadership positions in academic anesthesiology.

Conclusion: This study demonstrates the growing presence of women as first authors over the past century, reflecting broader trends in gender equality within the field of anesthesiology. However, further efforts are needed to bridge the gender gap, particularly in academic leadership roles, to ensure a more balanced representation in scientific contributions.

Keim AA, Pelkey MN, Broadfoot JE, et al. Women Authorship Trends in the Highest-Impact Anesthesiology Journals from 2005 to 2021. J Womens Health (Larchmt). 2023;32:592-7.

Actions to improve researcher mental health in anaesthesiology: the importance of Researcher Mental Health Observatory (ReMO)

D. Mijakoski¹, S. Stoleski¹, J. Minov¹, A. Dimitrovski², A. Trposka-Poposka²

¹Faculty of Medicine, Ss. Cyril and Methodius, University in Skopje, Institute of Occupational Health, Skopje, North Macedonia, The Republic of, ²UK TOARILUC, KARIL, Skopje, North Macedonia, The Republic of

Background and Goal of Study: Occupational safety and health community puts particular focus on the improvement of workers' mental health. Work organization and other psychosocial factors has been emphasized by international organizations (WHO, ILO, ICOH), and EC as an emerging topic. Literature data clearly show that majority of academic staff find their job stressful with levels of burnout higher among researchers than in general working population. Among anaesthesiologists and intensivists job stress is common issue related to various workplace factors (e.g., long working hours, working over the weekend, lack of control over time, handling high-risk patients). The urgent need to improve mental health and well-being in academia was highlighted by the Researcher Mental Health Observatory (ReMO) COST Action and ReMO Manifesto.

Materials and Methods: Desk analysis and available online resources as well as ReMO recommendations were used to define a set of actions and expected outcomes towards promotion of mental health and well-being in researchers from anaesthesiol-

Results and Discussion: Workplace mental health and well-being are topics of increased interest in recent years. Health workers are frequently surveyed taking into consideration the strong evidence between determinants and effects of job stress and burnout in this occupational group. On the contrary, knowledge and attitudes about researcher mental health, and activities implemented worldwide to enforce their well-being are still on a basic level. The data obtained show low levels of awareness about this issue in policy makers, employers, and workers. Based on these findings, preventive and coping strategies need to be introduced at community, institutional, and policy level. In setting the activities and measurable outcomes, the scientific community and policy makers have to take into consideration that job stress in health workers is associated with reduced quality of patient care. Characteristics of job tasks and work organization together with the most important job demands (e.g., work overload, work-home interference) and job resources (e.g., professional development, team work) have to shape the efforts for the improvement of researcher mental health in anaesthesiology.

Conclusion(s): National occupational health and safety strategies have to focus on the mental health and well-being of researchers working in anaesthesiology.

Implementation of a "Learning from Excellence" greatix scheme for theatres staff at the Royal Alexandra Hospital, NHS Scotland

K. Ravi1, A. Muir*1, K. Harper1, N. Lal1 ¹Royal Alexandra Hospital, Department of Anaesthesia, Paisley, United Kingdom

Background and Goal of Study: Excellence in clinical practice is intentional and can be learned from1. To

- 1) increase learning from excellent practice and
- 2) improve workplace morale by formally recognising excellent practice, a reporting system to recognise excellence within the Royal Alexandra Hospital (RAH) Theatres department, named "Greatix"², was launched in February 2024.

Materials and Methods: An online survey of workplace morale was conducted before and 6 months after the launch of the Greatix system among staff working in Theatres (Anaesthetists, Surgeons, Obstetricians, Anaesthetic Nurses and ODPs, Scrub Nurses, Recovery Nurses, Midwives, and Healthcare Support Staff). An online form was created to allow staff to report excellent practice across Theatres. Form submissions were reviewed and Greatix certificates issued to recognised staff members. A 3-monthly Greatix newsletter was circulated, summarising key learning points from the submitted reports.

Results and Discussion: 51 Greatix submissions were received during the first 6 months of implementation. Communication, teamwork, patient care, and conduct during emergencies were highlighted as themes of excellence that could be learned from. 68 participants took the pre-Greatix workplace morale survey, and 40 participants took the survey 6 months into implementation. Consultant and Trainee Anaesthetists constituted the greatest proportion of participants. With 1 representing poor morale and 5 representing excellent morale, the overall median morale improved from 3/5 pre-implementation to 4/5 at 6 months. Among those who felt they were least likely to be valued at work and least likely to receive positive feedback from another staff member (i.e. self-reported ratings $\leq 3/5$ for these survey items), the median morale improved from 3/5 to 3.5/5, and 3/5 to 4/5 respectively following Greatix implementation. Among those who felt they were least likely to be thanked at work (i.e. self-reported rating ≤ 3/5 for this survey item), the median morale rating remained the same at 3/5 before and after Greatix implementation. Conclusion(s): In addition to promotion of learning from excellent practice, there is evidence of improved workplace morale among Theatres staff following Greatix implementation.

Influence of decision fatigue on length of mechanical ventilation in intensive care medicine – a pilot study

A.L. Leibold¹, V. Kimmerling¹, J. Rosenberger¹, A. Herrmann-Johns², L. Schiessl¹, M. Kees¹ ¹University Hospital Regensburg, Anesthesiology, Regensburg, Germany, ²University Hospital Regensburg, Medical Sociology, Regensburg, Germany

Background and Goal of Study: Decision fatigue (DF) describes the psychological phenomenon that the quality of decision-making (DM) deteriorates after a long period of DM. Investigations concerning DF in other specialties e.g. emergency medicine and legal sciences have proven a significant impact. A study of parole judge's verdicts in Israel showed favorable outcomes for the defendants whose cases were decided early in the day. The reason given was keeping the defendants locked up poses the "safer option". We postulate that DF can also have an influence on DM in intensive care medicine where many difficult decisions need to be made. The goals of this study are to prove a possible influence of DF on physicians' DM and on ventilation time on the ICU.

Materials and Methods: We are currently conducting a semistructured interview study with 20 ICU physicians to get deeper insights on DF influence on physicians' DM.

We analyzed retrospective patient extubation data over a period of 2 years in preparation for the pilot observational study on the ICU. We will observe ICU physicians over a period of one month and count the number of decisions made, decisions postponed, and interruptions in the DM progress and look for possible confounders and create a time line with daily averages in order to calculate a needed observation time to gather enough data for statistical power.

Results and Discussion: First interview results show physicians tend to postpone difficult decisions after having made many decisions before or towards the end of their shifts and shift series. During night shifts, in emergencies, when alone and when over-

whelmed with many decisions DM is perceived especially hard. Especially residents think of extubations of long-term ventilated patients as a hard decision.

Diagram 1 shows a significant difference between extubation times. Long-term ventilated (n=296) patients are usually extubated before 6 p.m. with numbers declining steadily after 2 p.m.. Short-term ventilated patients (n=1908) are extubated 24/7.

Conclusion(s): DF might have a negative influence on mechanical ventilation and ICU time and therefore increase the risk for VAP and patient outcome.

60AP01-5

Perceptions of artificial intelligence among anaesthesia and intensive care professionals: an ESAIC international survey

R. Theilen¹, M. Scharffenberg¹, T. Kramer¹, B. Sedelmayr², R. Huhle¹, J. Wittenstein¹

¹Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, Department of Anaesthesiology and Intensive Care Medicine, Dresden, Germany, ²Faculty of Medicine and University Hospital Carl Gustav Carus, TUD Dresden University of Technology, Institute for Medical Informatics and Biometry, Dresden, Germany

Background and Goal of Study: Artificial intelligence (AI) offers opportunities to enhance diagnostics, treatment, and workflow efficiency. However, successful integration into clinical practice depends on users' acceptance. This international survey among anaesthesia and intensive care professionals explores perceptions of AI-based tools to identify benefits, barriers, and challenges.

Materials and Methods: The survey was distributed to 38,989 members of the European Society of Anaesthesiology and Intensive Care between January and July 2023. We assessed knowledge, experiences, expectations, and concerns regarding Al-based tools, alongside demographic data. Statistical analyses included □² tests, odds ratios, and Spearman rank correlations.

Results and Discussion: A total of 510 respondents completed the survey, primarily from Europe (78%) and Asia (14.5%), and the majority were board-certified anaesthesiologists (86.3%).

Knowledge and Experiences: 86.5% were aware of Al tools, but only 36.8% reported regular encounters. Familiarity was higher among males (90.7% vs. 81.7% in females) and intensive care specialists. 94.5% expressed interest in Al training, particularly younger and less experienced professionals.

Opportunities: 94.7% expressed willingness to use Al tools, citing benefits such as improved decision-making (92.7%), complication anticipation (88.6%), and workload reduction (80.1%). Younger and female respondents were more optimistic about Al's benefits. **Concerns**: Key concerns included lack of explainability (68.4%), over-reliance on Al (80.8%), and medico-legal uncertainties (58.4%). Ethical concerns were more pronounced among females (odds ratio: 1.9; p=0.002). Scepticism was attributed to insufficient validation studies and fears of inaccurate outputs, particularly among experienced clinicians. Although there is strong optimism about Al's potential to enhance patient care, significant

barriers remain, including concerns about reliability, ethics, and regulation. Younger professionals demonstrated greater enthusiasm, while experienced practitioners were more cautious, revealing a generational divide.

Conclusions: This survey shows cautious optimism among anaesthesia and intensive care professionals regarding AI tools. Tailored training, robust validation studies, and clear ethical and legal frameworks are essential for building trust and acceptance. Addressing demographic-specific concerns will further support AI adoption in clinical practice.

Conclusion(s): There was heterogeneity among the answers regarding the care of elderly patients. Evidence-based medicine must be combined with the application of bioethical principles throughout patient care. There are potential forms of bias and unfair discrimination towards elderly patients that must be further investigated and addressed.

60AP01-6

Ageism as a barrier in equitable healthcare provision

<u>G. Mitos</u>¹, S. Soteriades¹, A. Marchi¹, G. Thoma¹, E. Kiourtzieva¹, E. Argyriadou¹ ¹Aristotle University of Thessaloniki, Department of Anesthesiology and Intensive Care, Thessaloniki, Greece

Background and Goal of Study: We recorded and analysed the knowledge, attitudes and practices of healthcare professionals at hospitals in the Thessaloniki, Greece in relation to the care of elderly

patients.

Materials and Methods: A questionnaire was distributed to physicians and nurses at several. Thessaloniki hospitals. It included questions regarding knowledge, attitudes and practices in the care of the elder healthcare receivers. The questions were mainly binary (yes/no) and summarised as percentages. Potential associations were investigated between the individual characteristics of healthcare professionals (specialty, work sector) and the recorded trends.

Results and Discussion: A total of 298 healthcare professionals completed the questionnaire, 49.3% of whom were female, 39.6% were nurses, 50.3% worked in internal medicine departments, 40.7% in surgical departments and the remainder in other sectors. Of all participants, 55.4% defined the elderly patients as those above 80. A selection of questions along with the proportion that replied positively is presented below:

Elderly patients experience less pain	48.3%	
I am aware of the term ageism	41.3%	
I spend more time taking medical history from elderly patients	74.8%	
I am burdened with less responsibility during the treatment of elderly patients	61.7%	
I like caring for elderly patients	55.0%	
I prefer having nothing to do with elderly patients at my job	26.8%	
I treat all patients the same, regardless of age	43.3%	

Compared to the healthcare professionals working in surgical departments, those in the internal medicine departments were more likely to be reluctant in providing care to the elderly patients [adjusted odds ratio (aOR): 24.1, 95% confidence interval (CI): 10.8-53.7] feeling less responsability in treating them (aOR: 8.47, 95% CI: 3.87-18.6). Compared to men, women were more likely to declare that they did not like caring for elderly patients (aOR: 4.44, 95%

Cl: 2.04-9.62) and more likely to consider that the elderly have a negative impact on the economy (aOR: 17.5, 95% Cl: 8.26-37.3).

Gastrointestinal tract, endoscopy	Infection, nosocomial	Lung, interpleural space
13AP01-1, 13AP01-5, 13AP02-7,	24AP01-3	33AP05-10
41AP01-10	Intensive care	Lung, oedema
Gastrointestinal tract, lower oesophageal	21AP03-1, 23AP02-2, 24AP03-1,	33AP06-10
sphincter	32AP02-3, 33AP01-10, 34AP02-3,	Lung, pathophysiology
22AP01-1	51AP01-5, 51AP02-12, 51AP03-2,	11AP04-3, 33AP05-3
Genetic factors	51AP03-9, 51AP04-1, 51AP04-5,	Lung, physiotherapy
11AP09-4, 31AP03-12, 42AP07-8	51AP04-8, 51AP05-8, 51AP06-1,	33AP05-2
Geriatrics	51AP06-5, 51AP06-6, 51AP06-8,	Lung, respiratory distress syndrome
23AP03-4, 23AP03-5	51AP07-11, 51AP07-3, 51AP07-5,	33AP04-11
Head, injury	51AP07-7, 51AP08-10, 53AP01-1,	Lung, transplantation
31AP04-12, 31AP07-8	53AP01-2	33AP01-9, 43AP03-10, 51AP04-10
Heart, arrhythmia	Intensive care, audit	Malignant hyperthermia
22AP01-3, 32AP03-3, 32AP04-4,	23AP01-1, 51AP07-1, 52AP02-7,	10AP02-8, 11AP07-5, 11AP07-8,
32AP05-11, 32AP05-6, 41AP01-4,	53AP01-10	11AP09-12, 21AP06-10, 24AP01-4,
51AP08-11	Intensive care, infections	41AP04-11, 41AP04-12
Heart, arrhythmia, electroversion	22AP06-9, 24AP03-6, 32AP07-2,	Measurement techniques, Doppler
11AP03-1, 22AP05-4	34AP01-4, 34AP01-5, 34AP01-7,	echocardiography
Heart, blood flow, myocardial	34AP02-8, 34AP03-7, 34AP03-8,	32AP08-10
11AP06-8, 32AP07-7	34AP04-1, 34AP04-4, 34AP04-6,	Measurement techniques, calorimetry
Heart, cardiac output	34AP04-7, 34AP05-1, 51AP02-6,	51AP05-4
32AP10-2	51AP02-7, 51AP06-3, 51AP07-2,	Measurement techniques, cardiac output
Heart, cardiopulmonary bypass	51AP07-8, 51AP08-4, 51AP08-6	32AP02-6, 50AP04-7
32AP02-10, 32AP03-1, 32AP05-7,	Intensive care, sedation	Measurement techniques, electrodes,
32AP06-10, 32AP08-12, 32AP08-8	32AP06-3, 32AP06-4	impedance
Heart, catheterization	Intubation nasotracheal, technique	51AP05-9, 51AP06-9
32AP02-7	22AP01-8	Measurement techniques,
Heart, conduction	Intubation tracheal	electrophysiology
21AP05-1	42AP05-8, 42AP10-12	31AP01-4
Heart, congenital defects	Intubation tracheal, difficult	Measurement techniques, neuromuscular
11AP03-11, 21AP02-1, 32AP01-6,	22AP03-7, 22AP06-7, 42AP02-10,	block
32AP04-5, 32AP05-9, 32AP10-4	42AP03-7, 42AP05-12, 42AP06-2,	50AP05-10
Heart, coronary artery bypass	42AP06-3, 42AP07-6, 42AP08-10,	Measurement techniques,
32AP06-5, 32AP08-4, 32AP08-5	42AP08-9, 42AP09-7, 42AP11-10,	thrombelastography
Heart, coronary occlusion	42AP12-7	43AP01-4, 43AP01-8
10AP02-2, 32AP07-1	Intubation tracheal, extubation	Measurement techniques, transthoracic
Heart, esmolol	32AP03-6	electrical impedance
25AP04-4	lons, chloride	33AP04-1, 33AP04-9
Heart, ischaemia	43AP02-8	Measurement techniques, ultrasound
26AP01-1, 26AP01-2, 32AP03-10,	lons, magnesium	12AP05-9
32AP04-12, 32AP05-10	10AP13-11, 41AP04-7	Measurement techniques, ventilation
Heart, myocardial function	Kidney, failure	volumes
10AP12-3, 32AP04-8, 32AP05-5	10AP07-6, 10AP08-7, 22AP04-2,	33AP02-8
Heart, pacemakers artificial	33AP01-3, 34AP02-1, 34AP02-6,	Metabolism, DNA
41AP01-5	35AP01-1, 35AP01-6, 50AP01-8,	26AP02-8
Heart, resuscitation	51AP03-5	Metabolism, energy expenditure
24AP01-11, 24AP03-2, 24AP03-5,	Kidney, filtration, glomerular	26AP02-3
50AP03-9, 50AP05-1, 54AP03-4	10AP11-1	Metabolism, fasting
Heart, tamponade	Kidney, transplantation	10AP01-8, 10AP02-9, 10AP05-11,
21AP03-9, 32AP04-2, 32AP07-9	25AP02-2, 32AP07-12, 52AP01-9	
	Liver, blood flow	11AP04-11, 11AP08-6, 21AP01-6 Metabolism, insulin
Heart, transplantation 32AP07-8	35AP02-2, 41AP05-9	26AP02-7
	Liver, cirrhosis	Metabolism, lactate
Hormones, adrenal 11AP10-7, 26AP01-6	•	10AP01-7, 26AP01-7
•	35AP01-7, 35AP02-10 Liver, hepatitis	•
Hormones, glucocorticoid 32AP07-5	35AP02-9	Methaemoglobinaemia
		41AP03-6, 51AP03-4
Hypertrophic obstructive cardiomyopathy 21AP07-10	Liver, transplantation	Microcirculation
	35AP01-11, 35AP01-12, 35AP01-5,	10AP08-11
Hypnotics benzodiazepine	35AP02-12, 35AP02-6, 35AP02-7	Model, animal
41AP02-6	Lung, adult respiratory distress syndrome	31AP07-3
Immune response	33AP02-11, 33AP03-7, BAPC-01	Model, computer simulation
33AP03-1, 34AP05-8	Lung, atelectasis	35AP02-3, 50AP01-6, 50AP04-1,
Induction, anaesthesia	33AP02-2, 33AP02-4, 33AP05-5	54AP03-10
41AP02-5	Lung, damage	Model, heart
Infection, bacterial	43AP01-3, 51AP05-3	32AP08-3
34AP01-11, 34AP01-12, 34AP02-10,	Lung, function	Model, mathematical
34AP03-11, 51AP03-8, 51AP08-5	11AP11-12	25AP06-2
Infection, central nervous system	Lung, hyperoxia	Model, statistical
34AP02-5	27AP01-5	50AP03-6, 50AP04-5

Monitoring, anaesthetist activity	Pain, acute	Recovery, psychomotor
10AP11-5, 50AP03-4	10AP05-12, 12AP01-6, 12AP07-5,	24AP01-12
Monitoring, apnoea	12AP07-6, 12AP13-1, 12AP13-5,	Research, anaesthesia
52AP02-8	12AP14-1, 25AP04-10, 25AP06-10,	50AP02-12, 50AP03-3, 54AP01-12,
Monitoring, arterial pressure	54AP03-12	55AP01-6
23AP01-9, 32AP01-10, 51AP04-4	Pain, chronic	Risk 11AP11-7
Monitoring, cardiopulmonary 33AP06-5, 50AP03-8	22AP02-1, 25AP01-11, 25AP02-10, 25AP02-3, 25AP02-5, 25AP02-6,	Safety 10AP07-8, 11AP04-8, 11AP08-10,
Monitoring, depth of anaesthesia	25AP02-3, 25AP02-3, 25AP02-0, 25AP02-8, 25AP03-12, 25AP03-7,	50AP01-9, 50AP03-5, 52AP01-3,
11AP01-8, 11AP04-10, 22AP05-3,	25AP03-9, 25AP04-3, 25AP05-11,	52AP01-4, 52AP01-8, 52AP02-1,
31AP01-8, 41AP03-4, 50AP01-4,	25AP05-12, 25AP06-4, 25AP06-8,	52AP02-10, 52AP02-2, 52AP03-9,
50AP02-1, 50AP04-2	33AP07-2, 35AP01-13	60AP01-2
Monitoring, echocardiography	Pain, experimental	Safety, drug
11AP01-7, 32AP06-12, 32AP08-9,	25AP05-10, 25AP05-4	10AP08-9, 41AP05-10, 41AP05-2,
51AP02-9	Pain, mechanism	52AP01-6, 52AP03-12, 52AP03-4,
Monitoring, electrocardiography	25AP03-10, 25AP05-7	52AP04-1, 54AP02-7
24AP01-6	Pain, neurolysis	Safety, equipment
Monitoring, electroencephalography	25AP01-12, 25AP01-9, 25AP06-5	24AP03-4
31AP01-10, 31AP01-6, 31AP01-7, 31AP03-2, 50AP02-2	Pain, neuropathic 25AP02-4, 25AP03-3, 25AP05-1,	Screening 23AP01-5
Monitoring, evoked potentials	25AP05-3, 25AP06-6, 41AP02-1	Sedation
22AP04-9	Pain, postoperative	10AP02-4, 10AP03-2, 10AP05-10,
Monitoring, intracranial pressure	10AP04-1, 11AP08-7, 12AP01-3,	10AP05-3, 10AP13-1, 10AP13-12,
10AP03-5, 31AP02-9, 31AP03-9,	12AP03-3, 12AP05-3, 12AP06-10,	11AP08-1, 12AP03-5, 13AP01-3,
31AP04-2	12AP07-2, 12AP11-10, 12AP11-6,	13AP01-7, 13AP01-8, 13AP02-1,
Monitoring, intraoperative	12AP13-6, 25AP01-4, 25AP01-5,	22AP02-12, 31AP05-8, 32AP05-2,
11AP01-9, 11AP06-11, 11AP11-4,	25AP03-2, 25AP05-5, 25AP06-12,	33AP06-7, 41AP02-11, 41AP02-12,
32AP03-5, 50AP01-11	35AP01-9	50AP02-4
Monitoring, neuromuscular function	Parasympathetic nervous system	Serotonin(5-hydroxytryptamine),
11AP07-11, 22AP05-6,	31AP03-5	antagonism
31AP04-8, 41AP02-10, 50AP02-8, 50AP03-2,	Parkinsonism 11AP06-9	10AP05-9 Sleep
50AP02-8, 50AP03-2, 50AP05-12	Partial pressure, arterial-end-tidal	23AP03-10
Monitoring, ultrasound	33AP06-11	Spinal cord, cranial nerve palsy
10AP07-5	Partial pressure, nitrous oxide	22AP03-1
Muscle cardiac	51AP06-12	Spinal cord, evoked potentials
32AP05-1	Pharmacology	12AP01-7
Muscle skeletal, diaphragm	41AP03-7, 41AP05-3,	Spinal cord, sensory block
51AP01-7	41AP05-7	10AP11-3
Muscle skeletal, metabolism	Pharmacology, dose-response	Stress
26AP02-2	12AP04-3	55AP01-7
Muscle skeletal, myoglobin	Placenta 21AP07-4	Surgery, abdominal
51AP08-7 Muscle skeletal, relaxation	Polypeptides, cytokines	10AP01-10, 10AP01-12, 10AP04-12, 10AP06-2,
41AP01-3	32AP07-4	10AP08-3, 10AP00-2,
Muscle vascular, responses	Position, Trendelenburg	34AP01-2
32AP02-5	10AP07-7	Surgery, aneurysm
Myotonia dystrophica	Position, effects	32AP10-6
11AP03-4, 11AP05-1, 11AP08-9	52AP02-11	Surgery, autonomic response
Neuromuscular block	Position, prone	52AP04-8
41AP04-2, 41AP04-6,	12AP11-2	Surgery, cardiovascular
52AP04-2	Pregnancy	32AP01-12, 32AP01-7, 32AP02-1,
Neuromuscular block, allergy	21AP01-1, 21AP01-12, 21AP01-4,	32AP02-12, 32AP02-13, 32AP02-8,
11AP09-1 Neuromuscular block, rocuronium	21AP03-11, 21AP04-9, 21AP06-8, 21AP06-9, 21AP08-11, 21AP08-7,	32AP02-9, 32AP04-6, 32AP06-2, 32AP08-2, 32AP10-5, 43AP01-5,
11AP11-8, 41AP01-7, 41AP04-8,	25AP04-5, 55AP01-5	43AP04-10, 43AP04-5, 43AP05-10,
41AP05-4	Premedication	43AP07-10
Operating rooms, contamination	22AP04-10	Surgery, gastrointestinal
53AP01-5	Recovery	10AP06-1, 11AP08-11, 12AP05-5
Operating rooms, exhaust systems	53AP01-4	Surgery, gynaecological
53AP01-6	Recovery, cognitive	10AP10-9
Operating rooms, personnel	10AP10-11, 10AP12-6, 10AP12-9,	Surgery, hepatic
50AP03-7, 52AP02-5, 53AP01-7,	11AP05-12, 23AP01-4, 23AP01-6,	35AP02-1
53AP01-9, 55AP01-3, 55AP01-8	23AP01-7, 31AP03-6, 31AP07-11,	Surgery, laparoscopy
Osteogenesis imperfecta	32AP06-1, BAPC-05	10AP05-1, 11AP11-9, 25AP04-12
22AP03-8 Pain 11AP10-2, 22AP06-10, 25AP01-3,	Recovery, postoperative 10AP02-11, 10AP04-9, 10AP08-8,	Surgery, laparotomy 10AP05-6
25AP01-6, 25AP01-7, 25AP01-8,	10AP12-5, 35AP01-4, 51AP01-11,	Surgery, neurological
25AP04-7, 25AP05-8	52AP01-10, BAPC-04	10AP09-4
